The LTG project is an efficacy study of the learning and teaching geometry professional development materials: Examining impact and context-based adaptations, sought to improve teacher's own knowledge and instructional strategies in transformations-based geometry. This PD consists of 54 hours of highly specified video-based PD that is grounded in modules of dynamic transformations-based geometry aligned with the Common Core State Standards in mathematics (CCSSM). Through video analysis and analysis of student work, teachers work together to solve problems and further their knowledge in mathematics teaching in the domain of geometry. The PD allows teachers to better support students in their attempt to gain a deeper understanding of transformations-based geometry through activities like rate of change on a graph, scaling activities, and similarity tools. The material strongly connects to other critical domains including similarity, proportional reasoning, slope, and linear functions.

Problem-Solving Cycle (PSC)

The PSC project developed two interconnected PD models--the Problem-Solving Cycle (PSC) and the Mathematics Leadership Preparation (MLP) models for preparing PD facilitators (Borko et al., 2015). The PSC model consists of a series of interconnected workshops organized around a problem that can be solved using multiple representations and solutions and can be adapted for multiple grade levels. Each cycle focuses on a different math problem. During the first cycle, teachers collaboratively solve the focal math problem and develop plans for teaching it to their students. Teachers then teach the lesson in their classes and videotape the lessons. Subsequent workshops focus on participants' classroom experiences teaching the problem using videotapes and artifacts of practice to anchor their conversations.

Visual Access to Mathematics (VAM)

The VAM project aimed to build skills in mathematical problem solving and communication using visual representations. This PD consisted of face-to-face PD as well as online workshops where teachers implemented problems from the PD and shared their student work to discuss access for English Learner's (EL's) and all students. The project investigated the instructional strategies and supports that teachers of EL's need to provide access to mathematical learning while advancing academic language development. The approach was grounded in the use of visual representations, such as diagrams and geometric drawings, for mathematical problem-solving with integrated language support strategies. The intended goals of VAM were to help teachers properly select appropriate visual representations for the use of different rational number task types and communication tools to show and explain mathematical thinking.

Methodology

Sampling, Data Collection and Analysis

During Spring 2021 pairs of project researchers conducted two one-hour semi-structured interviews using "think aloud" protocols with the 19 teachers individually (LTG 10; VAM 7; PSC 2). The participants selected two to three video clips that showed their routine daily teaching practices yet potentially could show instructional strategies and/or content from their respective PDs. The participants included time stamps and a justification for why they selected the clip prior to each interview. Pairs of researchers watched the entire video as well as the clips before interviewing participants and analyzed the lesson and the selected clips for instances where the participants could show evidence of instructional impact from the PD that they participated in- including content, resources, or instructional strategies. Then participants watched the clip with the pair of researchers on a video conference that was recorded and the participant discussed why they selected the clip and what it represented in terms of their learning related to their PD. With these data, field notes from the interviews and prior survey data, we created initial profiles for each teacher collaboratively in pairs. These profile documents initiated the development of our case studies – three of which are presented here.

Results: Three Case Studies

Tyra (LTG): Case of a Teacher's Evolving Learning

Tyra has taught math for eight years at two different high schools. She was warm, reflective and engaging throughout our semi structured interviews and enthusiastic about how much she learned from PD over the last five years. Interestingly, she team teaches with Diantha, another teacher with six years of teaching experience. Tyra and Diantha regularly talk about their own learning and reflect together especially when they attended the same PDs. Tyra has taught 9-12 graders throughout her career and typically teaches Algebra, Algebra II, Geometry. Tyra and Diantha teach in an urban high school in the northeastern part of the United States where more than half of the students receive free/reduced breakfast and lunch. Trya spoke highly about her administration and mentioned that her assistant principal serves as a mentor by providing feedback and suggesting PD opportunities that she believes will assist Tyra in her ongoing professional learning. There appears to be mutual respect between them.

Tyra participated in the LTG PD in the 2016-2017 school year and shared with us that she was "very committed" to the PD sessions – and that she always completed homework (which was voluntary). She recounted the transformations-based concepts that she learned and how she uses the content and resources from the PD in her classroom. This was also evidenced in the videotapes that she shared with us both when she was teaching with Diantha and without. Tyra explained that attending the LTG PD that was focused on geometry, and another PD offered through a university in her area that was focused on algebra, dramatically changed the way she teaches in the classroom.

She explained that these two PDs that she had taken at the same time (five years ago) moved her from using "chalk and talk" (direct instruction) to using mathematical practices and collaborative learning techniques. Tyra indicated that "before the PD she would give the rule and then give students problems to apply the rule." She also shared that she did not originally think that these methods would "work for her kids" but once she started using them her students responded and seemed more engaged and learned more. In addition, she explained that she wants her students to know how to derive formulas through tools such as tracing paper, but had not thought about using tracing paper when learning geometry concepts. She explained that when students used tracing paper (when solving dilation problems) she said, "they are remembering a process rather than just a rule." She reflected that talking to her peers during the LTG PD influenced much content and pedagogy that she learned, as a result she started incorporating more time for students in her own class to talk to one another for more engagement and learning to take place.

When we spoke about the school climate, she stated that “her environment was great because she had professional freedom in her classroom and a collaborative math department.” Diantha and Trya shared what they learned from LTG with the math department and the following year they made some significant changes to how they teach geometry. In addition, they incorporated a transformations-based geometry unit to begin their Algebra II course. They saw the connections between the two and realized that understanding proportionality and similarity are keys to understanding the foundations of algebra.

Megan (VAM): Case of a veteran teacher’s evolving learning

Megan is a veteran high school math teacher that lives and teaches in a northeastern town in the US. She has taught for 28 years and courses ranging from 6th grade math through Calculus. Megan teaches in a school where most of her students are English Learners (EL’s) and more than half of the students receive free/reduced breakfast and lunch. Megan appeared to be a very committed teacher and she relayed her excitement about participating in the VAM PD to learn more about how she could reach her EL’s. She told us some stories of her students and the difficulty she had teaching students that spoke a variety of languages in one class. She felt that she needed to learn strategies to support the different languages. Megan participated in the VAM PD in 2016-2017. She shared that she really liked the PD and that the philosophy aligned with her own thinking about teaching mathematics, “Some of the strategies I had already been using but the others were new and built on the directions of the district.”

A highlight of the PD for Megan was “sharing instructional strategies and resources with teachers from other districts.” She remembers learning how to “create visual representations to solve problems and apply language strategies to make sense of word problems.” She selected a video clip to share with us that showed aspects of her learning from the VAM PD that she continues to use in her classroom today. In the video clip, she teaches remotely with a white board application using a double number line. The double number line represented two quantities from a word problem that the kids had to solve. She explained to us that she had never used or heard of a double number line before VAM. After we watched the clip, she emphasized how cool she thought the double number line was because it allowed her to show students the varying quantities on the number line and how the quantities translated to a coordinate plane visually. She attributed this to have a big impact on students’ conceptual understanding. She also commented that she learned how to use color in representations to help students “see” the math and she believed the use of color had “visual impact.”

Megan continues to use representations for access that she learned in the VAM PD as well as other strategies that she has researched or developed to provide more access to her students. Megan shared a story about how she decided to use easels to support five students with Individualized Education Plans in her class that struggled with the amount of time they had to sit during remote instruction. In her school, some students came to class in person while others joined remotely through a video-based conferencing application. These boys were in the classroom with her during instruction. Megan decided to bring in easels and the students worked in pairs to work on the math problems. They only had one pen and they had to take turns using the pen, again strategies that address access and collaborative working relationships. At the end of the class, the students wanted to do another problem. She said that this ended up being “the best teaching day all year.” She shared the “vertical workspace” strategy with the rest of the staff at her school and they have implemented this technique in their school - using easels, chart paper and white boards, which Megan believed helped the students collaborate and talk with one another. This is an example of how instructional strategies from PD can be modified and translated into best practices in schools. Noticing and listening, aspects important in the VAM PD, potentially provided Megan new perspectives on addressing student needs.

Linda PSC: Case of a teacher leader’s continual learning with other leaders

Linda is a math and science teacher as well as a PD leader in her school and district located on the west coast of the US. She is a veteran teacher that has taught in the district for many years. Linda served as a teacher leader, a person that was trained to lead the PSC PD with teachers in the math department at her school. Linda explained that her involvement in the PSC PD “has been a defining and productive exploration of herself as a math teacher.” She said she appreciated being part of a professional community and she noticed growth in her math teaching. Linda found the PSC PD experience “productive and valuable”, and she valued being around people passionate about teaching math and teaching in general. Linda believes that the involvement in the facilitator group helped her and the other participants to become better mathematics teachers and bring back instructional strategies to their math departments. She also said that this group supported the facilitators in becoming leaders and helping each other as colleagues.

Linda reported that participating in our TaDD project helped her reflect on what she learned six years ago when she participated in the PSC project. She compared it to other PDs focused on learning strategies and found it challenging to incorporate something new without practice and reinforcement. Linda found great value in participation because the PSC PD was ongoing, and she was involved in it for 2-years. She explained that extended involvement was important for her as well as developing as a teacher. She appreciated the opportunity to be part of a community and that revisiting her learning by “doing math, practicing math” was a more valuable experience than other PDs because she learned “good math teaching strategies” and gained more confidence as a math teacher.

Linda told us that one of her current goals is trying to use academic vocabulary with her students. She also mentioned that she is in support of “productive struggle” in math and trying to engage students and have them “do the work” for three reasons. She believed productive struggle helps to amplify student voice, respond with academic language, and allows students to answer informally.

Laura felt positively about the facilitators in the PSC PD—she appreciated how they set up the PD so that the participants could explore ideas together. She said it is hard to separate what she learned from how they facilitated the PD. When asked about her role as a facilitator of the PSC at her school, she admitted that it didn’t go well, in fact “it was a disaster”. She loved her own participation with the community of facilitators but struggled with how to productively facilitate the PSC with the teachers at her own school stating that they did not want to participate.

Discussion and Implications

Our current study aims to understand and capture long-term learning from a more nuanced perspective. Teachers have shared their own perceptions of learning that is more detailed and provides clarity about the evolution of their practice including new ideas from other PD opportunities that may or may not have aligned with the various PDs in our study (VAM, LTG, PSC). These other professional opportunities ranged from additional formal professional development workshops to professional conferences, to collaborations and conversations with colleagues, as well as advice from key constituents, such as a principal. In the US and in other countries as well, professional learning is required in most contracts, but teachers also participate because they are motivated to learn formally and enjoy debriefing with colleagues either formally or informally. We believe these additional learning opportunities do not shade the results of our study but rather illustrate the actual ways teachers learn. Even though as stated above, our goal is to understand how teachers use the content, pedagogy, and resources from PDs in our study, we believe it is necessary to consider these additional learning situations and how they may have also contributed to the learning of a teacher not only because it is the reality of their job but also in order to be transparent in our research.

The three case studies illustrate continued learning at least five years post PD experience. The full case studies illustrate much more complex and nuanced variance among cases but the shortened versions in this paper show the ways in which three different teachers' learning has evolved over time. They all have shifted practices and are trying new teaching strategies, noticing and listening to students in new ways, and recognizing the importance of PD and reflecting on their everyday teaching practice.

All three case study teachers are motivated to learn and had a purpose for attending and learning from their respective PDs. Tyra was motivated by the geometry content and resources for teaching transformations-based similarity. Megan was motivated by a need to learn more strategies for supporting her English learner students. Linda was motivated by an interest in becoming a teacher leader and participating in a learning community of facilitators from others outside of her school. Yet they were each different as well. Tyra was interested in learning content and better ways to reach more students. Megan needed new resources and strategies to serve her students while Linda wanted a new challenge as a teacher leader. Each of our 19 teachers are on their own journey and we are continuing to investigate the trajectories of change which vary across participants yet have the potential to provide and contribute understandings of variance across different teachers and different types of PD. We anticipate a cross case analysis will help us disentangle similarities and differences within and across the three PDs and contribute a more in depth understanding into what teachers take up and enact in their classroom context.

Structured lesson preparation improves teacher behaviour

Marjolein Kool[1]

[1]HU University of Applied Sciences, Utrecht, The Netherlands; marjolein.kool@hu.nl

Keywords: Higher order skills, problem solving, primary teacher education.

People need mathematical higher order skills to participate successfully in society (Hoogland, 2016). Working together on and discussing non-routine math problems promotes the development of these skills. In Dutch primary education however non-routine math problems are most of the time presented to high-performing students only (Van Zanten & Van den Heuvel-Panhuizen, 2018) and whole-class discussions on solving problems to develop higher order skills are rare. In what way can whole-class discussions be organised to foster the development of higher order skills of all students?

Theoretical framework

A productive whole-class activity on problem solving should start with a non-routine mathematical 'low-floor-high-ceiling task' (Boaler, 2016). Teaching such problems involves: (1) explaining the problem, (2) putting students to work, (3) observing their problem-solving approaches, (4) guiding whole-class discussion and (5) summarising learning outcomes (Stein et al., 2008). In the whole-class discussion the teacher encourages his students to present, compare, evaluate and defend their problem-solving approaches. This places high demands on teachers. They must deal with a broad spectrum of students' problem-solving approaches and simultaneously challenge all students to think and reason about those approaches. To achieve this, mathematical and pedagogical content knowledge is needed (Ball et al., 2008), together with specific teaching skills as described in the Mathematical Quality of Instruction (MQI) instrument, like mathematical sense-making, using multiple problem solving-approaches and using students' ideas (Hill et al., 2008). Stein et al. (2008) advise teachers to prepare their problem-solving lessons thoroughly, by (1) solving the problem in multiple ways, (2) predicting mistakes of students, (3) devising hints and support, (4) selecting and order problem-solving approaches to be used in the discussion and (5) predicting learning outcomes.

Research question

To support preservice teachers in preparing and performing whole-class activities with non-routine problems we developed a preparation form based on the aspects mentioned by Stein et al. (2008). During the activity, while the students work on their problem, the preservice teacher observes their problem-solving approaches. Having his own preparation in mind he then makes a selection to be used for the whole-class discussion. During this discussion the preservice teacher invites students to present their problem-solving approach. The preservice teacher then challenges the other students to discuss and evaluate these. The preservice teacher guides the discussion and ensures participation and understanding. His thorough preparation will support him in responding to and developing the thinking and reasoning process of the students. The discussion is more productive when the preservice teacher has explored beforehand how students might solve the problem (Stein et al., 2008). In light of the above, the following research questions emerge:

How and to what extent are preservice teachers able to prepare a whole-class activity on a non-routine mathematical problem using a structured preparation form?

How and to what extent does structured preparation of a whole-class activity on a non-routine mathematical problem improves the quality of teacher behaviour during this activity?

Method

Approximately 80 Dutch preservice primary teachers will participate. For their first lesson they will use a preparation form completed by a teacher educator (the so-called “expert”). For the next two problems, chosen from a selection of 30 problems, they will complete the preparation form themselves. After teaching with the three problems, they will complete a questionnaire evaluating their own teacher behaviour while performing the third lesson. They will score themselves on certain aspects of the MQI instrument using a four-point Likert scale (Hill et al., 2008). They will answer questions about the perceived impact of their preparation on various aspects of their teacher behaviour and about experienced differences in using their own preparations and that of an expert.

For the first research question, the preparations of the preservice teachers will be analysed and compared with the experts’ preparations. For the second question, the scores of the preservice teachers will be analysed and how they attribute these to their preparations and those of the experts.

To be continued

Rich preparation of problem-solving activities will support teacher behaviour (Stein et al., 2008). We plan to publish the problems and experts’ preparations in the near future. Should it turn out that teachers perform better while using their own preparations we will publish the problems with empty forms. In any case we will encourage the use and preparation of problems in whole-class activities.

What can be causing this error? - Preservice primary school teachers' interpretations of students' errors

Macarena Larrain[1] and Gabriele Kaiser[1]

[1]Universität Hamburg, Germany; macalarrainj@gmail.com

Keywords: Preservice teacher education, diagnostic competence, analysis of students' errors, mathematics teachers' competencies.

Introduction and theoretical framework

Teachers' diagnostic competence is crucial for understanding and evaluating students' thinking and differentiating teaching strategies. What teachers pay attention to in the classroom and their interpretation are decisive for supporting students (Kaiser et al., 2015). In mathematics classrooms, students' errors are a rich source of information about their thinking. They can reveal students' understanding of mathematical concepts and procedures. The *diagnostic competence in error situations* is the competence needed by teachers to identify, interpret and then manage error situations in a way that promotes students' mathematical understanding (Heinrichs & Kaiser, 2018).

The development of preservice teachers' (PST) diagnostic competence in error situations can begin in initial teacher education. Teacher educators can support PST in learning to identify relevant details, ask relevant questions and apply specialized content knowledge to understand students' thinking. However, such learning opportunities are complex, which raises multiple questions about the characteristics they should have to be effective. Moreover, it is necessary to extend our understanding of the characteristics of the competence in the early developmental stages and the interactions between the competence and PST's knowledge, beliefs and practical experience.

Thus, the goal of this study is to contribute to the characterization of preservice primary school teachers' diagnostic competence and its development. We focus on the interpretation dimension of the competence, i.e. on PSTs' competence to formulate hypotheses about causes of students' errors. This dimension of the competence is decisive for the subsequent pedagogical decision-making process and the quality of the teaching strategies that can be implemented.

Method

The goal of this study is to characterize PSTs' competence to formulate hypotheses about causes of students' errors and its development after they participated in a university seminar sequence. In addition, based on the model of competence as a continuum (Blömeke et al., 2015), we examine if beliefs, knowledge and practical experience are related to PSTs' competence. The seminar sequence was aimed at developing PSTs' competence to identify, interpret and deal with students' mathematical errors. It consisted of four 90-minute sessions, in which PST were engaged in individual and group analyses of students' errors and discussions about students' mathematical thinking. Short videos of error situations and samples of students' written work were used as prompts.

Participants were 131 undergraduates from 11 Chilean universities in their initial teacher education for primary schools. Before the seminar sequence, they answered an online survey, that collected demographic data, beliefs questionnaires (from the TEDS-M study) and two error analysis tasks. In addition, they answered a mathematical knowledge for teaching (MKT) assessment. After the seminar sequence, participants completed another two error analysis tasks.

In each error analysis task, they were asked to suggest three possible causes for the student error shown in a video vignette. Their responses to these open items were coded using qualitative text analysis. Five thematic categories were used to classify the types of hypotheses to which PST attributed the error: lack of conceptual understanding, lack of procedural understanding, instructional wrong decisions, ambiguous hypotheses and not valid hypotheses. In addition, the relationship of PSTs' competence to their professional knowledge, beliefs and practical experience was examined.

Results

Results indicated that PST had difficulties formulating hypotheses about causes of students' errors. They often gave incorrect, incomplete or contradictory suggestions. The valid hypotheses mostly attributed the error to a lack of conceptual understanding of some mathematical issue. Further analyses showed that beliefs, knowledge and practical experience were related to PSTs' competence. Their beliefs about learning mathematics as an active process showed the strongest correlation, together with practical experience.

Analyses revealed a significant improvement in the number of valid hypotheses PST could formulate between pre- and post-test. After the seminar sequence, PST formulated more hypotheses attributing the errors to a lack of conceptual and procedural understanding and to a lesser extent, hypotheses focusing on inappropriate instructional decisions. This showed that they were more able to focus on students' thinking. Study progress (number of finished university semesters) was a significant predictor for greater changes in the competence to hypothesize about causes of students' errors.

Our findings highlight the role of beliefs in the competence and its development. They also provide insights into the role of teaching experience and knowledge for the development of the competence. The poster format will provide us with the opportunity to share and further discuss characteristics of the seminar sequence and of PSTs that contribute to the development of the competence.

What remains? A longitudinal study of the effects of curated field experiences for preservice mathematics teachers

Jennifer M. Lewis and Chris Nazelli

Wayne State University, USA; jmlewis@wayne.edu

This paper examines the long-term effects of a teacher education program that prepares preservice elementary mathematics teachers to work specifically in Detroit schools. The study was designed to better understand the degree of alignment between the program's curated field experiences and the work graduates currently do as teachers; the aspects of program design that contributed or detracted from graduates' understanding of culturally relevant practice in mathematics classes; and the reasons for graduates' retention in high-poverty schools over time.

Keywords: Teachers, mathematics teachers, preservice teachers, elementary school teachers.

Objectives

This paper examines the long-term effects of a teacher education program designed to prepare teachers to work specifically in Detroit. Although teacher education programs are frequently studied for their near- and medium-term effects, this study sought to uncover the longer-term traces of the program for its graduates. The TeachDETROIT program was established in 2016, and its first cohort entered the workforce as teachers of record in 2017. The program was founded to contribute to the revitalization of the city with special emphasis on the importance of schools in their efforts to build a just educational system for minoritized people. The TeachDETROIT program welcomed its sixth cohort in fall 2021. As part of program evaluation, the program leadership along with external evaluators sought to understand the longitudinal traces of this context-specific (Matsko & Hammerness, 2014) urban teacher residency program, regarding graduates' perceptions of preparedness to teach mathematics in under-resourced schools; implementation of culturally relevant teaching practices in the context of teaching mathematics; and program graduates' current commitment to remain in under-resourced schools. The study was designed to better understand the graduates' pathway into, through and beyond the program; the degree of alignment between the program's highly curated field experiences and the work graduates currently do as teachers; and the aspects of program design that contributed or detracted from graduates' understanding of culturally relevant practice in mathematics classes.

Theoretical Framework

As one of the most important factors for improving student achievement (Darling-Hammond et al., 2009), teachers need to be prepared to offer their students the high-quality mathematics instruction they deserve and require (National Council of Teachers of Mathematics, 2000; Conference Board of Mathematical Sciences, 2012). Unfortunately, there is evidence that students in the United States are not experiencing high-quality instruction. The 2019 National Assessment of Educational Progress (NAEP) showed that only 41% of fourth-grade and 34% of eighth-grade students were "proficient" at mathematics. For Black students in large, urban school districts, those numbers fall to 18% and

13%, respectively. In Detroit, Michigan the situation is even more dire: only 5% of fourth-grade, and 5% of eighth-grade students were "proficient" in mathematics.

Researchers have long posited a connection between the quality of instruction teachers can offer and the quality of the preservice preparation they experience (Schmidt et al., 2011; Senk et al., 2012). Although the familiar mix of content, methods, and social science foundational courses, together with supervised practice teaching, has endured (Donoghue, 2006; Fraser, 2007), so has the finding that this type of preparation is disconnected from the work of teaching (Feiman-Nemser, 1983, 2001).

After decades of interest in learning to teach at some remove from classroom experience (Feiman-Nemser, 1985; Floden & Buchmann, 1993), the pendulum swung back in the early 2000s to emphasize a focus on learning "in and from practice" (Lampert, 2010). A flurry of work in teacher education called for preservice teacher education to focus on "practice" (Ball & Forzani, 2009; Grossman et al., 2009; Grossman & McDonald, 2008; Lampert, 2010; Zeichner, 2010). The emphasis in this line of work is that preservice teachers should learn "in and from practice" (Ball & Cohen, 1999), not just educational theory learned at a distance from classroom life. Today clinical residency programs abound, where preservice teacher education is predominantly a full immersion in a field placement classroom. Yet the quality and specifications of these field experiences can vary widely: the insides of the classroom environments, the quality of cooperating teachers and school principals, and the experiences that preservice teachers have can often go largely unspecified (Ronfeldt, 2012). Furthermore, there are few studies that investigate how well preservice teachers learn to do the interactive work of teaching mathematics in such programs. In this study, we describe an early field experience designed for preservice teachers to learn to carry out mathematics instruction in elementary classrooms, and we report on its relevance to participants five years later.

The curated field experience in TeachDETROIT is composed of four primary elements: 1) Highly scaffolded instructional activities in mathematics; 2) Shared classroom spaces where mathematics teaching and review of teaching is public; 3) Ongoing study and conversation about teaching mathematics to children of color living in poverty; 4) Group explorations of the city of Detroit.

In contrast to reports that the quality of field experiences is often poor (Greenberg et al., 2011; Ronfeldt, 2012), the field experiences described in this paper are carefully designed and sequenced. We have named this intentionally designed field experience the *curated field experience*, one in which the cooperating teachers and the instructional activities in field experience classrooms are highly specified and aligned, bringing together a team of teacher educators, cooperating teachers, school administrators and support staff. We used the word *curated* to refer to the careful selection and sequencing of field experiences, including the preparation of cooperating teachers for this program, the matching of cooperating teacher to intern, and the progression of field experiences where the complexity and demands grow according to the needs of each intern. Researchers designed this study to better understand how the early curated field experience was viewed by graduates of the program some five years later. In this section we provide some detail about the four elements of TeachDETROIT's early curated field experience.

Highly scaffolded instructional activities. One important feature of the curated early field experience is that interactive instructional work is woven into the mathematics methods class from preservice teachers' first day in TeachDETROIT. Each methods class session is held in an elementary school, and interns enter one 3rd grade classroom for 30-40 minutes during the methods class of 150 minutes. Preservice teachers work with small groups of children in the same classroom. Preservice teachers learn to conduct four instructional activities in mathematics to rising 3rd grade students in a summer school setting: teaching a mathematical game using compositions of ten; interval counting (Franke et al., 2018); modeling number facts with concrete materials; and using a variety of strategies to represent multidigit addition and subtraction. In this setting, preservice teachers learn to enact a short instructional activity by observing an experienced teacher conduct the activity, rehearsing the activity with a peer using a script, rehearsing the activity in front of the larger group of preservice teachers for feedback, and finally enacting the short activity with a small group of children. In the first weeks of the early field experience, the instructional activity is highly scripted. Although scripted teaching has been the subject of lively critique in teacher education, in the early field experience the script serves to quiet the complexity of classroom work by reducing some of the cognitive load for novices until strong mathematics teaching practices become more familiar and internalized. As the term progresses, novices rely less and less on scripted lessons and take on increasingly complex facets of planning and enactment. Preparing for teaching includes analysis of video from the previous session's lesson, reviewing and adapting lesson plans, and rehearsing for teaching enactment. The rehearsals underscore the unspoken notion that teaching is something to be studied, practiced, and constantly improved. This feature of TeachDETROIT draws on the scholarship of Lampert et al. (2013).

Shared classroom spaces where teaching is made public. Preservice teachers, host teachers, and the methods instructor are all present in one classroom for every class session, so that all teaching is always conducted in the company of others. From the very first day of TeachDETROIT, preservice teachers experience teaching as an activity that is witnessed by others, and the subject of collegial conversations towards improvement. The preservice teachers videorecord their teaching enactments and review them each day; following a teaching enactment, preservice teachers share excerpts of their recordings and write about them in journals and video platforms designed for such purposes. In this way, teaching is positioned as work that is done in the presence of other colleagues, with frequent collaboration, and guided by review of prior lessons with ongoing attention to evidence of student learning. Each lesson plan is shaped by the review of the previous day's teaching and learning as documented in video records, student work, and in consultation with peers, the instructor, and the host teachers. This feature of TeachDETROIT, making practice visible and shared, follows the work of Lewis (2007).

Teaching children of color living in poverty. In a course titled *Detroit Families, Communities, and Schools,* TeachDETROIT participants learn about the history of schooling in Detroit, and study the effects of poverty and systemic racism on families. The course is part of an ongoing open conversation in the program about working with children of color living in poverty and their families and caregivers, and promotes a strengths-and-assets view of students and their families. Curated field experiences are especially important in preparing preservice teachers to do ambitious teaching in high-poverty settings with children of color, since some preservice teachers may not have had such experiences themselves, either with children of color or with ambitious teaching practice—and the challenges of the two combined can be especially daunting. The empirical experience provided by curated fieldwork in conducting ambitious practice with children of color living in poverty serves as a kind of existence proof to preservice teachers: that such practice is possible, that teachers and their students are capable of doing such work, and that this kind of work is what is done in "regular" schools, real-time, day in and day out. Ambitious mathematics teaching may not be the norm in many schools that serve Black children living in poverty, or preservice teachers may not imagine that such practice can be done with minoritized populations. For this reason, the curated field experiences described in this article are intentionally situated in schools that serve children of color living in poverty. This feature draws on the work of Matsko and Hammerness (2014).

Exploring the city of Detroit. The TeachDETROIT experience includes multiple excursions around the city, especially to venues and events where families are present. Experiencing Detroit as a place of vibrant cultural and social ferment emphasizes the possibilities of a city that has been portrayed in the media as a blighted, scary place. Program participants come to see Detroit as a compelling place to work; being part of the city by visiting libraries, parks, artist studios, outdoor murals, urban farms, museums, coffee shops and lectures together is part of the education that TeachDETROIT provides beyond the preparation for teaching academic subjects. The required course *Detroit Families, Communities, and Schools* features such excursions, and optional social gatherings in the city are an integral part of the TeachDETROIT experience. This feature of TeachDETROIT was introduced following the literature on place-based education (cf. Gruenewald & Smith, 2014).

"Slow food, small batches." Although not a primary feature of the curated field experience, it bears mentioning here that an important characteristic of the TeachDETROIT program is the maintenance of small cohort size so that the preservice teachers receive individualized attention and wraparound services as needed. Each preservice teacher progresses through the program on pace with their own growing proficiency; individual strengths, resources, and interests are addressed as much as possible. For example, by knowing the preservice teachers well, the program is able to place them with mentor teachers who are matched to their needs. The program endeavors to be the educational analog to the Slow Food movement, which prizes the production of high-quality, environmentally responsible food over industrialized food production. Thus, TeachDETROIT cohorts are purposely small, and the program resists the trend to abridge the time and requirements for teacher certification 10.1111/0161-4681.00141

increasingly allowed by the Michigan Department of Education.

Methods

All members of the inaugural TeachDETROIT cohort were invited to participate in the study by external evaluators for the program. TeachDETROIT preservice teachers are eligible to join the program if they have a bachelor's degree with a 2.75 grade point average, some experience working with children (even minimal experience), and an expressed interest in working with children in Detroit. Candidates are often returning to school after other careers or raising families, so their prior educational experience may be distant and not necessarily a predictor of success in TeachDETROIT; for this reason, weak academic history is not necessarily a barrier to entry in the program.

Program graduates received three email invitations and three phone calls to take part in 45-60-minute interviews. Study participants were offered a gift card of $75 for joining the study, and were approached by the external evaluation team, not program personnel, and interviewed by the external evaluators to encourage study participants to speak candidly about their experiences. Stimulated recall (Calderhead, 1981; Kennedy, 1991) using photographs of the interns themselves during their first semester of program participation was used to prompt graduate recollections about their curated field experiences. These photographs were taken for marketing purposes at the time, and show each intern engaged in the instructional activities with children as detailed above, including the conduct of small group work, writing on the whiteboard, and peering over students' shoulders as they work, for example. The photographs were not staged; they were taken during regular instruction. A structured interview was developed making use of the photographs and the memories they sparked for study participants. As mentioned above, interviewers were external to the program and had conducted external evaluation activities in years prior to the current study. The study was conducted with IRB permission.

Data sources

67% of the cohort (N=4) participated in the study. Interviews were audio recorded and transcribed; the transcripts were then coded using an approach that closely follows methods explicated by Miles et al. (2019). This approach emphasizes well-defined study variables to ensure the comparability of data and reduction of data using data displays and matrices so that the common themes can be identified.

Findings

Findings of the study are summarized here.

1. Most graduates found out about the program through their academic advisors at the University.

2. Study participants reported that memories of their preparation experiences in the field were triggered when shown a photo of themselves in the classroom. Participants recalled particular instructional routines and named them.

3. All study participants said that their mathematics lessons did not go as planned in their first months in the program, and that they had to learn to adjust to what students knew in the moment. The following exchange illustrates this finding:

Interviewer: Do you remember any of the content of the lessons that you taught?

Graduate: Oh, my gosh. Yes. Shared reading, guided reading and read alouds for reading. And then for math, we did number talks.

Interviewer: Okay. And do you remember feeling that the lessons went as planned?

Graduate: Sometimes. I mean you never know what children are going to say and they're going to throw you off, but most of it, I would say that the majority of the time, yes, with the exception of you just don't know how many children are going to respond. And, for example, when we would do a number talk and talk to children about math, your expectation is that at some point, they're going to get it while sometimes they didn't. So in that regard, no.

4. All study participants valued the interactions with peers, found those relationships to be educative and sustaining, and reported that they continue to stay in contact five years later.

Interviewer: Do you remember discussing your teaching with your peers? And if you do, what do you remember kind of taking away from those discussions?

Graduate: Oh, absolutely. It was very beneficial because we would talk about what our strengths were during that lesson, what we could improve upon and how we would change it if we had to do it again. And the thing is we were talking to our peers, so some of the feedback came from teachers, mentor teachers, but then other times, it came back from our peers, which helps a lot.

5. Reflecting on their early mathematics teaching experiences, all graduates noted that those early preparation experiences were aligned with the teaching work they did after graduation**.**

Interviewer: So looking back on these experiences, were they kind of aligned or misaligned with the teaching work that you would do once you graduated?

Graduate: Oh, they were very aligned.

6. Graduates named classroom management as an area for which they felt underprepared upon entering the profession. Graduates felt that the program did not address this topic adequately, and noted that the demands of managing a classroom alone were greater than they had anticipated.

7. All graduates felt that the program prepared them to teach mathematics in a culturally responsive way. They reported learning about culturally responsive instruction through their coursework, specifically in their methods course and the course titled *Detroit Families, Schools, and Communities*; during discussions with teachers and university instructors and coaches; and by participating in a series on trauma-informed teaching.

8. Nearly all program graduates from all cohorts have remained in teaching and are working in high-needs schools. Typically, graduates stay for two years in their first job and then move to another school, to follow a principal or to work closer to home.

Scholarly significance of the study

Teachers, especially minority teachers, leave the profession at astonishing rates and soon after graduation (Ingersoll & May, 2011). This problem is especially acute in schools for children of color living in poverty. TeachDETROIT graduates defy this national trend: nearly every graduate from all six cohorts of TeachDETROIT has remained in teaching and serves in high-poverty schools. We hypothesize that the curated early field experience is a significant factor contributing to increased teacher retention in hard-to-staff schools. This study provides some preliminary evidence that teacher retention, particularly in schools for children of color living in poverty, can be strengthened by preparing teachers to teach ambitious mathematics, along with attention to teaching for equity. We hypothesize that the curated field experience provides teachers with the skills and knowledge to teach ambitious mathematics and work in schools much like those they will teach in, and this in turn leads to feelings of self-efficacy and job satisfaction once graduates are teachers of record. Their shared explorations of the city of Detroit further cement program graduates' sense of commitment to the families in the city and the sense that as teachers, they are part of something bigger than themselves. Although limited by the small number of participants, this study sheds some light on the longer term effects of a program that is designed for preservice teachers to learn "in and from practice" (Lampert, 2010). Further investigation is needed to understand the intersection of culturally relevant teaching practices and the instructional routines in mathematics that graduates learned while in the program. Additionally, external validation of graduates' perceptions would greatly strengthen the claims made here, and to obtain the quality of their instruction Finally, although retention in hard-to-staff schools is strong for TeachDETROIT graduates, we have yet to study the quality of teaching and the extent to which graduates continue to carry out ambitious mathematics instruction.

An exploration of how mathematics teacher educators invite pre-service teachers to participate in lessons about the teaching of number concepts and operations in early years

Justina Longwe-Mandala[1] and Janne Fauskanger[2]

[1]University of Malawi, Faculty of Education, Malawi; jlongwe@cc.ac.mw

[2]University of Stavanger, Faculty of Arts and Education, Department of Education and Sports Science, Stavanger, Norway; janne.fauskanger@uis.no

This study explores the nature of pre-service teachers' participation in their lessons on how to teach number concepts and operations to learners in early years of primary school. The paper is part of a qualitative case study aimed at exploring how pre-service teacher education prepares pre-service teachers to teach number concepts and operations in early years (Grades 1-4) in Malawi. This paper reports on findings from two mathematics teacher educators. The lessons were analyzed using the Mathematics Discourse in Instruction framework. The analysis involved segmenting the lessons into episodes, each of which was recognized by change in content focus. Findings indicate that the pre-service teachers were mostly invited to participate through answering yes/no questions or supplying one-word responses to the teacher educators' unfinished sentences. Implications of these findings are discussed.

Keywords: Pre-service teacher education, early years mathematics, learner participation, malawi.

Introduction

In any mathematics lesson, meaningful learner participation is fundamental for understanding the mathematics made available for learners to learn (Carpenter et al., 2003; Trocki et al., 2014). Mathematical understanding develops best when learners participate actively and are encouraged to discuss mathematical concepts and to generate and argue mathematical solutions with one another (Carpenter et al., 2003). However, Trocki et al. (2014) argue that it is usually challenging for teachers to facilitate such type of discourse in their mathematics lessons. This suggests that teachers need to be supported to learn the practice of inviting learners to active participation. Inviting learners to participate in the lessons is one of the practices that teachers perform regularly in their work of teaching. As such, teachers need to learn how to do it (Adler & Pournara, 2019). This learning needs to begin from pre-service teacher education because pre-service teacher education is expected to expose pre-service teachers (PSTs) to learning environments that help them to experience active and meaningful learning, while at the same time helping them to learn to create the same learning opportunities for their learners (Taylan, 2017).

In Malawi, little is known about how teacher educators (TEs) invite PSTs to participate in their mathematics lessons and how these PSTs are enculturated into the practice of inviting learners to participate actively in the lessons about number concepts and operations. Number concepts and operations is the predominant focus of early years mathematics in Malawi; it also takes a big part of mathematics teacher education content (Ministry of Education Science and Technology [MoEST], 2017). Mastery of number concepts and operations plays an important role in the development of learners' future mathematical abilities. Yet, studies continue to show that early years learners in Malawi perform below the expected achievement level in mathematics, including in the core-element of number concepts and operations (Brombacher, 2011, 2019). A study by Saka (2019) indicated some challenges in the way teachers teach number concepts and operations in early years. Saka argued that the way teaching is done in early years does not fully support the development of number concepts and operations for learners. This finding may indicate some gaps in the way PSTs are helped to learn to teach number concepts and operations. Research indicates that what teachers learn during their pre-service training greatly influences how they teach (Ball & Forzani, 2009). Thus, if PSTs are engaged in active and meaningful participation during their teacher education, they are likely to engage their learners in active and meaningful participation during their work of teaching. This makes it necessary to explore how the teaching practice of inviting PSTs to participate in the lesson is enacted in pre-service teacher education. The main argument being put forward here is that teachers' ability to encourage meaningful participation among learners does not come naturally; it is a function of how they were enculturated into the practice during their pre-service teacher education. Thus, this study focused on answering the question 'How do mathematics TEs invite PSTs to participate in the lessons about how to teach number concepts and operations in early years?' In this paper, 'teacher educator' refers to the one teaching pre-service teachers how to teach, 'pre-service teacher' is the one learning the work of teaching, while 'learner' is the one whom the PSTs are expected to teach at the end of their pre-service teacher education.

Theoretical Framework

This study was guided by the Mathematics Discourse in Instruction (MDI) framework, developed by Adler and Ronda (2015). This framework was chosen for use in this study because it helps in describing the mathematics that is made available during teaching (Adler & Alshwaikh, 2019), and it specifically targets mathematics teaching practices that teachers meet regularly in their teaching. The framework considers four key elements to the teaching of mathematics: object of learning, exemplification, explanatory talk and learner participation as shown in Figure 1.

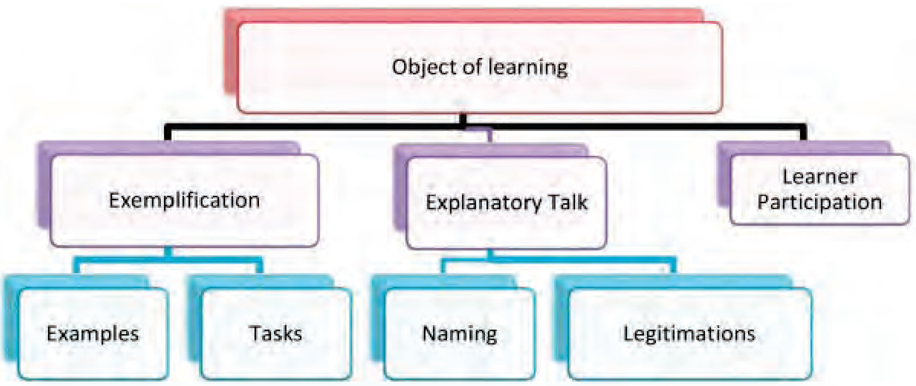

Figure 1: Constitutive elements of the MDI framework (Adler & Ronda, 2015, p. 239)

The object of learning is what learners are expected to know and be able to do. In a mathematics lesson, the object of learning is brought into focus through three mediational means: exemplification, explanatory talk and learner participation. Exemplification is concerned with examples and tasks used in the lesson, and how these provide opportunities for learners to learn mathematics. Explanatory talk is talk which names and legitimates important aspects of the object of learning, while learner participation is about how learners are invited to participate in the lesson (Adler & Ronda, 2015).

In the larger study, which explored how pre-service teacher education prepares PSTs to teach number concepts and operations in early years (Longwe, 2021), all these elements of the MDI framework were used to analyze how the TEs enacted the teaching practices of exemplification, explanation and PST participation in helping PSTs to learn how to teach number concepts and operations. However, the focus in this paper is on the element of learner participation, which is concerned with interactions that happen in a mathematics lesson. With this element, attention is focused on how learners are invited to talk mathematically and verbally show their mathematical reasoning (Adler & Ronda, 2015). Adler and Ronda (2015) characterize learner participation in three categories depending on the level of participation and opportunities they provide for learners to learn mathematics. Level one is where learners are invited to either answer yes/no or supply words to teachers' unfinished sentences. Level two is where learners are invited to answer what or how questions in phrases or sentences, while level three is where learners are invited to answer why questions, present ideas in discussion and the teacher re-voices, confirms or asks questions (Adler & Ronda, 2015). This framework was used in the present study to analyze how mathematics TEs invited PSTs to participate in their lessons about the teaching of number concepts and operations.

Methodology

This was a qualitative case study (Creswell, 2014). Four mathematics TEs were purposively selected for participation in the larger study where all the lessons were conducted through face-to-face mode of learning. Data being reported here is from two TEs. These were selected for this paper because data from one of the two TEs showed some differences in the way PSTs were invited to participate while the other one was selected as a representative of the three TEs who presented some similarities in the way they invited PSTs to participate. Data were collected through lesson observations. From the first TE (TE1), six lessons were observed. Two lessons focused on the teaching of place value of whole numbers and four lessons focused on the teaching of addition. This class had a total of 37 PSTs. From the second TE (TE2) four lessons on addition of whole numbers were observed. In TE2's class, there were 39 PSTs. It is important to note that the core-element of number concepts and operations is a wide area which encompasses many topics, and the topics of place value and addition of whole numbers also fall under this core-element (MoEST, 2017). Each of the lessons was videotaped and subsequently transcribed.

Data analysis was done by dividing the transcribed data into episodes. Coding for PST participation was done by indicating beside the utterances whether the PSTs participated by answering yes/no; answering what/how questions; or answering why questions, involved in discussions, or asking questions. At the end of each episode, a descriptive summary of all forms of participation was provided. The summary also included the number of occurrences of each form of participation. This quantification guided the analysis in determining the extent to which each form of participation was enacted and later make claims of how PSTs were invited to participate based on how each form of participation was enacted.

Findings

As stated earlier, this study explored how mathematics TEs invited PSTs to participate in the lessons on number concepts and operations. Following the MDI framework, analysis focused on whether PSTs were invited to either answer yes/no questions or one-word responses; answer what/how questions; answer why questions, present ideas in discussion, or ask questions (Adler & Ronda, 2015). Attention was also paid to how these forms of participation provided opportunities for PSTs to further their knowledge of number concepts and operations and learn how to teach these concepts to their learners. The findings are presented by first providing a summary of instances of how PSTs were invited to participate in all the lessons as shown in Figure 2. In presenting the findings in Figure 2, the forms of participation are presented as 'Y/N' where PSTs were invited to participate through answering yes/no or provide one-word responses, 'what/how' where they were invited to answer what or how questions, 'discussion' where they were invited to present ideas in discussion, 'why questions' where they were invited to answer why questions, and 'ask questions' where they were invited to ask questions. As explained in the methodology section, six lessons were observed in TE1's class (presented as L1-L6 in the graph) and four lessons were observed in TE2's class (L1-L4).

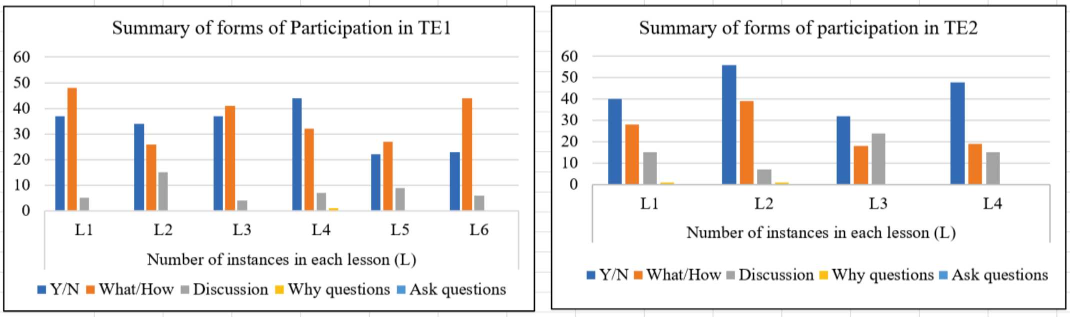

Figure 2: Summary of forms of PSTs participation in TE1 and TE2 lessons

As Figure 2 shows, TEs invited PSTs to participate through different forms of participation, as categorized in the MDI framework. PSTs were invited to participate through answering yes/no or one-word response, answering what/how questions, presenting ideas in discussion and answering why questions. However, these forms of participation were enacted to varying degrees.

Participation through answering yes/no or supplying one-word responses

While all forms of participation were observed in the lessons, findings indicate that TE2 mostly invited PST to participate through answering yes/no or supplying one-word responses. In all the 4 lessons the most common form of participation was where he invited PSTs to participate through this form of participation. For TE1, however, findings indicate that it was in 2 out of 6 lessons (L2 and L4), where he mostly invited PSTs to participate through answering yes/no or supplying one-word responses (see Figure 2). The following excerpt offers a representative example of how TEs invited PSTs' to participate through answering yes/no or supplying one-word responses (TE2, lesson 2 episode 1.2).

35 TE:	Yes. If I say ten plus nine, will this be a basic addition fact?
36 PSTs:	No
37 TE:	Why say no?
38 PST:	Because there's two-digit number

39 TE: Because we have used two-digit number, are we together?
40 PSTs: Yes
41 TE: Otherwise, we would like to concentrate on one-digit number added to one-digit number…In addition, what are addends? When you put two addends together, you get a sum, so what are addends. Yes!
42 PST: Are numbers which can be added
43 TE: The numbers that can be added. Are we together? So, in this case, if ten is added to nine, therefore, ten is a what?
44 PSTs: Addend
45 TE: Nine is a what?
46 PSTs: Addend
47 TE: And nineteen is what?
48 PSTs: Sum
49 TE: The sum, the result, are we together?
50 PSTs: Yes

In this dialogue, the TE focused on the basic facts of addition and how to come up with addition sentences from the basic facts of addition table. Throughout this dialogue, PSTs participated by answering yes/no or supplying one-word responses, except in utterances 38 and 42 where they went beyond giving yes/no or supplying one-word responses. This implies that most of the mathematical talk was being done by the TE while the PSTs were only supplying one-word responses.

Participation through answering what/how questions in phrases or sentences

Findings from data analysis indicate that PSTs were also invited to participate through answering what/how questions in phrases or sentences. For TE1, findings indicate that this was the most prevailing form of participation through which he invited PSTs to participate (see Figure 2). For TE2, findings have indicated that the most common form of participation was through answering yes/no or one-word responses, as indicated in the section above, but participation through answering what/how questions was also present as shown in Figure 2. Instances where TEs asked PSTs to answer what/how questions, such as to define concepts about number concepts and operations were observed. Below is an example of how PSTs were invited to participate through answering what/how questions.

TE: Our today's lesson is about place value, (writes place value on the board). Have you ever heard of that word, place value? Or what comes into your mind when you hear about these two words, place value? (TE1, lesson 1, episode 1.1)

In this excerpt, the TE invited the PSTs to explain what the concept 'place value' means. This form of participation invited PSTs to go beyond supplying single words to TE's questions, to reasoning about the concept of place value.

Participation through presenting ideas in discussion, answering why questions, and asking questions

In all the lessons, findings indicate some instances where PSTs were invited to participate through presenting their ideas in discussion. Some of the activities in which PSTs were invited to participate through discussion include discussing how to model addition of whole numbers using different resources such as place value box, spike abacus, and on a number line. Findings also show few instances where PSTs participated through answering why questions—one instance for TE1 and two instances for TE2 (see Figure 2). In these forms of participation, PSTs were seen to be exposed to more open discussions where they shared their mathematical thinking. Below is a representative example of instances where PSTs were invited to participate by answering why questions.

TE: Now, can you explain why addends in the basic addition facts do not go beyond nine? (TE1, lesson 3, episode 2.1)

This question provided opportunities for PSTs to go beyond just giving a definition, to applying their mathematical thinking considering the properties of basic facts of addition. Findings also indicate that participation through asking questions was not observed in any of the lessons (see Figure 2), implying that the PSTs were not exposed to the practice of getting to ask questions from their TEs.

Discussion and conclusion

In this study, an exploration of how TEs invited PSTs to participate in their lessons about how to teach number concepts and operations in early years, the observed TEs invited PSTs to participate through all the three forms of participation as characterized by the MDI framework, namely, participation through answering yes/no or supplying one-word responses, participation through answering what/how questions in phrases and sentences, and participation through discussions and answering why questions (Adler & Ronda, 2015). However, it was revealed that PSTs were mostly invited to participate through answering yes/no or supplying one-word responses and through answering what/how questions. In few instances, they were invited to participate through discussion and answering why questions. Also, findings have revealed that in these observed forms of participation, there were some variation in the way the two TEs enacted them. It was observed that TE1 mostly invited PSTs to participate through answering what/how questions, while TE2 mostly invited PSTs to participate through answering yes/no or supplying one-word responses. Although there were such differences, both forms of participation—participation through answering yes/no and participation through answering what/how questions—as enacted by the TEs, did not appear to provide enough opportunities for PSTs to engage in more active and meaningful participation. This finding appears to be in contrast with what Taylan (2017) argues about engaging PSTs in meaningful participation. Taylan (2017) contends that PSTs are expected to create active and meaningful learning situations for their learners. But for these PSTs to be able to do this with their learners, there is need for them to encounter similar learning opportunities during their pre-service teacher education. This implies that if PSTs are given opportunities to participate meaningfully in their mathematics lessons, they are likely to provide the same learning opportunities to their learners during their work of teaching. Thus, this finding from the current study suggests that the PSTs had limited opportunities to learn to do this to their learners.

During mathematics teaching, What learners are invited to say determines their opportunities to talk mathematically and demonstrate their mathematical reasoning (Adler & Ronda, 2015). The same can be said about PSTs, implying that exposing PSTs more to participations that required them to answer yes/no or one-word responses limited their opportunities to talk mathematically, develop and demonstrate knowledge about number concepts and operations. Also, when PSTs are only invited to supply one-word responses, it is difficult for TEs to spot misconceptions that PSTs might have about the mathematics they are learning (Taylan, 2017).

On the other hand, inviting PSTs to participate through answering what/how questions in phrases or sentences appeared to create opportunities for them to show what they know and also opportunities to learn about number concepts and operations, but it may not have provided enough opportunities for them to argue mathematically and expose their mathematical thinking. The few instances where PSTs were invited to participate through discussions and making presentations appeared to have provided opportunities for them to engage in greater and more meaningful participation where they shared their ideas and were able to make mathematical arguments. The MDI framework advocates inviting students to participations where they present their ideas in discussion, answer why questions and also ask questions (Adler & Pournara, 2019). However, the finding that the practice of inviting PSTs to answer why questions was rare and that there was no instance where they asked questions may indicate that the PSTs had limited opportunities to demonstrate their mathematical reasoning and to learn to provide such kind of participation to their learners. It might also indicate that the practice of facilitating meaningful mathematical discussions is challenging for TEs. Encouraging PSTs to ask questions is an important practice for teachers to learn to do as it promotes active learning and also helps to unveil misconceptions that PSTs might have (Taylan, 2017).

The findings of this study suggest that PSTs were mostly exposed to participations that provided limited opportunities for them to talk mathematically and verbally show their mathematical reasoning. The challenges in the way teachers teach number concepts and operations, and the resultant poor learner performance (Brombacher, 2019; Saka, 2019), as indicated in the introduction section, might be related to the way these teachers were prepared to teach during their pre-service teacher education— how they were invited to participate in their mathematics lessons as PSTs, as visualized in this study. In order for early years learners in Malawi to improve from performing under the expected achievement level in the core-element of number concepts and operations (Brombacher, 2011, 2019), an implication from this study might be to extend the ways PSTs are invited to participate in Malawi pre-service teacher education. Learners learn more from their mathematics lessons when they are given the opportunity to discuss mathematical concepts and argue mathematical solutions with others (Carpenter et al., 2003; Taylan, 2017). Therefore, exposing PSTs to such a learning environment would be useful in helping them understand primary school mathematics better, and at the same time help them to develop knowledge of how to facilitate such type of participations with their learners.

In this paper we are interested in understanding how pre-service teachers use programming to design digital learning situations (learning objects). We discuss a case study of a pre-service teacher creating a learning object to teach a mathematics concept. Using a development-process model and the instrumental approach, with its concept of scheme, we analyze the pre-service teacher's engagement with the activity of creating the learning object and identify two schemes that she developed and mobilized for articulating the learning trajectory and articulating it in programming language. The analysis of schemes highlights the need for understanding operational knowledge in the context of pre-service teachers' experiences of using programming to design learning objects.

Keywords: Instrumental approach, programming, pre-service teachers, learning objects.

Introduction

Integrating computer programming into education is increasingly becoming a necessity in all levels and fields, from preschool to life-long learning (Schina et al., 2021). In the decades since Seymour Papert published his seminal work *Mindstorms* in 1980, the increasing research has emphasized the importance of programming in supporting students' understanding of mathematical concepts (Wilensky, 1995). Accordingly, teacher education and instructional programs are creating new learning paths and integrating programming. In particular, the Department of Mathematics and Statistics at Brock University has integrated programming into mathematics education for mathematics majors and future mathematics teachers through a sequence of Mathematics Integrated with Computers and Applications (MICA) courses (MICA I, II, III –for math and science majors / III* –for pre-service teachers). The MICA program is the context of the study reported in this paper. The learning objectives of MICA courses are to develop mathematics concepts in conjunction with programming skills and to encourage mathematical creativity. In the progression of the sequence of these courses, students engage in 14 programming-based mathematics investigation projects (4 in MICA I, 5 in MICA II, and 5 in MICA III or III*). Unlike other projects where instructors specify the topics, in each MICA course final project, students choose a topic of their interests and the type of project. Pre-service teachers may choose to create a "learning object (LO)" (Muller et al., 2009), i.e., a step-by-step guided learning interactive object of a school mathematics concept, and to work individually or in pairs in its design, which may be relevant to their future profession. Research highlights the importance of developing pre-service teachers' understanding of computational thinking in the context of the subject matter, such as mathematics (Yadav et al., 2014). However, there is limited research on pre-service teacher' learning experiences (Aslan & Zhu, 2016). This paper focuses on MICA pre-service teachers' learning experiences of creating LOs. Specifically, the paper discusses a case study aimed at exploring a pre-service teacher's engagement, and her development and mobilization of schemes through the activity of creating a learning object.

Theoretical Framework

We frame the pre-service teachers' engagement with the activity of designing an LO using a development-process (dp) model (Figure 1), proposed by Buteau and Muller (2010), that represents the student engagement in the activity, involving multiples steps that arise in a dynamic and non-linear way.

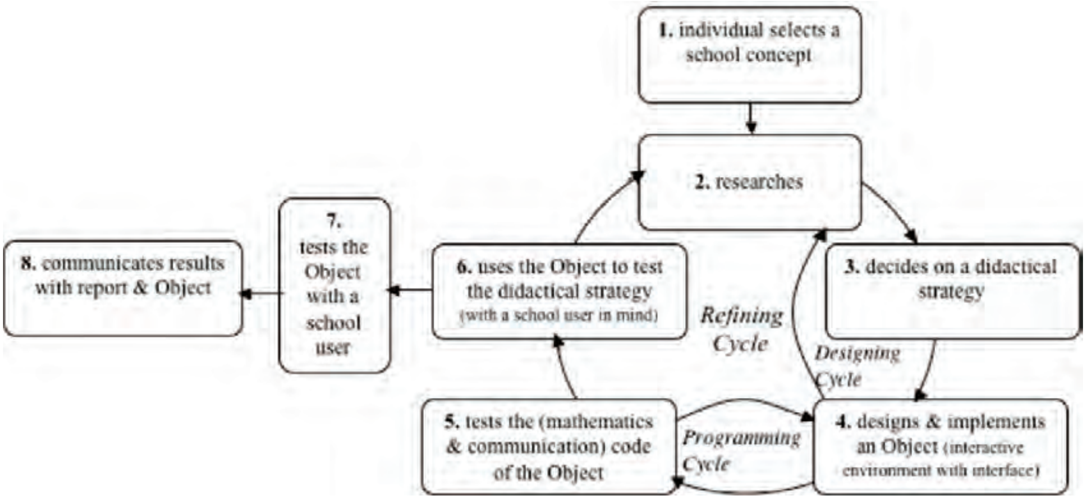

Figure 1: Development process model of an LO of a mathematical concept (Buteau & Muller, 2010)

Our understanding of pre-service teachers' development and mobilization of schemes is framed by an instrument-mediated activity approach –the instrumental approach– which was developed in the field of ergonomics to account for the active role that a user of an artefact plays, and the development of competence during his/her activity (Rabardel & Beguin, 2005). The instrumental approach has been further articulated and used in mathematics education research to conceptualize teaching and learning situations involving artefacts (Guin et al., 2005). In contrast with the dyadic subject-object interaction, the approach highlights the triad interactions among the subject, the instrument and the object towards which instrumented action is directed.

Critical to our study is the theory of instrumental genesis, which articulates a distinction between an artefact as a material or semiotic construct and an instrument as a psychological construct that emerges from the subject's activity with the artefact for a given goal. Put differently, "…during the activity and in situation… the user constitutes the artifact (whether physical or symbolic) as an instrument" (Rabardel & Beguin, 2005, p. 4) through an instrumental genesis process. The instrument is composed by a part of the artefact and a scheme of its use. A scheme (instrumented action scheme) is a stable organization of the subject's activity for a given goal, which is developed and mobilized by the user in action. It constitutes a whole or a set of mutually dependent components: i) one or several *goals* of the activity; ii) *rules-of-action* (RoA), to generate action, information seeking and control according to the features of the situation; iii) *operational invariants*: concepts-in-action (CiA), which are concepts considered as relevant and theorems-in-action (TiA), which are propositions considered as true and governing the RoAs; and iv) possibilities of *inferences* (Vergnaud, 2009).

Methodology

This paper is part of a 5-year ongoing research study, that seeks to examine how post-secondary mathematics students learn to use programming as a computational thinking instrument for mathematics inquiry. The naturalistic (non-interventional) study utilizes a mixed methodology and an iterative design approach. Data collected include each participant's programming-project assignments (e.g., the LO; and its associated report), and semi structured interviews with each of the participants after completing each of the project assignments. The design of the interview guiding questions was informed by the students' dp-model (Figure 1). In addition, data collected included post-laboratory session reflections and a questionnaire. After each of the 10 weekly 2-hour MICA lab sessions, participants recorded their reflections on their learning during the lab session (guiding questions were provided). All participants filled an online questionnaire before and after their MICA course. In this paper, we discuss the case study of a MICA II student, Kassie (pseudonym). Kassie was among eight MICA II participants recruited in year 2 of our larger study. Kassie was selected because she was particularly reflective and elaborative in her interview and lab reflections. Data for the case study include Kassie's final project –an LO and report, a semi-structured interview about her final project, and post-laboratory reflections related to her final project. The interviews were recorded as audio files and then transcribed into word documents. To describe Kassie's engagement with the activity, we analysed Kassie's final project interview, her report and the LO by trying to observe her activity in the steps of the dp-model. To analyse Kasie's schemes, first Kassie's interview and lab reflection data were coded individually by two coders, followed by a thematic analysis (Cresswell, 2014) done jointly by two coders. 16 subthemes were grouped in five main themes, two of which corresponded to strategies and perceptions. In addition to those themes, other themes specific to LOs were identified. Using codes under themes for the strategies (associated to rules-of-action) and the perceptions (associated to operational invariants) and informed by the steps in the dp-model, we then analysed the scheme according to its components (*RoAs* and operation invariants).

Findings

We present the results of the case study. First, we describe Kassie's engagement with the activity of creating the LO. Second, we present two examples of Kassie's schemes that were identified through analysis.

Kassie's engagement with the activity

As indicated below in Figure 1, the development process of an LO begins with the student selecting a school concept to teach (step 1). Kassie and her assignment partner started by looking for potential high school mathematics topics on the internet. They decided on the derivatives topic after discussing three possible topics between each other and their professor. They stated on their LO report that the focus was on first derivatives, specifically focusing on velocity. After deciding on the topic, they referred mostly to their personal notes from high school, the internet and library resources to find out when and how the derivatives are taught in the Ontario school curriculum and what the prerequisite mathematical knowledge for the topic would be (step 2). They chose grade 11 and 12 for their LO and assumed that the students would have sufficient background knowledge on derivatives and velocity because they would have just learned or would be in the process of learning about derivatives.

In deciding on didactical strategy (step 3), Kassie and her partner decided to focus on the derivatives as a concept and planned to show the relationship between the derivatives and the graphs. They aimed at enhancing the students' understanding of derivatives, give prompts and fun refreshers to help them understand one of the applications of derivatives–velocity.

After deciding on their didactical strategy, they began to design and implement (through code in the vb.net programming language) an interactive LO with a self- contained interface (step 4). Kassie stated that they gradually built on the LO as they were developing it. For this activity, Kassie and her partner created a random equations generator, derivatives and graphs and led the user to match the graphs to derivatives. They designed their LO in a way as to lead the user to find the derivative, then find the graph, then find the velocity. Kassie and her partner tested the interface in terms of its functioning, communication and/or navigation in several different cases, to ensure the accuracy of their coding (step 5). Kassie indicated that she and her partner had to debug the programming when they randomly generated the questions. She also stated that, after they tested the LO, they improved the look of the picture and textboxes for the user.

Kassie and her partner revisited their didactical strategy by having three university students who are not in a math program to use the LO and complete a survey to control if any change or improvisation was needed in the activities (step 7). Kassie stated that the feedback they received from the university students affirmed that their LO was adequate for high school grade 11 and 12 students, and that it portrayed the information in an entertaining and interactive way. Subsequently, they submitted the LO and their corresponding LO report, which included the didactical purpose and strategies, the target audience and the mathematical background of the target audience, a summary of the school pupil's experience, and a discussion (step 8).

Kassie's examples of schemes

Table 1: Scheme of Articulating the learning trajectory

Goal	Rules of Action	Operational Invariants (TiA or CiA)
Articulating the learning trajectory / development of the topic	I identify the way students learn the best I identify a concept development I identify an interesting context to capture interest (Friends) I identify the possible applications between the selected topic with other topics (not only in mathematics)	When learners can relate the topic that they are learning with something from their lives, they are more interested. (Theorem in action) High school students need interesting situations/contexts to learn math (Theorem in action). A good context or situation to learn is one that relates mathematics to other area (e.g., physics) (Theorem in action) Relation between math concepts and other contexts (Concept in action) Math concepts can be applied to other areas (e.g., physics)

Table 1 summarizes components of Kassie's scheme of articulating the learning trajectory (step 3 of the dp-model). During the interview, Kassie was asked to articulate on what kind of a didactical strategy she used for the LO user to learn, and she noted:

> Well, we wanted them to learn the most basic way possible, but in a way that they could relate to, not something that's like just straight math. So, we put like a storyline and tried to enhance that so they would be interested in actually doing it. (LO, 15)

We interpreted this description by Kassie as indicating a rule of action such as "I identify the way students learn the best" and a theorem in action such as "When learners can relate the topic that they are learning with something from their lives, they are more interested". We interpreted Kassie's reflection on how the students learn the best as she is aiming to establish connections between real life situations. Kassie assumed that a story that LO users can relate to, is likely to draw the targeted age group's interest to the mathematics activity. Kassie was asked if her focus was more on the algebra and calculations, or more on the concept of what a derivative is. She stated:

> I think I focused more on the concept of what a derivative is, because we were looking at velocity and how fast something moves. So, we did a Friends (tv series) theme, and we gave them three options for Ross (a character in Friends) to get to work, and what was the fastest way for him? So, we said that they had a background in derivatives, we just wanted them to understand the concept of velocity and what that means and how you see if something has a faster velocity than something else. (LO, 14)

We interpreted Kassie's answer as indicating many RoAs such as "I identify a concept development", "I identify an interesting context to capture interest", and "I identify the possible applications between the selected topic with other topics that are not necessarily in mathematics". Kassie's emphasis on the derivatives as a concept, indicated that she intended to design the LO to develop the user's understanding of the concept with its relationship to other concepts such as velocity. In her explanation, Kassie identified a learning objective (comprehension of the derivative concept); and its relations to other areas (velocity in physics); and how the mathematics problem could be presented to the learner in a relatable and entertaining context to capture interest (the Friends theme and going to work). On her LO report, she expressed her thoughts on how learners are more interested when they can relate the topic with something from their lives, stating:

> By having our program F.R.I.E.N.D.S. themed, it not only engages the students in what is being taught to them, but it also gives them ideas and leeway into being creative with other concepts of math in order to better their own understanding. The students will gain a better understanding of velocity by comparing the velocities of three different modes of transportation, and actually conducting their derivatives in order to find the fastest velocity. This not only enhances their understanding of derivatives, but also allows them to explore a real-life situation in regard to velocity. (LO Report)

We interpret her explanation as she regards a good context or situation to learn is to be one that relates mathematics to another area such as physics.

Table 2 summarizes the components of scheme of articulating the learning trajectory in programming language. The scheme relates to the planning stage of step 4 of the dp-model.

Table 2: Scheme of articulating the learning trajectory in programming language

Goal	Rules of Action	Operational Invariants (TiAs and CiAs)
Articulating the parts of the learning trajectory in programming language	I identify the parts of the learning trajectory to be coded I code the parts separately step by step (e.g., equations, graphs) I use the story/context of the to code the parts I use my previous programming knowledge from previous assignments to code the parts	Learning trajectory shows how the user will develop understanding of the concepts to be learned The parts of learning trajectory must align with the story/context of the learning Programmed math must help the user to visualize the mathematics

When Kassie was asked how she incorporated the graphs with the concept of velocity and derivatives in her design, she expressed that she envisioned the user to first understand what a graph is and how it looks, then understand what a derivative graph is and how it looks and finally understand the relationship of velocity with the graphs and the concept of derivatives through finding the actual velocity. Kassie noted: "We wanted them to know what the graph looked like, know what the derivative graph looked like, and know like, what the actual velocity was." (LO, 15)

We interpret the above as Kassie developing a RoA "I identify the parts of the learning trajectory to be coded" supported by the TiA, "Learning trajectory shows how the user will develop understanding of the concepts to be learned." To design and execute these steps in the LO, Kassie and her partner started to design and work with the original graphs, then with the derivative graphs and finally find the velocity to imitate the user's steps. Kassie noted: "So, I think we started with the original graphs, and then we started with the derivative graphs and then we went to find the velocity." (LO, 15)

We interpreted this explanation as Kassie developed a RoA, "I code the parts of the learning trajectory separately step by step (e.g., equations, graphs)". Kassie further elaborated on how she and her partner embedded a storyline –in this case, a character from a TV series trying to go to work– as they coded step by step the parts of the LO:

> We built on the learning object, because we explained the story where "he needs to get to work, let's try and find him the fastest way". So, then they had the graphs, the original graphs, and then they had to match them to what they thought it was, and then they took the derivatives, or they practiced derivatives, just like random equations, then they took the derivative graphs and matched it to the derivatives that they took and then they found the velocity. So, it was kind of "here's your first part, then find the derivative, then find the graph, then find the velocity. " (LO, 16).

We interpret this explanation as Kassie developing a RoA, "I use the story/context of the learning task to code the parts" and the TiA, "The parts of learning trajectory must align with the story/context of the learning object."

When Kassie was asked why they wanted to include the graphs and the function with its derivative in their LO, she elaborated:

> I feel like it's really important because they make sure you know it in high school but also for our own understanding, I thought that "you want to know what that looks like", you want to know that the derivative of a parabola is like a straight line. I feel that is really important to know, so that they can visualize it while they're actually learning, the concept of it. (LO, 26)

We interpret the above explanation as Kassie developing a TiA such as “programmed math must help the user to visualize the mathematics”. Kassie was asked if she referred to her previous programming knowledge that had been covered previously in the course and she stated:

> Yes, definitely. Because there was certain things that I didn't remember how to do that, but I know we did it in previous assignments, so it was easy to go back and be like "this is how you do it, okay let's do it like that". (LO, 18)

We interpreted Kassie’s answer as indicating a RoA she developed during her design process of the LO as “I use my programming knowledge from previous assignments to code the parts”.

Discussion and Concluding Remarks

In this paper we presented a case study of a pre-service teacher experience of using programming to design a learning object. Using the dp-model and concept of scheme we described a case of a pre-service teacher engagement, development and mobilization of two schemes for the activity. The concept of scheme is crucial in understanding Vergnaud’s (2009) distinction between operational form of knowledge (action in the physical and social world) and the predicative form of knowledge (linguistic and symbolic expressions of the knowledge). While both kinds of knowledge are important in understanding pre-service teachers’ activity, mathematics education research tends to focus more on predicative knowledge (Vergnaud, 2009). Our analysis of engagement and two schemes developed by the pre-service teacher highlights the need to understand operational knowledge in the context of pre-service teachers’ learning experiences of using programming to design learning objects. As integrating computer programming into mathematics education is increasingly becoming a necessity, more research is needed to understand this kind of knowledge and its implication to mathematics teacher education. In our previous work on exploratory objects for pure or applied mathematics investigations, we have argued that the schemes that students develop and mobilize are associated to steps in the related dp-model (e.g., Gueudet et al., 2020). Likewise, our case study on learning objects indicates that the schemes that pre-service teachers develop and mobilize are associated with the dp-model for LOs. The two pre-service teachers’ schemes identified in the case study are associated with Step 3 and 4 of the dp-model (Figure 1).

Investigating the concerns of post-primary mathematics teachers towards problem-solving following curriculum reform

Róisín Neururer[1] and Aoibhinn Ní Shúilleabháin[1]

[1]University College Dublin, Ireland; roisin.neururer@ucdconnect.ie, aoibhinn.nishuilleabhain@ucd.ie

Keywords: Teacher concerns, problem-solving, curriculum reform.

Background to the Research

In line with an international trend of curriculum reform towards a greater focus on problem-solving and mathematical literacy, significant reforms of mathematics curricula have taken place in Ireland in recent years. A new secondary curriculum was introduced in 2010 representing a comprehensive overhaul of content, assessment, and teaching and learning practices (Johnson et al., 2020). Incorporated in this reform was an attempt to move towards a more problem-solving approach to teaching mathematics. In 2015 the mathematics curriculum was revised once again for the junior cycle (ages 12/13 – 14/15). Classroom-based assessments (CBAs) were introduced representing a dramatic change in teachers' roles assessing their students' learning, as formal assessment in Ireland has traditionally been anonymous and centralized without any input from a student's teacher.

Teachers play a central role in the adoption of curriculum reforms and the successful enactment of reform depends on the teachers who will interpret and implement it (Spillane, 1999). However, educational reforms can aggravate teachers' concerns (Charalambous & Philippou, 2010), thereby influencing the implementation of reforms. Identifying and attending to the concerns of teachers can contribute to the successful implementation of educational reforms (Christou et al., 2004).

This research intends to gain an insight into the nature of Irish secondary mathematics teachers' concerns about problem-solving and asks the question: What is the nature of Irish secondary mathematics teachers' concerns with regards to problem-solving and the associated classroom-based assessment following recent curriculum reforms?

Methodology and Theoretical Framework

Hall et al. (1977) proposed seven "Stages of Concern" (SoC) which teachers experience as they implement a reform: awareness, informational, personal, management, consequence, collaboration, and refocusing. More recent studies have identified these stages of concern in teachers' interpretation and implementation of reform (Charalambous & Philippou, 2010) and found a pattern where teachers move through these stages, though not necessarily linearly, as a reform is introduced, implemented, and becomes established (Johnson et al., 2020). It has been suggested that the success of a reform depends on this development of concerns (McKinney et al., 1999).

This research uses a qualitative approach to generate data on teachers' concerns around problem-solving and the CBAs. Semi-structured interviews were conducted with 12 mathematics teachers, representing a range of teaching experiences (e.g. gender, mathematical background, years of experience etc.) and school contexts (e.g. urban/rural; single-sex/co-ed; small/large pupil population etc.). The SoC framework informed the design of the interview and data analysis is being undertaken using this same framework. The anonymized transcripts are being analysed through qualitative content analysis with the seven stages of the SoC framework serving as “a priori” codes.

Preliminary Findings

Following the initial phase of data analysis, the research provides a snapshot of participating teachers' concerns in each of the seven stages of the SoC framework. All participants demonstrated management concerns, most of which were related to time pressures with regards to classroom time within an already over-loaded curriculum.

> Mary: It's just being able to facilitate [problem-solving] in the classroom under the time constraints seems to be a serious challenge to me.

Collaboration was a dominant theme. It was highlighted as a source of support but there was also an explicit desire for more collaboration with colleagues.

> Cillian: I think having more opportunities there to engage with other schools around and share practice there would be the biggest thing.

Findings from this research will feed into the design of a specific teacher development initiative, where curriculum materials will be developed in order to provide targeted support for mathematics teachers enacting these reforms.

Revisiting the concept of reflection: An empirical investigation of mathematics teachers' articulations on the teaching practice

Yael Nurick[1], Abraham Arcavi[1] and Ronnie Karsenty[1]

[1]Weizmann Institute of Science, Department of Science Teaching, Israel; yael.viz@gmail.com

The scientific literature points to the importance of reflection and its contribution to teachers' work. However, the reflective process involves some challenges. Definitions of reflection are abstract, and models of reflection are complicated and not always accessible to practitioners. The goal of this study was to unpack the concept of reflection into categories – actions or phases which are part of a comprehensive reflective process. For this aim, we analyzed 11 mathematics teachers' reflective expressions, collected in three different settings of professional development. Six categories of reflection were identified in the study, which suggest different actions that teacher educators can consider when designing guiding tools to support teachers through the reflective process.

Keywords: Reflection, professional development, journal writing, stimulated-recall interviews.

Introduction

Beginning with John Dewey, reflection is a central concept in many fields, among them the field of mathematics education. Reflection is a special kind of thinking, a process of looking back at experiences and learning through and from them (Finlay, 2008). Involvement in a reflective process is considered to be important and beneficial for teachers' professional development: Reflection enables teachers to be more aware of their actions and of the beliefs and assumptions that stand at the basis of these actions, so decision-making processes become more deliberate (Finlay, 2008; Karsenty & Arcavi, 2017). Reflection is linked to the mechanism of knowledge development (Clarke, 2000; Karsenty et al., 2015; Schön, 1983), and was also found to be a key aspect in processes of change regarding teaching practices (Clarke, 2000; Karsenty & Arcavi, 2017; Schwarts & Karsenty, 2020).

However, there are still some considerable challenges in understanding this concept. Specifically, there is a need to understand what it is that mathematics teachers do when they reflect on the teaching practice. In this study, we analyzed mathematics teachers' reflective expressions, with the goal shedding light on the complex concept of reflection, and to unpack the definition of reflection into categories – actions or phases which are part of a comprehensive reflective process.

Theoretical Background

Based on John Dewey's ideas, Schön (1983) related to reflective practices, where practitioners examine their actions. Schön distinguished between two types of reflection: (1) *reflection in action* – the practitioner's thinking about his/her actions while doing them; and (2) *reflection on action* – a process where the practitioner is consciously looking back at a situation and critically examining, analyzing, and evaluating it, in order to gain new insights which will improve future practice.

Dewey's and Schön's ideas led to development of various definitions for the concept of reflection, which relate to diverse kinds of categories of reflection, to aspects included in the reflective process, to the purposes of the reflective process, or to its results (Finlay, 2008; Lyons, 2010). In the field of mathematics education, Clarke (2000) distinguished between three types of reflection: the first two are similar to Schön's – *reflection in practice* and *reflection on practice*. The third type, *reflection for practice*, refers to the development of teachers' awareness to decision-making processes. Geiger et al. (2016) offer a two-dimensional framework for looking at mathematics teachers' reflections: the level of reflection (technical, deliberate, or critical reflection) and the object on which the reflection is focused (self, practice, or students). As the basis of this study, we chose the following definition, which is concise, yet relates to diverse aspects of reflection which the literature emphasizes:

> [Reflection is a] detailed, analytical, and careful observation of ''what was done'' in order to attempt to understand intentions, plans, actions and utterances and to consider alternative decisions and their possible implementation (Karsenty & Arcavi, 2017, p. 435).

Different models were developed in order to support teachers, and other practitioners, in the process of reflection. Two central models are Gibbs' (1988) Reflective Cycle, which offers six phases for the process, and Korthagen's (2014) ALACT model, comprised of five phases, alongside the 'core reflection' model, which highlights the aspects teachers should relate to in the reflective process. Finlay (2008) stresses that different models for reflection are discerned from each other in the phases and actions they include, the aspects that the reflection relates to and the tools and means that the model offers (guiding questions, peer discussions, writing journals, etc.).

However, although reflection is a keyword in the field of education for many decades now, the literature shows that it is not easy to be involved in a reflective process (Finlay, 2008; Korthagen, 2014; Lyons, 2010). The definitions for reflection are somewhat abstract, and models for reflection include many components. It is difficult for teachers, as well as for teacher educators, to understand what the process of reflection should look like in actuality (Brown & Coles, 2012; Finlay, 2008; Korthagen, 2014; Lyons, 2010). Since the guiding lines for reflection are not clear, teachers tend to reflect on their teaching in technical, superficial, or inefficient ways, which do not necessarily support their teaching (e.g., Korthagen, 2014).

Rationale and Research Question

As we aim to support mathematics teachers as they are involved in reflective processes, the overarching goal of our study is to bridge the gap between the theoretical knowledge that exists on reflection on the one hand, and the way it is implemented and practiced by teachers, on the other hand. In our study, we analyzed mathematics teachers' articulations, in which they reflected on the teaching practice in three different settings of professional development (details follow). When we tried to analyze these articulations with the definition of Karsenty & Arcavi (2017), we found this definition does not capture all the actions that teachers perform when they reflect on their practice. Other existing definitions were not operational either. Therefore, the first step of the study, reported in this paper, was aimed at unpacking the definition of reflection into operational categories which relate to actions that mathematics teachers perform when they reflect on their teaching practices. Accordingly, the research question was: *What categories of reflection can be identified in mathematics teachers' reflective articulations, within different settings, and how do these categories relate to, correspond, or add to the existing literature?*

Methodology

Study participants

70 secondary mathematics teachers took part in one of seven VIDEO-LM PD courses held in Israel in 2015-2016. Out of the 70 teachers, 11 teachers were chosen to participate in this study. The 11 teachers were selected to represent various characteristics of the 70 teachers, such as teaching record, gender, academic education, and teaching experience (high/middle school; low/advanced track, etc.).

Data collection

For each teacher, data was collected from the following sources, which refer to three different settings of professional development that allow teachers to reflect on their mathematics teaching practices:

(1) **VIDEO-LM PD meetings**: The participating teachers all took part in one of seven VIDEO-LM PD courses' meetings held in Israel in the academic year 2015-2016. The VIDEO-LM project (**V**iewing, **I**nvestigating and **D**iscussing **E**nvironments of **L**earning **M**athematics) is a project aimed at enhancing mathematics teachers' reflection skills and mathematical knowledge for teaching. A typical VIDEO-LM course is composed of 7-10 meetings, 30 hours in total. In each meeting, teachers watch a videotaped mathematics lesson and discuss it, while using the "six-lens framework" – an analytic framework focused on aspects of mathematics teaching (see Karsenty & Arcavi, 2017). All meetings in the seven PD courses were videotaped. From these meetings, all excerpts in which the participating teachers spoke were transcribed. The number and length of excerpts vary between the teachers.

(2) **Weekly journals**: The 11 teachers wrote personal journals on a weekly basis, for five months. In these journals, the teachers were asked to write about the most significant event that happened to them during the past week, either while preparing for class or during a mathematics lesson. They were also asked to explain why it was significant for them. There were no additional guiding questions, and the teachers wrote the journals independently and without feedback. Each teacher wrote between 10 to 19 journals (15 in average). The average journal's length was 165 words.

(3) **Stimulated-recall interviews (SRI), based on a videotaped lesson**: One lesson of each of the participating teachers was videotaped. The teachers chose which lesson will be videotaped, with no limitations regarding the class, level of group or the subject/setting of the lesson. A while afterwards, an individual interview was held with each of the teachers, where the first author watched their videotaped lesson together with them. The teachers were asked to stop the video whenever they saw a "issue of interest" which they wanted to talk about. The conversation was held in an open manner, with no specific instructions, with requests for clarifications as needed. The interviews lasted some 60-90 minutes. The teachers stopped their videos about 10 times in average, and in most cases the conversation continued after the video watching has ended. All the interviews were videotaped and transcribed.

The three settings differ in many features, like the manner of expression (written or oral); the object in the basis of reflection (the teacher's own experiences, or another teacher's lesson); and the level of guidance in the settings (high level of guidance in the VIDEO-LM meetings compared to minimal guidance in the weekly journals and in the SRIs). These differences influence the manner of reflective process, and so can highlight different aspects in teachers' reflections.

Data analysis

The data analysis process consisted of moving back and forth between two processes: (1) The teachers' reflections in the different settings were analyzed in an inductive approach, in order to identify actions that teachers perform in actuality when they reflect on their teaching (i.e., analyzing the situation, referring to intentions\plans or considering alternative decisions). (2) Examination of definitions and models of reflection offered by the literature, both inside and outside mathematics education. While the result of the inductive process was in a list of coded categories of reflection, the comparison to the literature enabled us to refine these categories.

Results

The analysis resulted in the identification of six main categories of reflection (some have sub-categories): (1) analysis of the situation; (2) consideration of alternatives, doubts, or dilemmas; (3) re-orientation; (4) consideration of beliefs; (5) addressing the emotions that a situation evokes; and (6) addressing challenges of teaching. Below we describe and demonstrate each of these categories.

Category (1): Analysis of the situation

A central part of a reflective process is to look back at a situation and analyze it. In different models of reflection, such as the 'Reflective Circle' (Gibbs,1988), this is the first phase of the process. However, the literature is not clear on what is included in such an analysis. Therefore, we decompose this category into four subcategories: (a) Observation of 'what was going on' and thinking about reasons for what has happened; (b) Consideration of goals that stand at the basis of the teacher's decisions and actions; (c) Attendance to broad assumptions and contexts, such as social, political, affective, or institutional assumptions; and (d) Evaluation of the situation and of teachers' actions (e.g., practices, assignments, or interactions). In order to exemplify these subcategories, we will describe a section from Diana's SRI, where she watched her own videotaped calculus lesson:

After watching a part of the lesson where she phrased some conclusions to her students, Diana stopped the video and talked. She began with an evaluation of her action: "Horrible! I remember that while I phrased the conclusion, I felt I wasn't phrasing it in a good way. And now when I watch it, I wonder if it is even worthwhile to write down this conclusion". Diana then related to the reason for her action: "I did it because I always think about the weak student that learns in the advance track, and there are many here". Then, Diana explained that "We used to have only 12 students, in average, in the advanced level class […] and now we have 40 students. It is clear to us, the mathematics teachers, that not all of them are in the same level, and they need our help". This explanation referred to the political context of the situation: due to the Israeli Ministry of Education' reform, which aims at increasing the number of students in the advanced track classes, Diana' class became larger and more heterogenous. Diana continued and deliberated her reasons, while considering her goals:

Diana: When I phrase rules and conclusions, I always think about these students, that must have this reminder when they do their homework. It is a good goal, right? But now I think that these things must be well prepared, in advance. If a weak student gets home and reading his notebook – does he understand what is written there?

The first two subcategories were prominent in all the three settings, while the subcategory *evaluation of the situation and of teachers' actions* was identified mainly in the weekly journals and in the SRIs. The subcategory *attendance to broad assumptions and contexts* appeared sometimes in an implicit manner in the teachers' articulations. We will also mention that the subcategories are connected to each other and the distinction between them can be delicate, as can be seen in the example above.

Category (2): Consideration of alternatives, doubts, or dilemmas

This category includes expressions where the teachers discussed alternative actions, practices or perspectives, with correspondence to the second part of the definition of Karsenty & Arcavi (2017). This category also includes expressions where the teachers referred to dilemmas or deliberated some issues, which quite often were accompanied with consideration of alternative actions. The following excerpt exemplifies this category, when in her second VIDEO-LM PD meeting, Mila related to a situation she identified in a videotaped probability lesson in an 11th grade class:

Mila: It seems like the [videotaped] teacher believes she should present many solutions, and so she went along with the student's idea […]. It is a dilemma, to choose whose idea to hear, because some students can make things complicated. For instance, I sometimes choose to hear someone's idea personally, so he will not confuse the other students. I have this dilemma, but I didn't feel this teacher has it. On the contrary, it seems like she encourages the most problematic students, goes along with them: 'show me your way'.

According to Dewey, a situation of dilemma or doubt is the basis for reflective process. Consideration of alternative actions can be found also in models for reflection. For instance, Korthagen's (2014) ALACT model, creating alternative methods of action is the fourth stage, before a new trail. In the data, this category was more prominent in the VIDEO-LM PD meetings than in the other two settings.

Category (3): re-orientation

This category refers to gaining new insights or adjustments, and includes two subcategories:

(a) "looking forward": Expressions where teachers refer to possible future actions, as a result of their analysis. There is a subtle difference between this subcategory and the category of considering alternatives. Expressions were identified as "looking forward" when teachers referred to new insights they gained from their analysis which *could* be used in future actions. However, expressions were identified as considering alternatives when teachers explicitly referred to "what would I have done differently". The following excerpt, taken from Ivan's 8th weekly Journal, exemplifies this category:

Ivan: A concluding lesson in the subject of 'scale', in a low-track 8th grade class. I asked the students to draw a sketch of the class's tables. Then, after a short discussion, the students drew objects they chose. The lesson was more free than usual. During the lesson I felt uncomfortable, like there's no real learning. But in the end of the lesson, I was pleasantly surprised [by the students' cooperation and outcomes]. I plan to combine more activities of this kind in my teaching. I believe I should "let go" more often, to give the students opportunities to learn and to make mistakes.

(b) A change in perspective: Expressions in which a change could be identified in teachers' beliefs, attitudes, or perceptions regarding the teaching practice or the students. The change was either articulated explicitly, for example when teachers used expressions like: "I learned", "I realized" or "I noticed", or it was implied, for instance by a change in the teacher's tone (e.g., decisiveness vs.

hesitancy), or when a teacher expressed openness to new ideas. The following excerpt, taken from Nora's 4th weekly Journal, exemplifies this category:

Nora: This student's case helped me realize that students can go through a real change, and I should not stop believing this can happen (although, unfortunately, sometimes it happens to me).

Re-orientation is emphasized in the literature (Clarke, 2000; Finaly, 2008; Schön, 1983), since gaining new insights and tools for future practice is, in a way, the purpose of a reflective process. In the data, however, this category was identified only in some of the teachers' expressions, and it seems like teachers need more guidance in order to implement it.

Category (4): consideration of beliefs

Expressions where teachers explicitly referred to their beliefs, orientations and attitudes towards mathematics and mathematics teaching and learning – considered, wondered about, or doubted these beliefs. The following excerpt exemplifies this category when Sam, in his 4th VIDEO-LM PD meeting, watched an analytic geometry videotaped lesson and related to the teacher' choice:

Sam: How mathematics should be learned – is a question. In my opinion, this subject gets pretty heavy later, so [the videotaped teacher] tried to soften it in the beginning, when he connected it to worlds which were relevant to the students. I liked it. I teach both stronger classes, where the students are more active, and harder classes, where the students are less confident, less engaged, they don't even try to understand. But we should think about how to connect them [to the mathematics].

Beliefs influence teacher's actions and decisions (Karsenty & Arcavi, 2017), and awareness to teachers' beliefs is mentioned as one of the reflective process' goals (Finlay, 2008; Korthagen, 2014). This category was prominent in the data, in all the three settings and within all teachers' expressions.

Category (5): Addressing the emotions a situation evokes

Expressions where the teachers addressed emotions that certain situations evoked in them. This was realized explicitly ("I was glad to see", "it is hard for me"), but was also realized implicitly: For example, in a change of tone, in gestures, or in use of exclamation marks. The following excerpt, taken from Michelle's 2nd weekly Journal, exemplifies this category:

Michelle: A student does not respond to any of my questions, and not for the first time. For 10 minutes (during the lesson) I tried to get her to say something – but not even one word!! After the lesson – again, nothing! I was very angry about this situation. In similar cases before I was told that this student is "weird". This time I was very disappointed and could not tolerate such behavior. I turned to all the concerned parties and asked for their help […] I'm racking my head, how to deal with her.

This category was identified in some of the weekly journals and SRIs, but its frequency was relatively low. However, we decided to include it since the literature emphasizes the importance of connecting between a situation and the emotions it raises (Gibbs, 1988; Korthagen, 2014; Schön, 1983).

Category (6): addressing challenges of teaching

Expressions where the teachers addressed challenges and difficulties they experienced during their work, and analyzed them: the source of the challenge, its implications on their decision, etc. The teachers addressed various challenges: mathematical-pedagogical challenges (e.g., how to present mathematical subjects); challenges in classroom management; addressing students' pedagogical, personal, or emotional difficulties; challenges the teachers experience as part of their belonging to the institutional system. The following excerpt, taken from Leo's SRI, exemplifies this category:

Leo: Often, when I give assignments, many students have questions. And I still don't know how to, let's say, 'split myself' between them. Many times, I give a direction [to one student] 'do this in the meantime' and then go to another student. And then they tell me 'Stay, don't go!'. They don't understand that they are not alone, that while they do something I can help other students as well. This is something I still didn't figure out how to handle.

This category appeared sometimes with proximity to consideration of doubts or dilemmas. However, we chose to include this category separately since it was prominent in the teachers' expressions, especially in the weekly journals and in the SRIs settings.

Discussion

In this study, we analyzed the concept of reflection in a process that went back and forth between reading the scientific literature and gaining insights from the data. This process resulted in the unpacking of the concept of reflection into six main categories. The identified categories offer actions that extend the categorizations found in the literature. Furthermore, they relate to different aspects of a mathematics teacher's practice and require the teacher to address various factors, some of which are not emphasized in the domain of mathematics education. Observing different teachers through the three different settings simultaneously, resulted in a broad perspective on the concept of reflection. Such perspective might not have been possible from an analysis of only one setting. Connecting between the empirical analysis to the literature suggests validation of different aspects of reflection, in the sense that the categories are congruent with definitions and models offered by the literature.

The study suggests practical implications teacher educators can consider when designing guiding tools to support teachers through the reflective process. Following Brown & Cole's (2012) question "how do we do reflection?", the categories offer actions from which guiding questions for reflection can be derived, such as: What are the goals, assumptions or beliefs that influence your actions and goals? What alternative actions\practices could have been taken, and what are the advantages or disadvantages of each one of them? What emotions does the situation induce? What challenges can be identified in the situation? What can be done differently in a similar situation in the future? This study also offers theoretical contributions: The categories can be used as a theoretical framework for analyzing reflective expressions of teachers. Said framework was implemented in a continuance study, where we looked at opportunities for reflection teachers have in different PD settings.

The literature relates to issues and challenges of involvement in the reflective processes, such as a struggle to deeply analyze the teaching practice, to consider emotions situations evoke or to connect situations to broader contexts (Finlay, 2008). As the categories of reflection were identified in the data, the study indicates that teachers are **able** to perform such actions. However, the variety of categories stresses that reflection is indeed a complex concept, and teachers should have an adequate guidance and tools in order to be involved in a beneficial reflective process. Furthermore, teachers should experience reflective processes in different PD settings, as the results indicate that teachers' actions are influenced upon different settings and contexts in which the reflection takes place.

Operationalising de-ritualisation for the analysis of teaching-as-usual

Lisa Österling

Stockholm University, Sweden; lisa.osterling@su.se

To trace and represent changes in mathematics teaching over time is a challenge for research. This methodological paper proposes a framework for visually representing teacher moves in mathematics lessons. Based on commognitive theory, a framework of de-ritualising moves towards explorative teaching is developed. Two lessons of mathematics student teachers 'teaching-as-usual' in their final practicum are used for the development of a coding-scheme. The analysis enables to represent several de-ritualising moves, and the visual and fine-grained analysis is a promising result for longitudinal research on de-ritualisations in teaching-as-usual.

Keywords: Commognition, teacher education, secondary mathematics, analytic framework.

Introduction

This methodological paper proposes a framework for visually representing teacher moves in mathematics lessons. The challenge is to capture important characteristics in mathematics teaching, and at the same time avoid normative or idealised views of teaching. Research in mathematics teacher education was found to often take a fidelity approach, where teaching is researched relative to particular reform idea or intervention (Österling & Christiansen, 2018). In a classic article, reform mathematics is claimed to depend on cognitively demanding instructional tasks with multiple possible responses (Stein et al., 2008). However, the majority of mathematics lessons are not based on such tasks, and Nachlieli and Tabach (2019) remind us that the resilience among teachers to change in line with reforms may indicate that there are gains in engaging in ritual, so called 'traditional' teaching. In Sweden, contrasting norms are balanced in mathematics teaching. On the one hand, collective reasoning where both learners and teachers contribute with arguments is found (Eriksson & Sumpter, 2021). On the other hand, textbooks do *not* privilege problem solving tasks (Brehmer et al., 2016), and learners value mainly facts and procedures as important in mathematics learning (Andersson & Österling, 2019). In this paper, I use *teaching-as-usual* to describe teaching which is *not* part of a research intervention or reform initiative.

Categorisations, as traditional versus reform-based teaching, imposes a dichotomising view on mathematics teaching. Under dichotomising views, learning to teach means to choose between extremes, rather than becoming aware of complexities. Despite training in so-called reform-based or student-centred teaching, mathematics student teachers find it challenging to pursue such teaching in their classrooms (see f. ex. Bahr et al., 2014). When norms of the school context contradict norms from campus-based education, student teachers abandon the norms of campus-based education (Nolan, 2012). In addition, idealised views of mathematics teaching make norms and practices in the field unintentionally devalued (Horn & Campbell, 2015). However, when norms and practices are implicit in teacher education, they are less available to learn (Christiansen et al., 2019; Helgevold et al., 2015), and the dilemma between normative views on teaching and visible teaching practices raises a need for a descriptive way of talking about mathematics teaching, where dichotomies as good or bad teaching are avoided.

For that purpose, this paper aligns with recent developments in commognitive theory, and operationalises commognitive routines for the analysis of teaching. An assumption in commognitive theory is that mathematics learning, like all human activity, entails a modelling of actions based on what was done in the past in a similar situation, a *routine* (Lavie et al., 2019). Routines range between rituals and explorations, where *explorations* are the desired end-condition for learning, but *rituals* the essential starting point. Ritual activities are performed to please someone else, hence, ritual learning is to recognise and stepwise imitate different processes. Explorations on the other hand, are oriented towards truths about mathematical objects, where the performer has control over both the enactment and the end-conditions for the activity. Keeping in mind to not re-introduce dichotomies, Lavie et al. (2019) claim that no mathematics activity is fully-fledged rituals or explorations. Instead, teaching and learning mathematics means participating in *de-ritualising moves*, moving gradually from ritual routines, towards explorations. Six such moves are suggested by Lavie et al. (2019): flexibility, bondedness, applicability, performer's agentivity, objectification and substantiability, detailed below.

The strength in using de-ritualising moves for describing teaching is that it connects disparate aspects in mathematics teaching to a move towards explorations. The aim of this paper is to develop a coding-scheme for de-ritualising moves in teaching, and provide a visible representation of teaching-as-usual, to be able to compare lessons. The question posed is: What adaptations are necessary to operationalise de-ritualising moves for the analysis of teaching-as-usual?

Methodology

This section describes the data and context for the adaptations, and thereafter the steps taken for developing the analytic framework and visible representations.

Data

Two lessons were used for the development of the coding-scheme. The lessons were led by Eva and Kristin (pseudonyms), two secondary mathematics student teachers. Both Eva and Kristin followed a programme for upper secondary teachers in mathematics. The included lessons were part of their final practicum. Both had substantial mathematical and mathematics educational knowledge, however, commognitive theory, which is the basis of analysis in this paper, had not been part of their education. The students both agreed to participate in the TRACE-project (see acknowledgements), a longitudinal study where new teachers are followed from their final practicum through the first three years of teaching. For 17 student teachers, now teachers, over 90 lessons were video-recorded, with researchers present in the classroom, and with informed consent from participants.

The lessons were selected as examples of teaching-as-usual. They were similar in their mathematical level, and both were the last lesson before a test. The lessons reinforce what is important content, and learners can be expected to be familiar with it. Kristin taught a mathematics intensive class in the first year of upper secondary. The learners had worked on a set of three examples as homework, so-called "real-world situations" described by mathematical models: a linear, a quadratic and an exponential. Eva's lesson was from the third and final year in upper secondary mathematics. Eva had prepared three examples on antiderivatives to present in front of the whole class, thereafter, five different sets of examples were provided for learners to work on in five groups.

Method for developing the analytic framework

The developing framework of de-ritualising moves is based on recent developments in commognitive theory. An important contribution is the work by Nachlieli and Tabach (2019), who researched opportunities to learn in ritual-enabling and exploration-requiring teaching. Their approach informs both the connection between commognition and teaching, but also how the start and end of a task are important aspects in a lesson for determining who has the agency to determine initiations or end-conditions. Rather than using rituals and explorations, the present framework is based on six de-ritualising aspects, as Lavie et al. (2019) suggest are important for moving learning towards explorations. These de-ritualising moves were adapted by Österling (2021) for privileged teaching in mentor conversations, and the present paper presents a further adaptation for the analysis of teaching. The coding-scheme targets descriptions of teacher moves which encourage or legitimise de-ritualisations. A unit of analysis was obtained through two steps: First, when a new example is introduced, and second, when there is a transition into a new way of organising the lesson, i.e. from teacher presentation to learners group work, or from learners group work to presenting solutions.

The operationalisation of objectification, flexibility, bondedness, substantiability, applicability and performers' agentivity are based on first, a theoretical translation from learning processes to teaching moves, and thereafter iteratively coding and empirical fine-tuning of the coding scheme, exemplified below by transcripts from the two lessons. These units were the base for the visible representation.

Results

This result section first presents the development of the analytic operationalisation of de-ritualising moves, and the resulting coding-scheme. Next, the visual representations of the lessons are provided.

Developing a coding-scheme for de-ritualising moves

Objectification in Lavie et al.'s (2019) description is when the story about routines becomes more abstract, a narrative about mathematical objects rather than concrete objects or procedures. In upper secondary calculus, the task situation rarely involves concrete objects, as manipulatives, rather, calculus often involves examples with different mathematical realisations of the object, as graphs, tables, symbols or real-world-situations. Thus, learning objectification is the abstraction from questions and examples rather than from concrete objects. It is often recognised in language by the use of nouns. Objectification in teaching is hence when the teacher encourages discussions through the use of objects (as nouns), or about what characterises objects. Kristin posed several questions to encourage objectification, for instance:

Kristin How can we tell that this is a power function?

Kristin encouraged learners to focus the characteristics of objects, in this case, power functions. For Eva, objectification is traced in her explanations, as in the antiderivative of $f(x) = sin2x$:

Ari: But Eva, the $\sin 2\,x$, why does it get a negative sign?
Eva: It is always like this, now when it is like this [points to $f(x) = sin2x$] this must be sine, which means that it has been cosine. But the derivative of cosine is negative sine. There we have no negative sine [points at $sin2\,x$], therefore, this need to be negative [points at $(-cos2x)/2$].

Eva treated the derivatives of sine and cosine as familiar and abstract objects, as in "the derivative of cosine is negative sine", Even though her questions to learners never encouraged them to engage in objectification, her own explanation legitimised objectification when she referred to familiar content, such as derivatives, as abstract objects.

Flexibility, according to Lavie et al. (2019), is that learners realise there is more than one way of solving a task, or that previously unrelated procedures results in the same outcome. For teachers to encourage flexibility is to ask for different solutions, or the comparison of solutions. In the two lessons, the one instance akin to encouraging flexibility is when Kristin started the lesson by asking learners to discuss their solutions with a peer.

Bondedness is when the routine is changed from a mixture of steps into a compound, where the output of a given step is used as input in latter steps, and hence only necessary steps are performed (Lavie et al., 2019). In teaching, moves towards bondedness is to encourage turning previously disparate steps into a new compound procedure through focusing the connections between steps. Several examples were found in both Eva's and Kristin's teaching, and the transcript below is from the beginning of Eva's lesson on antiderivatives:

Eva:	This is a derivative, yes. [Writes $y' = 2x$]. Now, imagine going backwards, one step up with the derivative and get the function.
Ari:	It is x and remove two…
Eva:	So we are looking for this [writes y=], and we want… what must this have been before to obtain… x^2. [Writes $y = x^2$].

Here, Eva connected a familiar procedure, the derivatives of quadratic functions, to the antiderivative. The antiderivative is not yet treated as an abstract object in teaching, but the encouragement of bondedness between procedures for derivatives and antiderivatives is prevalent throughout the lesson. A similar pattern is found in Kristin's lesson. In both lessons, it was the teacher who made moves towards bondedness, whereas learners provided brief factual or procedural answers.

Substantiability is when learners provide criteria for the performed routine, rather than paying attention to the processes or rely on the judgment of those they regard as authority (Lavie et al., 2019). In teaching, this means an encouragement of substantiations beyond the steps of a procedure. Kristin used "why"-questions to encourage substantiations:

Kristin:	The maximum is 93, why is the maximum 93?
Frida:	Because it is 50, so take $18 - 1{,}5 \cdot 50$
Kristin:	[Writes the solution on the board] Exactly, because this is the amount of time where we leave the Sauna on, and hence the time for the temperature to rise. To 93 degrees.

Learners responded to the why-question by giving the steps of a procedure; however, Kristin reinforced the move of substantiability, and drew on the information given in the example and about the situation of a heating sauna in her substantiation. In the included two lessons, substantiations based on mathematical properties were rare.

Applicability is when the range of task situations for a given routine is expanded beyond the precedent situation (Lavie et al., 2019), and for teaching, this means encouraging the extension of task situations where previously known procedures can be used. One move of applicability was when Kristin applied the range of a function to the real-life situation of a heating sauna (above). Another is when Eva reminded her learners of familiar procedures:

Eva:	Ok, so we must find the antiderivative for this, h(x)=… [Points to $.h(x) = 6\sqrt{x}$]. Do you remember how to write square roots differently?
David:	0,5, the power of 0,5.
Eva:	So we have $6x^{1/2}$, I prefer to write it like this, as one over two. [Writes $h(x) = 6\sqrt{x} = 6x^{1/2}$].

In this example, the procedure of manipulating expressions of powers was applied in the new situation of finding antiderivatives. Thus, applicability moves include both the extension of task situations into real-world situations, but also into new mathematics content.

Performers agentivity contribute to de-ritualisation when performers are free to make a growing number of decisions without the help of others, as in the initiation, on how to proceed, and in the evaluation of a task (Lavie et al., 2019). Teachers' de-ritualising moves are when they encourage or legitimise learners' decisions, as in the transcript below:

Kristin:	What do we need to do to find the temperature after 20 minutes? What are your thoughts?

Here, Kristin asked for learners' thoughts, rather than the right answer or the way to proceed. Thus, she encouraged learners' freedom to make decisions on the way to proceed. Here, the distinction between de-ritualisation as learning, and de-ritualising moves in teaching come to a head. Even though Kristin encouraged learner agentivity, learners provided a correct answer or the steps of a solution, thus, learners interpreted the situation as if they were expected to engage in ritual participation. Nevertheless, for the purpose of this analytic framework, teachers' encouragement of learner participation is enough for the coding of a move for learner participation. Table 1 presents codings:

Table 1: Coding-scheme for de-ritualising moves in teaching

De-ritualising moves	Descriptions
Bondedness	Encourage turning a sequence or previously disparate steps into a new compound procedure through focusing the connections between steps.
Flexibility	Encourage learners to find more than one way of performing a task.
Substantiability	Encourage substantiation of results beyond the steps performed as procedure.
Applicability	Encourage the extension of task situations for previously known procedures.
Learner agentivity	Encourage learner agentive participation, e. g. to decide for themselves what the task is, what to do, and if a procedure worked or not.
Objectification	Encourage discussions of what characterises objects (rather than how to use it), or legitimise objectification in explanations.

A visual representation of de-ritualisation

After sectioning each lesson into time-slots based on the start of a new example, and/or a transition in the organisation of the lesson, the time-slots were marked as black where de-ritualising moves were engaged by the teacher. The shaded columns are sections where learners work in groups or individually, where only the initiation by the teacher was coded. Kristin’s lesson was divided into 12 sections, represented in columns in table 2 below.

Table 2: De-ritualising moves in Kristin's teaching

Total: 55 min.	0:00	1:55	4:05	6:20	7:27	10:21	13:30	17:21	22:00	26:40	30:45	33:10
Example	1	1a	1b	1c	1c	2ab	2ab	3a	3bc	3c	3c	individual
Bondedness												
Flexibility												
Substantiability												
Applicability												
Agentivity												
Objectification												

It is visible how Kristin engaged several de-ritualising moves, where bondedness and substantiability was used throughout the lesson, agentivity was prevalent at the start, and objectification and applicability relate to particular tasks. Eva’s lesson was divided into nine sections, as in table 3 below:

Table 3: The de-ritualising moves in Eva's teaching

Total: 50 min.	1:27	2:25	4:01	9:20	30:00	32:00	32:20	35:40	37:00
Example	1	2	3	1:1-5:3	2:2	3:3	3:3; 4:3	5	individual
Bondedness									
Flexibility									
Substantiability									
Applicability									
Agentivity									
Objectification									

Eva encouraged bondedness in the beginning of the lesson, where she repeated procedures for finding antiderivatives. In the follow-up discussion after group-work, Eva also engaged elements of applicability, objectification and learner agentivity.

The visual representation facilitates the comparison of the two lessons. In Kristin's lesson, the grey and black sections show how she uses several transitions between tasks, and between whole-class or group-work, and that these transitions initiate new de-ritualising moves. Although she encourages learner agentivity in the beginning, she abandons this ambition towards the end. Eva's lesson has visibly fewer black sections, and learner agentivity is only engaged after group-work section. Hence, although bondedness is a repeated move, more de-ritualising moves are only engaged after the group-work section.

Discussion

The visual representation provides an overview of the de-ritualising moves in mathematics teaching-as-usual. Thereby it facilitates comparisons of what moves are present and when they are used, and the model has the potential to capture developments in teaching over time.

The analysis of the two lessons adds aspects to be further investigated. First, objectification was found to be legitimised mainly in relation to familiar content, a pattern which is important to engage further. Second, bondedness is dominant, and it is interesting to enquire whether this is a characteristic for secondary mathematics. A third pattern in Kristin's teaching when she attributes learners agentivity, learners return to ritual responses, as asking for correct answers. Thus, the relation between de-ritualising moves in teaching and learning is a central investigation to continue. Analytically, the boundaries between the de-ritualising moves are not always sharp. There may be a need to add more distinctions or sub-moves in future analysis.

In the two included lessons, teachers engaged in teaching-as-usual, where a dichotomising analysis can be insufficient to capture the complexity of what is going on. Instead, the analysis of de-ritualisations has the potential of making the complexity visible, and thus possible to describe. To continue the logic of Nachlieli and Tabach (2019), teachers engage where they see potential for substantial gains. Therefore, I propose the analysis of de-ritualising moves in teaching has the potential to reveal not only what is going on, but also what teachers find important in teaching.

Systematic review: Teacher professional development programs in mathematics education and student achievement

Armando Peri and Florencia Gomez Zaccarelli

Pontificia Universidad Católica de Chile, Faculty of Education, Chile; ajperi@uc.cl; fgomezz@uc.cl

Keywords: Professional development, mathematics education, student achievement.

Introduction

The present poster proposal will show a Systematic Review of the Literature (SRL) on Teacher Professional Development (PD) programs in mathematics education and their relationship with Student Achievements (SA). A relationship will be established between the theoretical framework of effective PD programs and research outcomes that address and consider student achievements as a source of data on the programs' effectiveness.

Theoretical framework

Over the past few decades, the number of PD programs in mathematics education has increased significantly, as has research in the field (Sztajn et al., 2017). This has impacted guidelines, and characteristics suggested when designing an effective PD (Desimone, 2009; Sztajn et al., 2017). In particular, the most used characteristics are those proposed by Desimone (2009): 1) focus on content, 2) active learning, 3) coherence with the context and reality of teachers, 4) duration, and 5) collective participation. These characteristics have established a debate about their relevance, which has had researchers in favor (e.g., Sztajn et al., 2017) as researchers in opposition (e.g., Lindvall, 2017). This broad debate has led to progress in establishing those key elements that should be present in the design of PD programs even if there is not 100% agreement in the community about the minimum. In addition, it has made the scientific community debate about the most crucial objective of PD programs. Many academics agree that the main aim of PD is to improve the classroom practices of teachers and the SA (Jacob et al., 2017; Lindvall, 2017).

Based on the above, the problems addressed by this SRL seek to answer the question: What is the evidence in research on the approach to the relationship between effective PD programs and student achievements in mathematics?

Methodology

In this research, the methodology of a SRL was used (Boote & Beile, 2016). The search for articles was carried out in the two central education databases: Web of Science (WoS) and Scopus, with the criteria summarized in Table 1. Then the articles were reviewed on two more occasions to establish their relevance to the research, which finally obtained 35 studies.

Table 1: Search criteria in WoS and Scopus

Criteria	Data

Keywords included	1. Professional development; 2. Mathema*; 3. Student* effect*
Excluded keywords	1. STEM; 2. Science*; 3. Higher educ*
Type of documents	1. Articles
Languages	1. Spanish; 2. English
Years	2008-2020
Results found WoS	111
Results found Scopus	174

Results

From the analysis process, we identified a sparse presence of articles focused on student achievements between 2008 and 2018 (12 out of 24), while this trend changes in 2019 and 2020 (7 out of 11) with a greater focus on them. In particular, the 35 reports offer student information, but most present them as second priority data or a source used to support that the PD studied is effective in teachers and students. Indeed, only 19 projects explicitly state their objectives to measure, evaluate or relate the PD to student achievements. In addition, the results of this review show that 100% of qualitative studies (8 out of 8), 66.6% (2 out of 3) of mixed studies, and 79.17% (19 out of 24) of quantitative studies achieve favorable changes in student achievements in the analyzed programs. Finally, another relevant finding of this review is that the six studies that show no change in student achievements used some test as a measuring instrument.

Discussion

Based on the findings made in this SRL, we identify a tendency for studies that use PD effective characteristics (Desimone, 2009) to incorporate SA as one of their primary objectives. We also note the dominance of tests as an instrument to measure SA, where there is a clear trend to use standardized tests, which may not comprehensively determine the effects of PDs on the students. Finally, we recommend that to assess SA, instruments should be extended to standardized tests constructed by third parties and should increase the utilization of more than one of them.

Researchers and teachers involved in professional development: is convergence possible?

Gabriella Pocalana, Ornella Robutti and Ferdinando Arzarello

Università degli Studi di Torino, Italy;
gabriella.pocalana@unito.it, ornella.robutti@unito.it, ferdinando.arzarello@unito.it

The aim of this study is to discuss how specific educational researchers' choices, regarding the design of a professional development (PD) program for in-service mathematics teachers, influence the praxeologies of both the teachers and the researchers. In particular, we aim to highlight what learning mechanisms are activated by these choices. We use the Meta-Didactical Transposition (MDT) and the Boundary Object (BO) frameworks to describe the interactions between the two communities involved in the PD program, the researchers' and the teachers' one. The choices regarding the design of the program, made by the researchers, trigger internalization processes for both communities, as a result of the learning mechanisms activated during the joint work on a BO. These internalization processes led to an evolution of the initial praxeologies of the two communities and to the creation of a new, shared praxeology.

Keywords: Teacher professional development, meta-didactical transposition, boundary object, inquiry.

Introduction and theoretical framework

The study of mathematics teacher professional development has been an important focus of research over recent decades. Within CERME11 TWG18, open questions and issues emerged regarding, among the others, the crucial role of teacher educators (Zehetmeier et al., 2019). The present study is focused on the analysis of a teacher professional development (PD) program for lower secondary school (6^{th}-8^{th} grade), in-service mathematics teachers, held by a group of educational researchers (the authors), with particular regard to the researchers' choices in the design of the program itself. We aim to highlight the evolutionary process undergone by both communities, the teachers' and the researchers' one, and to describe how convergence on some theoretical and practical aspects was favored by specific researchers' choices.

Meta-Didactical Transposition

We use the MDT framework as an interpretative lens, which allows us to describe the interactions between two communities, one of teachers and one of researchers, in a dynamic way, showing the evolution over time of their respective praxeologies. The term "praxeology" was introduced by Chevallard (1999): it refers to the combination of a practical component, or *praxis*, and a theoretical component, or *logos*: in the case of didactical praxeologies, this combination is referred to teachers' activity in the class. The practical component includes tasks to be solved and techniques to solve them, while the theoretical component includes the justification and the explanation of the techniques. In the case of MDT, the praxeologies involved are meta-didactical ones, because they are referred to teachers' activities in the context of a PD program, not in their everyday classes. The evolution of the praxeologies of the two involved communities is described as the result of internalization processes of elements that were previously external to the communities.

Boundary Object

Robutti et al. (2020), in order to explain the evolution of praxeological elements from external to internal, suggest conceptualizing the meetings between mathematics teachers and educational researchers as “boundary encounters” between communities with different perspectives and objectives, which work together on a BO. Following Star (2010), we can say that a BO allows different communities to work together without preliminary consensus, due to its interpretive flexibility. Cusi et al. (in press) focus their attention on the internalization process during a professional development program. They show an example in which the MDT framework is integrated with the BO construct, to explain how the evolution of the praxeologies has been triggered.

Akkerman and Bakker (2011) identify four potential learning mechanisms activated by the joint work of two communities on a BO: *identification* of the practices of the different involved communities; *coordination* through cooperative exchanges between the two communities; *reflection* on the practices of both communities and *transformation* through the co-development of (new) practices and perspectives. *Transformation* has several steps, including: *confrontation* with some lack or problem, *recognition* of a shared problem space and *hybridization*, in which a hybrid cultural form emerges from the encounter and dialogue of different practices.

Aim and research questions

In this study, we use the MDT and BO frameworks as lenses to discuss how the researchers’ design choices for the PD program influence the praxeologies of both communities, in terms of activation of learning mechanisms. The learning mechanisms, identified by Akkerman e Bakker (2011), can explain how the development of a (completely or partially) shared meta-didactical praxeology between the community of the teachers and the community of the researchers took place. We will describe, in the following sections, the evolution of both the *praxis* and the *logos* components of the praxeologies of the two communities, the consequent internalization processes and the learning mechanisms triggered by specific design choices for the PD program.

In the light of what has been said, our research question is: *What researchers’ design choices for the PD program trigger learning mechanisms towards a shared praxeology, in the context of the joint work on the BO?* In order to better understand the effects of the design choices made by the researchers for the PD program, we will also answer two sub-questions: *Which internalization processes can be identified in the two communities, following the activated learning mechanisms?* and *Which evolution of the praxeologies of the two communities can be highlighted and which shared meta-didactical praxeology, if any, is developed?*

Context and features of the PD program

The PD program we are studying is included in the University project SSPM: Scuole Secondarie Potenziate in Matematica, which is part of the national project Liceo Matematico (Commodari et al., 2020). The program is directed to lower secondary school mathematics teachers, who participate because their schools signed an institutional agreement with the University. They are all experienced teachers, only two of them have less than 10 years of service, and they have already participated in the previous three years of the program. The PD program consists, in fact, of two phases: the first lasted for the first three years of the program, while the second began with the fourth year and will continue for two more years. The object of this study is, in particular, the first year of the second phase of the program.

During the first phase (10 meetings of two hours per year), the two communities worked on inquiry-based learning (IBL) (Maaß & Artigue 2013) in mathematics, with a specific focus on problem solving and laboratory teaching. The researchers designed mathematics IBL tasks for students, already in a complete form, plus tasks for teachers. The teachers, during the meetings, had to solve the students' tasks in small groups, and the teachers' tasks, based on educational requests. Later, they had to experiment with the resources in their classrooms and to provide reports.

During the second phase of the PD program (10 meetings of two hours per year, as for the first phase), the teachers have been engaged in the design of resources for their students in a collective work, with the cooperation of the researchers, who provided to teachers these tasks in a not completed formulation. After the group work, in every meeting there was a collective discussion on the potentials and the limits of the tasks designed by the different groups and on the most suitable learning environment to be experimented in the classroom. The last two meetings were devoted to teachers' reports about their classrooms experimentations, with the resources designed during the PD program, and to collective discussions about possible improvements for the re-design of the resources.

Methodology

The authors, who were also the researchers/educators in the PD program, collected data by written protocols and videos related to the 18 teachers who participated in the first year of the second phase of the PD program, which took place online in a synchronous mode during the pandemic period. In particular, data come from:

1. A written preliminary questionnaire, administered during the first meeting, with open questions and a Likert Scale. The questionnaire had the aim to investigate the teachers' praxeologies, with a particular focus on their *logos* component, including teachers' beliefs about their students and about the teaching and learning of mathematics.
2. Video-recorded semi-structured interviews, conducted in order to better understand the answers to the questionnaire about which we had doubts or we wanted a deeper insight.
3. Teachers' written protocols related to the design of resources, carried out during the group work, and written reflections about it.
4. Video-recordings of the collective discussions that took place during the meetings.
5. Teachers' written and oral reports about their classroom experimentations.

In all the collected material, we looked for elements of the teachers' praxeologies referred to the design of resources, both regarding the *praxis* and the *logos* component and we traced their evolution over the ten months of the fourth year of the PD program.

As a hypothesis for our study, we considered the IBL approach as the BO on which the researchers' community and the teachers' community have been working for many years. A BO should be conceptualized, according to Star (2010), as a dynamic object consisting of several components, so that, when teachers and researchers work together, they often focus only on some components and not on the whole object. Specifically, during the second phase of the PD program, the BO on which the two communities interacted consisted in the design of resources for students, according to the IBL approach.

In order to answer our research questions, we looked for clues of the activation of learning mechanisms, due to the joint work on the BO. According to Akkerman & Bakker (2011), *identification* occurs when a new insight is gained into what the diverse practices concern. *Coordination* entails a "communicative connection" between diverse practices or perspectives, allowing cooperation between two communities. *Reflection* entails the realization of differences between practices and thus the learning of something new about their own and others' practices. Finally, *transformation* is identifiable when profound changes in practices occurred, potentially leading to the creation of a new, in-between practice.

We also looked for evidence of internalization processes, occurring in both communities as a consequence of the learning mechanisms, that led to a shared meta-didactical praxeology. We particularly focus on the elements of the praxeologies of both communities, which refer to the design of resources for students: they include the mathematics tasks and all the elements of the learning environment. Each of the three authors worked, at first, autonomously, proposing also a possible correlation between the choices made by the researchers and the mechanisms observed. After numerous meetings, the three authors agreed on a shared proposal.

Results

The first and most general design choice for the second phase of the PD program was to involve teachers directly in the design of resources for their students, and it was inspired by what emerged in the ICMI Study 22 (Watson & Ohtani, 2015). This researchers' choice contributed to shed light on issues that had not emerged in previous years and constituted the basis of the activation of all the learning mechanisms that we will describe, in chronological order, in the following.

Identification

With the analysis of the preliminary questionnaire and of the collective discussions of the first meetings, we could identify some elements of the teachers' initial praxeologies, which did not emerge clearly during the previous phase. At the same time, during the collective discussions, the teachers could come to understand some elements of the initial researchers' praxeologies, that probably previously were not totally explicit. This objective has been pursued through the conscious choices made by the researchers in the design of the PD program and it led to the first learning mechanisms, i.e. the *identification* of the practices of the different involved communities, as well as of the justifications (*logos*) for these practices. The *logos* component of the initial researchers' praxeologies can be identified in the educational literature on IBL, recalled above. In the light of the literature and on the basis of their experience with classroom experimentations, the researchers deem it appropriate to propose inquiry-based tasks to all the students, without excluding anyone from this learning opportunity. For this reason, at the beginning of the second phase of the PD program, they asked teachers to design resources inspired by the IBL approach, in which all their students could have the opportunity to think, to explore, to conjecture and to share their ideas. We can, therefore, identify the *praxis* component of the initial researchers' praxeology, related to the design of resources for the students, with the proposal of inquiry-based tasks to the whole class, without reducing for anyone the learning opportunity to the resolution of too guided tasks. In this respect, there was an initial praxeological 'distance' between teachers and researchers. For example, in the written questionnaire, many teachers expressed doubts and reservations regarding the possibility to engage all the students in inquiry-based tasks and open problems:

Teacher 1:	At lower secondary school, we have to build problem solving ability, the horizon is limited. We have to work slowly, with guided problems. Only sometimes, someone in the class is able to treat a situation with something a little different from the acquired method.
Teacher 2:	Some [students] manage to identify the solution to a problem only among previously proposed strategies […]

During the first meetings, this kind of reservation emerged from different teachers in different moments, leading the researchers to understand that the teachers were used to propose inquiry-based tasks only to the high-achieving students. This can be considered part of the *praxis* component of the initial teachers' praxeologies, regarding the design of resources for their students. During the discussion related to the resources designed by the teachers during the second meeting, one of the teachers clearly stated her perplexities about the proposal of IBL tasks to the whole class:

Teacher 3:	We are always a lower secondary school, we have very heterogeneous classes, there is nothing to do, there is the one who, with all due respect, will learn a job, will live peacefully, knowing how to calculate the rest […], get up to there, is needless to hide it. […] There are one or two in each class that you need to stimulate, but there are one or two in the whole class.

We assume that these considerations, related to the idea that only few students should be exposed to inquiry-based tasks and the others should do the "basic things", have to be included in the *logos* component of the initial teachers' praxeologies, because they are justification for practices deriving from the teachers' experience in the classroom and from their didactical praxeologies.

Coordination and reflection

In order to foster a productive collaboration with the teachers, the researchers decided to prompt, during the third meeting, a collective reflection on some answers to the preliminary questionnaire and on some resources designed by the teachers, in order to highlight possible inconsistences and to promote awareness about them. For example, in the questionnaire the teachers were asked to express with a score, from 1 to 6, how much they felt that certain goals are central to the role of the mathematics teacher. The options that received the highest scores were: "To create situations in which students have to make decisions and choices", "To promote freedom of thought and creativity", and "To promote students' awareness and critical sense". The researchers showed these answers during the third meeting and asked the teachers to think if the resources they had designed were coherent with the goals chosen in the questionnaire. This discussion led to a *coordination* and *reflection* on the practices related to the design of resources, as exemplified by the words of this teacher:

Teacher 5: We actually gave some suggestions, so maybe we didn't think about a real exploration activity, it seems to me. At this point, if I reflect, the exploratory activity on the part of the students is missing.

Coordination and *reflection* laid the foundations for the subsequent learning mechanisms of *transformation.*

Transformation

The mechanisms outlined above led to the *confrontation* with a lack of coherence and to the *recognition of a shared problem space* (Akkerman & Bakker, 2011). The researchers understood that there was the need to build a hybrid, shared praxeology, fruit of the evolution of the meta-didactical praxeologies of both communities and of internalization processes on both sides. To do that, they began to look for an expansion of the theoretical framework of reference for the PD program and they found what they needed in the work of Cusi et al. (2017), performed in the context of the European Project FAsMEd. The researchers decided to propose to the teachers “theory pills” extrapolated from this work, regarding methods for formative assessment, which can be adapted, in this case, to inquiry-based resources for the whole class. In particular, the researchers proposed to integrate to the already established practices, the subdivision of students in level groups and the creation of “helping worksheets” (Cusi et al., 2012, p. 758) with specific suggestions or guiding questions, besides “problem worksheets”, to be given to the different groups, if they request or need it. This decision triggered the *hybridization* step of the *transformation* learning mechanism and the teachers began to elaborate on these new ideas, evolving their praxeologies. During the following meetings, the teachers introduced new elements, namely the “help cards”, that would constitute components of the hybrid, shared praxeology between the researchers and the teachers:

Teacher 6: […] we thought of preparing helping sheets, but without already addressing them to strong groups or weak groups, we have prepared them by points […] So, we give help cards to those who ask for them. We didn’t think of a single worksheet but, we give different cards with specific suggestions, depending on how the work in the groups goes. Because we create homogeneous groups but we cannot a priori know where they get stuck, what their difficulty is […].

An internalization process of praxeological elements occurred for both communities (as summarized in Table1), because of the introduction of “help cards” as part of the shared praxeology related to the design of resources for the students. The subdivision of students in level groups was a practice already internal to the teachers’ community, but, at the beginning, only the groups of high achieving students received inquiry-based tasks to work on. At the end of the fourth year, instead, the praxeology element related to the proposal of inquiry-based tasks to all the students became internal also to the teachers’ community, thanks to the introduction of “help cards” for the groups who needed them.

Table 1: Internalization processes for the two communities involved in the PD program

Internalization processes	Task design
Researchers’ community	• Level groups

	• Help cards with hints for the groups that need them
Teachers' community	• Inquiry tasks for the whole class • Help cards with hints for the groups that need them

The researchers asked the teachers to experiment with the new resources in their classes and to report the results during the last two meetings of the PD program. During the collective discussion about the experimentations, an ex-post reflection on what had been designed took place attested the creation of a new praxeology for the design of resources for students:

Teacher 7: The idea was to have a series of cards and, as we faced their difficulties, […] we gave them that help card just to help them take a step, without giving them too many elements, too much information.

In Table 2, we summarized the researchers' choices at the basis of the described learning mechanisms.

Table 2: Researchers' choices triggering learning mechanisms

Researchers' choices	**Learning mechanisms**
• Preliminary questionnaire • Teachers' involvement in the design of the resources to be used with their students • Collective discussions, during the first meetings, about teachers' practices and the justifications of their practices.	Identification
• Teachers' involvement in the design of the resources to be used with their students • Collective reflections on the questionnaire and on the task design proposed by the teachers	Coordination and reflection
• Teachers' involvement in the design of the resources to be used with their students • Integration of new elements in the theoretical framework of the PD program • Proposal of the integration of new practices • Request to experiment with the new practices	Transformation

Discussion

In this study, we discussed how specific design choices, made by a group of educational researchers for a PD program devoted to in-service mathematics teachers, influenced the evolution of the praxeologies of both the involved communities. We studied, in particular, the learning mechanisms activated thanks to these design choices and the subsequent development of a shared meta-didactical praxeology between the researchers' community and the teachers' community. We described the evolution of the *praxis* and the *logos* components of the praxeologies of both communities and the occurred internalization processes, relating them to the researchers' choices.

We highlighted how the choice to involve the teachers in the design of resources based on the IBL approach, including the tasks for their students and the learning environment, was at the basis of all the learning mechanisms activated during the PD program. Besides that, the choice to administer a preliminary questionnaire to the teachers, with questions about their practices and justifications for these practices, as well as the choice to make collective discussions about teachers' answers to the questionnaire and about their task design, triggered the learning mechanisms of *identification*, *coordination* and *reflection*. The subsequent choice to integrate new theoretical elements and new praxeologies, inspired by the work of Cusi et al. (2017), related to the FAsMEd project, and the request to incorporate these integrations in the design of resources and in the classroom experimentations, triggered the mechanism of *transformation*. In particular, the *hybridization* step led to the construction of a new, shared praxeology between the two communities, and to internalization processes of new elements for both communities.

In this way, we showed the process which led from an initial praxeological 'distance' between the researchers and the teachers, towards a shared 'in-between' praxeology, as a result of the contribution of both communities. The shared praxeology, at the end of the PD program, included the proposal of inquiry-based resources for all the students, the subdivision of students in level groups and the creation of "help cards" to be given to the groups that needed some guidance. Further research is needed to study if the shared praxeology between the two communities can be considered stable or other evolutions could be triggered during the future years. The analysis we conducted can be also extended to other PD programs, held in different contexts, in which other types of BO are involved.

Relevance and adaptations of a lesson study process within the context of initial teacher education in the canton of Vaud, Switzerland

Sara Presutti

University of Geneva, Lausanne University of Teacher Education, Switzerland; sara.presutti@hepl.ch

Keywords: Lesson study, initial teacher education, didactical situation.

Research context and aim

Lesson study (LS) is a model of teachers' professional development that originated in Japan at the end of the 19th century and gained popularity outside Asia almost a hundred years later. Since then, it has been at the centre of a growing interest by researchers in mathematics education, both in the case of in-service and pre-service teaching.

In the latter context, a large amount of experimentation has been made over the past twenty years. Research on this topic shows a variety of promising results for prospective teachers, such as increasing knowledge in and for teaching (Ni Shuilleabhain & Bjuland, 2019). Nevertheless, some issues have been highlighted, such as the risk of simplifying the process, and the subsequent changes in key features of LS itself (Ponte, 2017).

The PhD project outlined in this poster takes place in the context of the training program held at the Lausanne University of Teacher Education, in the French-speaking part of Switzerland, for pre-service mathematics teachers at the secondary level. The project aims to describe and analyse an LS-based class to pursue the following double-folded objective. On the one hand, it seeks to investigate the relevance of introducing LS in this particular context and the potential learning outcomes to prospective teachers. On the other hand, it intends to explore the adaptations and changes needed for LS to fit in with this new setting. For this poster proposal, I focused mainly on the first objective.

Theoretical background

Investigating the relevance of introducing LS into a new context can be done from multiple points of view, such as analysing pre-service teachers' knowledge or perspective-taking. In this doctoral research, these aspects are taken into account together with the study of the characteristics of LS as a didactical situation, according to Clivaz's research (2018) and the Theory of Didactical Situations (TDS, Brousseau, 2002).

In particular, Clivaz considers that in LS teachers are engaged in some *adidactical* situations, in which they can acquire new knowledge under the pretext of designing a lesson, which, in TDS terms, constitutes the *milieu* of these situations. To analyse a situation's potential, Hersant (2010) identified three properties of the *milieu*, namely the capability to provide feedback, bring out the desired knowledge and ensure that the knowledge needed to enter the situation is available to the learners.

Moreover, Hersant extended TDS investigation on situations where the *milieu* is less robust, and the didactical contract is more binding. This seems to be the case of LS when applied to initial teacher education. In fact, pre-service teachers' limited teaching experience makes the situation's *milieu* weaker. At the same time, the new setting implies constraints including a strict schedule, partially established content and evaluation, which entail a stronger didactical contract. In this case, Hersant analysed the didactical contract according to four dimensions: the mathematical domain, the didactical status of the knowledge at stake, the distribution of responsibility between the learners and the teacher and the characteristics of the didactical situation.

Methodology

The experimental design of the research is that of didactical engineering, in accordance with the TDS framework. The study of the LS class has been hence organised into three parts: *a priori* analysis of the *milieu*, data collection, *a posteriori* analysis of the *milieu* and the didactical contract.

The LS-based class included 12 sessions with five prospective lower-secondary school mathematics teachers. The class was organised around studying a teaching problem and the subsequent preparation, teaching and discussion of a research lesson related to it. The mathematical topic, chosen in advance, was that of integers. A university trainer with experience in LS served as the facilitator, while experienced schoolteachers supported the group's work during certain LS phases.

Data collected consists of the video recordings of each session and preparation meeting, the lesson plan, the prospective teachers' notes, and the documents shared within the group. These are used to reconstruct the situation's *milieu* during *a posteriori* analysis and examine the four dimensions of the didactical contract. To gain better insight into the participants' learning, *a posteriori* analysis will be supported by the course final assessment, and it will be completed by semi-structured interviews.

Since the data collection was postponed due to Covid-19, data analysis is at a preliminary stage. Some expected results include a dynamic description of the situation's *milieu* and an evaluation of LS potential as a didactical situation, despite some limitations due to the initial teacher training setting.

Is there a number in-between, and if so, how many? Analysis of pre-service primary teachers' knowledge of rational numbers

Karen Reitz-Koncebovski, Ana Kuzle and Ulrich Kortenkamp

University of Potsdam, Germany; karen.reitz-koncebovski@uni-potsdam.de, ana.kuzle@uni-potsdam.de, ulrich.kortenkamp@uni-potsdam.de

Research shows that a considerable number of pre-service primary mathematics teachers enter university with deficient mathematical knowledge, especially on fractions. As part of a design research project that aimed at improving the pre-service education of primary teachers (Grades 1–6), a normative question and a descriptive question arose: What should pre-service mathematics teachers know about rational numbers? And what do they know after completing an arithmetic course at university? The normative question was answered based on mathematical knowledge for teaching models. To answer the descriptive question, a test instrument was designed and administered to 123 pre-service teachers. The results show pre-service teachers' well-developed didactic knowledge, but difficulties in taking a meta-perspective on their knowledge. Some failed to catch up on school knowledge gaps. The results are discussed regarding their theoretical and practical implications.

Keywords: Pre-service teacher education, mathematical knowledge for teaching, school-related content knowledge, teaching fractions, natural number bias.

Motivation: A fractional math problem and pre-service teachers' solutions

Consider the numbers 1/9 and 1/8.

a) Is it possible to find a rational number that is between these two numbers? If so, please provide this number.

b) Could there be more than one number? If so, include any of the numbers that fall between these two numbers.

This problem might be posed to Grade 6 students. Pre-service teachers, as a matter of course, should be able to solve it correctly. — This is not as self-evident as it first appears. Equivalent tasks were given to all pre-service teachers that were enrolled in the 2020 (N = 111) and 2021 (N = 84) arithmetic courses in their first year of bachelor degree studies. They had to complete a test on the fractional computing ability (Stampfer et al., 2019) before starting the topic "rational numbers." The first task was as follows: a) "Enter a number between 12/4 and 13/4. If you think there is no such number, click impossible." In total, 32.4% of the pre-service teachers of the 2021 course stated "impossible," another 8.1% stated an incorrect intermediate number. The results of a 2020 survey were similar: 33.3% stated "impossible," and even 28.6% an incorrect intermediate. The latter result can be explained by the fact that this time there were fractions given with the same numerator and different denominators (6/18 and 6/19), whereby it was apparently more difficult for the pre-service teachers to calculate an intermediate number. The second task was as follows: b) "How many numbers are there between 10/4 and 10/8?". It is distressing that 69.4% of the pre-service teachers of the 2021 course gave a wrong solution. Particularly often (21.6%) the solutions 4, 3 or 2 were provided. This can be interpreted as an indicator of a natural number bias (Stampfer et al., 2019; van Hoof et al., 2015). Presumably, the participants simply counted how many fractions there were with the same numerator 10, and various denominators between 4 and 8. Again, the 2020 survey results were similar with 58.3% of wrong answers. These incorrect answers, and the underlying misconceptions, remained persistent even after six weeks of intensive study of rational numbers and the didactics of fractions. Concretely, in the 2021 post-test with similar tasks, still 21.6% of the pre-service teachers (compared to 32.4% in the pre-test) answered “impossible” for task a), and 24.3% for task b) (compared to 69.4% in the pre-test) gave incorrect answers. These results were used as a challenging starting point for a design research project which aimed to improve, among others, the arithmetic course for pre-service teachers (Grades 1–6), who will be teaching fractions in their future classes. Many of them, as our data showed, enter university with rather poor mathematical school knowledge, and more than a fifth of the total number of pre-service teachers do not manage to catch up on their knowledge gaps concerning fractions during their studies, as we found out with several further tests.

In this paper, we will first investigate what knowledge pre-service teachers should acquire, especially concerning fractions. This analysis formed the basis for the design of new university courses, in particular the arithmetic course mentioned above. The second part of the paper deals with the effectiveness of the newly designed university courses with respect to the first goal.

Theoretical background: What should teachers know?

Broadly speaking, mathematics teachers should know the subject they teach and they should know how to help learners to acquire that same knowledge in the setting of school lessons. When describing the content knowledge teachers need to carry out their work, Shulman (1986) discerned between *subject matter knowledge* (SMK) and *pedagogical content knowledge* (PCK). In the course of several decades of research on teachers’ knowledge, Shulman’s foundational work was differentiated in various directions. Ball et al. (2008) developed a framework of *mathematical knowledge for teaching* (MKT), distinguishing, inter alia, two subdomains within PCK, *knowledge of content and students* and *knowledge of content and teaching*. Furthermore, they recognized a type of SMK which was exclusive to teachers, namely *specialized content knowledge* (SCK). Another approach to define the content knowledge specific for the mathematics teacher profession is Dreher’s et al. (2018) model of *school-related content knowledge* (SRCK). This model is based on the fundamental distinction between academic and school mathematics[1], and describes the knowledge teachers need about the interrelations between the two in top-down and in bottom-up directions, as well as knowledge of the curricular structure and its legitimation. The latter includes knowledge about fundamental ideas of mathematics, and the significance of certain topics regarding these ideas (e.g., Why are fractions taught at school?) (Dreher et al., 2018). When we deal with content knowledge in this paper, then with the focus on SRCK. In the area of PCK or, to use the term common in most parts of Europe, *subject didactic knowledge,* we are particularly interested in pedagogical content knowledge that derives from mathematics itself (see Carrillo-Yañez et al., 2018). Thereby, we will follow the distinction of a learning and a teaching perspective (Ball et al., 2008; Carrillo-Yañez et al., 2018).

[1] … rather than that between common and specialized content knowledge as defined by Ball et al. (2008).

We exemplify the different relevant types of knowledge using the initial example. Starting with the *teaching* perspective of PCK, pre-service teachers need to acquire the knowledge of how to explain mathematical content to students, for instance a strategy to find or calculate an intermediate number. And not only one strategy, but several strategies, as their students might suggest different approaches, and they should be able to support each of them. Concerning the *learning* perspective of PCK, they need knowledge about students' typical errors, misconceptions, and difficulties in understanding in order to assist them in their learning. As to our example, a typical misconception might be that there is no (natural) number between 8 and 9, and subsequently, there is also no number between 1/9 and 1/8. An algorithmic hurdle could be that students come up with the strategy of expanding to the main denominator, but still cannot find another fraction between 8/72 and 9/72. Or students might find a few fractions between 1/8 and 1/9, but have no idea of how to provide all the numbers.

In order to explain the task correctly, when considering different levels of students' knowledge, pre-service teachers need to understand the mathematics involved deeper than their students. What mathematical content knowledge exactly, above mere school knowledge, should they possess? With respect to our example, we would argue that they need to know specific properties of rational numbers as distinct from those of integers, in particular the properties of order and density (Freudenthal, 2002; Padberg et al., 1995). For instance, a rational number, unlike an integer, does not have a clearly defined successor and one can always specify an intermediate between any two rational numbers (i.e., arithmetic mean). Pre-service teachers also need to know how rational numbers are mathematically constructed and defined as equivalence classes of pairs of integers (Padberg et al., 1995). This knowledge would allow them to flexibly shift between representatives within equivalence classes. This is academic mathematical knowledge, and pre-service teachers will not teach fractions in this way to their students. Sometimes, as we experience, pre-service teachers use this as an argument why they do not need university mathematics. We, however, consider important for them to possess this knowledge and we regard it to be close to or even coincide with what was described as SRCK above.

The idea of using equivalence relations to construct new number systems can be regarded as a fundamental idea or "big idea" (Kuntze et al., 2011) of mathematics, and the knowledge about fundamental ideas is part of SRCK (Dreher et al., 2018). Pre-service teachers should have answers to the above mentioned question "Why are fractions taught at school?" (Dreher et al., 2018) or more specifically, "Why is it interesting to know whether there is a number between two fractions and, if so, how many?", as the reasoning on the legitimation of curricular structure and content belongs to the SRCK.

Constructing new number systems as extensions of natural numbers by preserving some number properties and altering others is a typical mathematical procedure. We consider the knowledge about typical procedures, strategies for solving problems and paths of generating mathematical knowledge as an important (meta-)knowledge for teachers and would also assign it to SRCK. In a similar way, Carrillo-Yañez et al. (2018) distinguished the *knowledge of practices in mathematics* as an essential subdomain of teachers' mathematical knowledge in their *mathematics teacher's specialized knowledge* (MTSK) model. In order to convey an adequate image of mathematics, pre-service teachers should *do* mathematics themselves, and experience mathematics as a science. Such expectations are aligned with the demands paced on modern school mathematics: In the German educational standards for mathematics education (Ständige Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland, 2005), great importance is given to process-related competencies, such as communicating, arguing, problem-solving and modeling. In this sense, not only mathematics lessons, but also mathematics teacher education needs to meet these general educational requirements. Doing mathematics is an integral part of human culture, and aspiring mathematics teachers should embody that culture.

Different conceptualizations of MKT (Ball et al., 2008; Carrillo-Yañez et al., 2018; Dreher et al., 2018) together with the above-mentioned considerations, led to a completely new design of courses for pre-service teacher education at the primary level which connect subject content and subject didactics at the curricular level (Mayer et al., 2018). The intended facets of MKT were mapped into specific design principles for these courses (Reitz-Koncebovski et al., 2020), namely *follow fundamental ideas of mathematics*, *connect fundamental ideas to main principles of mathematics didactics*, and *experience the process nature of mathematics.* Moreover, the principles of mathematics didactics are not only being taught, but are also implemented while teaching following the idea of a "*pedagogical biplane*" (Wahl, 2013), and by *making learning processes of students experienceable*. Lastly, a *cross-sectional principle* demands the design principles as well as the processes of teaching be made explicit and reflected with pre-service teachers *on a meta-level* (Reitz-Koncebovski et al., 2020). At the end of each course, we research to what extent this has been achieved. Especially for the arithmetic course, we were interested in the following research questions: To what extent have the pre-service teachers acquired the desired knowledge of rational numbers? What understanding (and what misconceptions) can we identify at the end of the two-semester arithmetic course?

Test instrument and methods of analysis: What do pre-service teachers know?

To evaluate the effectiveness of the arithmetic course and to answer the descriptive research questions just mentioned, we developed a knowledge test. This included, among others, an item on pre-service teachers' knowledge of the density of rational numbers in the real numbers which was an attempt to operationalize the aspired content knowledge of fractions with its different facets as was described earlier in the paper. The item comprised four subitems with respect to our introductory math problem (see above):

(1) Solve the problem parts a) and b) in the way you expect students in Grade 6 might solve it.

(2) Now give an explanation for a student how the problem can be solved correctly.

(3) What difficulties may arise when a student is working on the problem?

(4) Name two essential mathematical ideas that you as a teacher need to understand in order to use the problem in class.

Subitem (1) concerns mathematical school knowledge, the other subitems relate to different facets of MKT: (2) PCK in the teaching perspective, (3) PCK in the learning perspective, and (4) SRCK in the form of knowledge about the interrelations between school mathematics and academic mathematics in bottom-up direction: Starting point is a school mathematics problem (1), and the last subitem focuses on essential or "fundamental" mathematical ideas, in particular on the academic mathematics behind it. Both mathematical content and didactic knowledge are necessary for answering the test item. These were discussed in detail in the course, so the task appeared to be reasonable.

The knowledge test was carried out at the end of the two-semester arithmetic course as part of the final examination. The written answers to the exemplary item of all 123 pre-service primary teachers enrolled in the course were analyzed using the *qualitative content analysis* method (Kuckartz, 2019; Mayring, 2014). For it, a deductive-inductive category system was employed. Main categories were developed deductively (i.e., concept-driven) from a sample solution to the task which was derived from the desired teacher knowledge presented in the theoretical part. The inductive categories emerged from the data (i.e., pre-service teachers' answers) building a basis for subcategories. For an easier understanding, more details about the categories are reported below, together with the results. We created a coding guide which was supplemented by definitions and anchor examples, and used it for the coding of the entire written material. This approach made it possible to analyze the pre-service teachers' answers in great detail and to make visible different, often unpredictable, expressions of knowledge and understanding. In a subsequent step, a quantitative analysis was carried out using descriptive statistics to determine the frequency of occurrence of certain categories or subcategories (Kuckartz, 2019) as well as of correct and incorrect, complete or missing answers per participant.

Results

Table 1 shows that between 15% and 27% of the pre-service teachers did not give an answer to one or more subitems. Only very few (4.7%) answered all subitems correctly. The first subitem (1a), which requested school knowledge alone, was answered incorrectly, inadequately, or not at all by nearly 40% of the participants. The results to subitem (2) relating to teaching as a facet of PCK as well as subitem (4) relating to SRCK were particularly weak: nearly half of the explanations for Grade 6 students (2) were incorrect or missing, and less than 20% of the test participants were able to name adequate essential mathematical ideas.

Table 1: Rough quantitative evaluation of the test item on rational numbers (total N = 123)

Item with subitems	Completely correct answer	Incomplete or partially correct answer	Incorrect answer	No answer
(1a) „Is there a number between …“	61.8%	1.6%	21.1%	15.5%
(1b) „are there more … how many“	43.9%	26.0%	6.5%	23.6%
(2) Explain to a student	15.4%	36.6%	21.1%	26.9%
(3) Difficulties for a student	47.2%	27.6%	6.5%	18.7%
(4) Essential mathematical ideas	18.7%	56.9%	4.9%	19.5%

Qualitative content analysis allowed a more in-depth investigation of pre-service teachers' answers. In subitem (1a), the pre-service teachers chose different strategies to specify a number between 1/9 and 1/8, namely determining the arithmetic mean, expanding the fractions to the same denominator or the same numerator (possibly several times), the "wrong addition" (divide the sum of the numerators by the sum of the denominators) or converting into decimal numbers. Almost a quarter of the test participants chose the latter way. This preference of converting to decimal numbers was also seen in pre-service teachers' explanations for subitem (2), whereby most of them did not explain the procedure in detail. In general, a lack of accuracy and concreteness was the greatest shortcoming of many of the explanations for subitem (2). In addition to referring to decimal numbers, there was often a reference to a visual model (i.e., circle, rectangle, number line), but without an explanation of how exactly this was supposed to help. The didactically impeccable explanations (15.4%) used the strategies of arithmetic mean or expansion, and described in detail how this can be done several times in order to find more and more numbers in-between.

Subitem (3) that focused on possible students' difficulties tended to be answered much better than subitem (2). Many test participants considered problem part a) and mentioned difficulties at the procedural level (e.g., expanding and shortening, calculating the arithmetic mean, converting to a decimal number), but also typical misconceptions about the order of fractions (e.g., no number between 1/9 and 1/8, as there is no natural number between 8 and 9, or 1/8 is smaller than 1/9) were mentioned by 51.2% of the participants. Only 7.3% of them mentioned misconceptions concerning the density of fractions or lack of understanding of the concept of infinity required in part b).

Less than 20% of the test participants succeeded in naming essential mathematical ideas in subitem (4). Test participants could get partial credits for this subitem by naming suitable keywords. Most of those keywords were quite unspecific like "knowledge on basic ideas about fractions" (66.7%), without specifying which basic ideas, "general understanding of fractions" (37.4%) or "knowledge of number systems" (13.8%). Here again many test participants referred to procedural knowledge (60.2%). The intended answers regarding knowledge on the equivalence of fractions (7.3%), understanding of the order (10.6%), density (4.0%) or infinity of rational numbers (5.7%) were mentioned to a limited extent. Moreover, some test participants (4.9%) described knowledge requirements of the students, and not those of the teachers.

Discussion and Conclusion

In our study, we investigated what kind of knowledge of rational numbers the pre-service teachers had acquired at the end of the two-semester arithmetic course. Thereby, we focused on mathematical content knowledge at school and at university level, in particular SRCK, as well as subject didactic knowledge (i.e., PCK). Two major difficulties faced by the pre-service teachers stood out:

The first major difficulty concerns mathematical school knowledge. Obviously, a sizable group of pre-service teachers have the same or similar problems with the task as school students and thus lack basic subject matter knowledge (Dreher et al., 2018; Shulman, 1986). This can be derived from the incorrect and missing answers to subitem (1), incorrect explanations for students in subitem (2), and also from the results of the arithmetic test reported in the beginning. Hence, the pre-service teachers obviously need to catch up on school knowledge and skills in fractions. The arithmetic course alone seems not to suffice to compensate for their deficits. We might also ask: What are the causes of these deficits? Is it pre-service teachers' lack of motivation for their mathematics studies in general? Have there been obstacles as a result of mathematics anxiety since school? For pre-service teachers in the Inclusive Pedagogy Teacher Education Program, mathematics is a compulsory subject, and some of them have reported about own mathematics anxiety. Or do they perceive the mathematics university course having low relevance for their future professional work, which resulted in poor performance?

The second major difficulty concerns perspective adoption. As to different perspectives of the PCK considered in theory (Ball et al., 2008; Carrillo-Yañez et al., 2018), it seems to be easier for pre-service teachers to adopt the learning perspective addressed in subitem (3) than the teaching perspective addressed in subitem (2). This may be due to the fact that they are only in the second semester of their bachelor's degree. The results showed that it was particularly difficult for the pre-service teachers to adopt a meta-perspective, as was required in subitem (4). This finding is consistent with those by Kuntze et al. (2011) who reported that the pre-service teachers in their study often were unable to link mathematical content to the big ideas of mathematics. In view of this difficulty, the design principles for our course (Reitz-Koncebovski et al., 2020) require the lecturers to occasionally adopt the meta-level, and to make explicit what "school-related content knowledge" means in certain contexts, as outlined in the theory chapter above. Consequently, the lecturers explicitly motivated their audience to take a meta-perspective themselves. The participants' poor results regarding the latter aspect raise a number of questions: Why was subitem (4) so difficult? Is it generally difficult to adopt a meta-perspective? Do pre-service teachers lack a deeper knowledge about rational numbers (Freudenthal, 2002; Padberg et al., 1995) which we consider an essential part of SRCK? Or do they actually possess this knowledge, but rather have difficulties in articulating it in a written form?

A critical view of the test results implies further development of the course, in particular regarding the implementation of the *cross-sectional design principle* (Reitz-Koncebovski et al., 2020), namely adopting the meta-level and making explicit what SRCK (Dreher et al., 2018) means in certain contexts, and why this knowledge is important and useful for pre-service teachers. Our assertion is that it is not only necessary to allow pre-service teachers to question the usefulness of the content of the mathematics courses at university, but also to explicitly discuss their usefulness in seminars, and to a greater extent than has been done in the past. Some arguments for this kind of discourse with pre-service teachers can be drawn from the lines of argument in the theoretical considerations above. Another, perhaps even more difficult endeavor, is to address the level of attitudes and emotions. We assume that some pre-service teachers' poor performance on fraction tasks was related to specific aspects of the affective domain since the MTSK model of mathematics teacher knowledge (Carrillo-Yañez et al., 2018) places beliefs at the center of the various facets of knowledge.

Acknowledgment

This study is supported by research grant from the German Federal Ministry of Education and Research as part of the "Quality offensive teacher education" project at the University of Potsdam. We thank Peter Cierpinski for his preparatory research work in the context of his master thesis.

Using Concept Cartoons in primary school teacher training: the case of a mathematics content course

Libuše Samková[1]

[1]University of South Bohemia in České Budějovice, Czech Republic; lsamkova@pf.jcu.cz

The contribution focuses on an educational tool called Concept Cartoons and the possibilities to use the tool in teacher education. It perceives Concept Cartoons as educational vignettes and show how they can be incorporated into mathematics content courses to help assessing future primary school teachers' knowledge on topics related to the primary school curriculum. The paper introduces one of the Concept Cartoons created on the topic of divisibility and a qualitative empirical study conducted with 67 future primary school teachers within a mathematics content course. The aim of the presented study is to observe and investigate the nature of knowledge displayed in written data collected via the Concept Cartoon. The results of the study confirm the potential that educational vignettes such as Concept Cartoons have in future primary school teacher education.

Keywords: Concept cartoons, educational vignettes, elementary school teachers, mathematics education, preservice teacher education.

Introduction

An integral part of primary school teacher education consists of mathematics content courses where mathematical content related to the primary school curriculum is reviewed and applied in contexts outside the primary school level. For instance, the primary school curriculum in the Czech Republic covers the four operations with natural numbers (addition, subtraction, multiplication, division) and their properties, and the secondary school curriculum in this area starts with prime and composite numbers, common multiples and divisors, and criteria of divisibility. So that the content course for future primary school teachers contains all these secondary school topics, to bring the future teachers a broader perspective and to engage them in intensive argumentation related to the mathematical content they are supposed to teach in their future school practice. Such an arrangement helps verifying that the future primary school teachers understand and comprehend primary school concepts properly.

This contribution focuses particularly on the topic of divisibility and on subject-matter knowledge (Shulman, 1986) of future primary school teachers. From the more detailed perspective of mathematical content, it focuses on conditional reasoning within the topic of divisibility – an area that appears to be difficult for future teachers as they often tend to handling the topic of divisibility procedurally rather than conceptually (Zazkis et al., 2013) and having deeply rooted misconceptions about argumentation that affect their conditional reasoning (Simon & Blume, 1996).

The following text describes a qualitative study of an explorative character that uses an educational vignette (Skilling & Stylianides, 2020) in the form of a Concept Cartoon (Samková, 2020) as a tool for collecting data. The study addresses the research question *"What kind of subject-matter knowledge can be revealed in future primary school teachers when using Concept Cartoons as a written assessment tool within a mathematics content course?"* The paper follows up on the contributions from previous ERME conferences where various educational vignettes were used in teacher professional preparation: e.g. for investigating professional vocabulary of future teachers (Friesen et al., 2019), assessing how future teachers respond to hypothetical student ideas within primary school topics (Buforn et al., 2017; Samková & Hošpesová, 2015), how they respond to hypothetical learning support situations (Kuntze & Friesen, 2017) or what awareness they have about potential student ideas (Samková, 2019b). The presented study was conducted within the framework of the ERASMUS+ project *coReflect@maths* that aims at designing and evaluating vignette-based learning environments for various mathematics teacher education courses, with a particular focus on cartoon vignettes (Krummenauer et al., 2020).

Vignettes and Concept Cartoons

In this paper, educational vignettes are understood as stories representing school practice (Buchbinder & Kuntze, 2018), i.e. as representations of classroom situations or situations that relate to content taught and learnt in the classroom. In that sense, vignettes are rather short, descriptive episodes that may take the form of texts, single or multiple images, videos, or their combinations (Skilling & Stylianides, 2020). The protagonists of vignettes might be various combinations of teachers and students, e.g. a teacher with one or more students, one or more students without a teacher, one or more teachers without students. With future teachers as respondents of research or intervention, the purposes for implementing vignettes are wide (Herbst & Chazan, 2011); they usually lay in aiming for development or analysis of professional knowledge and skills such as noticing (Schack et al., 2017), professional vocabulary (Schleppegrell, 2007), etc.

Among vignettes, we may also include Concept Cartoons – individual pictures showing a content-related situation and a group of several children discussing the situation via a bubble-dialog. The opinions in the bubbles may be correct, incorrect, unclear or incomplete (Keogh & Naylor, 1993). Originally, Concept Cartoons were developed as a means of supporting the quality of discussion in primary school classrooms (Naylor et al., 2007), with the key aspects for the discussion being the absence of the teacher in the picture (i.e. the presence of just the peers) and the diversity of opinions given in the bubbles. However, Concept Cartoons may be created for different target groups and different purposes, including the target group of future primary school teachers and the purpose of analysing their pedagogical content knowledge (Samková & Hošpesová, 2015) or subject-matter knowledge (in this paper). Within this context, the protagonists in the picture may not be just children but also adults (future teachers, i.e. peers of the respondents). For the purpose of collecting data on teacher knowledge, Concept Cartoons are usually accompanied by some set of indicative questions, and this combination appears to be able to provide data that are ample and relevant (Samková, 2019a).

When creating a new Concept Cartoon, one has to choose the focus of the mathematical task in the background (calculation, proposition, application), its openness (e.g. single vs multiple correct solution procedures), determine the nature of correctness of individual bubbles (ambiguous, unambiguous, conditioned), and choose the form of texts in bubbles (results, procedures, statements); for more details on the typology of Concept Cartoons see Samková (2020). This study is based on a Concept Cartoon that has a group of future teachers as protagonists, a propositional task with multiple correct solution procedures in the background, four bubbles with unambiguous correctness, and texts in bubbles in the form of statements (see Figure 1).

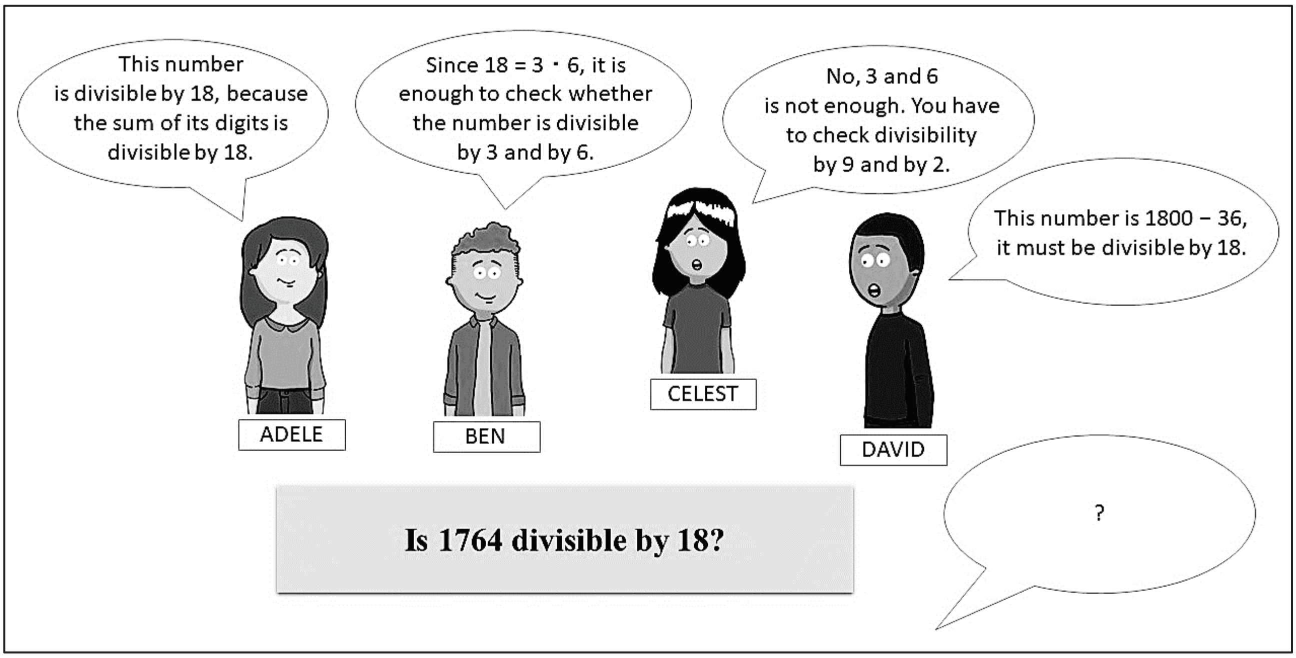

Figure 1: The Concept Cartoon on divisibility

The Concept Cartoon in Figure 1 presents two statements that are correct (Celest, David), and two that are incorrect (Adele, Ben). One of the statements (David) refers to a manipulation with numbers (based on finding a nearby multiple of 18 that is easily identified), while each of the other three statements (Adele, Ben, Celest) informally refers to an application of a general rule. The rules can be formally rewritten as follows:

Adele:	If the sum of digits of a given number is divisible by 18, then the number is divisible by 18.
Ben:	If a given number is divisible by 3 and by 6, then it is divisible by 18.
Celest:	If a given number is divisible by 9 and by 2, then it is divisible by 18.

For the rule behind the Celest bubble, the condition in the statement is necessary as well as sufficient, i.e., the rule is valid and can be also rewritten in the form of equivalence. For the rule behind the Ben bubble, the condition in the statement is necessary but not sufficient, since 3 and 6 are not coprime numbers; numbers 6, 12, 24, 30 are some of the counter-examples for the rule. For the rule behind the Adele bubble, the condition in the statement is not necessary (even the number 18 itself does not have the sum of digits divisible by 18) nor sufficient (swapping the order of digits does not change the sum of digits but may easily create a number that is not even and thus not divisible by the even number 18; e.g. 1467, 7641).

Such an arrangement creates an environment that challenges skills in conditional reasoning, by requiring proper differentiation between necessary, unnecessary, sufficient and insufficient conditions in an informally worded statement (Buchbinder & McCrone, 2019). The statement in the Adele bubble is also closely related to *overgeneralizing* – a frequent misconception consisting in improper use of analogical reasoning (Hemmi et al., 2017); here the overgeneralizing stems from criteria for divisibility by 3 and by 9 that are both based on the sum of digits.

Design of the study

Participants of the research study were 67 future primary school teachers – full time students of the first year of the 5-year teacher training program at the University of South Bohemia in České Budějovice. In the time of the study, they were attending the content course on arithmetic. They have not worked with Concept Cartoons before the study. The participants were randomly labelled by code names V1 to V67.

In the data collection stage, the participants were assigned the Concept Cartoon from Figure 1 and a set of indicative questions to respond. Having the new environment where the protagonists of the Concept Cartoon were not children but future teachers, also the set of indicative questions had to be newly created. Taking inspiration from various sets of indicative questions verified in previous research and proceeding from the fact that it has proved useful to have the indicative questions purposefully fragmented in their focus (Samková, 2019a), the following three indicative questions were distributed to the participants in order to find out about how they draw on their subject-matter knowledge: (1) What thoughts could be behind the student teachers' thinking? (2) How could you help the other student teachers to correct their answers or to improve their argumentation? (3) Write YOUR solution into the empty speech bubble. The participants worked on the task individually, in the form of a compulsory written homework.

Collected data were processed qualitatively, using open coding and constant comparison (Miles et al., 2014). The process of open coding focused on various displays of subject-matter knowledge or lack of it, and their interrelations. Data were compared repeatedly across participants, across bubbles, and across indicative questions.

Findings

The four following code categories appeared as relevant at the end of the analytic process: Coprime condition (codes *coprime forgotten*; *missing coprime reported*, *prime factorization misused*), Language (codes *inaccurate terminology*, *shifted meaning*, *shifted interpretation*), Argumentation modes (codes *counter-example for sufficient*, *counter-example for necessary*, *objection towards coincidence, overgeneralizing*, *rule followed instead of verified*, *use of assumptions not mentioned in the bubble*), and Alternative ideas (codes *favour on the use of rules*, *favour on the non-use of rules*). Below, we describe the code categories in detail and provide illustrative data excerpts related to them.

Coprime condition

The first of the code categories refer directly to weak or good knowledge of divisibility concepts. The most occurring concept in focus appeared to be the concept of verifying divisibility by decomposing the divisor into a product of two coprime numbers (e.g. $18 = 9 \cdot 2$) and verifying the divisibility by these two numbers. Almost half of the respondents (33 out of 67) forgot about the coprime condition and agreed with Ben who decomposed 18 into a product of two numbers that are not coprime. Usually, they then (incorrectly) included a prime factorization as a proposed enhancement of Ben's reasoning. As a direct consequence, these 33 respondents labelled Celest as incorrect:

V15 Ben: $18 = 3 \cdot 6 \rightarrow 6 = 3 \cdot 2$ divisibility criteria for 3 and 2 must be met
$3 \rightarrow$ sum of digits is divisible by 3 $2 \rightarrow$ must be even
$\rightarrow$ holds good (meets both criteria)

		I would be more specific and decompose as 18 = 3 · 3 · 2, it is enough to check whether the number is even and its sum of digits is divisible by 3.
	Celest:	She just made another decomposition. She is not right, both decompositions are good.
V31	Celest:	I think she is not right. It is enough. She must decompose the 6.
V65	Ben:	I think that the divisibility by six is a little extra. It is enough to verify divisibility by two and by three.

In responses to the third question, 22 of these 33 respondents offered as their own solution the decomposition into 9 · 2 or 2 · 9, and 5 respondents offered the decomposition 3 · 3 · 2 or 2 · 3 · 3. On the other hand, there were respondents who remembered the coprime condition and pointed it out:

V64	Ben:	We cannot decompose this way. The numbers you decompose into must be coprime (cannot be divisible by the same number) → 3 and 6 are divisible by 3, we do not want it.

Language

Some of the respondents displayed shortcomings in the language of mathematics that transpired in the form of an inaccurate terminology (V30), a shift of a meaning of a mathematical concept (V36), a shift in an interpretation of the text in a bubble (V47), or a combination of them (V34 – terminology & interpretation):

V30	David:	1800 is the closest whole number.
V36	Ben:	The idea is good, but it is not sufficient to have the number divisible by 3 and by 6, it must also, after dividing by one of the numbers, be divisible by the other.
V47	Celest:	According to Celest, we have to check divisibility by 3, 6, 9, and 2. It is sufficient to check just divisibility by 9 and 2.
V34	Celest:	She thinks that we have to check all variants of multiples, but it is not true.

Argumentation modes

The third code category refers to modes of argumentation and logical aspects in general. Among the proper argumentation modes, it included counter-examples that some of the respondents provided as a reaction to Adele. These counter-examples referred either to a condition that is not sufficient (V14) or a condition that is not necessary (V29):

V14	Adele:	She tried to sum the digits of 1764 → it came out 18, and 18 : 18 = 1, so that she thinks this is a rule for divisibility by 18. However, when we take e.g. the number 4455, the sum of its digits is also 18 but the number is not divisible by 18.
V29	Adele:	Her opinion surprised me. The sum of the digits is 18, so it is divisible by 18, but I did not find this kind of criterion anywhere. … I chose the number 126 (a multiple of 18) to check it → 126 : 18 = 7 → 1 + 2 + 6 = 9 → 9 : 18 = 0,5. Other example: 1710 : 18 = 95 → (1 + 7 + 1 + 0 = 9) 118764 : 18 = 6598 (1 + 1 + 8 + 7 + 6 + 4 = 27 → 27 : 18 = 1,5). In my opinion, it implies that we cannot use the sum of digits this way as decisive. It was just a coincidence that it worked out for her.

Surprisingly, none of the respondents offered a counter-example as a reaction to Ben. However, several of them provided to Ben an objection towards coincidence similar as the one by V29 to Adele:

V46	Ben:	That Ben's claim comes out in this particular case is, in my opinion, just a coincidence.

The improper argumentation modes included using an assumption that was not mentioned in the bubble (V18), overgeneralizing (V46/David) or following a rule in the bubble instead of verifying it (V46/Adele):

V18	Adele:	She is right, because if a number is even and a sum is divisible by 18 → it's true.
V46	David:	Number 1800 is divisible by 18, number 36 as well, in this case she is right. Check: $18 \cdot 4 = 72 = 100 - 28$ 100 is not divisible by 18 28 is not divisible by 18 In my case, it did not work out, which means that it was just a coincidence.
	Adele:	1 + 7 + 6 + 4 = 18 → 18 : 18 = 1 → she is right, it will work.

Alternative ideas

The last code category summarizes how respondents reflected the fact that there were alternative opinions shown in bubbles. Aside from the discourse between Ben and Celest that got assigned its own code category (*Coprime condition*, see above), there were also two different correct statements presented by Celest and David. Here, some of the respondents favoured the Celest‘s way based on a well-known rule (V13), others appreciated that David had managed without the rule (V29, V5); one of the respondents favoured both the statements (V44):

V13	David:	This procedure is logically correct, but might be time consuming. It is better to use divisibility criteria instead.
V29	David:	His opinion is interesting and might also be considered correct … He came to the conclusion logically even without knowledge of the divisibility criteria.
V5	David:	Nice, quick reasoning!
V44	(3)	I myself would support both opinions (C and D). C is a classical method. For D, we have to think a bit but, for one, it is faster.

Discussion and conclusion

As illustrated in the previous section, using educational vignettes, namely Concept Cartoons, as an assessment tool within a mathematics content course for future teachers might bring a broad insight into various facets of knowledge that is more or less related to the mathematical content that the future teachers would teach in their future teaching practice. The environment consisting in a Concept Cartoon presenting various correct and incorrect opinions on a chosen topic (divisibility by 18) and a set of three differently aimed indicative questions has proved to be able to indirectly provoke reasoning of future teachers and obtain rather talkative responses from them (even if only in writing). These responses reflected in detail how future teachers reasoned about the topic, how they understood key concepts, what mathematical language they used, what kind of arguments they were able to provide, and how they reacted to various alternative ideas.

The results of the study highlighted the advantage that Concept Cartoons have over standard written tests: 33 of the 67 respondents labelled as correct a solution that was not correct (Ben, missing coprime condition), however, 22 of them offered as their own solution a solution that was correct. It is reasonable to assume that if only a standard test were used as a method of assessment (e.g. with a task *"Is 1764 divisible by 18?"*), these 22 respondents would succeed in the test and there would be no doubt about their subject-matter knowledge. Moreover, using the format of Concept Cartoons for assessing subject-matter knowledge also allowed to learn about future teachers' mathematical language and argumentation. The findings of the study confirmed weaknesses in conditional reasoning (cf. Simon & Blume, 1996; Buchbinder & McCrone, 2019) as well as a tendency to overgeneralizing (cf. Hemmi et al., 2017), a tendency to handling the topic of divisibility rather procedurally than conceptually (cf. Zazkis et al., 2013), insecurities in mathematical language (cf. Schleppegrell, 2007). Such findings show that vignettes might be implemented meaningfully into teacher training not only to advanced courses focusing on pedagogical content knowledge and teaching practice (Buchbinder & Kuntze, 2018) but also to initial content courses.

‘I personally would have done it the other way’ – Pre-service teachers’ Perspective Taking when noticing mathematical thinking

Susanne Schnell and Carolin D. Fellenz

Goethe-University Frankfurt, Germany;
schnell@math.uni-frankfurt.de, fellenz@math.uni-frankfurt.de

Learning to notice is perceived as an important aspect of the professional development of pre-service mathematics teachers in Germany. It includes attending to specific elements of a complex situation and using one’s knowledge to make sense of them. This article makes the argument that taking over a different perspective might provide a valuable starting point to facilitate noticing of mathematical thinking processes. The qualitative content analysis of 280 pre-service teachers’ written statements shows that some participants take over different perspectives, which plays an important role in their describing, evaluating, and interpreting of the situation.

Keywords: Pre-service teachers, noticing, perspective taking, qualitative content analysis.

Introduction

Over the last decades, there has been a lot of research into teachers’ practices with a focus on professional vision and noticing (van Es & Sherin, 2021). Especially noticing students’ mathematical thinking is perceived as a prerequisite to providing rich learning environments and a productive mathematical discourse (Jacobs et al., 2010). Nevertheless, not only *what* teachers notice is important, but also *how* they analyze what they have noticed (van Es & Sherin, 2008; van Es, 2011). Several studies have shown how regular video club meetings can improve the way participants reason (van Es & Sherin, 2008; van Es & Sherin, 2021). Mathematical content knowledge (Friesen et al., 2015) and pedagogical content knowledge (Prediger & Zindel, 2017) provide categories along which certain aspects of a situation (including student thinking) can be noticed. However, more research is needed into to what extent pre-service teachers (PSTs) are able to notice specific aspects if they are provided with video material that allows them to focus more closely on a mathematical situation rather than a whole-classroom activity. In this paper, we will make the argument that *Perspective Taking* – i.e. imaging oneself in the teaching-learning situation presented in the video clip – facilitates noticing and especially interpreting rather than merely describing events.

Noticing as a goal in teacher education

Important aspects of teaching are to provide students with learning opportunities and to react adequately to their needs and potentials. The construct ‘teacher noticing’ refers to the process of making sense of complex classroom environments (Jacobs et al., 2010, p. 170). Generally, noticing is divided into three dimensions: (1) identifying what is noteworthy in the situation (*attending* or *selective attention*), (2) using one’s knowledge and experience to make sense of what is observed (*interpreting* or *knowledge-based reasoning*), and (3) constructing interactions to gain further information during the noticing process (*shaping*) (van Es & Sherin, 2021). According to van Es (2011) and van Es and Sherin (2021), there are three general stances to interpret what is noticed: descriptive, evaluative, and interpretive. Interpreting is perceived to be the most sophisticated action and is driven by a stance of inquiry, i.e. the intrinsic motivation to figure out what is going on: "interpreting is not only about trying to make sense of a phenomena [sic] but also involves seeing observed phenomena as something worth trying to figure out" (van Es & Sherin, 2021, p. 22; see also van Es, 2011).

As research has shown, the ability to notice can be facilitated by (regularly) reflecting on video clips from situations related to teaching and/or learning (Friesen et al., 2015; Prediger & Zindel, 2017; van Es & Sherin, 2021). Providing regular meetings of video clubs with in-service teachers, van Es (2011) and Sherin and Han (2004) found that the participants had a tendency to take a descriptive and evaluative stance in the first session, but adopted more often an interpretative stance in the last. In-service and pre-service teachers alike tend to focus on the teachers in the beginning, but over time shift their attention to students' actions and thinking (van Es & Sherin, 2008; Star & Strickland, 2008). Regarding the evaluative stance, Karsenty et al. (2019) illustrate how in-service teachers move from predominantly judgmental comments to justifying different perspectives over the course of a video club. While they argue that this allows for more productive discussions, they also find an overall decline in evaluating actions in favor of openly discussing specific aspects of practice and pedagogy.

Looking specifically at PSTs, it is not surprising that they tend to be less proficient in noticing as they normally lack the experience of teaching as well as the theoretical categories from content knowledge and pedagogical content knowledge. They tend to chronologically report on events rather than interpreting them (van Es & Sherin, 2002) and provide limited or no evidence for interpreting children's understandings (van Es & Sherin, 2002; Jacobs et al., 2010). However, the depth of the analyses by PSTs may depend on the type of video clip: Using a full-length video of a whole-classroom period, Star and Strickland (2008) found that PSTs had trouble focusing on important aspects and "generally do not enter teaching methods courses with well-developed observation skills" (p. 107) – but were able to develop them over time. In contrast to that, Prediger and Zindel (2017) used a shorter sequence from a one-on-one interview with a student in a study with 159 PSTs. Their findings illustrate how – even before an intervention - a majority (roughly 65 %) is able to focus on student thinking rather than making only surface judgments.

While the goal is to deal with the full complexity of a whole classroom, these findings indicate that it might be fruitful to start with a reduced setting for PSTs. Overall, learning to notice is complex, requires time and experience. Especially for developing an interpretative stance, PSTs should learn to be aware of themselves and their own expectations as a prerequisite for noticing (Mason, 2009).

Perspective Taking as a personal interpretative frame

Mason (2009) describes the importance of self-awareness to being able to notice and facilitate student thinking:

> Ongoing enquiry into the actions available to learners and into ways of both triggering them and making them available for inspection involves ongoing enquiry into the origins of the actions, which underpin different topics. Ongoing enquiry into the origins and variations of those actions in one's own experience is necessary in order to be sensitive to learners. (p. 207)

Thus, the own experiences and approach to a certain task can serve as an important starting point for understanding and interpreting students' actions. Freudenthal (2002) uses the term *reflection* for "mirroring oneself in someone else in order to look through his skin, to explore him, to take him in" (p. 104). This type of reflection leads to a gain of knowledge not only about the other person but also about their own behavior and knowledge. The own experience serves as an anchor and/or priming for perceiving and analyzing the student's behavior. It also plays into the idea of recognizing choices and alternatives for a specific situation (Mason, 2009).

Regarding the process of diagnosing, Nickerson (1999) proposes a descriptive framework, in which experts use their own knowledge as a model to compare to another (a child's) model of knowledge. As Philipp (2018) points out, using the own (expert) perspective as a starting point for assessing a learner might yield potential biases, such as over-or underestimating the challenge for a novice. However, carefully comparing and contrasting the own and the child's actions might lead to a higher awareness of both differences and commonalities, and support the focus on student thinking.

The idea of *Perspective Taking* as a means for noticing is included in the construct of interpretative frames proposed by Sherin and Russ (2014). These frames function as lenses, through which a situation is perceived: "In each interpretative frame, the way [a teacher] makes sense of the video ([i.e.] knowledge-based reasoning) is both constrained by and contributes to what [he/she] notices in the video ([i.e.] selective attention)" (p. 10). In an interview study with 15 in-service teachers, the authors identify 13 interpretative frames, one of which is *Perspective Taking*. This frame was found in regard to teachers imagining themselves in the role of the teacher in the video clip, but only four out of the 15 participants showed this frame. The authors offer as a brief potential explanation that the teachers only use *Perspective Taking* when the depicted instruction is in line with their own pedagogical approach. However, we see two problems with this explanation: First, by only taking the perspective of the shown teacher (rather than a student), *Perspective Taking* might not lead to a better understanding of student thinking. Second, if *Perspective Taking* only occurs in situations close to the own approach, it cannot help with getting to know alternative interpretations and actions.

Overall, one can assume that *Perspective Taking* has the potential to facilitate PSTs' learning to notice student thinking processes. In this paper, we address to what extent it might be found in PSTs' written analyses even at the beginning of their university studies in order to identify potential starting points for subsequent teacher education material. Thus, our presented study aims at the following research questions:

1. To what extent analyze PSTs the video clip by taking over a different perspective?
2. Which role does the *Perspective Taking* play in PSTs' analyses?

Study design & methodology

Data Gathering: To pursue the research questions, the study was carried out in the context of a lecture on mathematics education aimed at prospective primary school teachers (PSTs) in their first year of their three-year-long university studies in Germany. We collected written analyses of a video clip by 280 PSTs (35 male (12.5 %), 244 female (87.1 %), 1 diverse), of which 256 were in their first or second semester.

The video clip is roughly four minutes long and shows an excerpt from a one-on-one mathematical interview with the second-grader Mats, which is situated in the context of arithmetic learning. In the video, Mats first is working on a task where he has to find pairs of red and blue cards (unstructured and structured representations) with the same number of dots. Later, he describes his strategies. The video was uploaded to the lecture's accompanying online learning platform and was used as a preparation for the following lesson on counting and number sense. The PSTs were asked to answer the following questions in a text of up to one page: "Describe how Mats solves the task. What do you notice and which parts are especially interesting to you?"

Data Analysis: In order to see if PSTs were using a *Perspective Taking* frame and which role it played in their analyses, we used a qualitative content analysis approach (Kuckartz, 2019). The content analysis performed included the following steps:

1. Preparing the data
2. Segmenting written products of the 280 participants into idea units for analysis and coding each idea unit with one or more of the concept-driven categories based on the interpretative frames by Sherin and Russ (2014)
3. Focusing on all instances of the interpretative frame *Perspective Taking*: inductively identifying sub-categories from the data by comparing and contrasting the codings in regard to the questions whose perspective was taken (cf. resulting set of subcategories in Table 2). In addition to Sherin and Russ's (2014) definition of *Perspective Taking*, we included not only instances where someone in the situation was mentally replaced, but also where the participants imagined themselves (possibly additionally) in the situation.
4. Focusing on all instances of *Perspective of > PSTs as Task Solver*: coding each idea unit with one Stance identified by van Es and Sherin (2021) and van Es (2011) (cf. Table 1)

All steps were carried out by both authors and results were consensually validated.

Table 1: Deductively derived categories relating to the Stance, slightly modified to fit the situation

Stance (van Es, 2011; van Es & Sherin, 2021)		
Descriptive		Simply stating identified differences or commonalities
Evaluative		Evaluating the quality of the child's approach against the own perspective or proposing a (better) alternative
Interpre-tative	Reasoning	Identifying a cause/explanation for observed differences or commonalities
	Generalizing	Drawing a generalized conclusion in terms of either attribution of competence to the child or communicating a personal 'lesson learned'

Findings

Out of the 280 PSTs, 32 persons were identified to use a *Perspective Taking* frame with 38 different instances in total. Table 2 gives an overview of the findings. Overall, four different sub-categories were identified in terms of *whose* perspective was taken.

In nearly all instances (32), the PSTs imagined themselves in the situation *as the ones who had to solve the task* (but with their current mindset and skills). We identified three instances of taking the *child's perspective*, in which actions and/or statements of Mats were either explained or questioned from a student's point of view (as in the example in Table 2). There were two instances in which we used the category of *"Teacher"*, however, both are far less explicit than what Sherin and Russ (2014) found. Rather, in the example shown below, the assessment that the second part of the video is "where the actually important process of the task takes place" was interpreted as taking over a diagnostic perspective by identifying Mats' explanations as especially meaningful for understanding the student's thinking. The second utterance in this category also shows a diagnostic perspective referring to "immediately being aware of Mats' problems" (f1215). Lastly, one PST took the perspective of the *course instructors* who had administered the video analysis task (cf. Table 2).

Table 2: Inductively derived sub-categories of *Perspective Taking* > *Perspective of*

Sub-category (number of instances)	**Description for the sub-category**	**Exemplary quote from the PSTs' written statements (identification-code in parentheses)**
PSTs as Task Solver (32)	*Taking the perspective of being the one who has to solve the task presented in the video but with the current mind- and skill-set*	"What I find noteworthy here is that Mats split the blue card with seven points into six and one, while I myself would rather split between the lines into three and four." (f1059)
Child (3)	*Taking the perspective of Mats or another child with their mind- and skill-set*	"I would have thought - especially as a child - that he thinks of a die, which he knows from playing with it, and not of two rows of four with a dot in the middle" (f1148)
Teacher (2)	*Taking the perspective of the teacher/interviewer or another teacher with their mind- and skill-set*	"Afterwards, the student is asked to explain his approach. This is where the actually important process of the task takes place." (f1207)
Course Instructors (1)	*Taking the perspective of being the course instructor who administered the video analysis task to the PSTs*	"I think this assignment is trying to make us students aware of how important good arrangement and structured representations are for elementary school children to be able to understand abstract mathematics based on them." (f1017)

Due to the dominance of the *PSTs as Task Solver* category, further analyses were concentrated on these 32 instances. Of these, 26 instances focused on differences between their own approach and the one shown by the child in the clip, five referred to commonalities, and one did neither.

As Table 3 shows, all stances identified by Sherin and van Es (2021) and van Es (2011) were found when looking at *Perspective Taking > PSTs as Task solver*. In eleven cases, there was a mere *description* of differences (none of these instances related to commonalities) between the own and the child's approach. Looking at the *evaluative* stance, we included similar to Karsenty et al. (2019) assessments of the situation in which the different perspectives served as a sort of measure or suggestions of alternatives (as shown in Table 3). Here, in six cases, the PST's approach served as a better way to solve the task than what Mats did. In the only instance where a commonality was described, the PST gave a positive evaluation, stating how they were surprised that a child was able to tackle the task similarly to themselves.

Table 3: Identified sub-categories of *Perspective Taking > PSTs as Task Solver > Stance*

Sub-category	Exemplary quote from the PSTs written statements
Descriptive Stance (11)	"What I find noteworthy here is that Mats divided the blue card with seven points into six and one, while I myself would rather divide between the lines, so into three and four." (f1059)
Evaluative Stance (7)	"Here I notice in particular that I personally would probably have done it the other way around, [... because] I think it would be quicker to find the matching card." (f1083)
Interpretative – Reasoning (8)	"For me it was very obvious to calculate 3+4=7 but for him there were six dots and one more. Probably he compared the structure of the dots with a structure known to him, namely the two times three dots on the card with six dots." (f1062b)
Interpretative – Generalizing (6)	"What I personally also find very interesting is how each person uses a different method for counting points, as I myself would have approached some numbers very differently." (f1068)

Belonging to an *interpretative* stance, we identified two categories: *reasoning* and *generalizing*. There were eight instances in which PSTs described differences (5) or commonalities (3) and formulated possible reasons for these observations. Here, the participants used background knowledge for example on developmental levels or everyday experiences of young children (cf. Table 3). Lastly, there were six instances in which the *Perspective Taking* resulted in stating generalizations. Here, in two instances, the PSTs used the comparison with their own perspective to attribute certain competencies to the child. In the other cases, they communicated how they themselves as PSTs learned something from the differences perceived.

Discussion

Regarding the first research question, 32 out of the 280 PSTs did use an interpretative Frame by taking a different perspective in their analysis of the video clip. Comparing our results (Table 2) to Sherin and Russ (2014), it might be surprising how often our participants imagined themselves in the situation and how rarely they took the perspective of the teacher or the child. One explanation for this might be the type of video clip, in which the interviewer is staying mostly in the background so that there is not much of a teacher's perspective in the situation to take over - especially as academically young PSTs lack experience with teaching. Furthermore, relating to the thinking of a second-grader might be challenging due to the age difference, and therefore neither the perspective of a teacher nor a child is close to the PSTs. However, most of our participants recently graduated from school and might well remember how they themselves solved tasks. As Philipp (2018) pointed out, there is a potential risk of a biased judgment when using oneself as the sole point of reference. However, according to Mason (2009), drawing on differences between the own approach and the child might lead to widening the own knowledge of possibilities and make PSTs more receptive to student thinking.

As our analysis regarding the second research question shows, only in a third of the cases was the own perspective used for a mere description of the video clip. Some PSTs managed to use their own perspective in an evaluative or even interpretative stance. Keeping in mind that these PSTs were participating in their first course on mathematics education, not all did use adequate categories of content knowledge or pedagogical content knowledge in their analysis. However, they seemed to be inclined to not only describe the student's behavior in contrast to their own but also look for possible explanations. This might be an indicator of an inquiry stance, which was argued by van Es and Sherin (2021), van Es (2011), and Mason (2009) as the driving force in noticing. While one could argue that the generalization from one case (or video clip) might lead to an over-generalization and thus to an assessment bias (Philipp, 2018), we believe that especially those PSTs who communicated a 'lesson learned' widened their knowledge horizon on possibilities how young students make sense of a task, which is an important prerequisite for noticing (Mason, 2009).

Furthermore, the number of evaluating instances is lower than what was expected with respect to the study by Karsenty et al. (2019). A possible explanation lies in the sample of looking only at *Perspective Taking* instances – the ongoing analysis of other frames indicates a much higher number of evaluative stances overall. A carefully formulated hypothesis is that *Perspective Taking* might be less likely to lead to evaluating, which would be in line with the benefits described by Mason (2009).

Implications for teacher education and further research

Overall, the presented study showed that even though there was no specific prompt for it, roughly 10 % of the PSTs used *Perspective Taking* in their written analyses of a video clip from a mathematical interview. Imagining oneself as a PST being presented with the same task as the child in the video can lead to different interpretative stances. Similar to Sherin and Han (2004) and van Es (2011), describing and evaluating dominated overall in our results. However, roughly half of the idea units were identified as interpretative, which not only showed how PSTs without prior experience in mathematics education reason about student thinking, but also provided insights into how some of the PSTs became aware of their own personal learning from *Perspective Taking*. This is in line with Freudenthal's (1991) suggestion that reflection on another person's behavior by taking their perspective does not only provide insights into their thinking but also about *oneself*.

We perceive the results from this ongoing study as possible starting points for designing a teacher education course, which aims at facilitating PSTs' noticing from the beginning of their university studies. The next steps will be to finish the analysis on the other interpretative frames in order to acquire a more comprehensive picture of PSTs resources for noticing mathematical thinking.

Clinical simulations for mathematics teachers' training: the impact on preservice teachers' sense of self-efficacy regarding their knowledge

Iris Schreiber

Bar-Ilan University & Kibbutzim College of Education, Israel; iris.schreiber@biu.ac.il

Forty-four preservice teachers participated in clinical simulations as part of their training. The simulations were designed to improve teachers' knowledge. The study investigated the advantages and disadvantages of this method concerning the teachers' self-efficacy regarding their knowledge. Results demonstrate that the simulative experience did not enhance teachers' confidence and exposed gaps in teachers' knowledge.

Keywords: Mathematics, preservice-teachers, knowledge, self-efficacy, clinical simulations.

Introduction and theoretical background.

Clinical simulation is a learning process in which the learner copes with a simulated action or occurrence from the real world of employment. It is unique in that it allows the learner to experience an authentic scenario that may occur in real professional life (Sauvé et al., 2007). The main advantage of simulative experiences is the formation of a direct connection between abstract concepts and the reality of which one learns, allowing the learner to implement theoretical ideas and terms on a realistic event (Davidovitch et al., 2008). Such experience is considered more effective than mere theoretical training on the professional knowledge demonstrated by the learners, their self-confidence in their ability to cope with different situations, and their inner motivation (Kolb et al., 2014). It is extensively used in the context of vocational training for pilots, medical doctors, nurses, social workers, and more.

In recent years, clinical simulation has become common in teacher training institutions, as part of a general tendency to incorporate more real-life scenarios. Traditionally, mathematics teachers' training courses include content aimed at improving the knowledge needed for teaching and enhancing the sense of self-efficacy regarding the ability to teach; this could be achieved in diverse methods, such as workshops, lectures, and practical work in school. Nowadays, the use of analyzing real-life situations, rehearsing lessons, and discussing realistic scenarios is commonly used (Horn, 2010), sometimes using virtual reality that simulates a classroom (Barmaki, & Hughes, 2015). The present study focused and explored a method of clinical simulations, not by rehearsing scenarios in front of fellow students or colleagues, nor engaging in an imaginary scenario, but a simulation with actors. As part of the simulations, the preservice teacher (PST) takes on the role of the teacher, and the actors the role of the students. Each simulation can be conducted around a scenario that portrays either an event in the classroom (a teaching-learning event, or a disciplinary event) or an individual meeting conversation (with a student or a parent). The clinical simulation allows the PST to experience (or watch others experience) the event in a safe environment, so they can practice coping with different and varied confrontations, learn from them and receive professional feedback about them. Studies dealing with teacher training through clinical simulation with actors have mainly dealt with conflict situations (Cil & Dotger, 2015; De Coninck et al., 2021), and focused on discussions with parents or colleagues. These studies have found that this method of learning has improved teachers' awareness and empathy, and their sense of confidence for dealing with such situations in the future. The present study used simulations not for conflict situations, but for everyday teaching-learning experiences, to promote teachers' knowledge and to enhance teachers' self-efficacy regarding their knowledge.

What is the knowledge required for teaching? In the context of mathematics teaching, four components of knowledge were defined (Ball et al., 2008): Common Content Knowledge, CCK (e.g., knowing how to solve or calculate); Specialized Content Knowledge, SCK (e.g., knowing how to solve a problem in more than one way); Knowledge of Content and Teaching, KCT (e.g., knowing how to choose the suitable examples for presenting a topic); and Knowledge of Content and Students, KCS (e.g., familiarity with common student errors). Teachers' knowledge is a very significant factor in the teaching-learning processes: the broader the teachers' knowledge is, the better they cope with students' difficulties, the better intervention programs they prepare, and the better attainments their students have (Tchoshanov, 2011; Van Inger et al., 2016).

Another factor that may affect the teaching-learning processes is the teacher's sense of self-efficacy (Bandura, 1977): one's belief in his ability to successfully organize and perform a series of actions necessary to achieve the desired result. Performing a task properly requires both suitable skills and confidence in the ability to employ them. Thus, self-efficacy affects people's functioning: the higher self-efficacy is, the greater efforts and time they invest. Self-efficacy may affect teaching-learning processes: the higher teachers' self-efficacy, the better relations they have with school staff, the higher job satisfaction they have, and the more involved they are in promoting students (Dellinger et al., 2008; Sarıçam & Sakız, 2014). Studies exploring teachers' self-efficacy regarding their knowledge found a difference between the different components of knowledge. The highest level of self-efficacy is related to common content knowledge, and the lowest level of self-efficacy is related to knowledge of content and students (Schreiber & Fillo, 2019).

As mentioned above, simulative experiences might be used to promote teachers' knowledge and their sense of self-efficacy regarding their knowledge. Thus, it is important to explore the influence of simulative experience on the teachers' knowledge and the associated sense of self-efficacy. As far as I know, no simulative studies have been conducted that focused on the effect of simulations on mathematics teachers' knowledge and their sense of self-efficacy regarding their knowledge.

The aim of the study: To examine the effect of simulations on the teachers' confidence in their knowledge (both their knowledge in general and specific knowledge components). The research question: (1) Are PSTs able to express their knowledge during simulations? (2) What is the impact of clinical simulation on PSTs' level of self-efficacy regarding their knowledge?

Methodology

Participants: Forty-four PSTs, who participated in a practice-based course for mathematics teachers training, as part of their studies for a teaching certificate in mathematics. During the course, they participated in several simulation sessions with professional actors who played school students. In these sessions, 23 PSTs actively participated, playing the teacher in the simulation, while 21 participants watched them. Among the 23 active participants, 14 PSTs participated as a teacher with

3 players (class simulation), and 9 PSTs participated as a teacher with one player (individual meeting simulation).

The participants have a bachelor's degree in mathematics education/science/economy, and they have very little experience in teaching (only a few hours a week). During the course, they acquired theoretical knowledge regarding students' conceptions and misconceptions, and knowledge regarding teaching specific mathematical concepts and topics. They also watched and analyzed lessons videos.

Research tools:

1. Scenarios that were written as scripts and simulated a teaching-learning event. Two types of scenarios were constructed: a scenario that simulates a classroom event, in which the teacher teaches three actors, and a scenario that simulates an individual conversation, in which the teacher teaches one actor. In each script, there is a math problem, given to the teacher in advance. The actors (professional actors who do not know mathematics) get in advance the solution that they are supposed to present during the simulation (correct/wrong/correct but unusual solution) and are instructed how to react to every possible response of the teacher. The teacher must choose how to explain the problem to them, whether to answer their questions and how to respond to their suggestions for solutions or to continue in the path he has chosen. The solutions presented by the actors were aimed at probing the knowledge component needed for mathematics teaching (Ball et al., 2008): an unusual solution is aimed at SCK, the wrong solution is aimed at KCS.

An example for a scenario involving an arithmetic sequence problem: "the third number in an arithmetic sequence is 10, and the seventh number is 20. Find the fifth number". Each of the actors presented one of the following solutions: (1) A correct solution: using the equation $a_n=a_1+(n-1)d$ for the third and seventh numbers, and then solving a system of two linear equations; (2) A correct answer: finding the fifth number by performing arithmetic mean of the two given numbers; (3) An incorrect solution: the student wanted to find the constant difference between the consecutive numbers, so he wrote: 10, a4, a5, a6, 20, subtracted the values of the two given numbers (20-10) and divided the result by 5, instead of by 4, because he counted 5 numbers and not the 4 differences between them.

2. Simulation videos: Each simulation is filmed. The videos were transcribed and then coded - mapping events to the relevant knowledge component: CCK - participants knew how to solve the problem correctly, SCK - participants chose to show the students alternative or unconventional solution, KCT - participants prepared an explanation or a teaching method to the problem, KCS - participants addressed student difficulty or error. For the data analysis, the number of events in which participants displayed each knowledge component was counted, as well as the numbers of misses - events in which the participant was expected to demonstrate knowledge and did not (for example, an occasion in which a participant refused to acknowledge an easier solution suggested by a student).

3. Self-efficacy questionnaires: The participants were asked to address thirteen different statements that dealt with different components of knowledge and indicate whether their level of confidence increased, decreased, or did not change after participation in the simulations' workshops. For example, they were asked to refer their level of confidence in their ability to examine an unconventional student solution to a problem and determine whether it is correct (SCK). Or their

level of confidence in their ability to anticipate students' common errors (KCS). In addition, participants were asked to answer a concluding question: whether they generally felt that their level of confidence in their knowledge increased, decreased, or did not change after participation in the simulations' workshops.

4. Interviews: To elaborate on the self-efficacy questionnaire findings, interviews were conducted with 10 PSTs who participated as teachers in the clinical simulation. Participants explained their answers regarding their general level of confidence in their knowledge and elaborated on the reasons for the change in their confidence level.

Procedure: The actors were instructed how to respond and what to say to the PST. The active participant, who played the role of teacher, was given in advance the mathematical problem the simulation deals with. He could think about it and choose the solution and the way he wanted to explain it. But he did not know what solutions the actors would present, what their errors would be, and what they were going to ask. This was intended to imitate a real experience in the classroom, in which a teacher does not know in advance what the students will ask and what solutions they will offer. Each simulation lasted from 6 minutes to 15 minutes and immediately after it a feedback discussion was held with all present. During this feedback session, the teacher explained his motives, what guided him in his responses, the difficulties he had in managing the scenario his conclusions for a similar situation in the future; the actors explained how they felt as students, what the teacher’s strengths were and what they would offer him to do differently; viewers highlighted the teachers' strengths, his actions they approved of, and suggested additional approaches and additional possible responses to the simulative situations.

The participants could (if they wanted) participate again in another simulation.

Results

Teachers' knowledge: As previously written, in each simulation, the PSTs coped with a problem they received in advance. The solution they chose to present, their reaction to an error or an unconventional solution, revealed their knowledge and their ability to use it in real-time. Watching the videos, I analyzed the responses and pedagogical decisions the teachers had made and examined what components of teachers' knowledge were expressed during the simulation.

The PSTs showed common content knowledge, but they had partial and even lacking knowledge in specialized content knowledge and knowledge of content and students. Regarding CCK, the teachers had no gaps: all the PSTs but one solved the problem correctly. The one teacher who brought a wrong solution noticed it right at the beginning of the simulation and corrected her solution right away. But, regarding SCK, some PSTs were not familiar with solutions presented by the actors, either choosing to ignore it or forbidding the actor to present it. Most teachers did not know whether and how to present a second solution after one was presented, so they chose to adhere only to one solution –in all the scenarios but two, no solution was discussed other than the one that the teacher had prepared in advance. Furthermore, no connection was made between different representations, and many PSTs found it difficult to explain the mathematical principle underlying the solution they chose. All these expressions of SCK were missing or partial among the PSTs. Another gap in teachers' knowledge was regarding KCS: it was found that there was great difficulty among most PSTs in dealing with a student's error or wrong solution: most of them could not identify the difficulty, and none understood what the source of the error was. While most of them did pay attention to the actor who played the struggling student, their communication was merely personal, expressing empathy and patience, rather than educational; it lacked the necessary instruction tailored to a specific difficulty or specific error. Since the teachers did not understand exactly what the difficulty was, they chose to repeat the same solution instead of explaining to the student what the mistake was and how it could be avoided in the future.

Teachers' self-efficacy: The findings of the concluding question in the self-efficacy questionnaire (Table 1) vary depending on how the PSTs participated in the simulation.

Table 1: Changes in the level of confidence in the knowledge

	Increase in confidence		No change in the confidence level		Decreased confidence	
Active participants:						
All active participants N = 23	4	17%	10	44%	9	39%
Active with 3 actors N = 14	1	7%	7	50%	6	43%
Active with one actor N = 9	3	33%	3	33%	3	33%
Inactive participants:						
Only audience N = 21	8	38%	12	57%	1	5%
Total N=44	12	27%	22	50%	10	23%

Table 2 demonstrates that in general, only a quarter of those present in the simulation reported an increase in the level of confidence in their knowledge. Among those who were observers only, the simulation seemed to raise the confidence level or at least did not cause a decrease. Among those who were active with one actor, there was no difference in reporting between increase and decrease of confidence: a third of them reported an increase, a third of them reported a decrease, and a third of them reported no change in their confidence. In contrast, participants who were active as teachers with three actors were more likely than other participants to report a decrease in their level of confidence in their knowledge, even though in the discussions that took place immediately after the simulations, the strengths of the teacher were emphasized.

For a better understanding of these findings, interviews were conducted with some of the participants to explore the reasons for the effect of the simulation on their level of confidence. The interviews, as will be explained in detail below, highlighted that the change in confidence level mainly depends on the knowledge component the teachers inadvertently focused on.

Four PSTs reported that coping with the scenarios strengthened their confidence in their knowledge and in their ability to deal with similar situations in the future. In their interviews, they all referred to their knowledge of content and students. One of them, David, had a successful simulation experience with three actors. When one of them posed a question, David felt he answered it well. In the self-efficacy questionnaire, he indicated that his level of confidence in the knowledge of content and students increased, and so did his overall level of confidence. In the interview, he said: "When I was at school and my students had difficulties, I realized that I had already experienced something similar during the simulation. That was the moment I felt more confident. The scenarios we were given are very similar to what is happening in a real class with real students. The simulations improved my sense of confidence in my ability to deal with different situations in the classroom". Another one, Eva, also reported an increase in her general level of confidence and referred in her explanation mainly to the knowledge of content and students: "A situation like the one I experienced in the simulation happened to me in a classroom, and then I realized I was given tools to deal with it. I knew what to focus my explanation on. It strengthened my confidence that I could deal with situations in a real classroom". In these statements, the PST emphasized that coping with a scenario helps to cope with a similar experience in the future and strength the sense of confidence in the ability to handle similar situations.

However, it seems that first-time encounters with real-life situations might have the opposite effect. Unlike the above statements, many PSTs reported that the simulations decreased their confidence. They also explained their feelings in the interview by referring to what they know or don't know. For example, Ron said: "I feel that I don't always know how to explain a solution that I am not familiar with, or how to explain errors to the student who made them". Ron's confidence was influenced by two components of knowledge: specialized content knowledge, e.g., dealing with an unconventional way of solving, and knowledge of content and students, e.g., dealing with a student's error. Lina, another PST, also focused on these two types of knowledge, because during the simulation she had to deal both with an unusual solution, and with a wrong solution: "During the simulation, I felt the need to bridge between my desire to show a nice mathematical solution and the actors' desire to get an answer... there were situations where I felt that I directed my explanations at a particular actor, while the others were not silent… On the one hand, it feels like a real classroom, but on the other hand, here it was a little harder for me, and it undermined my confidence. All I wanted at that moment was for the actors to listen to me and to understand their error, but I felt my explanation was lacking".

Summary and conclusions

In mathematics teacher training courses, PSTs are aimed to gain the knowledge required for mathematics teachers: learn teaching methods, different representations for mathematical objects, and common errors of students. One of the tools used in the training process is simulation workshops, in which the PST can experience a reality-like scenario that allows him to use the theoretical knowledge he has acquired. The rationale for conducting these is that teacher knowledge is best developed through the experience of teaching a classroom; for this reason, it is believed that PSTs should be trained to develop a wide range of skills experientially and practically (Ball, & Forzani, 2010). The advantage of this experience is that the scenario's focus is on specific types of knowledge and enables the participants to watch themselves and discuss with others their decisions and their responses.

The questions of the present study were: (1) Is the knowledge imparted to PSTs reflected during the simulation workshops? (2) Does attending workshops increase PSTs' sense of self-efficacy regarding their knowledge?

The study described in this paper does not seem to give clear-cut answers to these questions. Regarding the knowledge of the PSTs, the findings show that differences were found between the levels of proficiency and control the PSTs demonstrated in each component of knowledge. In common content knowledge, the teachers were more knowledgeable; in pedagogical-content knowledge, they were less knowledgeable, which may adversely affect their teaching and the learning process of their students; and in specialized content knowledge and knowledge of content and students, they were least knowledgeable. These findings support the findings of past studies, in which it was found that teachers in general, and particularly novice teachers, lack these components of knowledge (Schreiber & Fillo, 2019). If the teaching quality of teachers is an outgrowth of their knowledge, the findings suggest that PSTs should strengthen mainly the two components of knowledge that were found missing (SCK and KCS), and therefore training should include workshops with scenarios that require an online active use of these components; for example, unusual (SCK) and wrong (KCS) solutions.

Regarding the PSTs' sense of self-efficacy, the results indicated that the simulation might not be the best experience for the participants, since only a few participants reported improved confidence**.** It was found that after participating in the simulation workshops, most of the participants reported that their general confidence was undermined, as well as their confidence in their knowledge. A possible explanation for the results is that the teachers lack certain knowledge components. In the interviews, the explanations that teachers gave for their decrease in their general sense of confidence, usually focused on their difficulty to handle unconventional solutions and students' difficulties, which is linked to SCK and KCS. Most of the participants' explanations focused on a particular knowledge component that lowered their confidence. It can be deduced from the PSTs' answers that for each of them there was one component of knowledge in which they were less knowledgeable, and thus has more influence on their sense of confidence. Another possible factor for the decrease in the general confidence that was expressed in the interviews is the difficulty of addressing three actors at once while being subjected to criticism from many spectators, as well as from the actors themselves.

How can the benefits of simulative experience be maximized so that they improve participants' sense of competence and increase their level of confidence? How to avoid a situation of feeling 'failure' in dealing with the scenario? The results suggest that some measures should be taken to increase the positive effect of clinical simulations on preservice mathematics teachers. First, more work needs to be done to support the PSTs' development of SCK and KCS in positive experiences, to increase their self-efficacy before engaging in this type of simulation. Second, the self-efficacy aspect should be strengthened in the training process in general, and in the feedback for a simulation in particular; more emphasis should be put on the strengths of the participant and his empowerment. Third, simulations with one actor are less intimidating and should be the only kind used; the course and the simulations should focus on one type of knowledge. The present study and its findings imply that while providing guidance and consultation to novice teachers, it is important to strengthen their confidence while promoting their knowledge, especially concerning specialized content knowledge and knowledge of content and students. This recommendation has also been mentioned in previous studies (Schreiber & Fillo, 2019; Van Inger et al., 2016).

Improving pre-service teachers' diagnostic judgments regarding task difficulties in the domain of fractions and angles – A process-oriented investigation with Eye-Tracking.

Saskia Schreiter[1], Markus Vogel[1], Markus Rehm[1] and Tobias Dörfler[1]

[1]Heidelberg University of Education, Germany; schreiter@ph-heidelberg.de

In this ongoing study, the focus is put on the potential influence of specific knowledge on pre-service teachers' judgment processes when diagnosing the difficulty of mathematics tasks. It is assumed that pre-service teachers use their knowledge in order to identify difficulty-generating task characteristics and to evaluate them in terms of their difficulty for students. To examine this assumption, an experimental group, in which participating pre-service teachers acquire knowledge about typical student difficulties and specific difficulty-generating task characteristics is compared with a control group. Using eye-tracking technology and stimulated recall interviews, indicators for diagnostic judgment processes are collected and compared between conditions. First results suggest that specific knowledge leads to a more efficient judgment process and enables pre-service teachers to identify and correctly evaluate difficulty-generating task characteristics more frequently.

Keywords: Diagnostic judgment processes, knowledge, eye-tracking, stimulated recall interview.

Introduction

For effective mathematics instruction, the use of tasks that are adapted to the students' ability level in terms of difficulty is considered central (Leuders & Prediger, 2016). A prerequisite for this is that teachers are able to identify task difficulties and evaluate them adequately. The difficulty of mathematics tasks is influenced by mathematical task characteristics (e.g., in the domain of fractions: like vs. unlike fractions; Padberg & Wartha, 2017) and instructional characteristics (according to cognitive load theory (CLT): e.g., split-attention vs. integrated task design; Sweller et al., 2011), among other characteristics. However, research findings show that teachers often make inadequate judgments about task difficulties (Karing & Artelt, 2013) and do not sufficiently consider the task's instructional design (Schreiter et al., 2021). Specific knowledge of difficulty-generating task characteristics was found to play a significant role for the accuracy of teachers' diagnostic judgments regarding task difficulty (Ostermann et al., 2017). However, most of the research on teachers' diagnostic judgments has so far focused on judgment accuracy. Therefore, little is known about how teachers get to their result and what role knowledge plays in the judgment process (Loibl et al., 2020). To gain insight into internal judgment processes, eye-tracking in combination with eye-tracking stimulated recall interviews has proven to be an effective method (Schindler & Lilienthal, 2019).

Theoretical background: Diagnostic judgment processes

It is assumed that in the genesis of diagnostic judgments, teachers use the information available in a diagnostic situation and process it on the basis of their knowledge to get to their result (Herppich et al., 2018). When judging the difficulty of a task for students, the relevant information constitutes the task characteristics that hold information about the tasks' difficulty ("difficulty-generating task characteristics"; Leuders & Prediger, 2016). In the judgment process (Loibl et al., 2020), these difficulty-generating task characteristics should be identified by teachers and adequately evaluated in terms of difficulty for students. Diagnostic judgment processes, such as identifying and evaluating task characteristics, constitute internal cognitive processes that cannot directly be observed. Research showed that eye-tracking is an effective method to investigate prospective teachers' diagnostic judgment processes (Brunner et al., 2021). However, as the interpretation of eye-tracking data can be challenging and ambiguous (Moreno-Esteva et al., 2017), a triangulation with qualitative data, such as eye-tracking stimulated recall interviews (ET SRI), is recommended (Schindler & Lilienthal, 2019). ET SRI is a research method to investigate cognitive processes by asking probands to retrospectively describe their own thoughts using a video sequence of their eye movements. In their systematic review on teacher's professional vision, Grub et al. (2020) report that numerous eye-tracking studies determined significant differences in gaze behavior between experts and novices. For example, experts were found to have shorter fixation durations, which were interpreted as an indicator of faster information processing. However, in most of these studies, experts were distinguished from novices only by the number of years of job experience, and other knowledge components were not considered. It therefore remains unclear how and whether teachers' knowledge – regardless of job experience – influences their gaze behavior during diagnostic activities.

This Study

This ongoing study aims to examine pre-service teachers' diagnostic judgment process when diagnosing the difficulty of mathematics tasks in the domain of fractions and angles. In this regard, it is intended to examine which task characteristics (mathematical vs. instructional) pre-service teachers identify and evaluate when judging task difficulties. In addition, a particular research interest is to investigate the potential influence of specific knowledge about difficulty-generating task characteristics on identification and evaluation processes. Please note that this contribution constitutes a pre-report of an ongoing study and only covers a sample of the data and results of a larger data set. Based on the above-mentioned findings of Schreiter et al. (2021), we expect for both content areas (fractions and angles) that a) mathematical task characteristics are identified and correctly evaluated more frequently compared to instructional characteristics (H1a) and b) instructional task characteristics are to a large extent not identified and correctly evaluated (H1b). Furthermore, building on the results of existing research on the influence of specific knowledge on judgment accuracy (e.g., Ostermann et al., 2017), we assume that specific knowledge enables pre-service teachers to identify and correctly evaluate more difficulty-generating task characteristics (mathematical and instructional) (H2). As eye-tracking studies focusing on teachers' professional vision revealed significant differences in gaze behavior between experts and novices (here: teachers with and without job experience; Grub et al., 2020), we further aim to exploratively investigate whether specific knowledge influences the gaze behavior of pre-service teachers (who have no job experience) during their diagnostic judgment of task difficulties.

Methods

Participants. N = 25 pre-service mathematics teachers were assigned to two conditions: an experimental group (n = 11), that received a 90-minute intervention and a control group (n = 14) without treatment. The intervention addressed specific mathematical task characteristics in the domain of fractions and angles that are known to cause difficulties for learners. Furthermore, theoretical foundations of CLT and related instructional task characteristics were addressed.

Material. Eight mathematics tasks were created (four fraction tasks and four angles tasks). Between these tasks, difficulty-generating mathematical and instructional task characteristics were systematically varied. The mathematical difficulty of the fraction tasks was varied by modifying the denominators (like vs. unlike), by mixing natural numbers and fractions, and by using mixed fractions (Padberg & Wartha, 2017). The mathematical difficulty of the angle tasks was varied by the number of argumentation steps needed to solve the task and by the angle values used (tens vs. units) (e.g., Reiss, 2002). The instructional difficulty of both content areas (fraction and angle tasks) was varied according to specific CLT design principles (Sweller et al., 2011): based on the *split-attention effect*, the tasks' relevant information is presented either close or distant from each other. Furthermore, building on the *redundancy effect*, the tasks were created in such a way that a) one and the same information is presented by different information sources or b) additional information irrelevant for the solution is included or c) no redundant information is included. The instructional design of the sample fraction task (figure 1) causes potential difficulties, as different information sources (the graphic and the time information) are presented distant from each other (split-attention effect) and redundant information (the route from Neckarsteinach to Ziegelhausen) is included (redundancy effect). The instructional design of the sample angle task (figure 1) causes potential difficulties, as the same information (values of the given and missing angles, tip) is presented by the text as well as in the graphic which causes unnecessary processing procedures (redundancy effect).

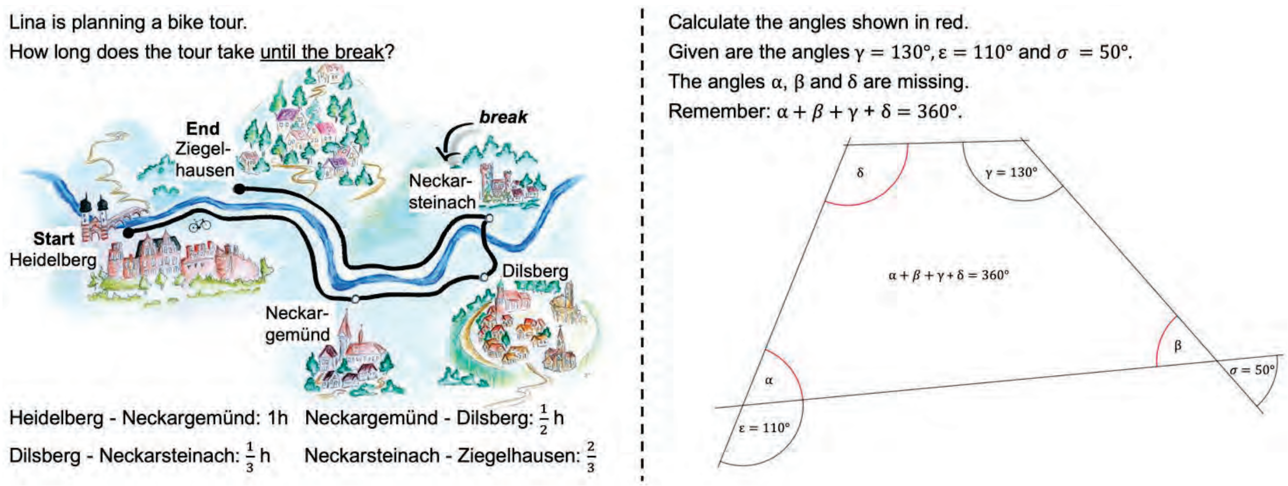

Figure 1: Sample of a fraction task and an angle task with specific difficulty-generating mathematical and instructional task characteristics

Procedure. The participating pre-service teachers were asked to assess eight mathematics tasks regarding the question "What makes the task easy/difficult for students?" The tasks were presented individually and in randomized order on a 24'' LCD screen. Eye-tracking data was collected using a monitor-based eye-tracker (Tobii Pro Fusion) that captures binocular eye movements at a sampling rate of 120 Hz. For adjusting the eye-tracker, a 9-point calibration was performed before each task. The time interval between the diagnostic task on the eye-tracker and the subsequent ET SRI was kept as short as possible to avoid loss of memory (approx. 1-3 min.). During the interview, subjects described what they did and thought during the diagnostic task, based on their shown gaze behavior. For the recording of the ET SRI, the software OBS was used, which records screen contents including sound, so that the videos of the eye movements with the corresponding comments of the subjects were available for the later analysis.

Data analysis. Tobii Pro Lab software was used to analyze the eye-tracking data. In each task, specific Areas of Interest (AOIs) were defined around the varied mathematical and instructional task characteristics. The number of fixations and fixation durations were determined using the Tobii I-VT Fixation Filter. To determine the number of transitions between two AOIs, the videos of eye movements were visually inspected. A mixed-methods approach was used to analyze the ET SRI data: The ET SRI were first transcribed and coded deductively using qualitative content analysis. The following category system was used and binary coded (in parentheses): difficulty-generating task characteristics can be *identified* (1), or *not identified* (0) when diagnosing a task. It turned out that some task characteristics are only identified when reflecting on one's own gaze behavior during the SRI. This resulted in another category *retrospectively identified*, which was evaluated as a subcategory of *not identified*. Identified task characteristics can be *correctly evaluated* in terms of difficulty for students (1) or *incorrectly / not further evaluated* (0). Task characteristics that are only evaluated during the SRI are assigned to the category *retrospectively evaluated* that counted as a subcategory of *not further evaluated*. Transcripts were coded by two raters with high interrater reliability (Cohen's Kappa = .88). The assigned codes were then integrated into a quantitative data set to examine differences across experimental conditions using variance analysis.

Preliminary Results

Identification and evaluation of difficulty-generating task characteristics

Two repeated-measures ANOVAs were calculated with the within subject factors *task characteristics* (mathematical/instructional) and the between subject factor *condition* (experimental/control group), separately for the fraction and angle tasks. Figure 2 gives an overview of the average percentage of difficulty-generating task characteristics that were identified and correctly evaluated in terms of difficulty for students.

Regarding the fraction tasks, the results showed that there is a significant difference with high effect size between the identification and evaluation of mathematical vs. instructional task characteristics ($F(1,23) = 15.01$, $p < .001$, $\eta 2 = .40$). This effect is, however, dependent on the experimental condition. Bonferroni-adjusted post-hoc analysis showed that differences between mathematical and instructional task characteristics can only be determined for participants of the control group (cf. figure 2). Here, significantly more mathematical task characteristics were identified and correctly evaluated compared to instructional characteristics (H1a). Instructional task characteristics were to a large extent not identified and adequately evaluated (H1b). Without specific knowledge, less than half of the instructional task characteristics were identified and correctly evaluated on average (M = .42, SD = .12). A significant difference with high effect size could be determined between experimental conditions ($F(1,23) = 31.29$, $p < .001$, $\eta 2 = .58$). Bonferroni-adjusted post-hoc analysis revealed that participants of the experimental group identified and correctly evaluated a significantly higher number of both mathematical and instructional task characteristics (cf. figure 2). Specific knowledge about difficulty-generating task characteristics has thus enabled pre-service teachers to identify and adequately evaluate more difficulty-generating task characteristics when judging task difficulties for students (H2).

Regarding the angle tasks, however, no significant difference could be determined between the identification and evaluation of mathematical vs. instructional task characteristics ($F(1,23) = 0.43$, $p = .521$, $\eta 2 = .02$). In the case of the angle tasks, both the mathematical ($M = .34$, $SD = .24$) and the instructional task characteristics ($M = .29$, $SD = .30$) were to a large extent not identified and correctly evaluated by the participants of the control group. Thus, only H1b can be confirmed for the angle tasks. Comparing the two study groups, a significant difference with high effect size could be determined ($F(1,23) = 26.29$, $p < .001$, $\eta 2 = .53$). As can be seen in figure 2, participants of the experimental group identified and correctly evaluated a significantly higher number of both mathematical and instructional task characteristics. H2 can thus also be confirmed for the angle tasks.

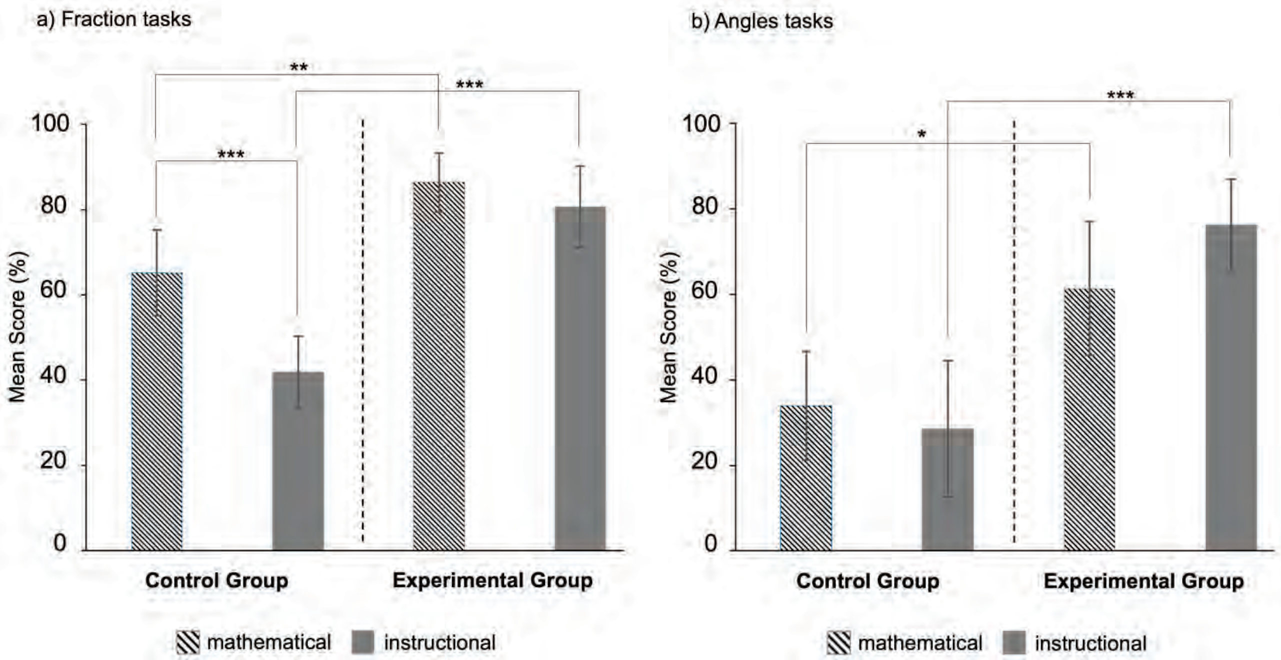

Figure 2: Means and Standard Error for identified and correctly evaluated difficulty-generating task characteristics (mathematical and instructional). *p<.05, **p<.01, ***p<.001.

Analysis of gaze behavior

The collected eye-tracking measures were used as indicators of visual attention in diagnosing task difficulty. Regarding the fraction tasks, a lower number of fixations and lower fixation durations within predefined mathematical AOIs as well as shorter total recording durations could be determined for the participants of the experimental group compared to the control group. These group differences are statistically significant with high effect sizes (cf. table 1). Against the background that participants of the experimental group identified and correctly evaluated significantly more difficulty-generating task characteristics, these eye-tracking measures may indicate a more efficient approach to diagnosing with specific knowledge. For the instructional AOIs, however, no significant differences in gaze behavior were found between the control and experimental group. Regarding the angle tasks, the eye-tracking data analysis is not yet complete but will be presented at the conference.

Table 1: Eye-Tracking measures (only fraction tasks)

AOI	ET measure	Control Group M (SD)	Experimental Group M (SD)	t	p	Cohens d
Mathematical	Fixation count	28.71 (12.71)	19.14 (7.84)	2.19	.039	0.91
	Fixation duration	8.31 (4.34)	4.89 (2.22)	2.55	.019	1.00
Instructional	Fixation count	34.35 (6.95)	34.21 (11.03)	0.04	.972	0.02
	Fixation duration	6.92 (1.37)	7.68 (2.93)	0.79	.442	0.33
	Transition count	9.04 (3.90)	8.68 (4.24)	0.22	.830	0.09
Overall	Total record duration	118.62 (12.74)	102.07 (12.03)	3.30	.003	1.34

Discussion

The aim of this ongoing study is to investigate which task characteristics (mathematical vs. instructional) pre-service teachers identify and evaluate when judging the difficulty of mathematics tasks in the domain of fractions and angles. Furthermore, a particular research interest is to explore the potential influence of specific knowledge about difficulty-generating task characteristics on identification and evaluation processes during the judgment.

In line with expectations, instructional task characteristics were to a large extent not identified and adequately evaluated, both regarding the fraction as well as the angle tasks. These findings support existing research on diagnostic teacher judgments (Schreiter et al., 2021), which showed that instructional task characteristics are insufficiently considered by teachers. In comparison to the instructional task characteristics, difficulty-generating mathematical task characteristics were identified and adequately evaluated significantly more frequently in the fraction tasks. In the case of the angle tasks, however, both mathematical and instructional task characteristics were to a large extent not identified and adequately evaluated. One explanation for this finding could be differences in prior knowledge. The results of the prior knowledge test of this study (results will be presented at the conference) showed that the participants of both study groups have more prior knowledge regarding difficulty-generating mathematical task characteristics in the domain of fractions compared to the domain of angles. Overall, the results of the study point to deficits with regard to the identification and evaluation of difficulty-generating instructional task characteristics, and, depending on the content area, also regarding mathematical task characteristics. However, for an effective mathematics instruction, teachers should choose, modify, or create tasks in such a way that task difficulties occur in appropriate doses and students are neither over- nor under-challenged (Leuders & Prediger, 2016). To do so, teachers need to be able to identify difficulty-generating task characteristics and to adequately evaluate them in terms of difficulty for students.

In line with expectations, the results showed that specific knowledge enables pre-service teachers to identify and correctly evaluate more difficulty-generating task characteristics. This effect could be found for both mathematical as well as instructional task characteristics. These results are consistent with existing research that highlights the importance of specific knowledge for the accuracy of teachers' diagnostic judgments (e.g., Ostermann et al., 2017). In our study, the collection of direct process indicators allowed to gain insights into the positive influence of specific knowledge on identification and evaluation processes that underlie teachers' judgment. Regarding the fraction tasks, the collected eye-tracking data further suggested a more efficient approach to diagnosing with specific knowledge: pre-service teachers with specific knowledge showed fewer fixations with shorter durations in task areas with difficulty-generating mathematical task characteristics. At the same time, they identified and correctly evaluated more difficulty-generating task characteristics. These results indicate that prospective teachers with specific knowledge are able to process relevant information faster, which is often seen in experts compared to novices (Grub et al., 2020). For instructional task characteristics, however, no significant group differences were found in terms of gaze behavior. It might be possible that there are no observable differences between persons who focus on task characteristics and process them fast and those who only pay little attention to the same characteristics. One possible explanation for our study finding could be that pre-service teachers without specific knowledge may have paid little attention to instructional task characteristics overall.

Overall, impulses for teacher training can be derived: An intervention on specific difficulty-generating task characteristics enables pre-service teachers to identify and adequately evaluate more difficulty-generating task characteristics and allows a more efficient approach to diagnosing. These results point to a need for learning opportunities to build specific knowledge during teacher training. Such learning opportunities should cover a wide range of difficulty-generating task characteristics (Leuders & Prediger, 2016) and typical student difficulties.

In addition to the practical relevance, the research strategic approach of this study should be emphasized: In the present study, theoretical predictions were made about how person characteristics (here: specific knowledge of prospective teachers) and situation characteristics (here: difficulty-generating task characteristics, content area of the task) influence the assumed information processing processes (here: identification and evaluation of task characteristics). These hypothesized relationships were then experimentally tested by systematically varying both situation and person characteristics and collecting process indicators (here: Eye-tracking data, and ET SRI) to examine internal judgment processes. This research strategy allows to generate knowledge about the information processing involved in the formation of diagnostic judgments, as has been widely called for (e.g., Herppich et al. 2018).

Acknowledgment

This ongoing study is carried out as part of the graduate school "DiaKom" funded by the Ministry of Science, Research and the Arts in Baden-Wuerttemberg, Germany.

A comparative study of the role of the external facilitator in lesson studies in Denmark and China

Charlotte Krog Skott[1] and Liping Ding[2]

[1]University College Copenhagen, Teacher Education, Copenhagen, Denmark; cksk@kp.dk

[2]Norwegian University of Science and Technology, Norway; liping.ding@ntnu.no

Collaborative forms of mathematics teachers' professional development, such as lesson study, are integrated parts of the educational systems in many East Asian countries, while these forms are often new in Western countries. In this paper, we focus on a central role in lesson study, that of the facilitator. We compare how they talk with teachers and what they focus on in their talk in a lesson study context in Denmark and in China. We use a framework consisting of mentoring strategies and content categories; both developed empirically in a Chinese respectively a European context. Our analysis shows big differences in the facilitators' ways of engaging in talk with teachers. One big difference is the dynamic and relational patterns in the Danish case as compared to the lengthy talk of the Chinese facilitator. We analyze these patterns deeply and argue that their differences are not only related to the fact that lesson study is new in Denmark, but also to social and cultural differences.

Keywords: Comparative study, lesson study, the facilitator, mentoring strategy, content categories.

Introduction

In this paper, we compare the role of the external facilitator (the expert teacher, the knowledgeable other, etc.) in the varied forms of lesson study (LS) in Denmark and Shanghai, China. While LS is new in Denmark, it has long been a school-based teacher professional development activity in China which vary in forms for teachers with different teaching experiences (Huang et al., 2017). Given the challenge of importing a routine developed in one culture and one educational system into countries with different cultures and systems (Stigler & Hiebert, 2016), it is important to develop insights into the roles of central actors in LS, in particular the role of the facilitator. At the level of interaction between facilitators and mathematics teachers, we investigate the research question: To what extent are there similarities and differences between LS in Denmark and Shanghai in relation to *how* the facilitators talk to the teachers and *what* content aspects they talk about?

The role of external facilitators in lesson study

Research into the role of the external facilitator in LS is scare, though studies emphasize the role as crucial (Takahashi, 2014). In countries, where LS is new, there is a lack of external facilitators able to support and qualify LS, and the role become often to scaffold the LS processes, not to enhance their quality (Hart et al., 2011). Studies from East Asia warn against oversimplifying the role, emphasizing the complexity of conducting LS (Takahashi, 2014; Ding et al., 2019). We will highlight aspects of the role that have been pointed out in different countries.

In a study in the US, Lewis (2016) examines how teacher educators new to LS learn to lead this work. The author followed two teacher educators for 18 months, who, among other things, were apprenticed to experienced LS leaders before leading LS themselves. For our purpose, especially one challenge experienced by the teacher educators seems important: to define a form of leadership that is credible and valued and at the same time respectful of teachers' choices in directing the LS processes.

In a Japanese context, Takahashi (2014) investigates the nature of the final comment of the facilitator (i.e., the knowledgeable other). The three selected and popular facilitators (in the Tokyo area) focused on presenting new knowledge from research and the curriculum, showing the connection between theory and practice, and helping others learn how to reflect on teaching and learning.

Huang et al. (2017) contribute to a better understanding of Chinese LS as regards its social, cultural, and institutional aspects. They emphasize that the culture of respect to seniors makes it legitimate for teachers to learn from experienced facilitators and from watching exemplary lessons. They suggest that in a culture, where less respect is given to seniority and authority, modeling good lessons, and getting feedback from facilitators, which are crucial elements of CLS, may not work as effectively.

In another study in China, Gu and Gu (2016) examine the role of the facilitator (i.e., the Teacher Research Specialist) in post-lesson debriefings based on more than 100 h. of videos of 50 facilitators. They develop a two-dimensional framework for analyzing the mentoring activity: the first dimension encompasses the dynamic between the facilitator and the teachers, *the mentoring strategies* (see below), and the second dimension is the knowledge that mentors pay attention to (i.e., mathematical, pedagogical and practical knowledge). Regarding the mentoring strategies, Gu and Gu found that "the conversations between [the facilitator] and teachers were…monologues rather than dialogic in nature", with the facilitators paying most attention to "what they know and what they anticipated, rather than…what teachers were concerned about in their teaching" (p. 451). Regarding the knowledge, the facilitators focused on practical knowledge, helping teachers to analyze concrete cases that embraced mathematical and pedagogical ideas.

Theoretical approach

Given our research questions, we need a theoretical approach that allows us to capture both how the facilitators talk with teachers, and what content aspects they focus on. Regarding the 'how' question, we are inspired by Gu and Gu's (2016) four types of mentoring strategies, especially because they are developed in a Chinese LS-context. The strategies are: 1) *General comments*: what teachers in general should know and do, regardless of the specific LS. 2) *Comments on anticipated problems*: focused on problems, that teachers were expected to encounter, and advice on how to deal with them. 3) *Responses to teachers' questions*: related to issues occurring in the observed lesson. 4) *Dialogues with teachers*: the facilitator and teachers discuss and share their views on these issues. Gu and Gu (2016) characterize the conversation between facilitator and teachers as *authoritative*, if the first two types dominate, and as *dialogic*, if the last two types dominate.

Regarding the 'what' question, we are inspired by the *Knowledge Quartet* (KQ) (Turner & Rowland, 2011). The KQ consists of four categories: *foundation, transformation, connection*, and *contingency*. *Foundation* refers to the teacher's theoretical background and beliefs in terms of what they learned at school and teacher education etc. It includes knowledge of mathematics and of research on mathematics education, and beliefs about mathematics, its teaching and learning. The three other categories are different as they refer to ways in which "content knowledge comes into play in the classroom" (p. 199) as *knowledge-in-action*. *Transformation* relates to the choices, teachers make, when transforming their own content knowledge into pedagogical forms targeted at students, while *Connection* refers to teachers' choices and decisions about establishing coherence in students' learning across lessons and class levels. The last *Contingency* category concerns the teacher's response to unexpected classroom events. The KQ is suited for our purpose since it focuses on content that comes into play in classrooms (or in conversations as in this paper), and not explicitly on the knowledge possessed by the participants or the knowledge they ought to possess. This perspective on knowledge is different from the one in Gu and Gu (2016).

Methodological approach

We conduct our comparative study as a multiple case study based on two cases from existing research projects, one in Denmark (Skott & Møller, 2020) and the other in Shanghai (Ding et al., 2019). We introduce briefly the two projects, their contexts in each country, and our analytical strategy.

The Danish LS case

Introduced around 2010, LS is new in a Danish context. A LS project is typically initiated by persons outside a school as short-termed initiatives that are self-contained and aim to learn teachers to do LS on their own. The 1½ year long project, that was initiated by the first author's research group in 2014 at a school in the Copenhagen area, fits this description (for details see Skott & Møller, 2020).

At the time of the project, there were radical educational changes at the political level in Denmark. Particularity, one change was important: the steering documents now encouraged teachers to plan in a certain way and to formulate measurable learning goals. This challenged teachers in general.

The project used a Japanese approach to LS (Murata, 2011), but with repeated teaching of the revised lesson plans. The selected case was from the project's second year, and the group consisted of three experienced mathematics teachers and two facilitators (teacher educators) from the research group (Ea and Pia) of which only Ea had experience with LS. Ea and Pia facilitated all the LS processes (three two-hour planning sessions, three repeated teaching – one by each teacher – and three one-hour post-lesson debriefings) and participated in them on equal terms with the teachers. The teachers aimed to design a new teaching approach to the solution of linear equations in which their 6th grade students would be supported in developing a structural understanding of the equal sign.

For this paper, we selected the second planning session since it was representative of the facilitators' ways of engaging in conversations with the teachers. During this session, the teachers presented their pre-prepared learning goals and tasks, which the participants further developed together. Transcripts of the video-recordings of this session comprise our primary data, but we also include lesson plans.

The Shanghai Lesson Design Study case (SH LDS)

The LDS is a variation of the forms of LS (called "Keli" in Chinese) in the school context in Shanghai. LS is one form of school-based development in which each teacher participates as part of their work (Huang et al., 2017). The LDS model has three LS cycles (L1, L2 and L3) (for more details see Ding et al., 2019). It was conducted at an international school in a suburb of Shanghai from 2012 to 2015.

The selected case was one of seven Keli topics focused on in the LDS. The LDS group consisted of seven Keli elementary teachers (Grades 1-5), two expert teachers invited by the school (one was the mathematics Teacher Research Specialist, Zhang, in this paper), one researcher (the second author), and five other mathematics teachers (Grades 1-8) from the school's teacher research group (TRG). The Keli teacher was a junior with two years of teaching experience. The case topic was to investigate the relationship between perimeter and area of rectangles in the Shanghai Grade 3 textbook.

In this paper, we focus on Zhang's talk in the first post-lesson debriefing of the selected Keli case. There were roughly two parts of his talk. The first part lasted 40 min. and focused on the problems in L1 and how to redesign the lesson in L2. The second part lasted 35 min. and focused on how to reimplement the redesigned lesson. The meeting lasted 75 min. Transcripts of video-recorded TRG-meetings are our primary data materials, but we also draw on lesson plans and a teacher interview.

Strategy of analysis

To examine both the 'how' and the 'what' questions, we analyzed the facilitators' utterances line-by-line and coded them in a two-folded way: mentoring strategies and KQ-categories. However, in the Danish case, Gu and Gu's four types proved to be insufficient to capture all the strategies used by the facilitators. We thus added three more types based on our preliminary data analysis: 1) *Encouraging comments*, such as emotional recognition of teachers' ideas and suggestions (e.g., "I think you did the right thing by choosing goals"). 2) *Challenging comments*, such as disagreeing with teachers' proposals and understandings (e.g.," I think [your learning goals] are too comprehensive to be reached in a single lesson"). 3) *Building on or reformulating teachers' ideas*, that are expressed in the conversation (e.g.," but as you said [this] could have been taught in the previous lesson, so in this lesson we could start from …").

Regarding the KQ-categories we were inspired by the codes provided by Turner and Rowland (2011). We did not code short utterances that only had a clarifying purpose and was unrelated to the KQ.

Results of the analysis

The Danish case

Few of the facilitators' utterances in the second planning session fell within the first two of Gu and Gu's (2016) mentoring strategies, while slightly less than half fell within their last two types, and slightly more than half fell within in the three added types. According to Gu and Gu, the facilitators, thus, seemed to talk with the teachers in a dialogic way. However, we nuance this characteristic later.

The main part of the facilitators' utterances fell within the KQ categories. Of these, the majority fell within the connection and transformation categories, while the rest was of a foundational nature. There was almost none in the contingency category, which is not surprising, as the focus was on planning. The contributions outside the KQ, was primarily encouraging comments, such as "What you suggest sounds reasonable" (Ea). This indicates that the facilitators primarily focused their contributions on knowledge-in-action, which we will elaborate below.

We will give three examples of different combinations of mentoring strategies and categories. The first is an example of: response to teachers' question (third type) and foundation. The example is interesting, since this is the only combination where the facilitators brought foundation in the form of mathematics education research into play. Initially, a teacher asked, “what does research say, should it [the context of the task they were designing] be something that the students can relate to, or could it be purely mathematical?”. Ea answered that “research does not say anything about that is has to be a context from students’ everyday life, but Realistic Mathematics Education emphasizes that it should be a context that the students can imagine and experience as meaningful”. Here, the facilitator transformed her foundational knowledge of the specific research result into forms that made sense for the teacher in relation to the specific issue and that helped all the teachers to broaden their perspective on the issue. Note that it was a teacher asking for this kind of knowledge.

The second is an example of the combination: building on teachers’ ideas (added type) and foundation. The participants discussed learning goals in relation to the task they were designing, when a teacher claimed that an equation “can be interpreted in many ways as” something to do with concrete materials and “something about x”. Pia replied, “That is exactly why it makes sense to break down goals … you need to focus only on parts of them in specific lessons”. Breaking down goals is a term introduced by the new steering documents, which the teachers have difficulties assigning meaning to in practical situations. As such, the term can be said to be part of the foundation as it needs to be learned formally for instance by studying the documents. The facilitator built on the teacher’s idea of many layers of goals to provide practical meaning to the term by meta-communicating its purpose and how it can affect their planning. We argue again that the facilitator transformed her foundational knowledge into forms that were meaningful for the teachers in the specific situations.

The third is an example of the most frequent combination: dialogues with teachers (the fourth type) and connection. The participants discussed how to introduce the task to students. Pia suggested to use scenarios that they had formulated because “it is a difficult process for students to make up a scenario that can be solved without including weird numbers. Then you can also formulate different scenarios to meet the needs of different students”. This example is one of many where the facilitators intended to make the teachers themselves understand and realize what would be the most appropriate decision in a particular situation, instead of telling them what to do. The facilitators formulated their advice as suggestions, which they provided reasons for. In this case, the reason was the anticipated epistemological difficulty for students (i.e., the connection category).

In summary, the facilitators contributed to establish a conversation with the teachers, that was much more dialogic than authoritative in nature. It was characterized by being dynamics in terms of short contributions (less than two min.) from all participants, open and negotiable. The negotiations were on the terms of the teachers (as the aim was to produce a lesson plan that suited their needs) and based on their contributions (i.e., building on their ideas, questions, and concerns). The facilitators did not make decisions (not even when asked) but attempted to support the teachers in making these by encouraging and supporting pedagogical reflections. The content of the facilitators’ contributions was mostly related to knowledge-in-action (transformation and connection), but also to the foundation category. However, then the facilitators contributed something of a foundational nature, they tended to transform it into forms that were meaningful for the teachers in specific situations and not to present it as knowledge per se. Hence, contributions of this kind tended also to be knowledge-in-action.

Instead of describing this type of conversation as dialogic, we suggest to characterizing it as *relational*, as it was crucial for the facilitators to establish a good relationship with the teachers (cf. the nature of the added types). This seemed to be a prerequisite for producing a joint lesson plan.

The SH LDS case

During the 75 min. long post-lesson debriefing, Zhang talked most of the time and the teachers listened. The conversation can, thus, according to Gu and Gu (2016), be characterized as authoritative. However, after a close analysis of the content of Zhang's talk, we consider the conversation as dialogic, which we will illustrate by two examples. First, Zhang initiated the debriefing by saying to the teacher, "In LS, you need to pay more attention to other's critical and creative ideas about your lesson…merely praising your lesson will not help you to improve your teaching". This comment can be perceived as contributing to an authoritative conversation. However, given the limited time of the school-based LDS and the business of teachers, the general cultural atmosphere in China is to be humble and to first learn from the facilitator's input to the LDS by listening carefully. Second, in the end of the first part Zhang said to the teacher, "So now you understand what problems you had in L1, and why we must modify the lesson plan. The key learning goal of this lesson is to enable pupils to participate into and thus gain learning experience of the whole process of plausible reasoning in mathematics". Hereafter all the participating teachers smiled to Zhang. They thus used a professional sign in China to show their respect and high appreciation of his input and practical wisdom. This indicates that Zhang's talk was not driven by his power or position above teachers, and that the questions he posed helped them to reflect on alternative ways to deal with their problems of using the reformed textbooks. Hence, when we consider Zhang's talk as a whole, we will characterize it as contributing to a predominantly dialogic conversation.

Regarding the 'what' question, in the first part of Zhang's long talk we could identify the foundation category, but with strong links to the transformation and connection categories. For instance, "In the west the focus is on the ground theories of the cognitive/psychological processes. We focus on craft art on the application of the theories. That is, how we deliberately use these learning theories to improve our lesson plan and classroom teaching and learning". The same picture emerged in the second part but combined with an emphasis on contingency of how to design and implement tasks to support students' different needs in class as regards their anticipated reasoning through inquiry-based activities. Thus, it was difficult to categorize Zhang's utterances into the individual KQ categories.

We will give an example of the most frequent combination of mentoring strategies and KQ categories. The example combines the two types: responses to teachers' (not formulated) questions and (implicit) dialogues with teachers, with the foundation category that links to transformation and connection. In the first part of his talk, Zhang posed a sequence of questions, "Why chose this topic in the textbook? … From the van Hiele theory of levels of geometrical thinking …". Zhang further posed questions for teachers to reflect on the updated educational assessment of deep learning, such as "whether the construction of the lesson matches our fundamentally shared educational value by the majority in the field". Though, Zhang's talk may be considered as "monologic rather than dialogic in nature" (Gu & Gu, 2016, p. 451), we interpret his sequence of questions "why … (because)" and "whether … or" as a mean to support teachers to reflect on the use of updated theories and educational assessment in LS.

In the utterances, Zhang expressed foundational knowledge such as awareness of educational purpose, the van Hiele theory, and theories of deep learning of mathematics. However, this foundation knowledge is specifically targeted the transformation and connection categories that are related to teacher's struggle in understanding the concepts of mathematics inquiry and inquiry-based teaching addressed in the reformed curriculum and textbooks. That is, Zhang links foundational knowledge to the transformation and connection categories by relating to the teacher's actions in L1 and her struggle with understanding the key problems embedded in the reformed textbook. Note that the teacher's problems were only evident in an interview with her after L1. It was not uttered during the debriefing.

In summary, Zhang's talk was considerably long and dominated the post-lesson debriefing. However, our analysis illustrates that he addressed the teachers' shared problems with the reformed textbooks and supported their learning of craft skills according to updated theories and educational assessment.

Concluding discussion

We identified major differences by comparing how the facilitators talked with the teachers and what content aspects they talked about in the Danish LS and the SH LDS. In the Danish case, the facilitators contributed to a type of conversation that we called *a relational dialogue*. Contributing encouraging comments, challenging comments, and building on teachers' ideas (the three added types of mentoring strategies), it was crucial for the facilitators to establish good relationships with the teachers to work together in the new LS context. Moreover, the facilitators' way of talking with teachers (incl. also the strategies related to a dialogic conversation) aimed to encourage and support teachers in their reflections on appropriate decisions regarding specific issues related to their classroom teaching. Our analysis shows that the facilitators supported the teachers' reflections, among other things, by providing reasoned suggestions in close response to the teachers' expressed needs. This is contrary to how the facilitators in Gu and Gu's study (2016) talked with teachers.

In contrast, the Chinese facilitator did not need to build up relationships with the teachers due to the school-based LS systems (Huang et al., 2017). Thus, Zhang could directly use the limited school-based meeting time to guide the teachers to deliberately learn craft skills. The use of Gu and Gu's (2016) mentoring strategies shows that Zhang contributed to an authoritative conversation. However, our analysis shows that it is more dialogic in nature. We see roughly two dialogical layers. One layer is self-evident as different teachers' utterances were recorded and thus noticeable in the analysis. The second layer concerns the teachers' gesture (e.g., smiling) and appreciation of Zhang's contribution. We interpret this as an expertise of the facilitator, being able to notice (implicitly) the teacher's struggle and provide a way to reflect pedagogically through a sequence of why and whether questions.

Regarding the 'what', our analysis shows that the facilitators focused their talk on the content, but with emphasis on different aspects. In the Danish case, the foundation category played a lesser role than connection and transformation, but the analysis shows, that regardless of which category the facilitators related to, their contribution took the form of knowledge-in-action. That is, they tended to transform their knowledge into forms that were meaningful for the teachers in relation to specific classroom situations and not to present it as knowledge per se. This seems to some extent to be different in the Chinese case, where the foundation category was prominent in Zhang's talk. However, Zhang was expected to provide foundational knowledge and gained respect by doing it, while the

Danish facilitators only contributed such knowledge, when requested to do so. This difference might be explained in terms of the differences between the two countries. In Denmark, teachers generally have a high degree of self-determination, a so-called *methodological autonomy* (Skott & Møller, 2020). This means that the single teacher tends to acquire the legitimacy to decide on teaching matters themselves, not only on those related to methods. For a facilitator, it is thus often demanding to balance between orienting teachers' work in certain directions and at the same time being valued and credited, as in Lewis' study (2016). While in China, there is a cultural belief: 'there must be a teacher from whom one can learn when one works together with other persons', which conveys a collective belief that learning is a process that involves acting, speaking, listening, observing and thinking in a group where some may be more knowledgeable than yourself. Combined with the cultural values of seniority and authority (Huang et al., 2017), the facilitator is thus from the outset positioned as a competent actor to be listened to. Although, the participating teachers differed in terms of experience – the Chinese teacher was a junior – this did not seem to influence our results significantly.

One important contribution of this initial comparative study is that although LS is new in Denmark and requires a new actor role, this novelty alone is insufficient to explain the differences in 'how' and 'what' the facilitators talk with teachers. The study indicates that cultural, social, and power related issues at both the interactional and a broader level influence the role of the facilitator. We shall examine such issues and suitable analytical frameworks further in our future comparative work.

A resource approach to mathematics teacher education

Amalie Sødal

University of Agder, Norway; amalie.sodal@uia.no

The relation between pre-service teacher education and the day-to-day practice of mathematics teachers in schools is a recurring topic in research on teacher education. Furthermore, the Norwegian teacher education programme has been criticised for polarity between theory and praxis. The following pilot study investigates what aspects of working with resources in university coursework pre-service mathematics teachers perceive as valuable preparation for teaching mathematics. I found that university coursework can alleviate the gap between theory and praxis through resources for teaching mathematics. Working with resources can provide learning opportunities that pre-service mathematics teachers experience as practical and useful.

Keywords: Documentational approach to didactics, resources, mathematics teacher education, preparedness, theory-praxis gap.

Introduction

Novice teachers leaving the profession is a challenge in many countries. In Norway, nearly 30% leave their teaching position within the first four years (Boyesen, 2021). The relation between pre-service teacher education and the day-to-day praxis of mathematics teachers in schools is a recurring topic in research on teacher education, and there is a call for better alignment of the knowledge development that takes place within universities and schools (Winsløw et al., 2009). Norwegian teacher education has been criticised for polarity between theory and practice, and developing a teacher education programme which better prepares pre-service teachers for their professional lives is pivotal (Mosvold et al., 2018).

In Norway, pedagogical content knowledge and, in this case, mathematical knowledge for teaching has been prominent in teacher education. However, the past decade witnessed a shift of focus from mathematical knowledge for teaching to core practices in the work of teaching mathematics (e.g., leading group discussions), both in the Norwegian teacher education programmes and in the international research literature on teacher education (Mosvold et al., 2018). Nevertheless, several researchers have expressed concern about this shift in ignoring content knowledge while highlighting the teachers' practice (Hovtun et al., 2021). I suggest that both approaches hold promise with respect to educating mathematics teachers who are well prepared for their profession.

Paving the way for a more extensive Ph. D study, the research question for this pilot study is: What aspects of working with resources in university coursework do pre-service mathematics teachers (PSMTs) accentuate as beneficial in preparing them for teaching mathematics in elementary school? In line with the shift towards core practices, the participants in this study showed an inclination towards teaching and experiences derived from praxis and school placement. However, as will be elaborated upon in due course, they also expressed appreciation of university courses that facilitate connections between knowledge acquired in university and in school placement.

The overarching goal of my inquiry is to contribute to mitigating the transition from pre-service teacher to novice teacher, aspiring to retain novice teachers in teaching positions. I contend that working with resources "hands-on" in mathematics teacher education can be beneficial in addressing the gap between theory and praxis, albeit not confined to core practices but rather as an activity that might amalgamate core practices and mathematical knowledge for teaching.

Theory

I propose taking a resource perspective on the issue of connecting theory and praxis. Hence, I chose to use the documentational approach to didactics (DAD) as my framework. Moreover, for the pilot, I rely on the concept of schemes as retained in the instrumental approach by Vergnaud (1998), which draws on activity theory and sociocultural theory of teaching and learning (Gueudet, 2017; Gueudet & Trouche, 2009). Further, I consider the process of instrumentation (how an artifact influences the subjects' activity) and instrumentalization (how the subject shapes the artifact) as operationalising the PSMTs' interplay with resources.

Pepin (2018) argue that research on curriculum materials (in mathematics education) to date has largely focused on how these support student learning with less attention to teacher learning. She further claims that simply exploring how teachers interact with curriculum resources “as is” is not sufficient (e.g., investigating schemes of use), but that extending the research area by also addressing ways of how teachers can usefully work with these “tools” is equally important (ibid., p. 366). For this purpose, Pepin distinguishes between curriculum materials and educative curriculum materials. The latter are materials designed to support teacher learning as well as student learning. Retaining this perspective on teacher learning, I contend that this is also pivotal to pre-service mathematics teachers learning and teacher education. However, as described by Pepin (ibid.), this perspective focuses largely on materials designed for teachers (e.g., by researchers/ teacher educators) to further help teachers design learning sequences. In comparison, the tentative position derived in this pilot study is that (student) teachers learn from choosing, transforming resources, implementing them, revising them, etc. This is in line with the perspective proposed by Gueudet and Trouche (2012) in terms of taking a broad view on resources as anything likely to re-source the teachers’ practice. Hence, I argue that involving PSMTs in all aspects of working with and developing resources, not limited to curriculum resources, is pertinent. Therefore, I consider the DAD framework apposite for this study as it regards teachers’ work with resources as pivotal in their professional activity and professional growth (ibid.).

Thus, following the DAD, the aspects accentuated by the PSMTs in preparing them for teaching mathematics are operationalised through the concept of schemes, and studying the first three elements of a scheme. According to Gueudet (2017, p. 200), a scheme has four parts:

- An aim (can correspond with the goal in activity theory);
- Rules of action: regular ways of acting for the same aim;
- Operational invariants of two kinds: theorems-in-actions (propositions considered as true by the subject) and concepts-in-action (concepts considered as relevant for the subject);
- Possibilities of inferences: the subject can adapt his/her activity to the special features of a given situation corresponding to the same aim.

Delineated by Vergnaud (1998), a scheme developed by a subject is associated with a class (“set”) of situations which in turn correspond to the same aim of the activity. In this case, the aim I have chosen to consider (inferred from the data material) is *knowing how to teach mathematics* corresponding to the situation of being part of a teacher education programme attending classes on mathematics education. Hence, the activity considered in this case is at a rather general level and associated with a “big scheme” (Gueudet, 2017). One might be critical of this level of generality. However, as I have chosen to focus on consistent schemes in all the participants' responses, I suggest that a “big scheme” is applicable for rendering the different aspects in this context.

As the participants in this pilot study have not been followed and observed over time, rules of action represent what the PSMTs perceive to be regular ways of receiving lectures and teaching in their education programme. This is operationalised through their answers in this inquiry, consisting of a questionnaire and written reflections. Moreover, rules of action also represent omissions in relation to the same education programme as evidence of what the PSMTs would have preferred their education to contain. The operational invariants are inferred from these rules of action as the reasons/beliefs behind said omissions and experiences. As long-term follow-up was not done, the last element of schemes, possibilities of inferences, is beyond the scope of this interim study.

Finally, the process of instrumentation/instrumentalization details the PSMTs' interaction with resources. Resources in this case, denotes an activity that, in their own view, prepares the PSMTs for teaching mathematics supporting their learning process for the aim presented above.

Methodology

Since 2017, the Norwegian teacher education has been a five-year education programme (previously four years), and the graduates receive a master’s degree. In their fourth year, the student teachers choose their specialisation. The participants in this pilot are in their fourth year. They specialise in mathematics education, which also entails having at least 60 ECTS credits in mathematics from previous courses, which are didactical courses focusing on the learning and teaching of mathematics in primary schools. The data collection for the pilot was based on the participants’ efforts in coursework in the fourth year of their educational trajectory.

As I try to solicit the opinions and experiences of the participants, the pilot study is conducted from an interpretivist position (Scheiner, 2019). Through a qualitative case study involving seven student mathematics teachers, I investigated what aspects of working with resources this group of PSMTs accentuate as beneficial in preparing them for teaching mathematics in school. The participants attended a course on problem-based mathematics education at a university in Norway. In this course, the PSMTs are introduced to a variety of resources on the subject of problem-solving and exploration as work methods in mathematics. At the end of the semester, the PSMTs were required to write down some overall reflections relating to their experience in this course, at which point they had only had one week of school placement. Seven responses were produced and gathered from the participants. Further, the participants took part in a qualitative questionnaire with open-ended questions at the end of the academic year. The questions focus on resources and the feeling of preparedness for teaching mathematics in elementary school. When completing the questionnaire, the PSMTs had been in school placement for five weeks, giving them opportunities to test and use their resources.

The overarching aim of the pilot was to gain an account of what the PSMTs regard as important in their mathematics teacher education. Simultaneously, I also ventured to discern what encourages or stymies their vocation for teaching mathematics. The concept of schemes as described within the DAD is pertinent for both objectives. Moreover, the data have been analysed using a qualitative content analysis approach where the theoretical categories (Kuckartz, 2019) are derived from the concept of schemes, namely aims, rules of action, and operational invariants, and further, the resources associated with the aim. The data analysed are the participants' answers to the given questionnaire and their written reflections from the coursework. The questionnaire was in Norwegian while they wrote the "overall reflections" in English.

As the data material in this pilot is limited, a discussion on trustworthiness is apposite. It is important to observe that this paper should be viewed in the context of a report on a pilot study. With respect to transferability, the sampling has indeed been purposeful as these participants are the predecessors in line of study to the participants selected for the main study. Hence, despite the lack of "thick" descriptions, I argue that the collected data give a reasonable foundation for interim inferences. Further, some degree of triangulation is applied by juxtaposing the overall reflections and the questionnaire.

Results

Because the scope of this pilot is not to study the resources used in a specific teaching unit nor the PSMTs documentation work per se, I do not present the data using specific tools from the DAD, such as a document's table. Rather, in the following, I present excerpts from both the PSMTs' reflection notes and their answers in the questionnaire, emphasising shared features or attributes in the PSMTs' schemes that might inform the overall goal of better alignment of the knowledge development happening within schools and universities. For the situation of studying to be a mathematics teacher, the aim at the crux of all the PSMTs responses was knowing how to teach mathematics. In this paper, I have chosen to focus on this aim as it is salient both for theoretical and practical knowledge development.

Aim: Knowing how to teach mathematics

In the questionnaire, the PSMTs were asked what they had found useful in their teacher education so far and what made them (better) prepared to teach mathematics:

PSMT 1: Lectures in didactics of mathematics, so how to teach mathematics.

PSMT 2: Another thing that I think has been very useful is learning about different strategies for teaching which we can use to plan good lessons for teaching mathematics.

PSMT 4: More school placement and to learn more about ways to teach [mathematics][1].

These excerpts serve as examples of an attribute present in all the participants' responses, without exception, namely the expressed desire to know more about how to teach mathematics to children in elementary school. Typically, they emphasised learning about methods for teaching mathematics as particularly useful so far in their teacher education and simultaneously as something they wanted to

[1] Words enclosed by brackets are added for the sake of context when not evident from the excerpts themselves.

learn more about to be more prepared for teaching. Several of the PSMTs put this in contrast to what they discern has been the norm in their teacher education:

PSMT 3: They often focus more on teaching us mathematics and not on how to teach mathematics.

PSMT 7: The introductory course was mainly doing mathematics. A lot of the curriculum was repetition from upper secondary school.

As demonstrated in the quotes above, some of the participants criticised previous mathematics courses in their teacher education programme, claiming that they focused too much on learning mathematics (which they, e.g., PSMT 7, described as a repetition from upper secondary school) and not on teaching mathematics. Triangulating these results with the PSMTs' "overall reflections", the PSMTs have a want for understanding how the knowledge acquired in their teacher education programme can have practical applications:

PSMT 3: This is the first course [problem-based mathematics education] that has allowed us to use what we already know and have learned before to make something that is going to be useful for us as teachers in the classroom.

The PSMTs express a lack of relevance and a call for practicable knowledge in their teacher education. Investigating this further, I now turn my attention to the rules of action and operational invariants interconnected with the aim described in this section and proposed resources thereof.

Rules of action and operational invariants

A possible operational invariant inferred from what has been explored thus far can be that the PSMTs consider themselves proficient in mathematics and that teacher education should focus on learning how to teach mathematics in elementary school practically. The rule of action in the PSMTs experience has, to a large extent, been learning mathematics. However, drawing on the operational invariant expressed above, what they would have liked to be the rule in their education is rather learning practical ways to teach mathematics. Examples they list, among others, are teaching methods, how to introduce new mathematical topics to young students, learning about how to differentiate their teaching to include all the students in a class, and learning about students with learning difficulties in mathematics.

In the question of what could help them to be better prepared for teaching mathematics, five out of seven participants answered more school placement:

PSMT 5: We could use more school placement, and to work with connecting what we are taught [in university] to practical situations and how to use it.

When comparing with the "overall reflections", all the participants have contemplated the connection between what they learn in university and in praxis. Drawing on these responses, another operational invariant is deduced. The connection between what is taught at university and the field of praxis is, in many cases, not apparent to the PSMTs. Hence, learning in and from praxis is seen as more relevant and useful. Albeit this is by no means a new discovery (Hammerness, 2013; Solomon et al., 2017), it is still salient in context of this study as an overarching goal is to find a viable way to attend to the gap between theory and praxis. The PSMTs then perceive theoretical learning as the rule of action while they prefer learning in and from school placement. However, when they receive help in connecting the two, they are more positive as elaborated upon in the following section.

Resources: What helps the PSMTs in learning how to teach mathematics

With respect to preparing them for teaching mathematics, the PSMTs endorse activities that help them connect theoretical and practical considerations – here represented by two of the participants reflections:

PSMT 6: Some of the [problem-solving] task [sic] has been hard to find the "right" learning goal [from national curriculum], and then we had some discussions around different goals. This has been so learning full [instructive] for me[2].

PSMT 7: It has been exciting to read about what authors think students think and feel about problem-solving, and afterwards go out and actually see that a lot is true. I use a lot of what I read, and have used it both when planning a lesson plan, but also during planning in practice [school placement] and as a substitute teacher.

All the participants accentuated how working practically with tasks in coursework at the university helped them connect research on mathematics education to practical situations. Further, as PSMT 6 exemplifies, connecting this activity to the national curriculum was experienced as positive and instructive. Through a process of instrumentation, problem-solving help the PSMTs reflect on practical and theoretical considerations for teaching. Moreover, as PSMT 7 shows, it leads them to enact what they have learned in coursework in their own teaching and thus, appropriating the knowledge from their coursework (instrumentalization). This holds implications for mathematics teacher educators as it exemplifies what activity PSMTs might experience as meaningful and relevant in their further work as pre-service teachers.

Moreover, the PSMTs appraise problem-solving tasks as an asset both for their understanding of students (experience how the students might think/feel) and as a method for teaching which supports them in several ways:

PSMT 1: Having the opportunity to work practically with tasks we can bring to the students ourselves has given me a greater experience of what it is like to work with such tasks with the students.

PSMT 7: Now I am so lucky that I have many problem-solving tasks in my folder, as well as which learning goal they are under. This helps me a lot later. I have already planned to have a folder with problem-solving tasks that are sorted by year level. This way they are easy to retrieve when needed.

Thus, in working with resources for problem-solving, some of the PSMTs' requests for their education appear to be met (instrumentation) e.g., learning methods for teaching (problem-based teaching) and ways to differentiate their teaching through using mathematically rich tasks. Moreover, as PSMT 7 shows, it can also affect their overall practice as mathematics teachers.

Discussion and conclusion

The RQ of this study was the following: *What aspects of working with resources in university coursework do pre-service mathematics teachers accentuate as beneficial in preparing them for teaching mathematics in elementary school?* I venture that explicitly working with resources for teaching mathematics might be one feasible way to align better what pre-service mathematics teachers learn in university coursework with what PSMTs themselves accentuate as beneficial in

[2] I have not corrected their English writing to prevent conveying misconstrued reproductions.

preparing them to teach mathematics in elementary school (as expressed by PSMT 7 above). The PSMTs in this study express discontent with the current allocation of theoretical and practical learning in their mathematics teacher education, claiming that praxis and school placement provides more relevant and applicable knowledge. The PSMTs express that when entering mathematics teacher education, they expect coursework and teaching to give instruction on how to teach mathematics to students in elementary school. In contrast, their experience is that more attention is given to teaching them (the PSMTs) mathematics rather than how to teach the subject themselves (e.g., PSMT 3). However, when they work with resources for problem-solving in university coursework, they perceive this activity as practical, instructive, and relevant to their future professional work as mathematics teachers. Following this, I claim that working with resources in university coursework can be auxiliary in amending the strategy of mathematics teacher education.

Further, two important aspects of working with resources is evident from the participants' responses. First, it is the mathematical content of the problem-solving tasks themselves and the opportunities these provide in the teaching of mathematics as expressed by both PSMT 6 and 7. They appreciate both solving the tasks themselves in preparing them for what meets the students, but also how these tasks facilitate learning with respect to the national curriculum. Hence, they regard content knowledge as relevant in preparing them for teaching mathematics. Second, they accentuate the methods for teaching that problem-solving tasks provide, such as problem-based teaching, differentiation, and the more general activity of gathering problem-solving tasks they can use later in their own teaching. As PSMT 3 exemplifies, such activity is "useful for us as teachers in the classroom". This suggests that working with resources may also promote core practices in university coursework.

A recent study in Norway shows that student teachers often see theory and praxis as separate entities and that theory does not have a place in discussing their experience when in school placement (Brekke & Leikvoll Eide, 2021). The results presented in this paper are in line with these findings and show that PSMTs need help establishing meaningful connections between knowledge acquired in university and in school placement. Evidently, these results are the expressed experiences of a small group of PSMTs. However, from what has been conveyed in this pilot I consider it reasonable to suggest that there is an imbalance between teaching related to praxis and strictly teaching on mathematical content in their educational trajectory. Moreover, Hammerness (2013, p. 411) found that when asked about learning opportunities grounded in practice, teacher educators, in line with their student teachers, saw the school sites as the places that provided those opportunities suggesting a discrepancy in the structure of the teacher education and how student teachers prefer to be educated. As seen from the results of this pilot study, the PSMTs accentuate working practically with resources for teaching mathematics in university coursework as meaningful and relevant to them, hence, supporting their vocation for teaching. Thus, resources for teaching mathematics can provide learning opportunities grounded in practice while at university, showing that coursework can also contribute to alleviating the gap between theory and praxis. How such work can facilitate professional growth (as described by Gueudet and Trouche (2012)) for PSMTs in mathematics teacher education requires further study, and is the scope of my ongoing PhD study.

Comparing and contrasting solutions to foster diagnostic competence

Jan Philipp Volkmer, Andreas Eichler and Elisabeth Rathgeb-Schnierer

University of Kassel, Institute of mathematics, Germany; jan.volkmer@mathematik.uni-kassel.de, eichler@mathematik.uni-kassel.de, rathgeb-schnierer@mathematik.uni-kassel.de

A main focus in the field of research on competences of teachers is on diagnostic competence. Although it is stated that prospective teachers' diagnostic competences are trainable, they are still described as too low. Therefore, the present study aims to foster diagnostic competence of prospective primary teachers. In the study diagnostic competence is conceptualised with so-called epistemic activities. The treatment bases on empirically known factors about fostering diagnostic competence and follows the teaching and learning method of comparing and contrasting. The success of the method is proven for various fields but has not yet been researched in the field of professional development of prospective teachers. The article introduces the theoretical framework, the method and results of the data analysis.

Keywords: Diagnostic competence, developing diagnostic competence, measuring diagnostic competence, comparing and contrasting, inquiry-based learning.

Introduction

Within the field of teachers' competences an important focus lies on diagnostic competence that we understand as a teacher's ability to identify weaknesses and strengths in students' mathematical work. It is considered as an essential part of teachers' professional knowledge which impacts the quality of teaching and students' learning (Baumert & Kunter, 2006). Research showed that teachers' competences are trainable (Herppich et al., 2018) but it is also stated that teachers' diagnostic competences are too low (van Ophuysen & Behrmann, 2015). Therefore, the systematic development of teachers' diagnostic competence has become a relevant issue of educational research (Chernikova et al., 2020; Larrain, 2019; Hoth, 2017).

For this reason, the aim of this PhD-project is to design interventions that improve prospective primary teachers' diagnostic competence and to analyse the effect of these interventions. The PhD-project is called "KoVe-Dif" (Comparing and contrasting solutions to inquiry-based leaning tasks as a basis for improving diagnostic competences of prospective teachers). The design of our interventions is particularly emphasising different processes of comparing and contrasting products of students' mathematical work (Alfieri et al., 2013). Comparing and contrasting is also an integral part of the diagnostic process of teachers (Philipp, 2018). The teachers' ability of identifying students' competences based on students' written mathematical work is the main focus referring to teachers' diagnostic competence. The project addresses the following main question:

(RQ): What is the effect of different interventions based on the teaching and learning method of contrasting and comparing on diagnostic competence?

Diagnostic competence

Competences are defined as "[…] context-specific cognitive dispositions that are acquired and needed to successfully cope with certain situations or tasks in specific domains" (Koeppen et al., 2008).

Context specificity can be interpreted in different ways. On the one hand, it can refer to different school classes and, on the other hand, to different subject areas. In the project described below we are focussing on a specific set of tasks from the arithmetic which will be described in the description of the treatment. We assume that the diagnostic skills developed in the context of the specific topic are transferable to different school classes.

In the past, diagnostic competence was conceptualised in three different ways (see also Philipp, 2018). First, there is research about cognitive dispositions such as knowledge or motivation. Focusing on the cognitive disposition such as knowledge, diagnostic competence is part of professional knowledge of teachers. For example, Brunner et al. (2011) conceptualised diagnostic competence as a part of pedagogical content knowledge and of pedagogical psychological knowledge. Second, diagnostic competence is equated with the so-called judgement accuracy (Südkamp et al., 2012). This research line focused on the performance of teachers regarding the comparison between a teacher's estimation of students' performance and the actual test scores of their students. This approach got criticized for being distant to a teacher's daily work (Praetorius et al., 2012). As an answer to this critique, the diagnostic competence started to get framed as a process. According to this conceptualization, research focuses on the diagnostic process itself (e.g. Klug, 2013) and on the cognitive process during the teacher's diagnosis (e.g. Philipp, 2018).

In the framework of Loibl and Leuders (2020) diagnostic competence is understood as a process of diagnostic thinking influenced by situation characteristics and person characteristics. While a situation is defined through framing and cues, the person characteristics include cognitive dispositions. The external diagnostic behaviour is either observable by process indicators (such as "think aloud") or by product indicators (such as a "decision"). Diagnostic thinking is the core of the framework, and Leuders et al. (2018) state that it is possible to conceptualise this thinking process similar to the "clinical reasoning". In our study we use this approach and follow Chernikova et al. (2020) as well as Fischer et al. (2014) who conceptualise processes of diagnostic thinking based on clinical reasoning by epistemic activities. These activities are characterised by "(a) identifying a problem, (b) questioning, (c) generating hypotheses, (d) constructing artefacts, (e) generalizing evidence, (f) evaluating evidence, (g) drawing conclusions, and (h) communicating process and results" (Chernikova et al. 2020, p. 161; see also Fischer et al. 2014). These epistemic activities are an adequate basis for modelling the process of a teacher's diagnosis of students' written solutions. For example, a teacher may identify a problem in a students' solution by perceiving an error. The teacher he/she asks for the reason of the error and develops a hypothesis. If possible, the teacher sustains his/her hypothesis by other errors and generalise the hypothesis by evaluating evidence. In this PhD-project, we analyse the diagnostic processes conceptualised with the epistemic activities of prospective teachers while looking at school students' solutions to tasks. In our research, we refer to students' solutions of inquiry-based tasks that are comprehensive and offer many possibilities for teachers to use their diagnostic competence to draw conclusions about the students' solutions.

Fostering diagnostic competence

Recently, Chernikova et al. (2020) published a meta-study investigating different approaches to foster diagnostic competence. The meta-study contains studies that investigate teacher or medical education. In these studies, a special context, a specific problem or the method of scaffolding was used to foster diagnostic competence. While all aspects showed positive effects, orientation towards specific problems (problem orientation) stands out most positive. So-called inquiry-based tasks are specific problems and, particularly, diagnosing cases of extensive students' solutions of these inquiry-based task comprise the orientation towards specific problems of diagnosing. Therefore, the present study is based on recommendations on how to design a course aiming to foster diagnostic competences concerning problem orientation.

The epistemic activities that are the basis of diagnostic thinking rely more or less on contrasting and comparing. Chernikova et al. (2020) state: „More generally, diagnosing first focuses on comparing the current state of learners' knowledge and skills to predefined learning objectives“. Referring to Nickerson (1999), Philipp (2018) describes the ongoing comparison of a solution with relevant prior knowledge or further information as a central part of the diagnostic process. Beyond the specific subject of developing diagnostic competence, Alfieri et al. (2013) pointed out contrasting and comparing to be an effective teaching and learning strategy. However, it has not been investigated regarding the professional development of prospective teachers yet. With our research we target to fill the gap by addressing contrasting and comparing to foster teachers' diagnostic competence.

Method

The design of our study is shown in Table 1. Both, the three treatments and the control group were conducted in winter 2020 and in summer 2021. All three treatments (see Table 1) follow well-known characteristics to effectively support the development of teachers' diagnostic competence (Chernikova et al., 2020).

Table 1: Treatment-Design

Treatment 1 (n = 37)	Treatment 2 (n = 40)	Treatment 3 (n = 35)	Control group (n = 25)
Pre-test	Pre-test	Pre-test	Pre-test
Students solve inquiry-based tasks	Analysing primary school students' solutions to inquiry-based tasks	Students solve inquiry-based and analyse primary students' solutions to these tasks	Neither analysis of students' solutions nor analysing of arithmetic tasks
Post-test	Post-test	Post-test	Post-test

The main element of the three treatments were inquiry-based tasks. In each treatment group we provided the same inquiry-based tasks; one example is shown in Table 2. Those tasks are challenging for prospective teachers and primary school students. As our example in Table 2 shows also primary school students are able to provide substantial solutions. In addition, all solutions to be analysed are genuine, to make them as authentic as possible.

Table 2: Example

Task-Example	Solution example of a student
How can you get to the number 20? Choose two numbers for the first and second position in the row. Add these two numbers up to get the third number. Finally, add the second and third number to get the number at the fourth position. Your goal is to reach the number 20 with this step (position 4). For example, you choose 3 and 4 the result will be: 3, 4, 7, 11. This means you cannot get to 20 if you start with the numbers 3 and 4. Task is to find all possibilities to get to 20. (Birnstengel-Höft and Feldhaus 2006)	
In the first treatment group, prospective teachers got a brief introduction into inquiry-based tasks. Subsequently, they were encouraged to solve these tasks and to compare their solutions in pairs (first and second week). In the third week, the prospective teachers got the prompt to compare their approaches and solutions with the whole group. The prospective teachers repeated this proceeding for three inquiry-based tasks. Referring to Chernikova et al. (2020) the first treatment group followed the perspective of learners that solve mathematical tasks and got related prompts.

The second treatment group did not get the prompt to solve the inquiry-based tasks. Instead, there was a brief introduction in the process of diagnosing students' solution based on epistemic activities. Subsequently, the prospective teachers got the prompt to individually analyse the solution of school students and to afterwards compare their analysis of students' solutions in pairs (first and second week). In the third week, the analyses of all pairs were compared in the whole group. In this treatment group the same inquiry-based tasks were used as in treatment group 1. Similar to group 1 the procedure was repeated three times. Referring to Chernikova et al. (2020) the second treatment group followed the perspective of teachers that analyse primary school students' solutions to mathematical tasks and got related prompts (problem orientation).

The third group firstly got a brief introduction to inquiry-based tasks as well as in diagnosing students' solutions according to epistemic activities. Further, this group solved one inquiry-based task and compared their own solutions in the same way as treatment group 1 (weeks 2 and 3). Afterwards the group analysed the students' solutions and compared their analyses in the same way as treatment group 2 (weeks 4 and 5). Finally, the prospective teachers in the third treatment group solved a second inquiry-based task, analysed related students' solutions and compared their own solutions with the solutions of primary students (week 6 and 7).

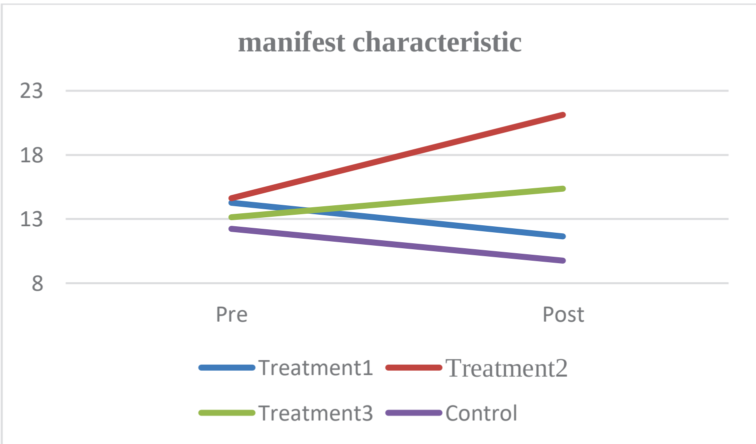
We conducted the pre-test before the semester started and the post-test after eight weeks. We developed these tests to measure diagnostic competence. Each test comprises three items with solutions of primary school students. The three items refer to three different inquiry-based tasks (in Table 2 an example of the pre-test is displayed). To prevent learning effects, we changed two items by slightly modifying the external form of primary school students' solutions, and we exchanged one item completely. Primary school students' solutions of the inquiry-based tasks provided in the pre- and post-test are analysed by the prospective teachers who participated in the treatment and control groups. The prospective teachers' analyses are the basis to investigate their diagnostic competence. Therefore, these analyses are categorized with content analysis regarding two dimensions. In the first dimension we distinguish between statements about manifest characteristics and hypotheses. Manifest characteristics are for example a student's wrong solution, a specific way of a student to write something down, or a specific way of a student to develop different examples regarding a problem. Statements that we classify as hypotheses are for example, prospective teachers' interpretations of (school) students' abilities shown in their solutions that were sometimes backed by manifest characteristics. With this dimension we want to measure the diagnostic thinking conceptualised by the epistemic activities described earlier. In the second dimension we assigned single statements to spheres of competence inspired by Rathgeb-Schnierer and Schütte (2011). The coded data was further analysed by descriptive and inferential statistics.

Results

In the following, the data is analysed regarding the two epistemic activities "identify manifest characteristics" and "generate hypotheses" while comparing the three treatment groups and the control group.

Table 3: identify manifest characteristics

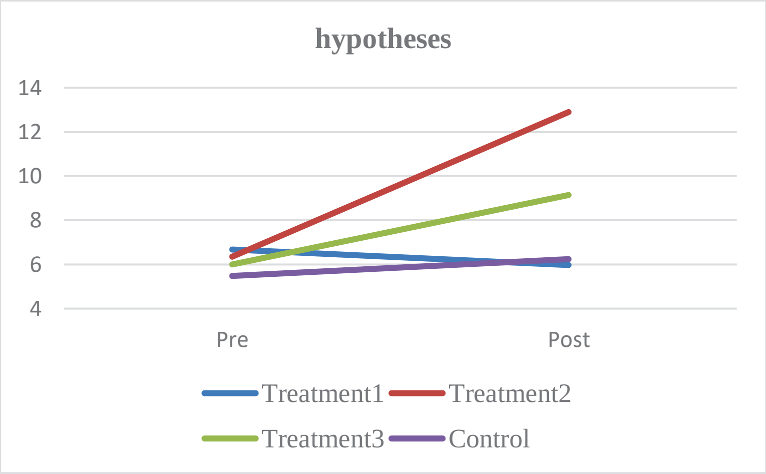
Treatment	N	Pre-M	Post-M
1	37	14,27	11,65
2	40	14,62	21,12
3	35	13,14	15,37
C	25	12,24	9,76



Regarding the identification of manifest characteristics (Table 3) in primary school students' solutions our results exhibit that all groups start at nearly the same level but differ at the post-test. Mixed-anova shows a significant interaction effect between time and group ($F(3,133) = 11,253$; $p < 0,00001$, $\eta^2 = 0,202$). Pairwise t-tests reveal that the difference between the groups is not significant in the pre-test ($p = 1$ with Bonferroni correction), but in the post-test significant differences were revealed. For example, treatment group 2 and treatment group 1 differ significantly (pairwise t-test $p < 0,0000001$ with Bonferroni correction). Only the pairwise t-tests between group 1 and the control group ($p = 1$ with Bonferroni correction) and between group 1 and group 3 ($p = 0,0548$ with Bonferroni correction) reveal no significant differences.

Table 4: generate hypotheses

Treatment	N	Pre-M	Post-M
1	37	6,68	5,97
2	40	6,35	12,9
3	35	6	9,14
C	25	5,48	6,24



Similar results are shown concerning the generation of hypotheses (Table 4). Mixed-anova shows a significant interaction effect between time and group ($F(3,133) = 12,209$; $p < 0,000001$, $\eta^2 = 0,216$). Again, all groups start on a close level in the pre-test (pairwise t-test $p = 1$ with Bonferroni correction) but differ in the post-test. For example, the difference between group 2 and group 1 is significant ($p < 0,0000001$ with Bonferroni correction). Again, the difference between treatment group 1 and the control group is not significant ($p = 1$ with Bonferroni correction).

In the presented study, diagnostic competence is conceptualised and measured with epistemic activities (Fischer et al., 2014). Presented results indicate that the analysis and the contrasting and comparing of primary school student solutions (treatment 2) have a significant impact on the development of diagnostic competence. In contrast, creating and then contrasting and comparing the own solutions with peers (treatment 1) does not seem to have influence on the diagnostic competence. Finally, creating and then contrasting and comparing the own solution with peers followed by analysing primary school students' solutions (treatment 3) also leads to an increase regarding the epistemic activities. Although this increase is not as high as focussing only on the analysis of primary school students' solutions (treatment 1). The results presented allow the interpretation that this applies independently of the specific epistemic activity. Accordingly, contrasting and comparing student solutions seems to be another aspect of effectively promoting the diagnostic competence of prospective teachers (Chernikova et al., 2020). We are left with the open question: Why is solving tasks and contrast and compare the solutions to peers not increasing or even decreasing the amount of epistemic activities? At this stage, only hypotheses are possible. It could be due to motivational reasons. Or the fact that it is about peers with whom is compared, hinders the development. In the future, we want to use different research approaches to gain deeper insight into how our treatments change diagnostic competence.

Keywords: Number sense, use of information, diagnostic competence, restricted focus viewer.

Introduction

A central goal of mathematics education in primary school is to develop flexible calculating and solid arithmetic competencies. These competencies require a comprehensive understanding of numbers and operations (number sense), which should be established during the early school years (Rathgeb-Schnierer & Rechtsteiner, 2018). In this context, teachers face every day the challenging task of comprehending their students' ways of thinking in order to provide them with appropriate learning opportunities. An essential condition for succeeding in this task is the teachers' diagnostic competence: When mathematics teachers want to find out what number sense a child has, they use information about the student's behaviour when solving arithmetic tasks to draw conclusions about his or her thinking and knowledge in this area. The quality of corresponding diagnostic judgements appears to depend on whether information valid for the diagnosis can be identified and used for this purpose. There is evidence that novices have limited ability to select valid information when diagnosing complex situations and also use invalid information, often resulting in lower quality of their judgements (Kellman & Massey, 2013). However, it is still unclear how and what information is used by pre-service teachers when diagnosing first graders' number sense, and whether the quality of their diagnostic judgments can be attributed to their use of information.

Theoretical background

In order to investigate how teachers form diagnostic judgments, a line of research has developed that focuses on the cognitive processes of information use that underlie diagnostic teacher judgments. Studies of this type examine cognitive processes, which are situational skills that mediate between a teacher's dispositions and actions (Loibl et al., 2020): Teachers, in order to accomplish a professional, complex task such as diagnosing learning processes, must (1) perceive information, (2) interpret it and (3) make decisions. Additionally, the influence of information use on judgment quality is illustrated in Brunswik's lens model (Brunswik, 1956): The better a person is able to select and use information with high validity, the higher the judgment quality will be. Although findings suggest that pre-service teachers are less likely to focus on children's learning and thinking processes when assessing their mathematical concepts, there is still little evidence on how pre-service teachers use information of different validity when diagnosing first graders' number sense and whether judgment quality depends on the information use. Accordingly, our research questions are: (1) How do pre-service teachers use information of different validity when diagnosing first graders' number sense?

(2) Does the quality of the pre-service teachers' diagnostic judgment increase when valid information is made explicit?

Methodology

The presented study uses an experimental design to investigate pre-service teachers' information use when diagnosing first graders' number sense. For this purpose, nine authentic text-image vignettes were designed based on literature, each showing a typical classroom situation with a first grader's learning of number sense. Each of the vignettes comprise of a task, a student's solution, notes on the observed solution process and a short teacher-student dialogue. After the validation with experts, four vignettes were provided in three varying information environments which contain: a) additional valid and invalid information about student behaviour, b) additional valid and invalid information about student behaviour, where validity is made explicit and c) only additional valid information about student behaviour. A valid information in the context of number sense is for example the use of manipulatives, an invalid information is for example the social behaviour of the student while solving an arithmetic task. The sample consists of N=173 pre-service teachers at the end of a one-semester course covering key topics on the development of number sense. The participants were randomly allocated to the three experimental conditions. Using the Restricted Focus Viewer (RFV) (Jansen et al. 2003), frequency, order, and duration in which the pre-service teachers accessed the different units of information were collected during the experiment. The analysis and comparison of the data between the experimental groups will provide information about the use of the presented information. Additionally, the participants will be asked to write down their diagnostic judgement in order to choose a suitable follow-up task. The analysis and comparison of the answers with the expert norm will show the quality of the diagnostic judgment. The poster presents the theoretical framework and methodology of the study, highlighting in particular the design of the text-image-vignettes and the use of the RFV for investigating the pre-service teachers' use of information.

This introduction for TWG19 offers a brief history of the group and describes past challenges the group has experienced when discussing papers — seeing papers as related and as contributing to a common effort. These challenges led us as TWG19 team leaders to develop three initiatives to support communication among researchers who work in different contexts with different purposes. The initiatives are presented and used to discuss the papers. We conclude with implications for the future.

Introduction

Thematic Working Group 19 (TWG19) is concerned with the study of mathematics teaching and teacher practice(s). From its inception, it has struggled to clarify its focus. TWG19 was created after CERME8 from a division of a TWG titled *From a Study of Teaching Practices to Issues in Teacher Education*. Having grown too large, this group split into three: one targeting teacher education and professional development (TWG18); another targeting teacher knowledge, beliefs, and identity (TWG20); and a third with an uncertain target (TWG19). Participants at CERMEs 9, 10, and 11 spoke of challenges in thinking and talking across papers. Studies had different purposes, were conducted in different contexts, and used different conceptualizations, theories, and methods. How should the group understand the "theme" and how should it make sense of submitted papers? The title was changed from *Mathematics Teacher and Classroom Practices* to *Mathematics Teaching and Teacher Practice(s)* after CERME10 to clarify interest in studying *teaching* rather than *teachers* and *teacher practices* rather than broader *classroom practices*. Still, the distinction between *teaching* and *teacher practice(s)* remains unclear and communicating across papers continues to be challenging.

Perhaps challenges should not be surprising. Despite its long history, research on mathematics teaching remains relatively underdeveloped. Well-developed learning theories abound, but teaching theories are scant. Important frameworks capture key aspects of teaching but fall short of comprehensive, elaborated theories. Two compelling reasons come to mind. First, teaching is extraordinarily complex. It is an involved human activity that navigates other complex human activities, such as learning, communication, child development, and social life in and beyond schools. Second, teaching has a familiarity that breeds a presumption that teaching is little more than common sense. As Lortie (1975) argues, the "apprenticeship of observation," carried out by everyone from the perspective of being a student for countless hours, renders teaching either invisible or distorted in ways that have to be unlearned. Nor are researchers immune. It is little wonder then that participants struggle to think and talk across the fragmented glimpses of teaching that papers provide.

To meet these challenges, as organizers of TWG19 who are both equal participants and responsible for leading, we have invited participants to experiment with three initiatives:

1. Think, write, and talk more explicitly about the meaning of "teaching"
2. Use five proposed analytic domains to stimulate communication and reflection
3. Contribute to and use shared datasets to provide common referents.

In addition, we have set goals in the spirit of ERME's commitment to communication, cooperation, and collaboration. First, we aim to give all participants opportunities to develop as scholars. We invest in thoughtful reviews and design sessions for participants to present their work, have colleagues react, and respond to others in turn. Second, we aim to support communication and collaboration among participants by having them explore the meaning of teaching across studies, use the domains to organise and reflect on studies, and study shared data. We offer these as ways to build bridges among diverse studies. Third, we aim to characterise TWG19's collective effort to study teaching and teacher practice(s), including reflecting on what we are learning and priorities for future work. This is no small feat, and our efforts are nascent at best, but this is an important goal.

Exploring the meaning of teaching

Papers studying teaching often take the concept for granted. The call for proposals for CERME12 asked that papers explicitly say what is meant by "teaching" in the paper. Nevertheless, only five papers did so (all involving an organiser as an author). Mosvold and Wæge offer a practice-based conception grounded in instructional interactions as collaboratively constructed between teacher and students around particular content, and situated in broader environments, where teaching is the work involved in managing these interactions. Grundén offers a linguistics-based conception grounded in sociolinguistics of power relations and power struggles, where teaching is a social, cultural, and political practice of situated and habitual actions and interactions. And Nowinska offers a discipline-based conception grounded in socio-mathematical norms and a developing theory of metacognitive-discursive activities that shape them, where teaching is expert participation in and scaffolding of the doing of mathematics. More implicit definitions differ as well. For example, Holmedal draws on discourse analysis to explore the idea of teaching as identity performance, and Arnesen and Dahl draw on commognition to explore the idea of teaching as expert participation in classroom discourse.

At CERME12, participants considered the meaning of teaching implicated each paper in group discussions and posted their in-the-moment thoughts on a *Padlet*[1] page for the paper. In additional sessions, participants discussed the meaning of teaching across papers and posted thoughts on another page. Discussions appeared meaningful and lively. Posts reflected thinking more deeply and together about what is meant by teaching. One participant reflected on teaching as a complex set of tasks and professional judgements made in real-time, and another wrote about the importance of finding a balance among six dimensions of a teaching-learning process: epistemic, cognitive, mediational, ecological, emotional, and interactional. Others highlighted teaching as creating opportunities to learn or as managing dilemmas. Some raised questions about how values and theories shape views of

[1] *Padlet* is an online digital canvas where users can post text, videos, and images.

teaching. One post asked for strengths and limitations of thinking about teaching as “what teachers do” versus “work to be done,” an idea discussed at CERME11 (Sakonidis et al., 2019). Another suggested that the two might be used alternately by looking for what teachers do in the classroom, analysing and discussing these observations, and then considering the specialised work to be done.

Some participants raised questions about the meaning of teaching in relation to teacher education and teacher development: What do we teach teachers when we teach teaching? Another asked where teachers learn what we as researchers expect them to do. These questions emphasised that how we as researchers and teacher educators think of teaching has consequences for what is possible for prospective and practicing teachers to learn. Participants also pondered whether a choice of how to conceptualise teaching might differ for mathematics teaching versus teaching other subjects; whether norms, values, beliefs, and emotions (as related to mathematics) influence what might be meant by teaching; and how intuition and habits might play a role.

Several insights emerged from attending to the meaning of teaching. First, meaning is not as obvious as often presumed. Furthermore, what is meant by teaching matters for understanding all aspects of a study (questions, methods, and claims). In addition, attending to the meaning of teaching made it easier to think across papers. No one argued for a single, shared meaning, but many saw a need for being clearer about what is meant and how this would help us make sense of research.

Domains of research on teaching

The second initiative is to experiment with using five domains as an analytic frame to locate and discuss studies being conducted. The domains are:

(i) Consideration of *mathematics* and the central endeavour of extending the subject to students.
(ii) Organizing and *enacting* the design, interactions, and discourse of teaching and learning.
(iii) Becoming acquainted with, relating to, and responding to *students* as people and learners.
(iv) Attending to broader social, cultural, and political *issues* that matter for teaching and learning, including imperatives of social justice.
(v) Addressing all domains of teaching in a *comprehensive* way, with that as an explicit aim.

The domains are based on the didactical/instructional triangle evident in studies of teaching across intellectual traditions (cf., Brousseau, 1970-1990/2002; Cohen et al., 2003; Jaworski, 1994; Steinbring, 2011; see Goodchild & Sriraman, 2012, for a discussion of this breadth). More recently, attention has been given to how the interactions of teaching and learning are situated in broad socio-political, historical, and cultural environments (cf., Ball, 2018; Jaworski & Potari, 2009). Any study of teaching necessarily involves all domains, but a study may foreground one while maintaining regard for others. Hoover et al. (2022) posit capacity for maintaining mutual regard for all aspects of teaching while focusing on a single aspect as key to professional growth of mathematics teacher educators but propose that this capacity is likely crucial to both doing and understanding teaching. The goal is to support thinking, not to prescribe studies. One can imagine a study investigating the interplay between two domains, with others in the background. Yet, we identify only these five, where a dual-regard paper could be addressed in either. The fifth domain, *comprehensive*, is meant for studies that deliberately attempt to attend to all aspects of teaching together.

The domains were first presented at the virtual meeting of TWG19 in February 2021 and, with some modifications, were used to organise papers and to stimulate discussion at CERME12. The intention is to use the domains to support elaboration and understanding of the contribution of each paper in relation to others. It is also hoped that the domains offer an analytic lens that might characterise our collective research and help make sense of research on teaching and teacher practice. All papers grouped together belonged, at least loosely, to the same domain. After individual papers were discussed, the papers and then the domain itself were discussed. Participants reflected on the types of research questions being asked and what other important questions might be asked for the domain.

At CERME12, papers were presented in the domains of *Mathematics*, *Enactment,* and *Issues,* with no papers submitted in the domains of *Students* or *Comprehensive*. The absence of papers in the *Students* domain was noted by participants but not much discussed.

Mathematics

Studies in this domain foreground mathematics and how it can be extended to students, but the meaning of mathematics and what it means to foreground it vary across studies. Hummes et al. and Lovemore et al. consider teacher engagement in collaborative processes, namely lesson study and a community of practice respectively, with a focus on irrational numbers in the Pythagorean theorem (Hummes et al.) and using music to support the teaching of fractions (Lovemore et al.). Within the context of teaching geometrical patterns, Gray and Kleve examine the demand on mathematical knowledge for teaching when supporting students' agency, identity and access to mathematics. Papadaki and Biza present a method of analysis suitable for investigating teachers' use of opportunities to go beyond the "mathematics of the moment" in the context of teaching geometry. Finally, Adler and Mosvold use shared data to illustrate how the Mathematical Discourse in Instruction framework identifies four tasks of teaching central to making mathematics available to students, regardless of the nature of the pedagogy employed (e.g., traditional or reform).

Studies in this domain are different, yet participants appeared to find it provocative and rewarding to reflect on these papers as located in a common territory that emphasizes mathematical considerations. All are concerned with teaching, but specifically with questions of creating mathematical opportunities for students and recognizing and taking them up as they arise. They focus on discourse, as well as identity, agency, and autonomy, as distinctly mathematical, central to the doing and learning of mathematics. Comments on the *Padlet* for this domain wondered how mathematics teaching is distinct from the teaching of other subjects and how conceptions of mathematics might shape conceptions of mathematics teaching. Considering this domain led to reflections on both the essential role it needs to play in studying teaching and how incomplete it is as a lens.

Enactment

Twelve papers and one poster foreground the enactment of mathematics teaching, with diversity in the focus and intent of individual studies, the underpinning theory, and the nature of the methods employed. Papers involve empirical investigations of teacher actions. In some cases, specific hypotheses are investigated, for example, whether teachers' use of why-questions supports student reasoning (Arnesen & Dahl). In other papers, efforts are made to investigate or describe aspects of teaching. Drawing on data from different classrooms, van Bommel et al. analyse teachers' communication of learning goals and Sigurjónsson investigates features of teaching in classrooms where cognitive activation was high. In a more fine-grained analysis, Gray et al. use data from a single lesson to report on the role of progressing and focusing actions in students' appropriation of mathematical ideas, while Gobede and Mosvold use data from a single classroom to identify dilemmas of teaching arithmetical notation to young learners. Some papers report descriptions and investigations of teacher or student actions after, or in the context of, interventions to support particular forms of teaching and learning. Kovács-Kószó et al. investigate a teacher's responses to significant moments of student thinking after participation in a professional development programme; Rösseland et al. report on students' participation in mathematics tasks where roles and positions were used to foster explorative talk.

Several papers explicitly aim to build or test theory or methodological approaches. Nowińska illustrates a set of negative discursive activities that may lead to negative socio-mathematical norms, while Svensson and Wester propose a method for identifying socio-mathematical norms through analysis of student and teacher responses in mathematical activity. Drawing on discourse and positioning theory, Drageset and Eidissen develop and test a framework using shared data gathered for TWG19. Their framework describes teacher positions based on an analysis of their interactions. Concepts from theatre practitioners, in addition to organisational and educational theory, inform the framework proposed by McIvor for identifying and analysing the practice of improvisation in the secondary mathematics classroom. Most papers in this domain analyse recordings of mathematics lessons. In contrast, Mosvold and Wæge examine collective planning activities within a professional development initiative to investigate and propose entailments of questioning practices.

Comments about this domain on the *Padlet* reflected on how much of the work in this domain focuses on what is easily observable, both with a sense that this domain is central to teaching yet also with questions about what we might be missing, the less observable. One participant commented that the students seemed to be missing in this domain, and others commented that studies in this domain do not attend to context, or to teaching as influenced by larger structural systems. Another wondered whether a focus on frameworks in different studies might hide similarities across studies.

Issues

Boundaries, influences, and contradictions are highlighted in the set of four papers in this domain. In the context of a collaboration between mathematics teaching and visual art teaching communities, Choutou and Potari use grounded theory to analyse data from group meetings to identify the boundaries that emerged, as well as the ways in which these were handled. In a paper where mathematics teaching is seen as a social, cultural, and political practice, Grundén investigates textbooks as actors in the transformation of the intended curriculum by conducting thematic analysis on focus group discussions among primary school teachers. Holmedal draws on the notion of big D Discourse and figured worlds to unpack the role of teacher identity in navigating contradictions. Finally, Mwale and Jakobsen use the Mathematical Discourse in Instruction framework to investigate teachers' practices when teaching mass.

Padlet posts that reflected on this domain surfaced concerns and new insights. The "name" of this domain, especially shortening it to "issues," is seen as inadequate. It lacks clarity, but participants have different ways of thinking about this domain and widely agreeable terms are hard to find. Participants discussed and commented on the advantages of “ecology” and “environment.” Part of the concern is about language; part is about meaning. Some participants wondered how broader social, cultural, and political issues matter for doing research as well as teaching. Several commented on the need to acknowledge differences among countries, both for teaching and for research. Another theme in the *Padlet* posts was about how much the teacher and teaching matter for how these issues influence what happens in classrooms. This insight prompted comments about needing to consider methodological tools for addressing such complexity. Prominent across comments was a newfound appreciation for needing to keep this domain in mind. One post described a view of teaching as being about classroom interactions and how the papers in this domain seemed initially unrelated to teaching. The participant went on to write:

> Thinking about them in light of this domain, however, at least helped me see how and why these can be considered as studies of mathematics teaching. Whereas many other studies focus on dialogue, moves or interactions, these papers identify and analyze different kinds of structures that might influence teaching and learning. This is a useful way of looking at teaching.

Views of this domain varied, but having it as a domain seemed to help the group see how these studies were contributing to research on teaching and to see the work as having challenging yet important implications for all studies in TWG19.

Sharing data to study teaching

The third initiative is to contribute to and use data that others in the group have shared — for analysis in papers, as illustrations in presentations, or more generally as a common reference point in discussions. For CERME12, five contributions were available. Most included video, along with transcripts, a document that provides information about the context, and a document containing information from the owners of the data about restrictions. Seven papers made use of the shared data for CERME11, and a session was devoted to discussion of these papers. The initiative appeared to create enthusiasm and productive discussions. For CERME12, only two papers used the shared data.

Gathering and preparing data for sharing and reuse can be rewarding but comes with challenges. One is navigating the General Data Protection Regulation (GDPR), which provides directives for protecting personal data. These regulations can discourage, but there are important reasons to work to make data available. Besides reproducibility and replicability of research, as Dewey (1904) points out, to teach is to be a student of teaching. Teaching is a public act, and its study is a foundational professional activity. In part, we need to educate ourselves and others in the role of responsibly generating and sharing records of practice. Responsible data sharing requires careful planning, crafting proper consent, and establishing secure infrastructure for storage and access. Among the benefits of sharing and reusing data, scholars have highlighted the promise of better utilization of data, access to rich and unique data, saved costs for data production, reduced burden for participants, validation and extension of previous work, and increased quality in analysis. In TWG19, we have experienced potential for new and productive research collaboration and having a common ground for improving communication as significant benefits. Going forward, we hope to explore new ways of organising this work.

Implications for the future of TWG19

The focus on the meaning of teaching, the use of domains to organise and examine studies, and the establishment of shared data have provided greater cohesion for TWG19. They are also helping the group realise CERME's commitment to communication, cooperation, and collaboration. Attending to what is meant by "teaching" is pushing participants' thinking regarding individual studies and is occasioning new conversations across studies. Seeing other's thinking about teaching and what it affords for their research adds perspective to our own thinking. Likewise, the use of domains is helping us think together about each study as well as across studies. So far, the domains appear to be functioning without privileging some work over other work. Instead, they are helping us see diverse studies as part of a larger, concerted effort to investigate teaching. Last, while establishing and using shared data is challenging, it remains a promising tool for supporting the work of TWG19.

In addition to these three innovations, the organisers have also been exploring ways of working together. The pandemic forced us into virtual meetings. Designing online sessions was not easy, but several new approaches may be worth keeping. Participants recorded 5-minute presentations beforehand, which seemed to encourage preparation, lead to better and efficient presentations, and helped everyone get familiar with the work. Viewing presentations does not replace reading all papers, but it helps everyone recall what they read and provides a quick way to revisit and remember.

A second novelty was designing sessions for authors to hear reactions from a small group of colleagues. These author sessions were highly structured to engage authors in listening and participants in honing professional skills. After viewing the 5-minute recorded presentation, one volunteer had 3 minutes to describe what they heard, then two other volunteers had 2 minutes each to say what stood out to them as significant about the work. This was followed by time for brief reaction from the author and then discussion of the meaning of teaching evident in the work and its place in the identified domains. Perhaps the skills identified in these sessions should be more scaffolded and the sessions facilitated. Perhaps participants should know ahead of time which papers they will be reacting to, so they might prepare. Notwithstanding potential improvements, participants appeared to appreciate deliberate attention to building professional skills, and authors appeared to appreciate the opportunity to listen to how their work was being understood and taken up.

In this design, individual papers were not presented to the whole group. However, the author sessions were seen as valuable to both authors and participants, and authors received several other types of feedback. Having an organiser comment on a set of papers after everyone had a chance to engage with one paper in a small group seemed to help participants go deeper with the one paper and extend thinking across the papers. In addition, having individual papers discussed in parallel allowed for more whole-group discussions across the papers, where authors again had a chance to hear their paper discussed, albeit in relation to other papers, a specific domain, or meanings of teaching. Last, we created a *Padlet* page for each paper. This allowed authors to ask for pointed feedback and provided all participants with an expedient way of offering comments and raising questions. We now have better ideas about how to support participants' productive use of these online tools and plan to continue exploring their use when we meet in person.

In planning for the conference, we strove to provide opportunities for in-depth discussions of teaching and teachers' practice(s). Our sense is that the three initiatives together with thoughtfully designed sessions contributed to such in-depth discussions. However, we think there is more to do. As we plan for CERME13, we will continue to consider how to design sessions that support each participant while also supporting our collective efforts to advance research on teaching.

Mathematics Discourse in Instruction: How it helps us think about research on mathematics teaching

Jill Adler[1] and Reidar Mosvold[2]

[1]University of Witwatersrand, Johannesburg, South Africa; Jill.Adler@wits.ac.za

[2]University of Stavanger, Stavanger, Norway; reidar.mosvold@uis.no

Mathematics Discourse in Instruction (MDI) is a framework developed to describe, interpret, and support development of mathematics teaching. Since its inception, it has been successfully used as a tool for research and professional development in South Africa, where it was developed, but it has been less used in other contexts. In this paper, we use shared data as a starting point to explore how the MDI framework can contribute to thinking about research on mathematics teaching. We elaborate on the conception of teaching underlying the framework, describe its elements and their rationale, and show how these can illuminate four core tasks of teaching mathematics.

Keywords: Exemplification, explanatory communication, learner participation, discourse, mathematics.

Introduction

In the past decades, multiple frameworks have been developed, each offering different perspectives on mathematics teaching. The underlying conceptualization of teaching is often not made explicit in these frameworks, and it can be challenging to communicate across theories and frameworks. To stimulate communication and move the group forward, sets of shared data were provided for participants of thematic working group 19 (TWG19) to use at CERME11. Papers applied different theoretical and analytical lenses on these data. For instance, Nic Mhuirí's (2019) application of the Teaching for Robust Understanding (TRU) framework enabled her to compare the quality of teaching across datasets according to the pedagogical norms of the TRU framework, but it also raised questions about underlying values of frameworks and usability across cultural contexts. Bass and Mosvold (2019) applied the instructional triangle as a conceptual framework, adding theoretical perspectives on agency, authority and identity. This allowed them to explore how various teacher moves may influence student agency and position. These examples illustrate how frameworks can offer different perspectives and allow researchers to notice different aspects of the data. Having shared data available in the group thus provided a productive space for discussion. In the present paper, we continue this effort by applying the Mathematics Discourse in Instruction (MDI) framework on one of the shared datasets to investigate what the framework might help us see, what underlying conception of teaching it has, and how a framework like this can contribute to research on mathematics teaching.

The framework[1]

MDI was developed in the Wits Maths Connect Secondary (WMCS) research and professional development project working with teachers in schools serving low-income communities in one province in South Africa. The goal was to improve teaching and learning. Mathematics teaching in

[1] References to 'we' and 'our' in this section are to the WMCS research team, and not to the authors of this paper.

secondary school classrooms is predominantly direct instruction, and typically described as ‘traditional’. Our initial observation was that within this similarity were both important teaching differences and incoherence in the mathematical messages across lessons (Adler, 2017). In this context, we sought a framework that describes what mathematically is made available (or not) to learn, irrespective of pedagogical norms, and provide for developmental trajectories that we could use with teachers to improve the coherence of teaching and opportunities for learning mathematics. In its initial form MDI was used analytically to describe and compare lessons (see Adler & Ronda, 2015). Between 2015 and 2019 the project focused on using it to develop practice. It is thus a living framework and has functioned as a boundary object, shifting flexibly across teaching and research practices in the project (Adler, 2017). This paper contributes to current work of refining MDI.

MDI is underpinned by key tenets of sociocultural theory. Briefly, these include an orientation to mathematics as coherent and connected scientific knowledge (Vygotsky, 1978); and to mathematics teaching as goal directed with mediation towards learners’ appropriation of increasingly sophisticated and increasingly general ways of thinking to progress in the discipline. Critically, teaching is always about something – an object of learning (Marton, 2015) – and the coherent mediation of that ‘something’ is the teacher’s work. To focus the project’s work, we foregrounded what we considered were high leverage practices in this work, and specifically in preparing for and teaching a lesson.

If teaching is always about ‘something’, a first core task of teaching is to identify the object of learning – that which students are to come to know and be able to do in a lesson. Our analysis below will show that while this task is obvious, its enactment is not trivial. Key next core tasks are selecting and sequencing examples, their related tasks, and representational forms (*exemplification*), attending to explicit mathematical word use and justifications/substantiations (*explanatory communication*) and to what learners are invited to do, say and write (*learner participation*). Our conceptualization of each of these tasks has been informed by two literature strands: on exemplification and variation in mathematics and mathematics education (e.g. Al-Murani et al., 2019), and on language as a resource in mathematics teaching and learning – including attention to lexicalisation (Planas, 2021) – and explicit criteria for mathematical explanations (Prediger, 2019). Our sociocultural perspective sees tasks of teaching as mediational, drawing in cultural tools that shape and are shaped by contexts (see Figure 1). The further salience of the four elements (tasks of teaching) in the framework was their resonance with practice and possibilities for connection and developmental work with teachers.

Task 1: Identifying the object of learning requires both mathematical and curriculum analysis. The ‘object’ in the lesson we study here is placing a fractional number on the number line (for more information about the context and task, see Ball, 2017). This task requires analysing (1) where this ‘content’ is located in the curriculum (and so on the trajectory of student learning), (2) its mathematical meaning and what other mathematical concepts, procedures and practices are connected and entailed. In analysis of shared data, we only had access to the enacted object (what is actually taught) and can only infer what was intended. Below, we show that the intended object of learning is provided in the description of the lesson, enabling mathematical and curriculum analysis.

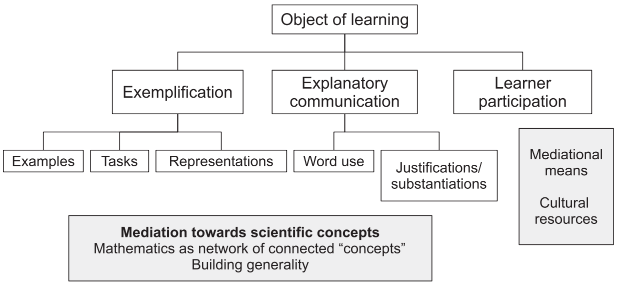

Figure 1. The MDI conceptual framework, adapted and refined from Adler & Ronda (2015).

Task 2: There is considerable literature foregrounding exemplification in mathematics education – as specialised knowledge for teaching, and as teaching and learning through discerning variation (for a review, see Adler & Pournara, 2020). Watson and Mason (e.g., 2006) brought these two strands together in mathematics. Al-Murani et al. (2019) build on this earlier work and use principles of variation to analyse example sets in mathematics lessons. They argue that discerning similarities and differences in an example set – what is changing over a stable background, or what is invariant as features change – is particularly useful in illustrating opportunities created for building generality and/or recognizing structure in mathematics learning. Resonant with this approach, two key principles of variation were recruited into MDI: similarity and contrast. We analyse variation amidst invariance (what is the same and what is different) and contrast (what is and what is not) across example sets to interpret opportunities made available for mathematics learning.

Task 3: Research in mathematics education has attended to important language practices – referred to as language responsive mathematics teaching (e.g., Prediger, 2019). That such teaching needs to extend beyond the communicative function of language to its epistemic function has long been recognised (e.g., Pimm, 1987). The epistemic function includes both vocabulary work, explaining words and phrases, thus requiring teaching to create opportunities for students to participate in (hear, see and use) specialised discourse (e.g., Planas, 2021). This is well illustrated in Planas' (2021) study of teaching equation solving, where she argues for the specific language practice of lexical elaboration. She shows how deliberate attention to the equivalence relation, and the appropriate words to support this meaning create opportunities for learning specialised discourse. The two elements of *explanatory communicatio*n (word use and justifications) in MDI link with this work.

Task 4: Learners obviously need to engage with mathematics to learn. MDI focuses on how students are invited to hear, see, write and speak mathematics, the latter beyond chorusing and one-word answers to teacher questions, and so to use specialised discourse themselves.

Exploration of framework with shared data

The MDI framework was developed for analysis of a lesson. Adler and Ronda (2015) operationalise key constructs of each task, with codes developed to distinguish, for example, similar and contrasting examples, differing task demands, colloquial and mathematical word use, criteria for explanations and learner participation. They describe how lessons are chunked into episodes and the analysis of episodes accumulate to describe the example set and other elements in terms of levels of a trajectory towards more coherent teaching. The exploration of the shared data below cannot do this kind of analysis as we only have one episode. Given the coherence of the overall lesson, the tasks would likely all be coded the highest level 3. As a coherent lesson, it thus is more useful to elaborate our exploration descriptively, and this is how we proceed.

The shared data we use – the Hoover data set – is a short episode (video recording and transcript) within a lesson together with a context document describing the class (rising fifth graders who attend a summer school in the United States), the motive for the lesson, its mathematical focus and student responses to a warm-up problem at the start of the lesson, and a similar exit task at the end. We use all of this for our analysis and discussion of what the MDI framework allows us to see.

The first step in MDI analysis is to identify the "ostensible" object of learning: analysis of the example set and related tasks, and the explanatory communication are all in relation to this 'object'. The warm-up problem asks: "What number does the orange arrow point to? Explain how you figured it out". The arrow points to the position of $\frac{1}{3}$ on a number line that extends from just before 0 to just past $2\frac{1}{3}$, with thirds marked on the line. In the context document accompanying this shared data set, the lesson is described as *marking a turning point in mathematical work* from *"naming fractions as parts of areas to identifying fractions as points on the number line"* (p. 1), with a critical aspect of the object of learning being the important *"shift" in understanding* that "on the number line the whole is defined as the distance from 0 to 1. With area models, the whole can be greater than 1" (p. 2). This is something students are to know. What they need to be able to do – the focus of the lesson – is to carry out "steps for naming a fraction correctly". This key procedure is evident in the chart provided. It is presented as the interpretation for teaching of *an extract from curriculum documents* (p. 7). The intensive mathematical and curriculum analysis highlighted in the italicized phrases that was done in preparation for this lesson are made visible. These foci for the lesson are not trivial and require specialized teacher knowledge of fractions as part of an area, and fraction as a number, where and how the progression from one to the other is located in the curriculum, and consequently what prior learning brings to the shift learners need to make. The next analytic step is to analyze the mediation of these object(s).

Exemplification – examples, tasks and representations

The focal example in the episode is the fraction $\frac{1}{3}$ and the task for the students is high demand. They are required to name the fraction being pointed to on the given number line which extends from 0 and past 2, and to explain their reasoning. There are no other given examples in the episode. The example in the concluding task is the fraction $\frac{2}{3}$, and the task is the same. The fraction $\frac{1}{7}$ is also discussed in the episode, bringing in a second fraction example. We see other fractions ($\frac{1}{4}$, $\frac{1}{5}$) written on the board and possibly offered prior to the $\frac{1}{7}$, and still other responses to the warm-up task such as $\frac{2}{4}$. We do not have access to other examples of fractions and their location on the number line that were likely to have been discussed later in the lesson. Specifically, we do not know whether different 'thirds' were discussed – where the 'whole' in thirds (the denominator) remained invariant, and the number of 'parts' (numerator) varied (e. g. $\frac{2}{3}$, $\frac{3}{3}$, $\frac{5}{3}$, $\frac{7}{3}$) – or whether there was discussion of examples with a different denominator, with a similar range of numerators (e.g. $\frac{1}{5}$, $\frac{2}{5}$ ...). There are thus limits to what can be said about the example set across the lesson and variation with respect to similarity, and so what of the written fractions were varying and invariant and how these might have been publicly discussed. The intended generality is the procedure for naming a fraction on a number line. What is observable is the chart that outlines the steps for the procedure in general terms, indicating that there were probably more examples of fractions with varying numerators and denominators, with the generalized fraction name written as $\frac{\mathrm{n}}{\mathrm{d}}$. The extent of how these varied, and what was invariant are what is salient to what is made available to learn.

What is observable in the episode is variation through contrast through the selection of $\frac{1}{7}$ for public discussion. This brings 'what is not' the name of the fraction, into focus i.e. specifically naming the fraction by counting the hash marks, or the 'parts' without reference to the unit whole. The selection of $\frac{1}{7}$ (as opposed to $\frac{1}{4}$, *or* $\frac{1}{5}$), is salient, provoked by the number line extending past 2. Unfortunately, the episode does not include the discussion of $\frac{1}{7}$ only some clarifications of the thinking that produced this, and so counting all the parts, making available a discussion following on the unit whole and not the length given (as in the case of the area model). Other student questions about starting at 'zero' and what was counted draw attention to the hash marks (as opposed to spaces). In MDI terms, and the application of principles of variation of similarity and contrast, we would conclude from what is available in the video, transcript and the context document, that the lesson provided opportunities for learning to discern the correct place of a fraction between 0 and 2 on the number line, specifically for identifying the whole, and focusing on counting spaces not hash marks.

Looking at the students' successful responses at the end of the lesson leads one to speculate that the whole lesson included discussion of a varied example set, with purposefully selected similar and contrasting examples, making available opportunity for generalizing the mathematical steps for marking a fraction on the number line (and through contrast not over-generalizing).

What is made possible to learn is, of course, not only a function of the selection and sequencing of examples, tasks and representations[2], but how the example set is discursively mediated.

Explanatory communication – word use and justifications

As the episode is restricted to the presentation and clarification only of the answer $\frac{1}{7}$, and questions posed by other students (the teacher's task here is focused on students hearing the explanation offered), there is limited possible analysis of word use towards the object of learning in the transcript. However, the description of the teachers' work through the rest of the lesson, and the extracts of students' explanations of their responses to the exit task in the context document enable analysis of what was or what was likely to have been made available in the classroom discussion.

From the selected written student explanations in the document, words they used initially to explain their answer included "count", "equal parts", "count from zero" indicating that they associated fractions with equal parts that needed to be counted, but not what or where these equal parts were nor the whole they were referring to. In contrast, in the exit task, we see the following: "You have to

[2] Of course, in this lesson and episodes the shift in representation from area to number line is built into the lesson and not focused on here.

count the space"; "all the spaces have to be equal"; "… because I saw what the howl (whole) was. Then I made sure it had equal parts. Last I counted the spaces."; "I counted the spaces"

The students' use of specialized discourse relevant to fraction as number is evident. Contributions to how this was made available to learn in the lesson is observable in the chart at the end of the context document that emphasizes the words: "Whole", "equal parts", "unit fraction", "count parts"; as well as in the extract below that elaborates the discussion (though we are not privy to who said what, when). From the context document (p. 4):

> … the discussion emphasizes the importance of partitioning the *unit interval* in *equal part*s and being sure to *count spaces (i.e. the intervals, not hash marks)* to *determine the distance from* 0 for a given point on the line. The students practice naming points on the line and also explaining carefully with *reference to the whole* and to *the equal parts* and to *counting spaces to determine the number*.

We have italicized the specialized discourse and interpret that these words and aspects of justifications for the fraction name were used in the lesson by both teacher and students. Moreover, as indicated in the underlined sections, we observe that students practiced this specialized word use and justifications, probably repeated on a range of different fraction examples.

Using MDI, we would analyze all episodes in a lesson for specialised discourse coding word use by distinguishing colloquial from mathematical, and coding justifications by distinguishing those that are non-or pseudo-mathematical (assertions – e.g. because the textbook says, or visual cues – e.g. the hash marks), from those that are local, partial, and then full explanations. Our data here is different and coding the given episode would put word use as colloquial and mathematical in name only. However, specialized mathematical word use coherent with the object of learning (whole, equal parts, counting spaces) was made available, as was a full explanation of the steps for correctly placing a number on the number line. If we had the full lesson transcript, MDI analysis by episode would show what and how word use and justifications build up through the lesson, and so through the temporal flow of the lesson, as well as who says what, and so what the teacher inserts, repeats, revoices and reinforces (as this is her work), and what students get to hear as well as say for themselves. This last point is apposite, for specialized discourse (word use and criteria for valid mathematical argument) is not spontaneously available, and thus a crucial aspect of knowledge for teaching and task of teaching (Planas, 2021; Prediger, 2019).

Learner participation

Given the traditional teaching context in which MDI was developed, the focus of research in the WMCS project was on the extent to which students themselves had opportunities to hear, speak and write mathematically. These opportunities are extensive even in this one episode. We discuss this further below.

Concluding discussion

Different frameworks enable scholars to notice different things about mathematics teaching. For instance, the TRU framework allowed Nic Mhuiri (2019) to evaluate and compare the quality of teaching across contexts in analysis of shared data. Theoretical constructs like agency and authority enabled Bass and Mosvold (2019) to explore different aspects of the same data sets. Their framework allowed them to notice how the pedagogical moves that teachers make can influence the agency and position of students in mathematics classrooms, and they argue that this is particularly important to notice when responding to apparent student errors. While these perspectives are indeed salient, the MDI framework was developed with the aim of describing the *mathematics* that is made available to learn. The emphasis is thus primarily on the mathematics as it is made available through examples, tasks and representations, and through word use and justifications. As we have tried to show in our discussion of shared data, selection and sequencing of examples is a key task in mathematics teaching, which is not straightforward, yet often overlooked. One thing the MDI framework allows for, is to highlight exemplification and how it may or may not contribute to the set learning goal.

A potential weakness of the framework is that the underlying conception of teaching is left implicit, linked only with being goal directed and involving mediation. We highlight two aspects of the conception of teaching underlying the MDI framework. First, like Ball (2017), it useful to think about mathematics teaching as a special mathematical work. Others have suggested a distinction between considering teaching as something teachers do, as opposed to a work to be done. This distinction was not considered in developing the MDI framework. However, the framework operationalizes four core mathematical tasks of teaching, and so the kind of work to be done: 1) deciding a mathematical object of learning, 2) selecting and sequencing examples, tasks, and representational forms, 3) attending to mathematical word use and justifications, and 4) considering what learners are invited to do, say, and write. Second is an underlying issue of teaching methods. Some frameworks of mathematics teaching are bound to specific teaching methods or pedagogical values. Nic Mhuiri (2019) highlights this in her discussion of the TRU framework, which appears to value an approach to mathematics teaching that corresponds with ongoing reform efforts in the United States. In contrast, the MDI framework aims at being useful across methods or pedagogies of teaching. It was developed in a context that is dominated by traditional teaching, but our effort to apply it to Deborah Ball's teaching in the shared data set indicate that it can be useful also for analysis of nontraditional mathematics teaching.

In the call for papers to TWG19, five domains were identified to facilitate communication and collaboration. When considering the potential contribution of MDI in relation to these domains, we first notice that MDI has a primary emphasis on extending mathematics to learners. Whereas the organization of interactions is less in focus, the framework does focus on the mathematical discourse. The MDI framework was not developed with an emphasis on responding to students, but equity was an underlying issue of concern. Although social, cultural, and political issues are not directly visible in use of the framework, access to mathematics *is* an issue of equity in many countries. Since learners in areas with significant poverty often do not get the opportunity to learn mathematics, improving their access to mathematics in the classroom is thus an equity issue – and a key motivation for the development and use of the MDI framework.

“Why have you written six times five?” Teachers’ use of *why* in Norwegian mathematics classrooms

Kristin Krogh Arnesen[1] and Heidi Dahl[2]

[1]Norwegian University of Science and Technology, Trondheim; kristin.arnesen@ntnu.no

[2]Norwegian University of Science and Technology, Trondheim; heidi.dahl@ntnu.no

From classroom data consisting of transcripts from 20 videotaped lessons, we studied five Norwegian mathematics teachers’ use of the word why. *It is our initial assumption that asking why in mathematics is a means to support students’ mathematical reasoning. We found evidence for this assumption in our data. However, the analysis of the 114 occurrences of* why *indicated that the most common purpose for asking why was to make students re-state thinking they had already done, thus not prompting new mathematical reasoning. Moreover, when teachers used* why *in questions not about mathematics, they usually did so in a rhetorical and reproachful manner. We discuss these ambiguities and implications for teaching.*

Keywords: Mathematical reasoning, questioning, mathematical discourse, interactions.

Introduction

In the mathematics classroom, teachers’ questioning is acknowledged as crucial in supporting students’ learning (see e.g., Franke et al., 2009). Martino and Maher (1999) claim that there is “a strong relationship between (1) careful monitoring of students' constructions leading to a problem solution, and (2) the posing of a timely question which can challenge learners to advance their understanding” (p. 53). Recent studies have pointed out that *asking why* is a type of question that particularly holds the potential to encourage students to explain or reason (Ingram et al., 2016; Drageset, 2021). In those studies, the researchers first identified students’ explanations in classroom data, and then considered what the teacher did to prompt the explanations. In contrast, we are taking as a starting point all teacher-initiations given in the form of a why-question, and we aim to categorize the possible implication of the question in the given situation, not unlike Enright et al.’s (2016) typology of questions according to the function they serve in instruction. We are particularly interested in the potential why-questions hold to challenge students to advance their reasoning, reflecting Martino and Maher’s (1999) “timely questions” mentioned above.

In our study, we take a commognitive view of mathematics teaching and learning (Sfard, 2008). Within this tradition, learning is seen as increased participation in a discourse, and discursive behavior is characterized in terms of routines (Lavie et al., 2018). Teachers have the role of expert participants in the classroom discourse, and the theory of commognition states that imitation of expert participants is a central aspect of the learning process (Sfard, 2008). Martino and Maher (1999) point out that students do not naturally seek to build a justification or proof of the validity of a solution. Thus, routines related to reasoning and proving in mathematics must be made visible by the teacher. Therefore, teachers’ use of why-questions influences students’ routinization (i.e., individualization of routines in the community), regarding when it is a timely question to ask, and what kind of actions such a question requires.

Thus, to get the whole picture of how teachers' why-questions relate to students' mathematical work, we need to extend our knowledge beyond the why-questions identified by Drageset (2021) and Ingram (2016) that actually led to students' conceptual explanations. Other uses of why-questions will also affect how students routinize asking why in mathematical discourse. To this end, we employ the following research question: *How is the word "why" used by five middle-grade teachers in mathematical classroom discourse?* The data for the study consists of transcripts of 20 lessons given by the five teachers. As all occurrences of the word "why" in the data material are part of a question (this includes a few instances of implicit questions), we will use "why" and "why-questions" synonymously in this paper.

The routines of asking why

Within the commognitive framework, *routines* are important features of discourse in a community (Sfard, 2008). Routines are discursive patterns which are evoked whenever a participant finds herself in a situation similar to one she has experienced before, and acts thereafter (Nachlieli & Tabach, 2018). Routines consist of an initiation, a procedure, and a closure (Nachlieli & Tabach, 2018). The initiation is the clue that is recognized and thus prompts the participant to perform the expected actions, and the closure is "the conditions under which a procedure is considered complete" (Nachlieli & Tabach 2018, p. 3), together they form the "when" of a routine. The procedure is the action taken in between the initiation and the closure, also referred to as the "how" of the routine. Lavie et.al (2018) consider two types of discursive routines in mathematical discourse: Explorations and rituals. Explorations are outcome-oriented routines, where the aim is to produce or endorse new narratives (i.e., statements about mathematical objects and their relations). They are motivated by the question "What do I want to achieve?" and are often performed by the more experienced participants of the discourse. In contrast, rituals are process-oriented routines, guided by the question "How do I proceed?". Rituals are often performed by novices in the discourse, typically by imitating the teacher's actions, and the motivation is social acceptance. Routines can be nested – a new routine can be initiated, carried out and closed as a sub-routine of another routine (Nachlieli & Tabach, 2018).

As previously mentioned, we are particularly interested in routines that are connected to students' mathematical reasoning (MR). Therefore, we need to elaborate on what we mean by MR. We employ Jeanotte and Kieran's (2017) conceptual model of MR for school mathematics, which is constructed in coherence with the commognitive framework. The model consists of two interrelated aspects: The *structural aspect* addresses the underlying construction of an argument (e.g., deductive, inductive, abductive), while the *process aspect* capture activities related to searching for similarities and differences, validating, and exemplifying. A search for similarities and differences is aimed at producing new narratives, a validation is aimed at establishing the correctness (or wrongness) of narratives, while an exemplification works as a support for the first two types of MR processes. We note that all the MR processes – when considered as overall routines performed by students – are exploratory routines, because they seek to produce or endorse narratives. We thus use the term *MR exploration* for an exploratory routine involving one or more MR processes.

Both Drageset (2021) and Ingram et al. (2016) found that why-questions were connected to student explanations of reasoning. However, in their studies, it is not possible to separate students' explorations and rituals, although it is likely that many of the explanations of reasoning were connected to an exploratory routine. Nor is it possible to see whether the teacher's question prompted the student to share his reasoning, or whether it invited the student to start to reason. This distinction between starting and explaining routines is also not evident in the typology of questions suggested by Enright et al. (2016). Our study aims to give more insights into these matters.

Methods

The study presented in this paper is part of an ongoing, large-scale study with a focus on reasoning and proving in primary education (ProPrimEd). As a first part of the ProPrimEd study, we collected classroom data (videotaped lessons, and interviews with some students and all teachers who participated in the lessons) to describe the "state of the art" of work with reasoning and proving in ordinary mathematics education. The data for the study reported here consist of the transcripts of the videotaped lessons. In total, we observed five teachers (T1, fifth grade; T2, sixth grade; T4, fourth grade; T5, seventh grade; T6, sixth grade) for two weeks each, a total number of 20 lessons of various lengths. All the five teachers were male. T1 and T2 worked at the same school, so did T4, T5 and T6. All were educated as primary school teachers with mathematics as one of their subjects. Some had additional professional development courses in mathematics. Their teaching experience varied between 2 and 17 years, with an average of 9 years. The researchers took the role of non-participating observants during the data collection and played no part in lesson planning. Topics of lessons were whole-number multiplication, addition and subtraction with rational numbers, problem solving involving geometrical shapes and multiplication, prime numbers, and operator precedence. Most classes consisted of a variety of activities. Although the data is limited to two schools and five teachers, we consider it to represent ordinary mathematics discourse in Norwegian classrooms.

The transcript documents consist of a total number of 143 448 words (including meta-data). From this material, we identified (using the search functionality in Microsoft Word) every occurrence of the word *why* used by a teacher in whole-class discussion and in discussion with (groups of) students. We found 114 occurrences.[1] For each teacher, we made a new document of cut-outs from the original transcript, consisting of a separate text block for each occurrence of *why* – including enough text before and after the word to make the context clear, so that we would be able to interpret the possible implication of the *why*. Sometimes, during the coding process, we would go back to the complete transcripts to review more of the context, and we also had the opportunity to consult the video recordings. We did not seek to identify differences between the teachers, and therefore treated all why-questions as a pool.

We were inspired by other studies on the use of certain words in mathematical discourse, such as Monaghan (1999) and Wagner and Herbel-Eisenmann (2008), who studied the words *diagonal* and *just*, respectively. These studies pointed to the influence of single words in mathematical discourse: Monaghan showed how an "informal" meaning of *diagonal* could possibly weaken the mathematical content at stake, while Wagner and Herbel-Eisenmann showed how a seemingly innocent word like

[1] The lessons, and thus the transcripts, were in Norwegian. We searched for the Norwegian word "hvorfor", which holds the same meaning as the English word "why". The data excerpts used in this paper are translated to English by the authors.

just could open or close discourse. In our study, we were guided by the commognitive concept of routines when analyzing and discussing data. The two authors read some of the material together and agreed on a temporary set of codes. These codes were:

- *initiating*, later renamed *routine-initiating*: *Why*'s that prompt new reasoning (based on the underlying assumption of the study)
- *recalling*, later renamed *routine-re-initiating*: *Why*'s that prompt students to share (aspects of) mathematical thinking they have already done
- *non-mathematical*: *Why*'s used in contexts not about mathematics.

Each author then coded the material separately. When discussing the coding afterwards, we found that we agreed for most occurrences and came to agreement on the few we had coded differently. We added a category *Other* for why's occurring within a mathematical context, but not fitting into the first two categories. We started the process of analysis with an open coding that was as close as possible to the data. As we interpreted our interim findings, we employed Sfard's and Jeannotte and Kieran's theories to further nuance the content of each category, and the categories were appropriately renamed. In the next section, we elaborate on some typical uses of *why* from each category.

Findings

Table 1 shows the number of occurrences of the word *why* in each of the categories routine-initiating, routine-re-initiating and non-mathematical (and other).

Table 1: Number of occurrences of the word *why*

routine-initiating	routine-re-initiating	non-mathematical	other
34	65	7	8

We note that the most common use of *why* is to recall mathematical thinking (routine-re-initiating). In the following, we provide examples from the four categories. The examples are chosen to indicate both "typical" usage of *why* and to demonstrate the variation within a category.

Teachers' use of routine-initiating why-questions

Routine-initiating why-questions invite the students to choose and take action. Almost all instances of routine-initiating why-questions in our data material called for an MR exploration. The data material provides examples that why-questions were used both to prompt students to search for similarities and differences, thereby producing a narrative, and to validate a conjecture. An example of the former is given below. Two students are working on a jigsaw puzzle of the multiplication table (the pieces in the puzzle consist of more than one number).

Teacher: What I'm wondering is why does it [a piece] fit so well here?
Student: Because here it says 36 and here it says 32
Teacher: Why do 36 and 32 fit together? And together with 28 and 24? What's going on with these numbers?
Student: Because (…) because. It's 4 between them.

In this example, it seems that the students first placed the piece in the puzzle because of its shape. The teachers' questions made them reason about the mathematical relationships, and eventually identify the pattern in the 4-times table. Next is an example of a why-question that is used to initiate a validation process. The excerpt is from a situation where the students are asked to calculate the surface area of the (glassed-in) walls of different buildings, all having the shape of rectangular prisms, and all having the same circumference of the ground floor and the same height.

Oline:	Like. Around the walls. It's the same for all around the glass? Isn't it the same for all?
Teacher:	Yes, why is it so?
Oline:	It's the same outline, it, it [Norw. outline is omriss]
Teacher:	The same circumference? [Norw. circumference is omkrets]
Oline:	Yes.
Teacher:	Yes. Why is the glass the same when it's the same circumference?
Oline:	I don't know, but it feels that way.

Here, the student claims that there is a relationship between the circumference of the ground floor and the area of the walls but has no ready-made reasoning to support the claim. Hence the two why-questions serve as possible initiators for a validation process of the student's hypothesis.

We conclude this section with two examples of routine-initiating *why*'s taken from a lesson on prime numbers. Common for these *why*'s is that they are not self-contained as routine initiators; they are a part of a more extensive initiation. In the first example, the students are investigating whether all whole numbers between 4 and 20 can be written as a sum of two prime numbers. During the students' group work the teacher reminds them of the task:

Teacher:	You'll get 3 more minutes. Remember that, although I claim, I claim that it's possible for all the numbers from 4 to 20, but it's not certain it's the case though. So it could be that you find some numbers where it doesn't work. But then maybe you have to say something about why it doesn't work. How can we be completely sure that it doesn't work? So we work for 3-4 more minutes (…)

Here, the *why* is a support for the process of validating a hypothesis, which is already going on in many students' work (thus, the *why* initiates a sub-routine nested within the routine initiated earlier, when the task was given). The students are working on a task, and this *why* clearly does not refer to an answer provided by a student. Later, the teacher discusses an answer with some students:

Teacher:	Yes, there you only have to explain why some numbers aren't prime numbers. Such that he said that 8 isn't a prime number, since you can get that by using the factors 2 and 4. You can just write down that computation.

The use of *why* here points to a validation, and the teacher add some information about the possible nature of this explanation. Thus, this *why* is connected to the structural aspects of a reasoning process. In our data material, we found very few examples of such *why*'s.

Teachers' use of routine-re-initiating why-questions

Routine-re-initiating why-questions invite students to recall, share and elaborate on the routine they have already performed. In most cases, this happens during a whole-class discussion after the students have worked on a task. As with the previous category, we find different uses of *why* within this category. In many cases, the why-questions were (mainly) addressing the procedure aspect, or the "how" of the routine performed. This is the case in the following example, taken from a lesson on negative numbers. The teacher is requesting details of a calculation:

Teacher:	Seven minus negative three. What will that be, Anja?
Anja:	Ten
Teacher:	That is ten. Why?
Anja:	Because it is the same as seven plus three.
Teacher:	It is the same as seven plus three. Yes.

In the next example, the teacher's why-question addresses the procedure of regrouping in addition with decimal numbers. Again, this excerpt addresses the "how" of the student's performed routine, but the "when" is also addressed as the teacher probably seeks to highlight conditions for taking this action (when to regroup: if we get ten tenths).

Teacher:	Yes, we get in a way zero tenths at the end. But why do we get zero tenths? What have you done then?
Anniken:	Because we transfer to the ones' place.
Teacher:	Yes. That is right. As soon as we get ten tenths, we have to regroup. That is the way the decimal system works.

In other cases, re-initiating why-questions were used mainly to highlight features related to the "when" of a routine. The next example, taken from a lesson on early multiplication, shows how a why-question seeks to emphasize the connection between the given context and the numerical expression, i.e., in what situations a multiplication procedure is called for.

Teacher:	Six times five. Ok. Adele, why have you written six times five?
Adele:	Because it [the worm] climbs six centimeter each hour.
Teacher:	Mm, it climbs six centimeters each hour. So it does.
Adele:	And it climbs for five hours.

There were also some examples where the teacher asked *why* to make students elaborate on a routine, but where the teacher (most likely) did not know what the student had done (e.g., when the student had provided a wrong answer). Why-questions used in this way have the potential to provide the student with an opportunity to revise his/her thinking, which would be a routine-initiating why. However, in our data we only find examples where the teacher guides the student to the correct answer by asking closed questions (like Drageset's (2014) *closed progress detail*). Thus, the student's possible contributions are limited to yes/no-replies and short answers, with few or no opportunities to engage in mathematical reasoning.

Non-mathematical and other uses of why

The few *why*'s in the *Other* category are either not part of a question to students, or meta-questions which we do not discuss further in this paper. Similarly, the non-mathematical why's are rare in the material, and occur in data from only two of the teachers. Yet, they are interesting because all of them are used in a rhetorical and even reproachful manner, such as:

Teacher: Six. Why don't you raise your hand when you know it?

This example, as well as the remaining six instances of this code, are rhetorical and reproachful because the teacher does not expect an answer and the aim of the questions is to address something unwanted in the student's behavior.

Discussion

We started this paper with an assumption that why-questions can serve as initiators of exploratory routines involving MR processes, in line with Martino and Maher's (1999) "timely question[s] which can challenge learners to advance their understanding" (p. 53). In our data, we found evidence that this indeed happens. Yet, we found that by far most examples of why-questions are routine-re-initiating. They are usually asked after the students have finished their work on a task. Thus, in commognitive terms, we could consider those why-questions initiators of subroutines that are nested within the closure of the outer routine, the task itself ("work on the task is done after the teacher has got all the details"). Still, they have an indisputable potential for developing students' mathematical reasoning: The student gets an opportunity to express her thinking; the (teacher and) other students get access to this reasoning; and the teacher is given the opportunity to emphasize for the whole class what he considers to be important ideas. Moreover, some of the routines expressed by the students may initially have been exploratory, and insights into explorations could model other students' later attempts at explorations.

So, is there a problem with this bias towards routine-re-initiating why-questions? Although earlier studies recognize the potential of why-questions as routine-initiating (Drageset, 2021; Ingram et al., 2016), we must remember that if students should interpret a why-question as a "signal" to start an MR exploration, then they must be exposed to why-questions used in this way. Lavie et al. (2018) write that "[t]he teacher's own mathematical discourse is the model for the learners to follow, and the question is whether its explorative nature gets through to the students" (p. 20). If why-questions are mostly restricted to the recalling of performed work (which may even not have been explorations), or to aspects that are non-mathematical, the connection between asking *why* and the need for MR explorations is not likely to be routinized by the students. Accordingly, we note from further reading of the transcripts that in many of the cases where routine-initiating *why*'s are used, explorations did not consequently occur. We do not elaborate on the reasons for that here – that would be outside the scope of the paper – but we remark that a possible reason could be that students simply does not interpret the question as a "signal" to start an MR exploration. One implication for teaching could be for teachers to be careful of how they use the word *why*. In situations where the aim is not to invite students to reason, but rather to invite them to share their thinking (and in particular when it concerns rituals and concepts rather than explorations), could there be other phrases to choose from? "What does that mean", "how does it work" and so on. But most important is probably that teachers should stress to use *why* in connection with MR explorations, also when it is the teacher himself who takes the lead in the process.

Boundaries between mathematics and visual art teaching communities

Chrysoula Choutou and Despina Potari

National and Kapodistrian University of Athens, Greece;
chrychou@math.uoa.gr; dpotari@math.uoa.gr

Focusing on mathematics and visual art teacher collaboration and drawing on Communities of Practice and boundary crossing, this study aims to examine the boundaries that emerge between mathematics teaching and visual art teaching communities in regard to mathematical practices and tools, as well as the way they are handled among collaborating members. Using a grounded theory approach, data from 10 group meetings of art and mathematics secondary school teachers who try to develop ways of linking mathematics and art teaching were analyzed. Results indicate the emerging boundaries by means of epistemological differences regarding "formal vs informal", "theoretical vs empirical", "analytical vs visual", "terms vs meaning" and "terms vs representations". In handling these, brokering, identification, coordination, reflection, transparency, and negotiability emerged.

Keywords: Mathematics teaching practice, visual arts teaching practice, interdisciplinary mathematics teacher collaboration, boundaries, boundary crossing.

Introduction

Recent research examines *arts integration* into other subjects and the benefits it provides in learning, such as supporting different learning styles (An & Tillman, 2014), enhancing motivation-emotions and constructing meaningful knowledge (Baird, 2015). Students of mathematics may also benefit from such an integration, by engaging in processes such as problem solving and modeling (Jacobs, 2000), supporting exploratory learning approaches through the process of creating art (von Renesse & Ecke, 2016), developing mathematical thinking and connecting classroom mathematics with students' personal experiences (Presmeg, 2009). After all, the connection between mathematics and art is not new and can be used in common curriculum content as well as in integrated curriculum, where teachers in both subjects are required to work together to reshape them (Bickley-Green, 1995). This interdisciplinary collaboration seems crucial, as teachers alone naturally do not have the knowledge needed to integrate art in their classroom. However, according to Akkerman and Bakker (2011), people collaborating across disciplines may face *boundaries* between different perspectives or practices. In response to these challenges, interest exists in how continuity in action or interaction is established despite of sociocultural differences. In describing potential forms of continuity across sites, *boundary crossing* and *boundary objects* seem central. According to Kisiel (2010), a successful collaboration "would rely on clarifying the potential boundaries between communities" and "on the introduction of appropriate boundary objects as well as the utilization of brokering to make fruitful connections" (p. 99). This inherent learning potential makes boundaries important to education fields, mathematics education included (Potari et al., 2019).

In mathematics education, interdisciplinary collaborations are often placed in a professional development context, with interactions between communities being studied in terms of boundaries and boundary crossing, often framed by Communities of Practice (CoP) (Wenger, 1998). For example, Psycharis and Potari (2017), by adopting an activity theory framework, use boundary crossing to study teachers' learning in relation to integrating workplace contexts into mathematics teaching; and Bouwma-Gearhart et al. (2014) focus on interdisciplinary collaboration between postsecondary STEM and education faculty, highlighting the critical roles of brokers. In our study, we focus on collaboration between mathematics teaching (MT) and art teaching (AT) communities of practice, via collaboration of teachers from these communities, as well as on boundaries and boundary crossing between the two practices. The research questions are: 1) What are the emerging boundaries between MT and AT communities of practice in regard to mathematical practices and tools? and 2) How are these boundaries handled by members in collaborative group discussions?

Theoretical perspectives

Arts integration, communities of practice, boundaries and boundary crossing

Burnaford et al. (2007) recognize arts integration as learning through/with the arts, a curricular connections process and collaborative engagement (pp. 11–12), citing aspects such as building links between learning in arts and in another subject area and professional development as a key element that defines it as an integration of people (p. 18). In addition, Silverstein and Layne (2010) define it as an approach to teaching where students construct understanding through an art form, engage in a creative process that connects the two fields and evolve in both. They consider that it can be used as incentive to enter the field being taught, as a tool for verifying existing knowledge or as equivalent to the other subject. This definition is embraced by our own conceptualization of mathematics and visual art integration. However, it implies a shift in daily teaching practice, something that is not easily achieved. It would seem, though, that it is the kind of engagement that the students will be drawn in that would be most crucial (e.g., problem solving, instead of coloring tiles in a worksheet).

Furthermore, the "integration of people" mentioned above implies the concept of community. On to this, Wenger (1998) describes CoP as groups of people who share a practice reflecting their mutual learning, being mutually engaged in a joint enterprise generating a shared repertoire, where negotiation of meaning is generated through participation and reification. Focusing on interactions between different communities, he is not the only one to talk about boundaries and boundary crossing. Boundaries are defined as "sociocultural differences leading to discontinuity in action or interaction", simultaneously suggesting "a sameness and discontinuity in the sense that within discontinuity two or more sites are relevant to one another in a particular way" (Akkerman & Bakker, 2011, p. 133). In relation to this, boundary crossing refers to a person's interactions across different sites (Suchman, 1994), facing the challenge of "negotiating and combining ingredients from different contexts to achieve hybrid situations" (Engeström et al., 1995, p. 319) in order to establish continuity across them (in Akkerman & Bakker 2011, p. 133). In this, people and objects that transcend boundaries are central: brokers introduce elements of one practice into another via creating connections, moving knowledge, exploring new territories (e.g., Wenger, 1998), and boundary objects enable multiple practices to negotiate relationships and connect perspectives, including artifacts (tools or documents), discourses (common language) and processes (shared routines or procedures) (Wenger, 1998).

Thus, although boundaries can be sources of misunderstanding, as moving across them means moving into unfamiliar contexts, so being unqualified (Suchman, 1994, as cited in Akkerman & Bakker 2011, p. 133), they can also be resources for learning, as moving across them also means engaging in dialogue and negotiating perspectives, through which new meaning and new possibilities may arise. In fact, Wenger (1998) suggests that communities must exceed their own boundaries so to preserve their dynamism and refers to three dimensions for boundary processes to create bridges that connect practices in deep ways: a) coordination (enabling coordinated actions, accommodation and standardization of practices so that everyone can engage in them); b) transparency (access to meanings and understandings of practices); and c) negotiability (negotiation of perspectives and multiple voices). Moreover, Akkerman and Bakker (2011) name four boundary-learning mechanisms: a) identification (recognizing what each practice is about and the boundaries that exist between them: how they do and do not relate to each other, how either differs from the other); b) coordination (ways that make transitions between practices smoother: a communicative connection, efforts of translation [with boundary objects serving as mediating artifacts], enhancement of boundary permeability and processes of standardization [organizing activity as smoothly as possible] and routinization [creating routines to rely on]); c) reflection (perspective making, i.e. defining the different perspectives that each practice brings or amplifying one's understanding and knowledge of a particular issue; and perspective taking, i.e. looking at one's own practice through the eyes of the other); and d) transformation (changes in practices or creation of an in-between practice [e.g., Wenger's "boundary practice", p. 114]: a confrontation with a situation, a recognition of a shared problem space, a hybridization and a crystallization of the new practices [Wenger's reification], maintenance of the characteristics of each practice and continuous work at the boundary).

Methodology

Situated in two Greek art-based schools (grades 7–12), the study initially adopted an ethnographic approach (Allan, 2017). R1 (first author) visited each school twice a week for a whole day for a period of 8 months and kept field notes from MT and AT classroom observations, audio-visual records of lessons and events and informal discussions with the teachers. In the next school year, 2 collaborative groups were formed, 1 at each school (2 mathematics teachers, 5 visual art teachers and R1 in each one (R2 [second author] was present in each of the first meetings). The meetings (sum of 17) were held in teachers' office once every two weeks and embedded in the daily school setting. In the first 10 the meetings, members engaged in a familiarization phase between the two communities. Special resources (visual-artistic artifacts, students' actions, common ground in curriculums, examples from teaching issues) were chosen by R1 as potential boundary objects and given for the group to negotiate upon. In the last 7 meetings, teachers were asked to co-design and co-implement integrated tasks in their classrooms and to reflect on what happened. Data included field notes, audio-visual records of the meetings as well as teachers' lesson plans and written reflection reports. In Choutou (2019), a more detailed view on the design of the study and R1's role as facilitator is provided.

In the analysis, grounded theory approach is used (Charmaz, 2014), identifying themes and categories in Atlas.ti. We are interested in the emerging boundaries (based on Akkerman's & Bakker's definition) in connecting MT and AT. Here, we draw on the data from the first ten meetings of one of the groups. We report the boundaries identified as epistemological differences or tensions that lead to discontinuity in action or interaction in regard to mathematical practices and tools, and the ways these are handled by members, tracing any action or interaction that relate to establishing continuity and characterizing them using terms related to boundary crossing.

Results

Boundaries between MT and AT communities

Several boundaries between MT and AT, in the form of epistemological differences between the two contexts, emerged, in relation to *mathematical practices* (including constructions, processes, procedures, ways of thinking and inquiring) and to *tools* (concerning language and artifacts [hands-on materials]). In Figure 1, we present the systemic network developed from the data analysis in relation to these emerging boundaries. Following, we discuss the categories and the subcategories offering examples from the data to illustrate them. MT1, MT2 stands for the two mathematics teachers and AT1, …, AT5 for the art teachers accordingly.

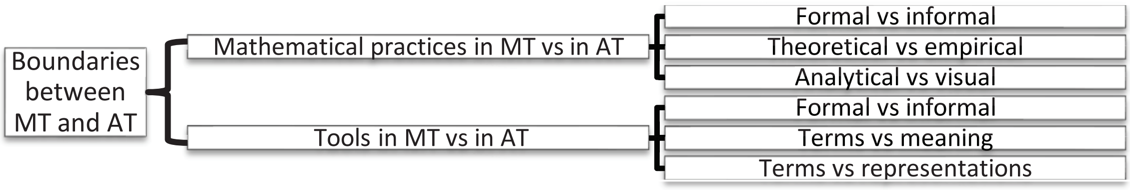

Figure 1: The systemic network describing the emerging boundaries between AT and MT

In regard to differences in *mathematical practices* a first difference concerns *formal (in MT) vs informal (in AT)* mathematical practices. For example, the following extract illustrates an artist's informal construction of a circle starting from a square:

R1: In the beginning he makes a square. And then he focuses on the middle of that distance and marks a little further inside. He does it in each of these points, he joins them as circularly as he can and so he gets a circle.
AT3: "A little further in" is not very mathematical… it can be visual-artistic (laughs) but it does not seem very mathematical to me (laughs).
R1: (laughs) It's a little over the mean… if you do it algebraically, a square root emerges. That's why it does not come out exactly in the middle.

A second difference concerns *theoretical (in MT) vs empirical (in AT)* mathematical practices. For example, towards the construction of the development of a solid in art, AT4 says: "it's not enough to construct a theoretical development. The development you'll make (e.g., out of cardboard) will probably have to have edges (left/glued around the sides of the development) so you can glue it all-closed-together." An interesting highlight here, is the non-existence of mathematical proof in AT as we know it in MT. More specifically, AT1 says that her interest lies in how she can support her students, so that they can learn mathematics more easily and without hating it, "because, theoretically, mathematics is the basis of everything. I cannot prove it, this is what science is for, but I really feel this", thus pointing to an empirical sense of feeling (vs proof) coming from her experience as an artist.

A third difference concerns *analytical (in MT) vs visual (in AT)* mathematical practices. For example, when inquiring about why the pentagon does not tessellate the plane, MT1 came up with the algebraic formula, whereas AT1 engaged in a visual inquiry in dividing the regular polygons into triangles in order to see what is happening with the angles. Ways of thinking in AT seem more visual in general:

AT1: Are there indeed two equal lines?
MT1: Mmm… it says… 10, 10. Yes, 10, 10.

AT1: So out of the 4, two are equal. And this helps (in making the tile tessellate the plane), I imagine… look. In the drawing (tile), here, this is equal to this, this is equal to this… and I imagine that this side is two times another side.

MT1: It's true! (enthusiastically).

AT1: You can see it with your eye.

MT1: YOU can see it with your eye...

AT1: Because, this is equal to this, so… this is true because, this side is equal to this, and this side here, I mean the one that lies next… is two times the first ones.

MT1: So they can complement the big one… hm...

AT1: Yes, because, the way this side is here, that's how these two should be here also. And then, the pattern can develop further. If it wasn't for this, the development of the pattern would not be feasible to develop...

In regard to differences in tools, a first difference concerns *formal (in MT) vs informal (in AT) tools*. These concern differences in *language*, as for example, mirror instead of axial symmetry and cookie instead of circle. Metaphorical descriptions are included, for example, directions and meetings of the lines (informal) instead of angles (formal), turning like a windmill, but at equal distances (informal) instead of rotation of equal degrees (formal). They also concern differences in *artifacts*, for example, rope and string or circular objects (informal) instead of compasses (formal) for making circles and "eye scaling" and measuring needle (informal) as means of comparison instead of ruler (formal), or even working only with their hands and drawing instinct. It must also be noted that hands-on materials "guide" the mathematical practices the artist will use (informal or empirical), as in the case of the construction of the development of a solid mentioned above.

Moreover, some of the concepts that appear both in AT and MT, such as positive-negative, rhythm, symmetry, small-big, shrinkage-enlargement, pattern, share the *same terms* but have *different meanings*. For example, the concept of pattern in AT, it seems to have the meaning of a single shape or a decoration instead of a sequence of shapes. In the next extract, R2 focuses on the pattern as a whole, whereas AT5 focuses on the shape that is repeated:

AT5: I am thinking of Minoan decorative rhythmic shapes that could be very useful in 10th grade. They can be made into friezes. And then move on to mandalas and what MTL was saying (fibonacci spiral) and end up in the costume (students' artwork).

AT3: Yes, because it's a repetition, it still has the (notion of) rhythm.

R2: Ok, that, in the sense of what we might say "pattern" in math.

AT5: A pattern and a blank space then a pattern and a blank space and so on.

In addition, the opposite relation emerged too, pointing to artifacts that share the *same meaning* in the two contexts, but appear with a *different term* in each. For example, during a discussion on the connections that teachers find between a grid resource for artwork and mathematics, MT1 says: "I see the Cartesian (coordinate) system, with squares. Like a millimeter sheet." Also, the concept of vanishing point (AT) (the point where two parallel lines seem to meet, in linear perspective), shares the same meaning in both contexts, but appears with a different term in MT, i.e., a point at infinity.

In addition, other concepts appearing with the *same term* have *different representations*. For example, AT2 reports for the stretching of a line in graphic design, that they have different thicknesses and sparsity, so when the artist chooses to do a line (in the program), he must choose the thickness he wants, thus, "… say I have scanned a line. The distortion starts and the line thins… because the pixels are removed. But the line doesn't have a second dimension, only one, so in theory this isn't possible!"

Handling of the emerging boundaries among group members

Results in regard to how boundaries were handled indicate several actions and interactions among members, including: identification processes (identifying other's way of thinking, recognizing own' disciplines features), perspective making (defining other's perspective in light of owns perspective), efforts of translation and explanations for coordination and transparency [translating and linking perspectives, translating terminology/perspectives in ones' own context, (AT) describing artifacts using formal language, translating informal/empirical/visual into formal/theoretical/analytical accordingly, explaining relative/according AT or MT content, proposing coordination of teaching, reducing teaching expectations/requirements, designing properly an activity], brokering (bringing mathematical knowledge), transparency (reasoning one's own context's practices) and negotiability (sharing an expert's perspectives on fixing students' negative feelings, counter-proposing own perspective). The following example from the data illustrates how a specific boundary was handled.

The group discussed on two students' construction of a ballerinas' tutu (a resource found in the ethnographic phase), where students made a circular ring out of cardboard and after cutting it (like a radius), crossed one edge over the other, forcing it to tilt (informal). According to AT1, "It was a very good job, but the mathematics teacher didn't interfere there at all. The mathematics used there is empirical. Clearly." However, MT2 disagrees, saying that what students did is mathematics indeed: "well, they've done mathematics so far. The fact that they want it to curve and the lines they made, it's still mathematics. It's fine, it's not bad." Here, AT1 stresses that the students had to construct a cone which would become the tutu, adding that "there is the form of truncated cone" (formal). At this point, AT2 comes to sooth things down by pointing out that using formal mathematics for this construction would be using stereometry (formal) for calculating the development of the shape and the dimensions of the tutu, thus proposing it as the solution: "We used to do stereometry at school…we took cardboard and they were teaching us how to cut it to make a cone, a pyramid. These are needed," adding that "the equivalent, if we collaborated, when I do this (tutu), you teach stereometry, even for 1 hour, so that we can have coordination, so students can see these important stuff," stressing the importance of having "an epistemological stance to coordinate our speeds." AT1 enthusiastically agrees and adds: "Well done, that's it! We (AT) go in (classroom) and show them: how to make a cube, how a cone is constructed. Basically, it's not exactly our stuff. We rely on it. But we introduce it. So, all I am saying is, I did not see this here, that's why I come a little like that. This is empirical." In addition to this, MT1 also identifies the matter of transfer from the empirical implementation of mathematics in AT (the tutu construction here) to the theoretical knowledge in MT, saying: "to start from what AT1 said about students liking to use geometric instruments, and see how far they can go from this to the most theoretical. That there are formulas, for how we calculate (and) construct, areas, triangles, taking advantage of the aim of this situation, this construction."

The tension described above seems to be generated by the difference between the formal (stereometry) and the informal practices of students. A trigger for it seems to be AT1's *brokering* ability to *bring and compare the formal mathematical practices* used in this construction with the existing formal "form of truncated cone". In negotiating with AT1, MT2 suggests the acceptance of the informal practices as "mathematics indeed" (negotiability), and the boundary is, finally, handled through AT2's suggestion of *coordination* of the respective teaching sides, for *linking the two for* *boosting students' learning*. AT2, here, acts as a *broker* between the two communities, bringing and naming formal mathematical knowledge of stereometry from MT community to the AT community and relating it to the according informal practices the students used. Side with AT2 lies MT1, who propose linking the empirical implementation of mathematics and the theoretical mathematical knowledge for achieving better results in respect to students' learning. It is evident that, here, the *coordination* mechanism/dimension between the two sides plays a central role, as being proposed to being the solution itself for bridging the formal-informal and theoretical-empirical gap.

Discussion

In this paper, we focus on the emerging boundaries between AT and MT communities and the ways these are handled among members in respect to boundary crossing. First, taking under consideration Akkerman's and Bakker's (2011) definition of boundaries, we focused on emerging epistemological differences between the two contexts in regard to mathematical practices and tools. Mathematical practices emerge as formal/theoretical/analytical in MT and informal/empirical/visual in AT accordingly. Tools in relation to language and artifacts bring to the fore different terms, representations and meanings of concepts and practices. For example, formal in MT and corresponding informal language in AT, as well as formal mathematical tools compared to informal in AT and tools with same meaning but different terms, describe ways in which MT and AT differ from one another. All these differences create forks between MT and AT, leaving "blanks" in member's actions and interactions and nevertheless, juxtaposition the two, suggesting that "within discontinuity (the) two…sites are relevant to one another in a particular way" (Akkerman & Bakker 2011, p. 133), implying a set of relationships between learning in art and learning in mathematics (Burnaford et al., 2007), thus giving meaning in an effort of crossing them. Secondly, for locating how boundaries are handled, we used terms related to boundary crossing. Here, brokering (bringing M knowledge) and coordination (e.g., linking theoretical and empirical ways of thinking), seem to be crucial, along with transparency and identification, as well as reflection and negotiability (Wenger, 1998; Akkerman & Bakker, 2011). Overall, our findings seem to indicate aspects of mathematics and their teaching, highlighting this teaching as something that is being or can be done, not only in the mathematics classroom but also in non-mathematical settings, and describing the nature of mathematical practices taught and tools used in either of them. Through their inevitable comparison, the co-existence of the two poles of the boundaries links these aspects and a more complete "image" of mathematics and teaching mathematics is provided. Their interplay is commented by members to be beneficial for mathematics teaching and students learning. Thus, the feasibility of building bridges to connect MT and AT communities and create learning potentials for both teachers and students is suggested. Future research will focus on the negotiation among members towards the integration of the MT and AT and the potential creation of a hybrid, art and mathematics integrated practice.

How do teachers share and develop student ideas?

Ove Gunnar Drageset[1] and Thomas F. Eidissen[1]

[1]UiT – The Arctic University of Norway, Norway; ove.drageset@uit.no; thomas.f.eidissen@uit.no

This article aims to try out a framework describing teacher positions based on an analysis of their interactions, and through this, gather ideas for further development of the framework. This article uses shared data from TWG 19, with data from five classrooms. These were analyzed by categorizing interaction from transcripts of the data. The analysis focuses mainly on the interactions related to one position: A teacher that shares and develops student ideas. The findings illustrate how this framework can characterize and contrast these five classrooms.

Keywords: Positioning theory, interactions.

Introduction

In all social settings, including classroom discourse, the participants position themselves and each other based on personal preferences and social interactions. In the classroom context, a teacher typically will position students continually, and this positioning can be seen by the type of questions asked, the types of tasks given, and who the teacher groups together (Harré & Langenhove 1999). This study aims to use the shared data in TWG19 to try out a framework describing five teacher positions: A teacher that knows and tells, a teacher that supports, a teacher that shares and develops student ideas, a teacher that participates, and a teacher that facilitates (Drageset, 2021). The results of this will be used as a base for further developing the framework. We will particularly study the third position with this research question: How can a study of how teachers enacted the third position, *a teacher that shares and develops student ideas*, be used to characterize and contrast different mathematics classrooms?

Theory

It is well established that in a discourse, a turn is thoroughly dependent on previous turns (Linell, 1998). Consequently, it is possible to argue that student interactions are affected by the teacher, and this is particularly true when the teacher speaks every second time as in the Initiation-Response-Evaluation (IRE) pattern. However, there is more to communication than responding to the prior turn. Other factors are in play, such as when a teacher asks a question, students might know what is accepted as an answer and not. This is not only related to the content of the prior turn (the teacher question) but might also be related to established classroom norms. Such norms are described by Yackel and Cobb (1996) as socio-mathematical norms. These are developed over time in all classrooms, whether worked on deliberately or not. Another factor that affects communication is related to positions in the classroom. When joining a social setting, one might have dispositions that guide one's preferences for positions, such as trying to keep silent because of insecurity or a feeling of safety and curiosity in mathematics, making you an active participant. On the social level, such positioning is a reciprocal, sometimes competitive, process where you do not choose a position freely but might be positioned by others' positions or actions, and your positioning affects others (Harré & Langenhove 1999). In the classroom context, a teacher typically will position students continually based on the teacher's beliefs about the competency and personality of the student (Harré &

Langenhove 1999). Also, this positioning of others, being by the teachers or fellow students, might be intentional or not. However, it is not just the teacher that positions students. It is more plausible that positioning is a form of negotiation, such as in socio-mathematic norms. One basic example could be when a teacher presents a rule to be used, and the student wants to know why. This can be seen as the student trying to position the teacher as something other than a teller of methods. Moreover, Drageset (2021), in a study of how explanations are initiated and responded to, has found that teacher interactions are far less dependent on the prior turn than student interactions. This illustrates how teacher typically has other agendas than responding to prior turns, and positioning might be a tool to describe the difference between how teachers and students contribute to classroom talk.

According to both Harré and Langenhove (1999) and Wagner and Herbel-Eisenmann (2010), positioning can be observed through a study of interactions. This means that one way to explore and describe different positions in a classroom is to study what each participant says. A framework that is being developed from a review of literature on classroom discourse in mathematics suggests five broad teacher positions (Drageset, 2021). The first position is a teacher that knows and tells. A teacher that knows and tells takes a position as somebody who knows something and has the authority to decide and evaluate. This position can be further detailed into three ways of telling: telling as initiation (such as teacher as initiator by Lobato et al., 2005), telling what or how to do (such as teacher explanation by Henning et al., 2012), and telling about connections (such as connections by Rowland et al., 2005). The second position is a teacher that supports. A teacher that supports helps students in their work to reach answers and develop their mathematical understanding. Also, this position can be further detailed into three ways of supporting: supporting by reducing the complexity (such as simplification by Drageset, 2014), supporting by assessing (such as confirmation by Henning et al., 2012), and supporting by progressing student thinking (such as probing guidance by Warshauer, 2014). The third position is a teacher that shares and develops student ideas. Such a teacher position focuses on student thinking as the source for discussions and learning. This position is based on a large number of concepts from the literature and can be further detailed into three parts. First, the position is based on the teacher accessing and sharing student thinking (such as eliciting student thinking by Fraivillig et al., 1999). When ideas are accessed and shared, the teacher might point out what is important in different ways (such as clarifying statements by Conner, 2014) or using student thinking as the core of the discourse (such as by encouraging reflection by Cengiz et al., 2011). Such use of student thinking has been described as uptake by Correnti et al. (2015). The fourth position is a teacher that participates. When a teacher participates, the teacher works together with students to find solutions or understand new concepts. This might be done in two ways, either by being a real collaborator in an inquiry where the teacher does not know the answer (such as in a landscape of investigation by Skovsmose, 2001) or by playing a role (such as in teacher in role, by Drageset et al. 2021). The fifth position is a teacher that facilitates. When taking this position, the teacher facilitates the discourse and mathematical work without engaging in the content. This can be further detailed into three ways of teacher facilitating: facilitating by orchestrating the discourse (such as guiding participation and norms by Drageset, 2019), facilitating the development of ideas (such as turn-and-talk by Kazemi et al., 2014), facilitating a focus on peer thinking (such as requesting evaluation by Conner et al., 2014).

Table 1: Five positions and further detailing (first row) and characterization of each (second row)

A teacher that knows and tells…	A teacher that supports…	A teacher that shares and develops student ideas…	A teacher that participates…	A teacher that facilitates…
… as initiation … what to do … about connections	… by reducing complexity … by assessing … by progressing student thinking	… by accessing and sharing … by pointing out … by using student thinking (uptake)	… as a real collaboration … as a teacher in role	… by orchestrating the discourse … by developing ideas … focus on peer thinking

Some teachers may maintain one position most of the time, while other teachers might change position frequently, deliberately or not. It is also probable that the students sometimes are willing to take positions aligned to the teacher positions, and at other times not. If the teacher takes the position as *a teacher that knows and tells*, this only works if the students align themselves by taking a position of *listeners*. Accordingly, a teacher can only facilitate the discourse without engaging in the content if the students are willing to take positions as active participants by asking questions, explain, evaluate, and argue. This negotiation can also be seen as part of developing classroom norms, where different teacher positions are accepted and aligned student positions are accepted.

Method

This article reports from a study of shared data within TWG19 for the CERME12 conference. Different participants of the thematic working group shared five videos from different classrooms. This is done so that the participants can achieve a deeper understanding of each other's analysis and frameworks when not only the results but also the data is shared. The article is also connected to the SUM project that aims to develop teachers' capacity to teach through inquiry-based learning.

We use a framework describing five teacher positions (Drageset, 2021) to explore characteristics and contrasts between the five classrooms, aiming at trying out and further develop the framework. The analysis is based on a turn-by-turn analysis, categorizing all teacher interactions related to the five positions and their further detailing (see table 1). Then we chose to explore the most frequently used position further (a teacher that shares and develops student ideas). We then used the characterizations from table 1 as categories (access and share, pointing out, using student thinking) and categorized all teacher interactions in this position. We discovered a need for a new category through the data analysis, which we named *requesting mere answers*.

The data from each classroom is too limited to say much about the classrooms. However, this type of data from different classrooms is valuable because one can try out how a framework might be useful to characterize different practices and use this for further development of the framework. This result also illustrates different ways teacher positions themselves during mathematical classroom discourse, which may be a foundation for conducting larger studies.

Findings

Table 2: Overview of the frequency of positions taken in each classroom (empty means zero)

	Classroom 1 Drageset 1 (King's birthday)	Classroom 2 Drageset 2 (whiteboards)	Classroom 3 Hoover	Classroom 4 Sakonidis	Classroom 5 Santos
A teacher that knows and tells	7 (16%)	27 (31%)		11 (34%)	21 (22%)
A teacher that supports	10 (22%)	9 (10%)			
A teacher that shares and develops student ideas	17 (38%)	42 (47%)	2 (15%)	18 (56%)	62 (67%)
A teacher that participates					
A teacher that facilitates	11 (24%)	11 (13%)	11 (85%)	3 (9%)	10 (11%)

When looking at table 2, we can see a considerable difference between the classrooms. However, the data from the classrooms vary in length and type of interaction to such a degree that it is not possible to use table 2 as a basis for comparison. But as Table 2 illustrates, the most frequent teacher position in these five classrooms is to *share and develop student ideas*. Since this position is most frequent in total and in four of the five classrooms, we will look more into how the interactions of this position look like and what these can tell us about classroom characteristics.

According to Drageset (2021), the teacher position of *share and develop student ideas* can be characterized by three types of teacher interactions: access and share, pointing out, and using student thinking (uptake). During the analysis, we discovered that these could not characterize all teacher interactions, and therefore, we added a new type: requesting mere answers. With these four types, we were able to categorize all teacher interactions related to this position.

Table 3: Frequency of each type of interaction within the teacher position of *sharing and developing student ideas* (empty means zero)

	Classroom 1 Drageset 1 (King's birthday)	Classroom 2 Drageset 2 (whiteboards)	Classroom 3 Hoover	Classroom 4 Sakonidis	Classroom 5 Santos
Access and share	7 (16%)	28 (31%)	2 (15%)	3 (9%)	12 (13%)
Pointing out	7 (16%)	8 (9%)			1 (11%)

Requesting mere answers		5 (6%)		14 (44%)	40 (43%)
Using student thinking (uptake)	3 (6%)	1 (1%)		1 (3%)	

As seen in Table 3, the first type of interaction, *access and share*, is the only interaction found in all the classrooms. Drageset's second classroom (whiteboards) is the classroom that uses this interaction most frequently, while the data from Hoover's classroom only have two interactions related to this position. Otherwise, we see a common pattern in these classrooms. To access student ideas, they all ask how, what, and why. Examples include "*How did you think?*", *"What do you mean?"* or simply "*why?"*. Typically, when asking what and how the teachers request a chronological explanation of how an answer was reached or what to do to reach an answer. When asking why, they request a reason or argument for why one should use this method or why an answer should be seen as correct. These three types of questions (how, what, why) are about what Fraivillig (1999) labels eliciting student thinking. When doing this in plenary talk, it is also about sharing student ideas with their peers. This can be seen as the foundation of the position of sharing and developing student ideas, as accessing is about sharing, and sharing is needed to develop the student ideas further, particularly to include other students in the development of the ideas.

The second type, *pointing out*, was found in three of the five classrooms. There was little difference in the frequency of the use between the classrooms, but we found two quite different ways of pointing out. Most frequently, the teachers used this position to revoice parts or all of what the students had said. There were two different applications of revoicing, either simply revoicing the student's point or revoicing while adding additional information. One example of simply revoicing is, "*Okay. So you used the fact that you know twenty present is one-fifth.".* The other way of pointing out was when the teachers summarized students' explanations. We saw this most frequently in Drageset's first classroom (King's birthday), where the teacher frequently gave a thorough summary of how a student had solved a given task, based on the student's explanation. One of these summaries is this one:

Teacher: First, she wanted to go to the year 2000 first, and then go from 2000 to the year the King was born. Right? So you started with 80 minus 17, and got 63. She removed 17 from 80. Then you got 63. Then she wanted to find what 2000, from here, and jumping 63 years backward from the year 2000. That's how she thought. So you tried to do 2000 minus 63, but this is a really difficult equation, to do it like this. Because... You haven't really learned this, with such large numbers. Did you manage to finish it, too?

This way of pointing out still focuses on the student's ideas, but the teacher takes an active role in repeating and emphasizing the student's solution, possibly also modeling how to explain.

The third type, *requesting mere answers*, is the most used interaction in this position, but we only found it in three of the five classrooms. There are mainly three ways the teachers requested mere answers. One way whereby asking yes and no questions, such as *"Did you agree that this was the best way?".* Often we recognized these types by how the students answered the given question. As we mentioned earlier, the student's response to the teacher's questions seems to be based on what their experience tells them is an acceptable answer for that type of question, in what looks to be an example of socio-mathematical norms (Yackel & Cobb, 1996). An interesting variant of these yes and no questions were questions that, in reality, were yes-questions (the correct answer was obviously yes) and no-questions (the correct answer was obviously no). A second way of requesting mere answers was by requesting answers to tasks, where the answers typically were a number, such as *"and here, how many do I need for a whole pizza?"*. A third way of requesting mere answers was to ask for the meaning, such as *"What did percentage mean then Ole?"*, which we only saw in Drageset's second classroom (whiteboard). Since we only saw this at the beginning of the lesson, it seemed that the teacher wanted to get the students thinking about the subject they were going to focus on in that lesson.

The fourth type, *using student thinking (uptake)*, was not observed in these classrooms. However, in Hoover's classroom, the teacher did use student thinking in a comparable way but without interfering in the mathematical content. Consequently, these interactions were seen as part of the position called *a teacher that facilitates* and the code *focus on peer thinking*.

Discussion and conclusion

This part will discuss what the findings related to the position of *sharing and developing student ideas* mean for each classroom and use this to characterize and contrast the classrooms. According to Harré and Langenhove (1999), teachers position students continually, so we will also comment on how the teachers' choice of positions might position the students.

Classroom 1: Drageset 1 (King's birthday)

In this classroom, we see that 38% of the teacher's interactions belong to the position of *sharing and developing student ideas*, primarily by *accessing and sharing*, and *pointing out*. This teacher was the one with the most thorough summaries of student's solutions when pointing out. This shows a teacher focused on getting access to and sharing the students' ideas and then gathering any loose ends into a coherent whole. This can position the students as owners of ideas while the teacher maintains the authority to define and model the solutions.

Classroom 2: Drageset 2 (Whiteboard)

In this classroom, 47% of the teacher's interactions belong to the position of *sharing and developing student ideas*, primarily be *accessing and sharing*, where the teacher's goal seems to be to share several different student ideas and methods. This teacher rarely summarizes the student's ideas but instead lets the students' answers stand on their own. This means that the students also here are positioned as owners of ideas, but without the teacher using the authority to point out a more precise or correct solution.

Classroom 3: Hoover

In this classroom, the teacher mainly takes the position of *facilitating*, but only twice the position of *sharing and developing* (see table 2), which is not enough to analyze related to the latter position.

Classroom 4: Sakonidis

56% of this teacher's interactions belong to the position of *sharing and developing student ideas*, primarily by *requesting mere answers* and occasionally *accessing and sharing*. This means that the teacher focuses on sharing answers and quite rarely on sharing solutions. This teacher positions students as task solvers and the teacher continually uses the authority to confirm or reject the answers.

Classroom 5: Santos

In this classroom, 67% of the teacher's interactions belong to the position of *sharing and developing student ideas*, primarily by *requesting mere answers*. However, this teacher also uses *access and share* as well as *pointing out* to a certain extent. This means that the teacher positions the students as task solvers and occasionally as the owner of ideas. At the same time, the teacher continually uses the authority to confirm and reject answers.

Conclusion

As illustrated above, the teacher position of *sharing and developing student ideas* is the most frequent one in this data set. However, while four of the five teaches use this position frequently, there are clear differences. One is most focused on sharing student solution methods and let them be the end product. Another is also focused on sharing solution methods but also refine them through long summaries. Furthermore, two others seem most focused on sharing answers and using their authority to confirm or reject them. This work illustrated how a study of the position of a teac*her that shares and develops student ideas* can be used to characterize and contrast different classroom practices, which indicates that this framework might be used for studies of larger datasets. This work has also revealed that the three original types of teacher interactions suggested by Drageset (2021) were not sufficient to characterize all teacher interactions related to the position of a teac*her that shares and develops student ideas*. By adding one new type, requesting mere answers, we were able to categorize all teacher interactions related to this position.

Dilemmas of teaching arithmetical notation to young learners

Fraser Gobede[1] and Reidar Mosvold[2]

[1]University of Malawi, Zomba, Malawi; fgobede@unima.ac.mw

[2] University of Stavanger, Stavanger, Norway; reidar.mosvold@uis.no

This study takes the analysis of a Malawian Grade 1 teacher's mediation of mathematics as a starting point for discussing dilemmas that might be entailed in the teaching of arithmetical notation to young learners. Two exemplar episodes are selected from six video-recorded lessons that were analysed using the Mediating Primary Mathematics Framework. The teacher introduced the writing of numbers and mathematical symbols with their corresponding hand movements and used these movements as the criteria for enabling learners to assess the correctness of their written inscriptions. Two inherent dilemmas of this complex work of teaching are identified and discussed.

Keywords: Early years, mediation, gesture, inscriptions, interactions.

Introduction and theoretical background

It has recently been suggested to distinguish between considering teaching as something teachers do and as work to be done. The latter corresponds with Ball's (1993) investigation of dilemmas that arise in mathematics teaching and the more recent conceptualization of the special work of teaching mathematics (Ball, 2017). Our study further explores this distinction. As a case, we use the introduction of elementary mathematical notation in a Malawian Grade 1 classroom.

When learners are introduced to new mathematical concepts and notation during the early years of primary school, they often make errors. The teacher's reaction to a learner's error made during whole-class activities has implications for the individual learner and the whole class (Bass & Mosvold, 2019). For instance, when a learner has made a writing error, the teacher may just compare the wrong inscription or notation made by the learner with the correct one presented on a chart or workbook. However, as observed by Venkat and Askew (2018), young learners may not have yet developed the mental faculties for distinguishing features of seemingly related representations and may require appropriate teacher's mediating talk and gesture to make these features apparent.

Handling learner errors is complex (Sapire et al., 2016). For persistent errors and misconceptions, learners may need to be equipped with strategies for checking the correctness of their work even in the absence of the teacher. One possible strategy is to embody some mathematical concepts and processes that learners often find difficult to remember. The embodiment of mathematical concepts enables learners to view the subject as an activity involving physical actions and gestures (Edwards et al., 2014). This makes the association of mathematical concepts and processes with their corresponding physical actions essential, especially to young and inexperienced learners, who are just being inducted into school mathematics. Eventually, the teacher is supposed to help the learners progress from the embodied physical representations to their corresponding abstract mental structures (Venkat & Askew, 2018). If the teacher sticks to the physical representations, the learners may no longer see the need to look for mental conceptual structures to make some necessary connections and generalisations (Askew, 2019; Wilson, 2002). This implies that teaching can either enhance or constrain what is made available to learn in a lesson—thus constituting numerous dilemmas. In this paper, we share the same understanding of a dilemma as Ball (1993) to mean paradoxical situations where the teacher has several alternative choices to make, each having varied consequences, and oftentimes the decision is required instantly.

Drawing on these insights from research on early mediation of mathematics, and on the perspective of considering the teaching of mathematics as work to be done, we ask:

What dilemmas can be entailed in the work of teaching mathematical notation to young learners?

To answer this question, we first apply the Mediating Primary Mathematics (MPM) framework by Venkat and Askew (2018) in the analysis of data to enable careful description of the mediating work that is performed by the teacher, before we discuss dilemmas entailed in this work. Like Bass and Mosvold (2019), we focus only on a small slice of the work of teaching mathematics here, namely what may be involved in attending to learners' errors.

Analytic framework

The MPM framework is guided by Vygotsky's sociocultural view of teaching as a set of mediated transactions, with the teacher as the main mediating agent in the classroom—who works with a set of sociocultural tools of mediation (Kozulin, 2003). We adopted the MPM framework to understand the sociocultural tools for mediating mathematics in the early years of primary school. The MPM framework identifies four strands or means of mediating primary mathematics, namely: Tasks and examples, artefacts, inscriptions, talk and gesture. The framework further subdivides talk and gesture into three sub-strands: Talk and gesture for generating solutions to problems, talk and gesture for making mathematical connections, as well as talk and gesture for building learning connections. Even though the teacher works with all the four means of mediation when teaching, we were particularly interested in the teacher's mediating talk and gesture for building learning connections (see Table 1). As shown in Table 1, teachers' mediating talk for building learning connections is manifested when handling errors from learners' offers. Venkat and Askew (2018) observed that learners' errors provide a context for richer mediation as teachers are prompted to make "responsive moves" to address the errors. In some cases, the learners' errors provide an ideal moment (or "teachable moment") where they could be more receptive to the teacher's remedial actions than if the error was just ignored or the teacher's response was deferred to a later time (Muir, 2008).

Research design and methodology

A qualitative case study design was adopted, which enabled an in-depth inquiry into the complex task of teaching mathematics to young children. Our case is a Grade 1 teacher with an overall teaching experience of seven and half years after graduating from a two-year teacher training programme. The teacher had been teaching mathematics to different cohorts of Grade 1 learners for four consecutive years. The teacher was selected as a paradigmatic case (Flyvbjerg, 2006), exemplifying outstanding learner achievement in resource-limited settings. The school consistently outperformed other primary schools in the same geographical area both during the standardised end of primary school examinations as well as during quiz competitions with nearby schools. The school was based in a remote village where learners mostly relied on the teacher as the sole source of mathematical instruction, as learners had limited access to extra tuition through books, parents and relatives, or educational television programs. The rural setting increased the possibility of attributing the school's exemplary learner achievement to the classroom practices of its teachers.

Data collection was scheduled for the week when the teacher was introducing the addition of whole numbers to the Grade 1 learners. This was done across six lessons that were observed and video recorded. Unstructured interviews were conducted at the end of each lesson to seek clarification on some observations made in the classroom. An in-depth video-stimulated recall interview was conducted with the teacher after a preliminary analysis of the lesson transcripts. Interview data were analysed thematically. Themes were centred around the reasons for the teacher's choices made in the use of the means of mediation observed during the lesson. Analysis of the affordances that were made possible through the teacher's presentation of the chalkboard inscriptions was done through the application of variation theory (Kullberg et al., 2017), which is one of the theoretical foundations of the MPM framework.

The recorded videos were segmented into instructional episodes that are considered as a unit of analysis in the MPM framework. Even though this paper reports on the observations that were made while the teacher was working with written inscriptions, the analytical focus was on the teacher's mediating talk and gesture for building learning connections that accompanied the inscriptions in each episode. We referred to the indicators for mediating talk and gesture for building learning connections provided by the MPM framework, as shown in Table 1 that follows:

Table 1: Mediating talk and gesture for building learning connections. Adapted from Venkat and Askew (2018, p. 90)

Indicators for mediating talk and gesture for building learning connections	Level
Pull back to naïve methods OR No evaluation of offers (correct or incorrect).	0
Accepts/evaluates offers Accepts learner strategies or offers a strategy OR Notes or questions incorrect offer.	1
Advances or verifies offers. Builds on, acknowledges or offers a more sophisticated strategy OR Addresses errors/misconceptions through some elaboration e.g., "can it be….?" Would this be correct, or this? Non-example offers.	2
Advances and explains offers. Explains strategic choices for efficiency moves OR provides rationales in response to learner offers related to common misconceptions OR Provides rationale in anticipation of a common misconception.	3

As indicated in Table 1, analysis of the teacher's mediating talk for building learning connections examines the extent to which a teacher handles the evaluation of learners' offers in a lesson episode. A learner's offer could be a correct or an incorrect response to the teacher's question or a strategy for solving a problem. In some cases, the teacher may verify an offer or build on it in response to "teachable moments" (Muir, 2008). Ultimately, the teacher may make a "responsive move" (Venkat

& Askew, 2018) or an “asset oriented response” (Bass & Mosvold, 2019) in the form of explaining strategic choices made or providing the rationale for each option while taking into account the common misconceptions.

Findings and discussion

During the study, the teacher was introducing the addition of two whole numbers with a sum not exceeding 5. By this time, the learners had been in Grade 1 for ten weeks, and the teacher had taught them how to write the numbers 0 to 5. In the Malawi context, about 60 per cent of learners do not attend pre-school education before starting Grade 1 (Robertson et al., 2017), hence the preceding ten weeks were their first school experience in life. During classwork, the teacher asked learners to write the worked-out solutions on pre-written papers and the chalkboard, thereby opening up more opportunities for making “responsive moves” (Venkat & Askew, 2018) to the “teachable moments” (Muir, 2008) made possible through the writing errors made by the learners.

Verbalisation of hand movements when working with the plus sign

The teacher introduced the writing of the plus (+) sign during the first lesson of the study by demonstrating how to write the sign in the air while verbalising the hand movements as “Dot! Down! Cut-in-the-middle!” She then asked the learners to do the same:

Teacher: Aa-aah! We have not yet started writing! Just raise your hand and get ready to write *[inaudible]*, alright? Everybody use your right hand! Begin!
Class and Teacher: *[Verbalise the movement of the hand while tracing the + sign in the air]* Dot! Down! Cut-in-the-middle!
Teacher: Again!
Class: *[Verbalise the movement of the hand while tracing the + sign in the air]* Dot! Down! Cut-in-the-middle!
Teacher: Again!
Class: *[Verbalise the movement of the hand while tracing the + sign in the air]* Dot! Down! Cut-in-the-middle!

After teaching the hand-movement for the plus sign, the teacher asked learners to suggest the hand movement for the equal sign. The hand movements verbalised by the teacher acted as the basis for the justification of the correctness or incorrectness of the notations made by the learners during the subsequent lessons. For instance, when reviewing how to write the plus sign in the introduction of the fourth lesson in the study, one learner wrote a plus sign that was not accepted by the class (see part (a) of Figure 1). The learner required a convincing explanation on why the written sign was rejected by the class. The teacher reasoned with the learner the original hand movement that was verbalised when the plus sign was introduced for the first time; that is, “Dot! Down! Cut-in-the-middle!” To remediate the error, the teacher asked a second learner to write the plus sign, but this time making sure that the downward stroke of the line making the + sign is cut in the middle by the horizontal stroke. The explanation of the hand movement clarified the contrasting feature of the sign offered by the first learner and the expected sign. After a second learner had written the correct sign, the teacher asked a third learner to re-write the correct notation for the plus sign (Figure 1, part b).

 (a) Rejected + sign.	 (b) Two accepted + signs.

Figure 1: Correction of an incorrectly written plus sign

The teacher used the verbalised hand movements as the rationale for either rejecting or justifying the offers provided by the three learners. We coded this as the highest level of the MPM framework's mediating talk and gesture for building learning connections (see Table 1) – where a teacher "provides rationales in response to learner offers related to common misconceptions."

The teacher's approach to verbalize hand movements when introducing new inscriptions was not only done for the plus sign. In the interview excerpt that follows, the teacher explained that even when teaching her learners to write numerals before the observed lessons, the same strategy of verbalising hand movements was used:

214	Teacher:	How to write? We have several ways. Aah, first, we start to write in the air.
215	Researcher:	Okay?
216	Teacher:	If you had come when I was teaching numbers you could see that. Because when we say: "Let's write four!" We say: "Dot! Then down! Then right! Then…." Those things. We first start in the air, then after in the air, it's when we go on the ground, before they write in the exercise book.

In the interview excerpt above, the teacher referred to an example of how she introduced the writing of the number 4 based on learners' aptitude. We notice towards the end of Utterance 216 that the teacher must decide when it is appropriate to present the notation as verbal, gestural, written, or any combination of these forms, without losing the mathematical meaning of the notation―thus constituting a dilemma to the teacher.

Using verbalised hand movements when remediating errors related to the writing of 4

The teacher demonstrated the third level of the MPM framework's mediating talk and gesture for building learning connections (Table 1) when responding to learners' errors related to the writing of 4 during the fifth observed lesson. The teacher gave strategic explanations targeting the main source of the observed errors. In that lesson, learners were given pre-written problems on pieces of paper and were asked to find the sum in their groups. The worked-out solutions were then pasted on the chalkboard. One group wrote the answer on their paper as shown in Figure 2.

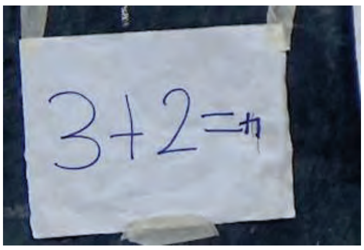

Figure 2: A wrong answer that was written as flipped 4

The representative of the group that was assigned the task shown in Figure 2 read the statement as "three plus two answer four". Rather than quickly dismissing the answer by looking at the expected sum of the given addends 3 and 2, the teacher approached the remediation in phases. Firstly, the teacher asked the class if 4 was supposed to be written as shown in Figure 2, and the class was divided. This posed another dilemma to the teacher—whether to quickly dismiss the incorrectly written numeral and work out the correct sum with the class or consider this as the right moment for remediating the inscription error first, even though the lesson's focus was on the addition of numbers.

The teacher started with remediating the writing error in Figure 2 by asking another learner to write 4 on the chalkboard (see part (a) of Figure 3) and asked the class if the 4 was written correctly. Instead of applying common logic or sentimentality, the teacher reminded the class of the verbalised hand movements for writing 4 ("Dot! Down! Turn-right! Cut-in-the-middle!") while moving a pointing stick. Thus, the teacher used the verbalised hand movement as the basis for justifying the correctness of the 4 offered by the group. The teacher repeated the verbalisation of the hand movement while writing another 4 above the one written by the learner as shown in part (b) of Figure 3.

		(a) A correct 4 written by a learner.	(b) Another correct 4 written by the teacher above the one written in part (a) by a learner.	(c) An incorrect 4 written by the teacher alongside the two correct 4s in (b).

Figure 3: Remediating errors related to the writing of 4 using similarity and contrast

The teacher employed similarity to emphasize the correct way of writing 4 (Figure 3, b), and she continued the discussion by providing a plausible contrast of an incorrectly written 4 alongside the two correctly written 4s (Figure 3, c). The teacher wrote the wrong "4" while simultaneously verbalising its hand movement as: "Dot! Down! Turn-left! Cut-in-the-middle". Rather than providing the contrast by rewriting the disoriented 4 shown in Figure 2, the teacher probably noted from the learners' inscriptions that the common error was the horizontal direction of the hand. After remediating the inscription error of 4 in Figure 2, the teacher then prompted the class to check if 4 was the correct answer to 3 + 2 as initially proposed by the assigned group. After working out the expected sum for 3 + 2, the next group of learners had been assigned to find 1 + 3 and wrote their answer (Figure 4, a).

	(a) Distorted 4 written by learners.	(b) Teacher's emulation of the error.

Figure 4: A distorted 4 written by one group and emulated by the teacher

The teacher used her technique of verbalising hand movements to check if the 4 shown in Figure 4 was correctly written. The teacher expressed the hand movement "Dot! Down! Go-up! Cut-in-the-middle!" while simultaneously writing the movements on the chalkboard (Figure 4, b). Next, the teacher isolated the feature that made the just written 4 incorrect, that is, the expected angular turn in the acceptable hand movement. This was verbalised by the teacher with an emphasis on the turn as "Dot! Down! Turn-right!" while simultaneously writing the hand movements on the chalkboard.

Concluding discussion

The findings indicate how the teacher worked with the MPM framework's mediating talk and gesture for building learning connections (shown in Table 1) related to the writing of arithmetic notations. After receiving an offer from the learners, the teacher first checked with the whole class whether the offer was correct or not. When the error was not apparent, the class was not sure if the offered notation was correct. By providing the rationales (verbalised hand movements) for justifying the learners' offers, the teacher achieved the highest level of the MPM framework's mediating talk and gesture for building learning connections (Venkat & Askew, 2018). Whereas the findings highlight remediation of notations written on the chalkboard, the teacher explained in an interview that the remediation starts with writing in the air, followed by writing on the ground, before using notebooks.

Analysis of data from this Malawian classroom illustrates two common dilemmas entailed in the work of teaching early mathematics. The first dilemma relates to deciding on how to establish correct mathematical notation in a way that is suitable for the learners' age and development (Ball, 1993), while at the same time maintaining mathematical integrity. In the episode analysed, the teacher used similarity and contrast (cf. Kullberg et al., 2017) to help learners identify key characteristics of correct mathematical notation, and she also used verbalised hand movement. Still, there is a risk of confusing learners about the underlying mathematical idea in the process. Instead of just telling learners if the offered inscriptions were correct, the teacher in this study attempted to justify the acceptance or rejections. This may provide the learners with an opportunity to learn about the importance of justification in mathematics. However, young learners may lack the necessary understanding on which the teacher can base justifications for actions taken during lessons (Venkat & Askew, 2018), and this provides a risk that the teacher must attend to. In this episode, the teacher used gestures to justify the correctness of the written arithmetic notations. This use of bodily based resources such as hands and fingers can make the learners feel competent to work out mathematical tasks anywhere anytime (Wilson, 2002).

A second dilemma relates to identifying and interpreting student errors on the fly and deciding on what errors to attend to first when several errors are present (Muir, 2008). The reasoning that is required for probing learners' errors on the fly tends to be one of the highest and complex forms of teacher knowledge (Sapire et al., 2016). In the second episode of the lesson, a learner presented an incorrectly written 4 as the sum of 3 + 2. The teacher then had to decide on whether to attend to the error, or to use other pedagogic moves that do not attend directly to the errors—like assigning competence to learners and positioning them as contributors (Bass & Mosvold, 2019). Deciding on whether a situation constitutes a teachable moment (Muir, 2008), and deciding on how to act in ways that provide opportunities for learning, constitutes a common dilemma for mathematics teachers.

The MPM framework provides a useful lens to describe observations in mathematics classrooms, and to evaluate the level of teacher mediation, and it provides a useful language to describe what teachers do. This can be useful to some point, and it provides a simplification of teaching that can be useful to teachers as well as researchers. However, shifting attention toward the work of teaching opens the way to understanding what is actually involved in carrying out the complex, dynamic, and situated work of teaching (Ball, 1993; Ball, 2017). This does not simplify the picture, and it does not provide immediate solutions for how to act, but it approves of the real nature of the complex work of teaching mathematics. The dilemmas of this special work of teaching cannot be easily solved, and their management requires professional knowledge and judgment.

Mathematical knowledge for teaching: challenges and potential in the case of geometrical patterns

James Gray[1] and Bodil Kleve[2]

[1]Oslo Metropolitan University, Oslo, Norway; james.gray@oslomet.no; bodil.kleve@oslomet.no

We report on an observation of a lesson where students were working on geometrical pattern tasks in pairs. The teacher's intentions for the paired setting and his reflections upon seeing a video of the lesson are presented, and through the lens of a TRU analysis and the Knowledge Quartet, we identify potential for exploiting the task and the environment to afford students' mathematical engagement. We focus on the interplay between the Contingency and Foundation dimensions in the Knowledge Quartet, and the potential of developing retrospective awareness into in-the-moment awareness.

Keywords: Paired learning, geometrical patterns, knowledge quartet, awareness, teacher insight.

Introduction and theoretical background

The new mathematics curriculum in Norway (LK20) has a specified learning goal that 9th grade students should be able to explore in the sense of describing, explaining, and presenting the structure and development of geometrical patterns and number patterns. Although geometrical patterns were not outside the remit of the previous curriculum, they were not mentioned specifically and the requirement to teach them is new. Within mathematics education literature, geometrical patterns have been promoted as a rich entry point to algebraic and functional thinking (Bednarz et al., 1996; Carraher et al., 2008). However, working with geometrical patterns in this way presents both possibilities and challenges for students and teachers (Orton & Orton, 1999). Moss and McNab (2011) argue that the challenges are due to pedagogical choices and not due to an inherent difficulty in subject material. Thus, mathematical knowledge for and in teaching plays a central role. In this article, we will study one teacher, here called Erik, while working with geometrical patterns as a means for developing students' ability to express relationships algebraically in a 9th grade class. Specifically, we will address the research questions:

> What demands were placed on the teacher's mathematical knowledge for teaching in exploiting the task and the environment to afford students' engagement with mathematics?

We explore how the teacher's intentions in carrying out exploratory activities were enacted in a setting where working in pairs was supposed to encourage collaboration. In that respect, we pay attention to how the potential in paired learning and the mathematical potential of the task were exploited and what demands it put on the teacher's mathematical knowledge for teaching, MKT. Several frameworks for investigating MKT have been developed, and much research on the theme has been reported (Skott et al., 2018). The Knowledge Quartet, KQ, (Rowland et al., 2005) is based on the work of Shulman and his categories of knowledge. KQ was developed through a grounded approach to video data focusing on how teachers' mathematical knowledge surfaced in mathematics lessons. 18 codes from the categorisation were grouped into 4 broad dimensions; Foundation (teacher's mathematical knowledge possessed), Transformation (teacher's capacity to transform his/her foundational knowledge to accessible knowledge for others), Connection (connections between concepts which bind different parts of the mathematics together), and Contingency.

Contingency is informed by the three other dimensions, and concerns situations in the classroom which are not planned for. In later studies, this dimension has been further explored. A new code, “Teacher’s Insight” which is demonstrated when a teacher is aware that students construct mathematical ideas and something which sounds “half baked”, was included in the Contingency dimension (Rowland, 2012). Rowland and Zazkis (2013) related the contingency dimension to Mason’s (1998) description of “knowing to act in the moment” (p.139). This in-the-moment-pedagogy is “the teacher’s capacity to engage flexibly and productively with their students” (Mason & Davis, 2013, p. 184). Knowing to act-in-the-moment, puts a demand on the teacher’s mathematical knowledge as well as on how he or she is aware of this knowledge and how it is used and exemplified. “A teacher who is aware [...] is in a position to direct student attention to what really matters” (ibid, p. 189). Contrary to teacher’s insight or awareness is what is known as funnelling of which the effects are described by Wood (1998): “students’ thinking is focused on trying to figure out the response the teacher wants instead of thinking mathematically himself” (p.172). A challenge for teachers will often be to balance between funnelling and scaffolding. A pitfall may be “fostering dependency on teachers and cap opportunities for more independent learning” (Mazenod et al., 2019, p. 2).

Methodology

We observed five mathematics lessons with one teacher (Erik) in two different mixed ability ninth grade classes. Here we report from one of these lessons. The students were seated in pairs and worked on growth pattern tasks. Prior to our first classroom observation, we had a semi-structured pre-interview with the teacher. We asked him to describe a typical mathematics lesson, his intentions in teaching mathematics and how he dealt with mixed abilities, adapted education, and grouping. Additionally, we interviewed some of the students in the classes. We also conducted a semi-structured post-interview with Erik one month after having observed in his classes. The interview included a session in which we showed him several episodes from the five observed lessons, so he could share his reflections with us. The lessons were videotaped, and the teacher wore a microphone. The camera followed the teacher as he moved from one pair to another. After the observations, we studied the videos and selected episodes which were transcribed and analysed.

During the classroom observation, we used the Teaching for Robust Understanding (TRU) Framework (Schoenfeld & Floden, 2014) as an observation scheme. Schoenfeld (2016) emphasizes that there is “no one ‘right way’ to teach. The key idea is that TRU specifies the attributes of learning environments in which students flourish” (p.2). In advance the researchers had prepared for the application of the framework to ensure reliability. The Framework offers ways to reflect along five dimensions: 1-The richness of the mathematical content (How accurate, coherent, and well justified is the mathematical content?). 2-Cognitive demand (To what extent are students supported in grappling with and making sense of mathematical concepts?). 3-Access to mathematics (To what extent are all students supported in meaningful participation in (group) discussions?). 4-Agency, Ownership, and Identity (To what extent did teacher support and/or group dynamics provide access to "voice" for students?) and 5-Uses of Assessment (To what extent does the teacher monitor and help students refine their thinking within small groups?). The Framework has different rubrics: Whole class activities; Small Group Work, Student Presentation, and Individual Work. Since students worked in pairs, we used the rubric for Small Group Work. TRU assigns scores of 1, 2, and 3 for each dimension. Although we assigned approximate scores when observing, we find it more appropriate to report the analysis with aspects of the content within the levels rather than scores, and we relate to the dimensions of KQ with a focus on teacher's insight and awareness in the Contingency dimension.

Findings and discussion

In the pre-interview, Erik explained his thinking in choosing the tasks that students were working on. We see that his intentions are inclusion based on differentiation:

> To include everyone, even the ones who aren't so good, I try to find self-differentiating tasks, that have a low entry threshold and that one can do a lot with them [e.g.] a figure that is growing.

In the post-interview, we asked Erik if he thought it made sense for the students to sit in pairs in mathematics lessons. He responded that he intended for them to problem-solve together:

> After all, maths is a language... When they are going to solve a problem, they should talk together and come up with ideas on how to solve it. And then the other partner comes up with "maybe that way" and that they …[in] a social way ... find some solution together.

Commenting in the post-interview he talked about the need for student agency:

> [There are] many ways of seeing the figure. Then they make a formula that looks different at first, then they simplify it and then they get the same formula in the end. [You] can solve the problem with different approaches. What do they want to be left with? Well … their agency that should be their own. [It] shouldn't be that the subject has its agency and on the other side the students have their identity and their agency and [it] should be … that they experience that they have a sense of determination over the subject…The subject should not define everything for them. They should also define what it means to have flexible solution strategies then, I think. For they should have their own strategies at the end of the day.

Erik used learning pairs actively in all his lessons. At the start of the lesson Erik encouraged the students to "help each other". Based on what the students said in interviews, this seemed to be an established way of working: "if I cannot complete an exercise, I ask my partner for help". This tells us that Erik's intention that students should collaborate in pairs was exploited by the students.

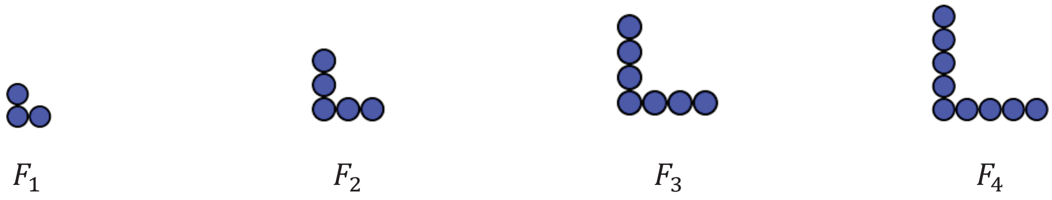

Figure 1: Task: "Find a formula for the n-th figure"

In the following we explore to what extent Erik realised his aims. The episode below was typical of the interactions that we observed between Erik and different pairs. Here Finn, who was working at a desk with another boy, had his hand up. Erik had just finished helping another pair and went over to Finn. The task they were working on is shown in figure 1.

Finn: Is the exercise there … is it … F_n plus … F_n plus two? Or?

Erik: erm ... n[o] .. [He takes the pen from the student] Add the bit that comes up here [He draws a dot to represent the figure F_0 on the task sheet.] This one will always be there. Then it's the arms that grow.

Finn: Yeah

Erik: It's always there. Plus one is always there. Right. That one, if you go back. F_0, I mean, then you will get rid of those two, then you will just be left with … with one, right. [He holds up one finger to Finn.]

Finn: Yeah

Erik: So there is plus one in each one there.

Finn: Hmm

Erik: Here is F_1. What do you times one with to get two? What do you times two with to get four? Three to get six? Four to get eight? What do you times with there?

Finn: Four to get eight[?]

Erik: Yeah

Finn: Two

Erik: Two yeah. [Holds up two fingers.] Then it's always plus one and then it's n times by…[Knocks the table several times with his finger and then holds up two fingers.]

Finn: Two

Erik: $2n + 1$

Finn: Yeah … yeah … $2n + 1$ [?]

Erik: Yeah. Because there you have … this one, if you look at this here, you will always have it … that there, right … that will always be there

Finn: Hmm

Erik: It becomes plus one.

Finn: Yeah

Erik: When you see… Here is F_1, then it is times by two. Here is F_2. Then it is times by … here there are four. Here there are six. Here there are…?

Finn: Four

Erik: Eight

Finn: Ah [Sounds resigned and disappointed]

Erik: It's $2n$. Two times by one is two, plus one is three. Two times by two is four, plus one is five.

Finn: Hmm

Erik: Here there are eight arms [points to the next task on the sheet]. You may see it better there because it is a bit better version. [He stands up and walks away.]

Finn: Yeah

Initially there was discrepancy between the student's question and the teacher's response. In the task, the number of dots per figure were increasing by two. The student therefore asked: "is it $F_n + 2$?". The student was trying to express the solution as a recurrence relation and was grappling with "half baked" mathematical ideas. Here was a potential for the teacher together with the students to explore the relationship and difference between recurrence relations and closed formulas for geometrical patterns. As reported in the research literature, this is a challenge both for students and teachers (Moss & McNab, 2011) which leads to mathematical and pedagogical demands. The Foundation dimension of the KQ, as well as teacher's insight and awareness are of crucial importance in order to exploit this potential. Finn's idea was not followed up by the teacher, who guided him to a full solution to the task based on the closed formula. During this episode Erik addressed only the student who asked for help while the other student paid attention without contributing nor being invited to contribute to the conversation. The potential in paired seating was not exploited. This differs from Erik's intention about the students working in pairs to find a solution together.

In terms of the mathematical content offered in this classroom environment - the first dimension of the TRU framework (Schoenfeld & Floden, 2014) - the teacher's focus was on the answer and how to get there. The question "What do you times one with to get two?", is an example of funnelling (Wood, 1998). The task in hand has been reduced to a simple question about multiplication with answer "two". In the TRU framework, this would indicate a low score on cognitive demand as teacher intervention constrained students to activities such as applying straightforward or memorized procedures, and was explaining how he would solve the task (Schoenfeld & Floden, 2014). It appears that Finn did not see the relevance of the answer "two", since when Erik tried to get him to relate it to the closed formula, he needed to hold up two fingers as a prompt. Later Finn answered wrongly ("four") on a related line of questioning, another indication that he was being funnelled into giving correct responses. As in Wood's (1998) description of the effects of funnelling, Finn appeared to be focused on answering the teacher and abandoned his own recurrence-relation based ideas.

In the conversation Erik asked closed-ended questions, and Finn's contributions after the initial question were just single word responses. Thus, the two boys were not given the opportunity to discuss, explain or reflect on their mathematical ideas, processes that would indicate a fostering of the students' sense of agency. Much of the episode had the feel of a teacher monologue because Finn interjected the "yeah" responses rather than them being invited by pauses from Erik. The monologue with closed questions indicated the teacher's ownership of the mathematics.

In the post interview the teacher realised that he had been too eager to give the solution to the task, remarking on his impatience both before and after seeing himself in the video. In response to the video of the episode, Erik said:

> I remember this one here, yes, the problem here is that he really struggled to understand - to crack the code here [What we] see immediately here [in the video] is that here I probably explain a bit more than…am probably, in a way, a little too quick to give him an answer or solution to the problem. I think. That he himself should have had a little longer to ponder the problem. I see that now, yeah. I should have done that. Eh, but it is clear that, on the other hand, if I help him with one task, then maybe he understands; can maybe move on to the next task and understand it …

We see that Erik's focus is on helping the student. However, he expressed an insight about the student's mathematical capacity - that he should have given him some more time to ponder himself. We consider this expressed insight and awareness as a potential for the teacher to develop his in-the-moment pedagogy so he can act flexibly and productively with his students so he instead of funnelling can direct students' attention to what really matters. However, in the actual moment of this lesson, Erik did not seem to try to analyse and understand Finn's thinking, what he has said and why he said it. In the post interview, we suggested to Erik that when Finn said "F_n plus two" he was trying to express how the number of dots increases, and we asked Erik how he might get from there to the closed formula. He said:

> He was thinking of this [the recurrence relation] I would assume. Because we spent a lot of time last year finding patterns in how it grows. We have been working on that. Then clearly to go from there and find that it is $2n + 1$. It is clear that we have not [done that]… We have worked a lot

> with the graphical representation. Because we should have had a … a type of square number variant then.

Here he went on talking about certain shapes (square numbers, rectangular numbers, and triangles numbers) that he had given the closed formula for on a hand-out sheet. In Norwegian, use of “clearly” in the sentence “Then clearly to go from there and find that it is $2n + 1$” is expressing that it is clearly difficult to do. We see that Erik struggled to suggest a way to support this transition. This quote indicates the heart of the matter: Erik struggled to understand the students’ utterances and he had to rely on his own solution and understanding due to not being able to transform the connection between the different parts of mathematics to something accessible for students.

The fourth dimension of the TRU framework considers the “extent to which students have opportunities to conjecture, explain, make mathematical arguments, and build on one another’s ideas, in ways that contribute to students’ development of agency, authority, and identities as doers of mathematics” (Shoenfeld & Floden, 2014, p.1). In the episode above the environment offered the chance for Finn to make a conjecture “F_n plus two”. Finn’s subsequent contributions were constrained by the teacher’s questions. The episode above was picked out because it was typical of the interaction between Erik and the students. Thus, we argue that there was little opportunity for developing a sense of agency, authority, and an identity as a doer of mathematics in this classroom environment.

There was one interaction between Erik and another pair of students (Anna and Berit) which was atypical due to the students explicitly saying that they wanted to retain authority over their work. As Erik approached the desk Berit said “No, we don’t want any help from you” and waved her hand as if to indicate that Erik should go. Erik persisted to ask questions about Anna and Berit’s progress, but, before they would show anything, Anna demanded that Erik promise not to “give any hints at all”. Anna underlined this point by saying it three times. Apart from confirming how the classroom environment constrained the students’ ownership of the mathematics, the interaction between Anna, Berit and Erik indicates potential within this environment. We noted earlier that the mathematical authority was retained by the teacher in his interaction with Finn. In the interaction with Anna and Berit, we see a willingness from Erik to give that authority to the students, and a relaxed classroom environment that allows the students to challenge established patterns of social interaction.

The ensuing conversation with Anna and Berit returns to a pattern that resembles the other interactions with the students. Erik asked Anna about her solutions to the questions on the worksheet, and sometimes told her the solution before she had time to answer. Erik commented on one of the expressions that Anna had found by saying “No, this one I would multiply with this, to make it look prettier”. Anna objected but eventually said: “Ah, but OK” in a resigned way. Schoenfeld’s introduction to TRU refers to Engle when defining agency:

> Learners have intellectual agency when they … share what they actually think about the problem in focus rather than feeling the need to come up with a response that they may or may not believe in, but that matches what some other authority like a teacher or textbook would say is correct. (Engle, 2011, in Schoenfeld (2016), p.9).

In the exchange between Anna and Erik, the response from Erik constrained Anna to writing expressions that conformed to his idea of pretty.

Discussion and Conclusions

We would like to highlight that there are many positive aspects that we observed in this classroom: the teacher's intentions were for the students to collaborate and explore mathematics; he was using low threshold high ceiling tasks to promote inclusion and collaborative learning; there was a safe working environment as demonstrated by the girls' frank comments to the teacher; and the teacher was aware of the ideas of agency and ownership in the context of mathematics. The analysis of the mathematics revealed that students were directed to the answers and their form, not included as a pair, and the mathematics was reduced to a step-by-step procedure. Thus, the mathematics being offered by the interactions with the teacher is only limited in nature and scope. From the pre interview, this seemed not to be his intention. However, when reflecting on this episode in the post interview, rather than having shown in-the-moment awareness, which is an important aspect of the contingency dimension of the KQ (Mason & Davis, 2013; Rowland & Zazkis, 2013) he displayed a retrospective awareness. It is unclear if the teacher was aware that the way he spoke mathematics with the students reduced their access to it. Rather than the potential of students' half-baked ideas being exploited, learning was capped by over-nurturing, fostering teacher dependency. In particular, there was little awareness of and planning to address the difficulties of the transition from recursive relations to closed formula. For teachers to understand students' starting points, and how these can be built on to develop genuine understanding and agency, this study has demonstrated the importance of developing awareness of the interplay between the Foundation and Contingency dimensions of the KQ, especially the aspects of teacher insight and awareness in the Contingency dimension. There is potential here in the teacher's retrospective awareness, and further research could look at how retrospective awareness can develop to an in the moment awareness.

Furthermore, we saw that it is not sufficient to place students in pairs to promote collaboration. There is a possible mismatch between the teacher's intention (problem solving together) and the teacher's instruction to the students (to help each other) - the latter does not necessarily imply working on a joint product. The teacher's intention also contrasts with the manner of the help (a conversation with an individual not a pair) and the nature (demonstration through funnelling). Exploiting the environment with paired learning thus places demand on teachers' skills to initiate a mathematically rich discussion. We have identified the need for Teacher Insight to be able to build on the students' utterances. Thus, the interplay between the Contingency and Foundation dimensions of the teacher's MKT plays a crucial role here. Initiating a mathematically rich discussion in paired learning activities may place other demands on a teacher's MKT than orchestrating a whole class discussion does. We see this as an avenue for further research. In our experience, paired learning has become widespread in Norwegian schools in the last decade and, thus, the demands of paired learning for teacher knowledge have general implications beyond the teacher in the present study.

Appropriation: The role of progressing and focusing actions

James Gray[1], Ida Heiberg Solem[2] and Annette Hessen Bjerke[3]

[1]Oslo Metropolitan University, Norway; james.gray@oslomet.no; ida.solem@oslomet.no; annette.hessen@oslomet.no

In a lesson in a challenging 5th grade classroom environment, we observed interactions between a teacher and a student that displayed characteristics of an appropriation process. We analysed the conversations focusing on the teacher's contributions that build on the student's ideas using a framework to identify redirecting, progressing, and focusing actions. A pattern emerged from the analysis: focusing actions dominate initially with a later shift to progressing actions. The implications of this pattern, and also how the teacher introduced the progressing actions, are discussed with regard to the fostering of the student's appropriation process.

Keywords: Appropriation, classroom observation, conversation analysis.

Introduction

The way teachers and students interact with each other in the social context of the mathematics classroom is of central importance to student learning (Franke et al., 2007). In every classroom, no matter how challenging such a demand might be, there needs to be room for students to engage in sense making and productive struggle (Schoenfeld, 2019). Maintaining this room creates a dilemma for the teacher: How to help without "robbing the student of initiative" (Schoenfeld, 2019, p. 367)? Drageset (2014) provides a framework for analysing teacher responses but points out that "in order to understand classroom communication, it is necessary to study both a single [teacher] question…and the larger picture" (p. 288). To this end, this paper studies all the interactions between a 5th grade mathematics teacher (Joe) and one of his students (Mira) during a lesson where they engage in sense making. With the intention of setting the scene, we start by providing a short narration from the beginning of the lesson:

While most students have found their seats, some keep walking around. It is not quiet: Some throw rubbers in the air – there are constant movements of arms and legs. In this tumult, Joe starts the lesson by asking his students to write down different calculations that give 36 as an answer. Then he begins a whole class conversation, trying to tune them in on the connection between multiplication and division. During this 10-minute whole class conversation, Mira leaves her desk five times. One of her many 'errands' is changing a bin liner, causing her to leave her desk for three minutes.

Despite this start, the lesson ended with Mira presenting a detailed solution to a fairly complicated division on the blackboard. By viewing Joe and Mira's interactions through the lens of Drageset (2014), we search to understand a teacher's role in how a student can *appropriate mathematics*.

Theoretical framework

When studying how a student appropriates aspects of division and its close connection to multiplication, we draw on the work of Moschkovich (2004). As most research on different forms of appropriation, Moschkovich (2004) takes the work of both Newman et al. (1989), Rogoff (1990) and Radford (2001) as her point of departure, and uses it as a foundation when elaborating on the notion of appropriation. Appropriation is a central Neo-Vygotskian concept that has been used to describe how learning in students is mediated by interaction with others and how students learn through the teaching and guidance of a teacher (Newman et al., 1989). It involves joint productive activity, a shared focus of attention, and shared meaning (Rogoff, 1990). Additionally, Newman et al. (1989) focused on the situation of an expert helping a novice, where the expert provided alternative interpretations of the novice's actions. Grounded in these rudimentary insights, Moschkovich (2004) set forward two aspects of appropriation: what the learners appropriate, and how learners actively transform what they appropriate (pp. 49–50). This involves "taking what someone else produces during joint activity for one's own use in subsequent productive activity while using new meanings for words, new perspective, and new goals and action" (Moschkovich, 2004, p. 51).

By drawing particularly on Newman et al. (1989) who used appropriation to describe in detail how interaction with an adult can affect cognitive change in children, we focus on the teacher's role in an appropriation process where both aspects set forward by Moschkovich (2004) are under investigation. That is, we seek to see the teacher's role in what Mira appropriates, and in how she actively transforms what she appropriates. Drageset (2014) reminds us that "an appropriation process often includes actions that in isolation can be labelled as funnelling, teacher-dominated communication, or IRE [where the teacher does the main work], but as part of the appropriation process these actions might be both beneficial and necessary" (p. 288). While acknowledging the many possible theoretical lenses that can shed light on classroom communication (such as wait time (Ingram & Elliott, 2016); funnelling (Wood, 1998); and revoicing (O'Connor & Michaels, 1993)), we turn to Drageset (2014) who states that, in so doing, there is a need to consider both single questions and the larger picture, such as an appropriation process. In this quest, it is necessary to take utterances, dialogue and sequences of dialogues into consideration.

Viewing a dialogue as a joint construction "made possible by the reciprocally and mutually coordinated actions and interactions by different actors" (Linell, 1998, p. 86), Drageset (2014) focuses on the value that is hidden in the details in teachers' comments and questions. He proposes a framework consisting of 13 categories of teacher comments that are grouped into redirecting, progressing, and focusing actions (the detailed categories are given in Table 1 below). These categories summarise how communication can contribute to students progressing towards a conclusion, "or to redirect the students into alternative approaches focusing on the mathematical content" (Drageset, 2014, p. 281).

Drageset (2014) proposes several ways of using his framework, one of which is to study how combinations of his categories occur and if there are patterns that can have "explanatory power beyond the study of single comments, for example by studying how a teacher uses different actions or categories as part of an appropriation process when the students have to learn something new" (p. 303). Solomon et al. (2021) used Drageset's framework to analyse an appropriation processes in the case of whole class discussions and found that, in addition to focusing actions, "the teacher is forced to intervene with a series of … progressing actions in order to progress the lesson" (p. 186), and "although teachers keep the intellectual authority in such actions, their strong focus on the students as originators of the appropriated contributions appears to provide the means by which they …leave students with the responsibility of solving the problem" (p. 187). This paper builds on Solomon et al.'s (2021) approach, but in the case of a one-to-one interaction.

Table 1: Redirecting, progressing, and focusing actions (Drageset, 2014)

1. Redirecting actions a Put aside b Advising a new strategy c Correcting questions	2. Progressing Actions a Demonstration b Simplification c Closed progress details d Open progress initiatives	3. Focusing actions a Requests for student input i Enlighten details ii Justification iii Apply to similar problems iv Request assessment from other students b Pointing out i Recap ii Notice

As both researchers and teacher educators, we are drawn to the transformation of Mira's practice during this lesson and wonder what it was about her interactions with Joe that fostered Mira's process in this case. Hence, we use Drageset's (2014) framework to analyse the nature of different sequences of conversations. Assuming that there is an appropriation process that has happened, we ask the following research question:

> How do redirecting, progressing, and focusing actions facilitate the appropriation process in a one-to-one interaction between a teacher and a student?

Methodology

As part of a larger research project on inclusive mathematics teaching in Norway, a series of observations of 5th grade mathematics classes (ages 10–11) in an inner-city school were conducted. There were three parallel classes of between 23 and 27 students. The school had a diverse student population with many students who had Norwegian as a second language. The classrooms were organized with rows of paired desks, facilitating students working in pairs with their assigned learning partners. All classes were video recorded using a fixed camera at the back of the classroom. A wireless microphone recorded the teacher's voice and voices of nearby students.

The video allowed us to identify a possible appropriation process in the interactions between Joe and Mira, and additionally the way in which Joe acts in the classroom. These interactions appeared to change over the course of the lesson, and Mira seemed to be gradually more engaged in the mathematics. We chose therefore to analyse the dialogue in the interactions to see what they revealed about the teacher's role in the emerging mathematical processes. This was performed in a three-step process. We first transcribed all of their conversation in the original language (Norwegian) and watched the video paying careful attention to their movements and interactions. Then, we coded the transcriptions using the 13 categories from Drageset (2014) framework, which we operationalised in close connection with the understanding put forward by Drageset (2014) (see Table 1). Each of the authors coded the transcripts, the codes were discussed until agreement was reached, and associated discussions were noted as these gave us a deeper understanding of the material. The dialogues were translated to plausible English, making sure that the intended meaning was kept. We used the transcription conventions given in Table 2 to indicate the rhythm and intonation of the original. Finally, we conducted a holistic reading of the data in order to capture their changing actions and the development of the conversations and interactions.

In presenting our analysis, we have referred to the numbering of the categories given in Table 1. The three dialogues between Mira and the teacher appear in the analysis in chronological order.

Table 2: Summary of transcription conventions adapted from Jefferson (2004)

(1)	Numbers in brackets represent elapsed time measured in seconds
(.)	Brief pause of less than a second
=	No pause.
↑word	Noticeable rise in pitch
[word]	Overlapping talk.
wo:rd	Colons indicate a stretched sound
((description))	Indicates the transcriber's description

Findings

We continue Joe and Mira's story where we left off in the introduction. At the end of the initial whole class conversation, the students were assigned a new task – to discuss in pairs the connection between multiplication and division. Joe went straight to Mira's pair:

Joe:	How are timesing and dividing related? ((Interruption from another student. Joe turns back to Mira)) [How]
Mira:	[Times]ing and dividing (.) Timesing and dividing are just about the same, it's just that when you times, then you sort of add (.) but instead of adding (.) you are to (9)
Joe:	What do you think? ((addressed to Mira's learning partner who looks down and then up again but does not speak)) (19) If you look at these ((points at the blackboard)) calculations, how do you think they connect?=It says 36 divided by 9 (.) is 4, (.) because 4 times 9 (.) equals 36.
Mira:	It is because it's backwards=
Joe:	=Yes, it's backwards. (.) Is it possible that it's the opposite, is that another way to look at it?=
Mira:	=Yes (.)
Joe:	So the opposite of timesing is dividing and the other way around? (1) So can we use (.) ((looks at the blackboard)) timesing to (.) calculate dividing ↑perhaps?
Mira:	↑↑Maybe= ((sounds satisfied, not doubtful))
Joe:	=↑Maybe? (.) If you know that 4 times 9 is 36, (.) can you turn it around? (.) Then 36 (.) ((He looks at the blackboard, and then back at Mira)) divided by 9 must be 4?
Mira:	Yes ((she sounds very satisfied and nods eagerly))
Joe:	↑Yes. (.) If you know how to times, then you actually know how to divide, maybe? hm: Good ((Joe leaves))

When Joe is asking for input from Mira we identify his actions as enlighten details (3.a.i) or justification (3.a.ii), while Joe makes details explicit to Mira with recap (3.b.i) and notice (3.b.ii) actions. A possible interpretation of Joe's two turns where he introduces the term "opposite" is as a progressing action either in category (2c) or (2d). Drageset (2014) describes these progressing actions as a way of "moving the process forward" (p. 294) either with closed or open questions. We argue that the purpose is rather that of highlighting and clarifying the connection so that it may be used later. Indeed, Drageset (2014) expands on to the description of the category *notice* (3.b.ii) by adding that "[t]he teacher often slightly changes the statement or adds new information to make the point clearer... to support the students by pointing out... important aspects to notice which they should understand or use in the future" (p. 297).

Two minutes after Joe left Mira a new whole class discussion took place. During this discussion Joe asked if Mira could repeat what she said during their conversation:

Mira: 36 divided by 9 is 4. So if you do it (.) ba:ckwards, first you take 4 divided by (.) 4 times 9 is 36, so, it is just the opposite!

We note that Mira has adopted Joe's academic language using the word "opposite". Joe highlights this to the whole class by writing "The opposite of multiplication is division" on the blackboard at the end of the discussion. Then a new task was given: 264 divided by 4.

After four minutes working on the task, Mira left her chair and interrupted Joe (who was speaking with other students) asking "Does 200 divided by 4 equal 50?" He confirmed and continued his ongoing conversation. Mira listened for a while before she started doing dance moves. A few seconds later, Joe followed Mira back to her desk, where she immediately started to explain her thinking:

Mira: 100 divided by 2 is 50=
Joe: =Yes=
Mira: =100 divided by 4 is 25=no 100 divided by 4 is not 25, is it? (1)
Joe: Yes, (.) because 25 times 4 is 100.=
Mira: =And then, 200 divided by 2 is 100 and then I thought, then it has to be like, since 100 divided by 4 is 25, 25 plus 25 is 50. So if 200 divided by 4 (.) then 200 divided by 4 needs to be 50.
Joe: =Mm. I agree. And then we have spent 200, and we are left with 64. (.) Ok. Then we know that they all get 50 each (.) and we are left with 64. ((Interruption from one student and then another. Joe encourages them and says he is coming.)) Yes, and next it is 64 divided by 4. (1) Can we make this number any easier?
Mira: Yes, maybe ((Mira sounds positive. Joe leaves to get students back in place.))

During this dialogue, Joe begins with a notice action (3.b.ii) and then makes an open progress initiative (2.d): "Can we make this number any easier?"

Mira worked for a couple of minutes before she started wandering around looking thoughtful counting on her fingers. Suddenly, she jumped, turned around, and ran to Joe while shouting "Joe, I have the answer!". She continued to shout it six times, and "104. 104. It is 104". He took her back to her desk:

Mira: Because I divided it by 2, and it is 36= ((referring to her calculation 64 : 2 =32))
Joe: =Yes
Mira: And, (.) it is sixty (.) 64=And six (.) 50, 50 pl[us 64]
Joe: [but, look,] you took 62 divided by 2 is 32, and then half of that is?
Mira: Half of tha[t]
Joe: [Then] 64 divided by 4 must be half of this one? ((points at something in Mira's notebook, presumably 32))
Mira: Yes [Don't look]
Joe: [What is half] of 32? (.) That was very smart. ((Presumably 64 : 2 = 32 in Mira's notebook.)) (.) What is half of 32? (1) What is half of 30?
Mira: Half of 30 is 15.
Joe: Then half of 32 needs to be one more. (.)
Mira: 16

Joe: Yes (.) So (.) So then 64 divided by 4 is 16.

Mira: Is it 50 + 16? ((Mira sounds unconvinced, but another student grabs Joe’s attention and he leaves to help them.))

Both Mira and Joe mis-spoke in this conversation. Mira said 36 when she meant 32 and Joe said 62 when he meant 64. It is noteworthy that this did not affect the meaning and we will discuss this later.

It seems that Mira had incorrectly calculated 50 + 64 = 104 as the solution when she invited Joe to her desk (see also the right hand column in Mira’s notebook in Figure 1). Hence Joe made a redirecting action which could be interpreted as a correcting question (1.a). However, this turn also has elements of a notice action (3.b.ii), “you took [64] divided by 2 is 32”, and a progressing action, “half of that is?” Even though this progressing action is a closed question it could be interpreted as an open progress initiative (2.d). Drageset (2014) points out that “comments in this category...are also aimed at moving the process forward, but without pointing out the direction” (p.294) and, by asking “half of that is”, Joe was following up a strategy determined by Mira, not Joe. In any case, and crucially, Joe’s response allows Mira to retain at least part of the intellectual responsibility. Joe continues by pointing out both orally and physically, and repeating the question “What is half of 32?” After a short pause, Joe makes a simplification action (2.b) by splitting 32 into 30 + 2 and taking Mira through step by step.

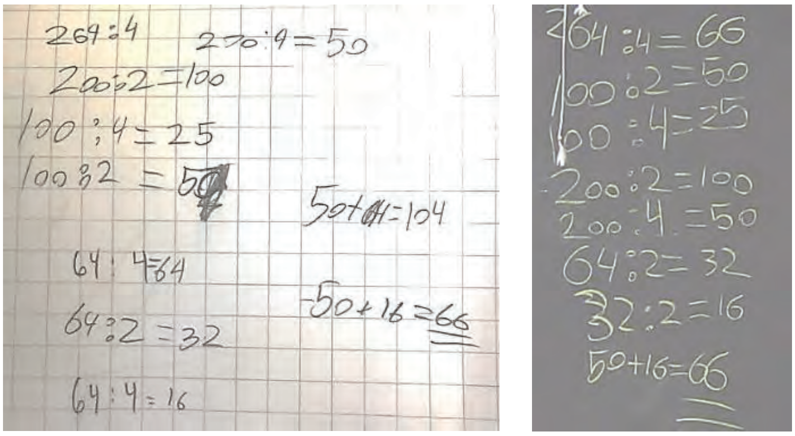

Figure 1: Mira’s notebook (left) and her presentation on the blackboard (right)

Less than one minute after Joe had left her desk, Mira ran to find him again, repeating “Joe, I have the answer!” She was very eager, shaking her book, jumping, saying, “66, can I show my answer on the blackboard?” Joe agreed. She climbed on a shelf placed under the blackboard and began to write. While she wrote nothing was commented upon by her or Joe (see Figure 1 for her presented solution).

We note that Mira’s presentation on the blackboard diverged from her notebook. In particular, she had reorganised the calculations so that they follow a logical progression. Crucially, Mira’s presentation of 64 divided by 4 used her strategy of repeated halving, and she did not split 32 into 30+2. This was now her solution.

Discussion and concluding remarks

Appropriation involves joint productive activity, a shared focus of attention, and shared meanings (Rogoff, 1990). As noted earlier, both Joe and Mira misspoke in the last conversation without it affecting the communication or the dialogical flow. We take this as a sign that they are locked-in to the mathematical process as a shared focus of attention. In addition, appropriation involves taking what someone else produces during joint activity for one's own in subsequent productive activity (Moschkovich, 2004). After the first conversation, Mira adopts Joe's alternative interpretation (Newman, 1989) by using the word "opposite" in her whole class discussion contribution, and, in the end of the previous section, we saw that Mira had made the solution her own when she presented it at the blackboard. We thus argue that the interactions between Joe and Mira displayed characteristics of an appropriation process where the student is working with mathematical practices. But, what has the analysis uncovered?

An overarching view of the analysis with respect to Drageset's framework (2014) reveals a shift in Joe's responses during the lesson. In the first conversation, Joe used focusing actions exclusively, and these were also present in the other conversations. In the second conversation, there was an open progress initiative. Progressing actions were also present in the third conversation in addition to simplification and a correcting question. This pattern may play a part in the appropriation process. The initial focusing actions may have indicated to Mira that her thinking was valued. Once this was established, progress was encouraged with actions that allow the student to retain intellectual authority (Drageset, 2014), wholly or partially. Finally, there was a simplification sequence. This final sequence taken out of the context of the lesson could be interpreted as a case of funnelling (Wood, 1998). However, Joe's previous careful handling of Mira's intellectual offerings allowed for a shared focus to be retained and a shared meaning to be developed (Rogoff, 1990) as evidenced in Mira's presentation to the class. The pattern is similar to the strategies employed by the teachers in Solomon et al.'s (2021) study of whole class discussions. In the whole class setting, the teachers explicitly emphasised student authorship (Solomon et al., 2021). Joe makes one such move ("that was very smart") in the conversations analysed above, but as we have argued, his choice of actions emphasises student authorship and "help maintain the shift of authority away from the teacher towards at least shared responsibility" (Solomon et al., 2021, p. 187).

Our analysis highlights what we believe to be an important feature of this interaction: The way in which Joe starts with focusing actions, and later introduces progressing actions sparingly. However, it is clear that this is not the whole story. Depending on what we focus on, there will always be nuances that come to the fore and we see potential for fruitful further research. For instance, the wait of nine seconds and then 19 seconds after Mira's first turn is unusually long (Ingram & Elliott, 2016) and especially so in this busy classroom environment. It is possible that these indicate to Mira that her thinking is valued. Similarly, we saw several instances where vocal intonations featured. In the first conversation when the idea of "opposite" is introduced, it is accompanied by a high pitched "maybe" that is then repeated by both parties in the following turns. This may function as a way of softening Joe's imposition of intellectual authority on the conversation. These diverse features have a commonality that is also revealed in the analysis: Through the interactions Joe and Mira co-produce a way of thinking that Mira can eventually inherit.

Textbooks as actors in the transformation of the intended curriculum

Helena Grundén

Dalarna University, Sweden; hgn@du.se

Teachers are central in the process of making learning situations out of intentions expressed in governing documents, such as the national curriculum. However, there is no straight line from intentions to learning situations – the teacher actively designs the planned curriculum and the enacted curriculum. In the process of planning, the teacher interacts with the material, and her decisions are also influenced by, for example, textbooks. This study aims to explore in what ways the textbook participates in the process of planning, i.e., the transformation from intended to planned curriculum. Based on focus group discussions with primary teachers, results show a variety in teachers' relations to the textbook, which have consequences for how the textbook participates in decisions. Results also show that students' positive feelings about the textbook influence the planning and that textbooks sometimes function as "emergency exits" in the process of planning.

Keywords: Curriculum, planning, teachers, textbooks, issues.

Introduction

Often curriculum materials are seen as ways to implement reform and influence teaching. However, teachers do not just transfer the content in them; they rather interact with the curriculum material (Remillard, 2005). Hence, teachers are central in the process of transforming ideas in tasks and pedagogical recommendations into events in the classroom (Lloyd et al., 2009), which means that the teacher – rather than being a transmitter or an implementer – is an active designer of curriculum. Consequently, there is a need to distinguish between the intended and the enacted curriculum (Remillard, 2005). The intended curriculum can, for example, be described as "the overt curriculum that is acknowledged in policy statements as that which schools or other educational institutions or arrangements set out to accomplish" (Kridel, 2010, p. 489). In a Swedish context, this would mean that the national curriculum and other policy documents such as national tests in school years 3, 6, and 9, and the mandatory tests in pre-school class and school year 1 can be seen as the intended curriculum. According to Remillard (2005, p. 213), the enacted curriculum is described as "what actually takes place in the classrooms (Gehrke et al.[, 1992])."

Taking teachers' active role as curriculum designers seriously and using the terms intended and enacted curriculum means that what is stated in the intended curriculum is processed by the teachers and transformed into the enacted curriculum. However, there may be reasons for dividing the process further. Teachers seem to be active designers and make decisions of importance for their teaching both in the process of planning and in the process of transforming the plan to classroom events, which means that there in addition to the intended and the enacted curriculum there is also a planned curriculum (Grundén, 2022). When teachers construct the planned curriculum, they are influenced by actors and structures on different levels – one such actor is the textbook which in a focus group conversation with primary mathematics teachers about planning, emerged as a prominent actor related to the teacher and her decisions (Grundén, 2022). The textbook as a prominent actor means that although the teacher is central in the construction of the planned curriculum – she is the one making the decisions – the textbook influences the decisions to a fairly large extent. A common notion about textbooks is that the use of textbooks increases the older the students get, which is supported by results from the latest national review of mathematics teaching in Sweden (The Swedish School Inspectorate, 2009).

Research on textbooks is a common theme in mathematics education research. According to Rezat et al. (2018), the research field has moved from focusing on the textbook itself to focusing on the design and use of textbooks, and textbooks are seen as one resource among many. Several studies focus on understanding processes involved in teachers' textbook use (Rezat et al., 2018). However, textbooks have consequences for teaching based not only on how they are used and how teachers interact with them but as previously mentioned, also on how they participate in the process of planning – the curriculum transformation. Hence, textbooks' role in the transformation from intended to planned curriculum might be one of the keys to understanding more about why intentions in the intended curriculum do not always reach all the way into the mathematics classroom. This paper aims to shed light on in what ways textbooks as actors participate in transforming the intended curriculum to the planned curriculum in primary school and to discuss possible consequences and implications for mathematics teaching.

Background

Mathematics teaching

There is a diversity in what is meant by mathematics teaching, and depending on how teaching is conceptualized, researchers can contribute in various ways to the expanded understanding of mathematics teaching and learning. In this paper, mathematics teaching is seen as a social, cultural, and political practice, which according to Fairclough (2015), means that there are situated and habitual actions and interactions going on. In a practice, there are people and relations involved, and the people involved act among other things by using language. Included in a practice is also the material world (Fairclough, 2015). In a practice, such as mathematics teaching, actors participate in the actions and interactions, and structures are influencing them. However, the structures are also influenced by the actors in the practice (Fairclough (2015).

When the intended curriculum is transformed into a planned curriculum it is done within the practice of mathematics teaching. Hence, the process is influenced by structures as well as by actors. An actor is, according to Oxford University Press (2021), "a participant in an action or in a process" and according to Enserik et al. (2010), an actor is "able to act on or exert influence on a decision" (Enserik et al., 2010, p. 79). Leaning on a definition of practices as including the material world (Fairclough, 2015) opens for actors as physical objects. In this paper, this means that planning involves several actors. Some actors are human, such as colleagues and school leaders. Some are organizational, such as the National Agency of Education. Others are material, such as textbooks or templates for planning. When a group of primary teachers talked about planning, textbooks were one of the most prominent actors that influenced decisions by virtue of how often they showed up in the discussion (Grundén, 2022).

Textbooks in Sweden

In Sweden, there is no national control of curriculum materials. The national curricula state that each principal is responsible for students having access to and conditions to use teaching materials of good quality (The National Agency of Education, 2019). Although no recent national large-scale studies focus on textbook use, results from prior studies might give indications. TIMSS 2007 and 2011 show that teachers in Sweden use textbooks as a base for mathematics teaching to a high degree compared to other countries. However, there seem to be differences depending on school years. In a national review of mathematics teaching students in school years 1–3 work with tasks in the textbooks 11% of the time in the observed lessons, in school year 4–6 31%, and in school year 7–9 47% of the time (The Swedish School Inspectorate, 2009). Although these numbers indicate that younger students work less with textbooks than older students, textbooks seem to influence teachers' planning (Grundén, 2022).

Traditionally, textbooks in Sweden do not consist of detailed lesson plans or instructions (Van Steenbrugge, & Ryve, 2018). However, as Van Steenbrugge and Ryve point out, a prior study by Boesen showed that teachers follow the content as it is sequenced in textbooks.

Method

This paper builds on four focus group discussions with teachers who teach mathematics and other subjects in school year 1–3. The teachers that participated in the four groups worked in three different schools. In total, the groups consisted of 17 teachers.

In focus group discussions, participants interact with each other in the conversation, which often leads to greater insights into experiences, and hence, richer data than individual interviews would have given (Carey & Asbury, 2012). In the discussions – where teachers were asked to freely talk – the theme was planning for mathematics teaching. At the beginning of the discussion, pieces of paper with words written on them (aspects identified in an earlier study) were placed in the middle of the table and used as stimuli. The words were *students*, *school management*, *national tests*, *template/forms*, *parents*, and *textbook*. The teachers could remove aspects or add things they thought were missing. My role during the discussion was to – by small words and gestures – confirm that I was hearing. I also asked follow-up-questions on themes already introduced by the teachers and invited all participants into the conversation, for example, by asking: "What do you think when you hear her say …"?

Analysis

Before the analysis, passages in the transcript of the four discussions where textbooks influenced considerations and decisions in the process of planning were extracted. This phase can be seen as the first step – getting familiar with data (Braun & Clark, 2006) – in the thematic analysis that followed. Each extract was coded with respect to what it was about. The next step in a thematic analysis is to collect extracts together within each code (Braun & Clark, 2006), and the different codes were sorted into sub-themes. Relations between codes and sub-themes were considered, resulting in four main themes: Teachers' relations to textbooks, Students' relations to textbooks, The teaching and textbooks, and Governing documents and the textbook.

Results

In this section, the four themes that represent the core content of how textbooks influence decisions in the process of planning are presented. Not all teachers or all groups of teachers talked about everything that is in the results. However, some issues came up in all discussions and when those are presented in the result, I emphasize that they came up in all discussions. When only one teacher, or a few teachers, say something, that is marked in the text as well.

Teachers' relations to textbooks

When textbooks are actors, i.e., participate in decisions in the process of planning, teachers' relationship to the textbook has an impact on how the textbook's participation looks like. Many teachers in the study seem to see the use of the textbook as something negative that they would rather avoid. Although mentioned in all the groups, especially teachers in one of the groups talk a lot about "dare to let go of the textbook." In this group, the teachers agreed on that they need something that supports them with the structure, but they are not satisfied with the way the textbook does that. One teacher expresses: "I think we will have to do such thing by ourselves," and another teacher continues, "We simply write a textbook," and the other teachers in the group agree.

All groups agreed that textbooks give teachers confidence – following the book is, according to some of the teachers, a way to ensure that nothing is left out and that students learn everything in the right order. The more experienced teachers get, the more they can let go of the book, and according to one of the teachers, the critical evaluation of textbooks comes with experience.

According to one of the teachers, planning is first and foremost about coming up with fun activities. When the teacher does not have enough energy to do so, she turns to the textbook and lets the students work in it. The teacher ends her post by saying: "But fortunately, the periods that you are so tired are not that long."

Students' relations to textbooks

Students' relationship to textbooks also plays a role in how textbooks participate as actors in teachers' process of planning. In the planning, students' individual work in the textbook seems to be considered an alternative that often brings out positive feelings in students, which is an argument for planning to use it in teaching. The teachers talk, for example, about how the students love their textbook and how they enjoy working with tasks in the book. One teacher says: "They – most of them – can tackle them [the tasks in the book] with life and desire because they think it is so fun when they come to the stop". However, some teachers talk about the importance of thinking about when and how they use the textbook with students in the early school years. For example, how to plan so that students who cannot read the tasks themselves can work independently. Some teachers beforehand choose tasks for individual students while others in their plan think that students shall work with some pages and adjust the plan for those who cannot keep up. When teachers use the textbook for planning, it seems common that they do it with their students in mind. They evaluate the tasks based on their knowledge about the students and decide what students shall do. However, there are also examples where teachers express that the goal is that students do all tasks, for example, when a teacher says: "You can skip these tasks and go back and do them later if you have time."

One of the reasons for students' positive feelings that teachers consider when they plan is that when students work in their textbook they can see a result – what they have done – while when they do other things there is no visible evidence of what they have done. One of the teachers points to her head and says: "The only thing left is in here." This means, for this teacher, that when she plans for activities outside the textbook, she also needs to plan how to make visible for students what they have learned.

The teaching and the textbook

This section presents results concerning the textbook and its relation to the teaching that comes out of the planning. Teachers in the study agree that what textbook is used influence the teaching. Most common seems to be that teachers are the ones who decide what textbook to buy, although there are examples where the school district has decided that all teachers must work with the same book series from year 1 to 9. A reason for keeping the same book for several years is that when teachers have worked with the same textbook for several years, planning gets easier. The book used must not be too advanced; the students must be able to work on their own. However, one teacher talks about how she has her students working in pairs to communicate and figure out together how to solve the tasks.

Some of the teachers talk about textbooks as an obstacle to teach the way they want. According to many of the teachers, using the textbook as a base for planning implies a focus on procedural skills. In one of the groups, teachers agreed that the best would be to make a structure and a plan together. A teacher expressed one of the reasons they emphasized: "I want to decide by myself when and how much procedural training I do [with the students]". However, all groups emphasized the textbook as a source for structure and tasks. Textbooks facilitate the planning work, and by following the book's structure, the teaching is about the same things in parallel classes at the school.

There are also examples where a teacher talks about how she turns to a specific textbook for specific mathematical content, for example, when teaching algorithms with regrouping. One textbook covers this content and has better tasks and activities than the others. Some of the teachers express that when they use the textbook in their planning, they choose what to do in the textbook based on their experience about what students need. For example, one teacher says: "Now we will work with multiplication. There are endless ways to work outside the textbook. You still see all the parts [in the book], but we pick this part out and work experimentally with it. And I think you can actually do that without having to feel that 'oh now we have not done these pages' ". Another teacher who advocates that she as a teacher can be flexible when she plans, i.e., the textbook does not decide what she does and when. She talks about how the students she has now need more challenges than other groups she had. She decided to introduce algorithms in year 2, although it was not in the textbook until later.

Teachers in the study seem to agree that procedural skill training is an important part of mathematics learning, and when they plan for that, they use the textbook. When teachers need to keep students busy, for example, when the teachers are absent or when they know some students will work faster than others, they also plan for students to work individually with tasks in the textbook. As one teacher expressed it: "It [the textbooks] is self-propelled. The students know what to do". Several teachers express that the textbook functions as an "emergency exit" they can use when the energy is running low or when the teacher is to be absent. Then the planning becomes “the students shall work individually in their books.”

Governing documents and the textbook

When textbooks participate as actors when teachers plan, the relation between governing documents and the textbook plays a role. In the discussions, teachers refer to the governing documents: national curriculum, national tests for school year 3, and mandatory assessment material for school year 1, and how they influence decisions in the process of planning. However, references to the national curriculum are rare and sometimes implicit. There are differences in how the teachers in the study think of the textbook in relation to the national curriculum. For some of them, it is obvious that textbooks do not cover everything in the national curriculum, while others state that textbooks are approved by the National Agency of Education and aligned with the national curriculum. Many of the teachers agree that the textbook needs to be evaluated against the national tests and mandatory assessment material when planning. What is not in the book, the teachers need to supplement with. According to several teachers in the study, there are differences in what students need to know to manage the mandatory assessment material and the national test and what is in the textbooks for that age group. Hence, following the textbook’s structure might make students less likely to pass all the tasks on the tests.

Some teachers state that the national curriculum is where the goals for teaching are presented, and the textbook is just a resource among others that the teachers can choose to use in their teaching. According to teachers in one group, textbooks participate in planning by offering the “what” – the content – while the “how” – which according to one teacher is the abilities [stated in the national curriculum] – is what teachers need to come up with by themselves.

Discussion

The purpose of this paper is based on results showing that for teachers in one of the focus groups, the textbook was an actor in the process of planning (Grundén, 2022). The results of this study confirm that the textbook participates in the planning for the other groups of primary teachers as well. In this section, the most prominent results about in what ways textbooks are actors in primary teachers’ process of planning will be discussed. The discussion will also highlight some possible consequences and implications for mathematics teaching.

Firstly, the structure and the content of the textbooks are often used to do rough planning. However, teachers in the study see the influence of textbooks as negative, as an obstacle to teaching the way they want. At the same time using the textbook when planning gives a feeling of confidence. This can be interpreted as teachers wanting support when they plan their teaching. The national curriculum with its overarching goals and content that should be covered during three years (National Agency of Education, 2019) is not enough. Or at least, it is not enough when teachers plan on their own. Several teachers in the study expressed that during the in-service teacher development program *Matematiklyftet*, textbooks did not participate in the planning as much as they usually do. Instead, the teachers cooperated with colleagues, which raises questions about whether collegial work with transformation using textbooks as resources is a way to develop the support.

Secondly, there is a great deal of variation in how textbooks participate in planning – from using them as a “smorgasbord” to seeing the textbook as an extension of the national curriculum, from choosing what tasks to work with to working from page to page. Sometimes, the textbook function as an “emergency exit” in the process of planning. These results are not surprising given previous research on textbooks (e.g., Van Steenbrugge & Ryve, 2018). However, looking at them in the light of textbooks as actors in the transformation from intended to planned curriculum gives new insights. The variation raises questions about what would be the best support in the transformation process? Is it to go the way some countries do – detailed textbooks and teacher guides teachers can follow? According to Remillard (2005), the answer is no, which also the results in this study indicate. The use of textbooks in the process of planning is not just a practical operation for teachers but is deeply associated with assumptions about mathematics and the learning of mathematics. It seems reasonable to believe that these assumptions remain although the textbook is changed. Hence, instead of “teacher-proof” textbooks, results indicate that teachers would benefit from support in another way. In addition to various textbooks, perhaps discussions with colleagues where assumptions are made visible and challenged is one alternative support.

Thirdly, students’ positive feelings about working individually with their textbooks is an argument for planning for such work. However, the positive feelings teachers refer to do not build on an idea that students learn more when working in textbooks, but rather that students gain good self-confidence by working on tasks they can manage to do on their own. The teachers also emphasize the evidence of “what has been done” that the textbook offers. One may wonder if this has to do with a tension between *performing mathematics* and *learning mathematics,* and one of the teachers might sense this tension when she emphasizes the importance of making visible to students what they have learned when working with other activities than textbooks – what they are able to do and talk about that they could not do before. When students’ positive feelings about *performing mathematics* are an argument for the participation of the textbook when planning, this might build on students’ ideas about what counts as mathematics and mathematics learning that might not benefit their learning. Hence, rather than letting the textbook be the planning to meet the students’ preferences, teachers can involve them in discussions about learning and signs of learning.

This study indicates reasons for learning more about the transformation from the intended to the planned curriculum. In this paper, the focus is on the textbook as an actor. However, there are also other actors – and perhaps other assumptions - that somehow participate in the transformation and might be obstacles to intentions formulated to benefit students’ learning.

Navigating the contradiction between attainment grouping and inclusion in mathematics: the role of teacher identity

Sigrun Holmedal

Oslo Metropolitan University, Norway; sigrunh@oslomet.no

This paper focuses on teaching mathematics in attainment groups as a means of fostering "equal opportunities for learning" (Norwegian: tilpasset opplæring, TPO) and thus meeting the Norwegian education system's historical aim of inclusive teaching. I report on interviews and classroom observations of one teacher working in a school which has introduced attainment grouping, focusing on how she explains her practice in the context of TPO. Applying Gee's (2014) theory of language in use and situated meaning, I focus on her enactment of practice in relation to teacher identity and the notion of big D Discourse. The analysis highlights the contradiction between the practice of attainment grouping and the policy of TPO and its implications for the role of teacher identity.

Keywords: Attainment grouping, inclusion, big d discourse, teacher identity, issues.

Introduction

The Norwegian school system has deep roots in inclusive mainstream schooling where teaching is mainly organized in whole class mixed groups. Indeed, the Education Act § 8-2 (Opplæringslova) states that "students shall not *normally* be organised according to level of ability, gender or ethnic affiliation" (my emphasis) (Opplæringslova, 1998). In addition, the national curriculum emphasises the pedagogic principle of "equal opportunities for learning" (*tilpasset opplæring* in Norwegian, or TPO) which emphasizes that education should develop each student's full potential; it is the teacher's responsibility to facilitate this. Despite this background, some schools have introduced attainment grouping as a means of organizing TPO, particularly in mathematics. This appears contradictory in the context of an inclusive approach to mathematics teaching and based on what we already know from research on attainment grouping. Drawing on observation and interview data, this paper explores how one teacher navigates this situation in both her teaching and her account of attainment grouping as a means of organizing for TPO. It argues that exploring teacher identity is crucial if we are to understand her stance.

Background literature

There is little research in Norway on the impact of teaching mathematics in attainment groups, particularly on classroom level practices. However, international research reports on differences in teaching practices between groups: teaching in lower attainment groups tends to be more traditional and is dominated by teacher-led teaching and the use of restricted and repetitive tasks. Teachers' questions are often closed with little opening for critical reflections on mathematical thinking (Kaur & Ghani, 2011). High attainment groups on the other hand are often characterized by more reform-oriented teaching, emphasizing critical thinking and deep learning through problem solving and open-ended tasks. However, work can also be fast-paced, emphasising fluency in procedural algorithms (Beswick, 2017; Francis et al., 2019; Solomon, 2007). Research also suggests that teaching in mixed groups may be less restricted and more investigative: teaching in mixed groups tends to be more differentiated, while attainment grouping treats students as a homogenous group on the same level (Francome & Hewitt, 2020; Taylor et al., 2017). Attainment grouping may therefore lead to a more restricted access to mathematics in terms of both pedagogy and content, leading to student labelling and a fixed ability view of both low and high attainers (Francis et al., 2017; Taylor et al., 2017). Teachers' perceptions of students are important. Beswick (2017) asked teachers to describe "poor" and "rich" students, finding that poor students were described as lacking proficiency, understanding and ability to explain mathematics. "Rich" students were described as being proficient in describing skills and knowledge. On this basis the "poor" students were offered restricted tasks and "good" students more open-ended tasks (Beswick, 2017). Similarly, Mazenod et al. (2019) found that teachers of lower attainers took a nurturing approach, believing that students should not be over-challenged; this led to an "over supportive" pedagogy which limited development.

As noted above, the literature indicates that attainment grouping leads to limited access to mathematics and differences in teaching approach which suggest that the practice of attainment grouping is not consistent with the view of inclusive mathematics teaching encapsulated in the Norwegian emphasis on inclusion through TPO. This tension is observed by education researchers in Norway, but the increasing practice of attainment grouping is largely unquestioned, driven as it is by pressure from international tests which show Norway underperforming in comparison to other countries (OECD, 2016) and arguments that grouping benefits higher attainers (National Centre for Science Education, 2015). Hence, to explore how teachers meet TPO policy in the context of attainment grouping, this paper addresses the Research Question: *How do teachers navigate the relationship between TPO and attainment grouping*?

Theoretical framework: "big D Discourse"

In this paper I draw on Gee's (2014) theory of language in use and situated meaning to enable a focus on teachers' enactment of their classroom practice within the context of policy requirements and school organisation. Gee's theory emphasizes the role of "big D" Discourses which are distinct from "small d" discourse and its focus on language. "Big D" Discourse captures actions as well as words, and in this sense, it also captures identity performance, which involves

> ways of enacting socially situated identities and associated practices in society through language and ways of acting, interacting, valuing, knowing, believing and using things, tools and technologies at appropriate times and places. (Gee, 2014, p. 127)

Enacting and being recognized in a Discourse requires more than language. When people are engaged in Discourse, they use language to engage in a practice to do things, but also to *be* things as they take on socially situated identities. Gee emphasizes that saying-doing-being gains its meaning from the practice it is a part of and enacts (Gee, 2014, p. 11). He foregrounds identity, arguing that saying things "never goes without also doing things and being things" (Gee, 2014, p. 3), and thus concerns recognition as a certain kind of person engaged in a certain kind of practice. To "pull off" a Discourse therefore requires the individual to both "talk the talk" and "walk the walk" (Gee, 2014, p. 24).

Gee also draws on the idea of figured worlds (Holland et al., 1998) to understand how situated meanings are constructed:

> Figured worlds is a theory, story, model or image of a simplified world that captures what is taken to be typical or normal about people, practices, things or interactions. (Gee, 2014, p. 226)

A figured world is thus a local simplification which mediates between local social interactions and Discourses, enabling enactment of a Discourse. This simplification aspect of figured worlds means that they often relate to particular values about how things are, or should be. The concepts of big D Discourse and figured worlds provide not only a theoretical perspective on the nature of situated meanings, but also a method of inquiry as outlined below.

Methodology

The work presented here is part of a larger study focusing on attainment grouping in mathematics teaching and TPO, involving four 9th grade mathematics teachers in one lower secondary school (Berg School) in Norway. Berg School had organized mathematics teaching so that the four 9th grade class groups were taught for two of their three weekly lessons according to attainment level, and in their remaining lesson as a whole class mixed group. Each of the four teachers were responsible for one attainment group and one whole class mixed group. This paper focuses on a case study of Lena, who teaches group 4, the highest of the attainment groups. The data includes two semi-structured interviews and classroom observations of three of Lena's lessons (one week of teaching). The first interview took place before observation and focused on her view of teaching in attainment grouping and TPO; the second interview took place after the classroom observations and included reflections on the lessons observed. All names of people and places are pseudonyms.

Interviews were transcribed in full and analysed by searching for references to "big D Discourse" (what kind of teacher Lena described herself as or how she wanted to be) and "figured worlds" (Lena's theories of teaching and learning, in particular her references to values about how mathematics teaching is or should be). The observation episodes were also transcribed and annotated to record Lena's and students' movement about the classroom, student hands up and so on. My analysis focused on Lena's use of questions and discussion, wait time, her use of tasks, and her use of explanations. I was interested in her choice of whole class teaching or individual work for particular activities. I also noticed how she distributed time among students and her use of positioning. Seeing big D Discourse as enactment of identity and associated practices, these references enabled an analysis of Lena's teaching practice as socially situated identity performance – that is, as performed within the context of TPO and the school's emphasis on attainment grouping.

Analysis

In this section, I draw on both the interview and observation data to analyse Lena's enactment of teaching in attainment groups and TPO, bearing in mind the big D Discourse emphasis on "saying, doing and being". Hence the interview and observation data are presented together in the analysis, since they mutually support each other in the application of big D Discourse.

A figured world of fixed ability

In the interview, Lena is clear that she sees attainment grouping as the best way for organising mathematics teaching for TPO. Her arguments suggest that she draws on a figured world in which mathematical ability is fixed. This becomes evident in her descriptions of teaching in different attainment groups and students learning according to different levels: “everyone gets something on their own level (…) and everyone is about the same level then (…) it will not be too easy or too difficult. That it is right where someone is”. Lena talks about the students as “different kinds of students” and describes them in the context of homogeneous groups based on different levels, where the students in one group are alike and have the same ability, both in terms of understanding mathematics as well as in their way of thinking: “...the others [in the group] have the same opinion, ... and everyone really thinks the same way”.

This view of students being alike can also be seen in how she describes what characterizes the mathematics and teaching approaches in the different groups. Referring to teaching for the low attainers she talks about “the “didactics” of the weak”, in which teaching is “a bit easier and a bit more practical”. In contrast she describes high attainers as taking a more formal approach to mathematics. This approach was also evident in the observation data, where her group 4 teaching valued a procedural approach to practicing Pythagoras’ theorem and how to write it down correctly:

> Lena: And then when we write down and solve those tasks, what do we always start with then? …
> Kari: Writes that formula.
> Lena: Writes that formula $k^2 + k^2 = h^2$ (Lena writes the formula on the board)

She also contrasts the low and high attainers in terms of what she sees as the usefulness of drawings for the low attainers, while the high attainers are not in need of images and examples to the same extent as the low attainers “…because that’s the way their brains are made”.

Lena’s figured world of fixed ability is also apparent when she refers to how she limits the content of talk in mixed whole class discussions because of all the different levels represented in the class.

> When I have a whole [mixed] class, I often set the level on use of concepts and… like I do not go into depth in the class talks…. Have them explain to me what they think… Instead of (…) problem solving tasks where there is a little ... high level then.

This assumption of a figured world in which there is an average level of whole class mixed group was also evident in her teaching in this group. Lena started the lesson by giving a short repetition of how to make diagrams in Excel before the students were asked to try this out as a repetition activity.

Being a caring teacher

Lena is concerned about having a good relationship to the students and she refers to this as “most of her job”, assuming a figured world in which good relations between teacher and students is an important basis for learning. This perspective indicates a Discourse of being a kind teacher who cares about the students. This is also evident in how she justifies parts of her teaching based on what the students “like to do” and what they think is “fun”: “…they like to do tasks. (…) at least in the high group, they learn a lot from working for themselves. (…) And at the same time, it is the task that they want for themselves”

The Discourse of a caring teacher is also visible in her theory of the importance of providing a comfortable learning environment for all the students in an attainment group. Comparing teaching in group 4 with teaching in whole class mixed groups, she says that it is “better” with group 4, because:

"… the students may feel a bit more comfortable, that it's kind of okay to be quite good. Because here all are good".

This caring aspect is also evident in her teaching. Often, Lena's discussion with the students does not focus on mathematics but is more about everyday life. Her language can be characterized as youthful and friendly in tone, almost like chatting. For example, Lena joins in when some of the girls start to talk about the price of the food in the school canteen, and when other students talk about the next tests and assignments in other subjects that week. Lena also enacts the caring teacher when the students work individually on tasks. As she circulates around the classroom, her comments are mainly "how is it going" rather than on the mathematics in the tasks – she does not probe what lies behind the students' frequent answers of "fine". There is thus a lot of social work going on in the lesson. Lena's position in the classroom in this part of the lesson is more as a "mate" to the students than as the teacher in a position of authority.

Lena's argument for teaching in the different attainment groups also draws on a theory of the need to take a nurturing approach to teaching. She is concerned that the mathematics teaching and content should be manageable for the students, and especially the low attainers, and that teaching should not expose the students to "too much or too difficult" stuff. As a caring teacher, Lena argues that they should be exposed to a limited mathematics content, just enough to get by: "…they should at least be able to ..., enough to do well enough on the exam anyway".

This theory of teaching is also evident in a group 4 lesson where one of the students, Tom, stops Lena in her teaching of the procedural solution of Pythagoras' theorem. Although this is the higher attainment group, Tom is unhappy with the pace, and asks (implicitly) for things to slow down. Lena's immediate response and her subsequent action suggests that she positions him as weak in the group and in need of individual attention:

Tom: It's going too fast
Lena: Am I going too fast? ... We'll look at that a bit afterwards.
Tom: Yes

Lena does not treat Tom's interruption as a request for the whole group to engage in further explanation of the mathematics. Instead, she finishes her teaching with the whole group, then comes back to talk to Tom individually. She repeats the procedure for him, going through it step by step, but now at a slower pace. Importantly, she limits her explanation to how to write the solution down, telling him to use the example as a model for the next questions. It seems as though she tries to reduce the demands on Tom, making the question merely manageable for him.

"I need control in teaching"

Lena is also a teacher who needs to be in control in her teaching. She explains that she chooses teaching approaches which are comfortable for her. One of these is talking to the students individually instead of in whole class discussion, so that she can maintain control, as in the example with Tom above. She also explains that she prefers to teach the high attainers in group 4, and that she is not comfortable with teaching the low attainers: "And, you maybe need to go down to the practical level, which I am not fond of. And then I get uncomfortable too, it just gets messy all together".

For Lena, attainment grouping makes it possible to avoid “uncomfortable” teaching where she is not in control. She argues that Jon, one of the other teachers, is the best person to teach the low attainers, simultaneously ensuring that she should not have to teach this group.

> … the one who has group 1, he has actually always had group 1, is very good at the [pedagogy]/didactics of the weak. (...) and is very good with that kind of student ... So, he wanted to have that group.

Although Lena argues for attainment grouping as the best way to teach TPO she also argues for it as better for teachers, because they are more in control: “And then we wanted to try it out to make it a little better for us teachers, to have a little more, control of the lesson then”. This emphasis on control is enacted in her practice in her emphasis on ensuring that the students write solutions in “the right way”. For example, she tells the students to start each new question by writing up Pythagoras' formula:

> And what is it that is important to watch out for when we are going to WRITE pieces like this? (…) The equal symbol below each other (Lena points to her correct notation on the board) … because then it looks much tidier.

Identifying with the high attainers

Lena's wish to teach in group 4 is not just related to her need for control in teaching. When she describes her own mathematical thinking, she identifies herself with the group 4 students:

> I like, I like it best in group 4. Because they, eh, I'm a bit bound by rules myself. Because I'm kind of the same type. (…) Eh, so that's a bit like that, there I can see how it, why they think what they do too. Because that's also the direction I'm going.

She describes herself as the same kind of mathematics person as the students, as a mathematically strong teacher. In her teaching, this view appears in how she explains the mathematics to the students, positioning herself as the authority in the classroom. She appears to emphasize the mathematics in group 4 as the most valued, enacting the Discourse of a mathematically strong teacher which assumes a figured world of fixed ability both about the students and herself as the teacher. She appears to see herself as ideally suited to teaching the high attainers.

Discussion

In this paper I have addressed the research question, “how do teachers navigate the relationship between TPO and attainment grouping?” I have focused on the story of one teacher, Lena, and her enactment of teaching in attainment groups. The analysis reveals that Lena brings TPO and the way her school organises mathematics teaching together by identifying as a caring teacher, and by drawing on a figured world of fixed ability which enables her to enact the big D Discourse of the mathematically able teacher meeting the needs of mathematically able students.

Inclusive mathematics teaching means that all students are included regardless of assumptions we might make about their potential for learning. Lena argues for attainment grouping as the best way to address TPO and inclusive teaching, but her enactment of teaching does not necessarily lead to an inclusive mathematics teaching for all students. In her fast-paced work on applying the Pythagorean algorithm she excludes Tom from taking part in the teaching with the rest of the class. Rather than opening up a whole class discussion, Lena isolates Tom and enacts the approach of the caring teacher, giving him a barely modified instruction that repeats her original teaching more slowly, with an explicit instruction that he should just follow the procedure with other questions. Lena's teaching can also be seen as non-inclusive in that she sees procedural knowledge as valuable for the high attainers, compared to limited content and restricted tasks for low attainers. It appears that her view of TPO and inclusive mathematics teaching concerns adapting teaching approaches and mathematical content in accordance with a figured world in which ability is fixed. Furthermore, her procedural approach excludes group 4 students from an explorative approach to mathematics and discussion for deep learning. This too is closely connected to a figured world in which ability is fixed. Coincidentally, this appears to serve a need for control, which may itself be an element of the same figured world in which teachers are authority figures.

Lena's enactment of teaching in attainment groups and her figured world of fixed ability is also related to the Discourse of being a caring teacher, in line with the nurturing approach to low attainers identified by Mazenod et al. (2019). Lena justifies limiting content for the low attainers on the grounds that they need only to pass the exams, and for her, seemingly as a good way of organising for TPO and inclusion. Although the Discourse of being a caring, nurturing teacher may be a way of enacting inclusion, Lena appears to prioritise good relationships and care for her students as a basis for their learning, but the result is their exclusion from engagement with mathematics learning.

This big D Discourse analysis of Lena's identity as a mathematics teacher brings together observation of her enactment of teaching in attainment groups and her account of her practice within TPO. It reveals complexity and tensions in her practice, values and enactment which make sense when we take the context she operates in into account. As noted above, in Norway the move to attainment grouping is not contested despite research evidence that it is not beneficial. Locally, Berg School has compounded this situation by deciding that TPO in mathematics teaching will be addressed through attainment grouping. Although Lena has been party to this decision, it is not hers alone; additionally, there are pressures outside of the school which prioritise examination performance. In this general context, Lena's socially situated identity as a mathematics teacher draws on particular figured worlds in which doing mathematics is seen as procedural and fixed in order to support her enactment of the mathematically able and competent teacher who supports all her students.

Lena seems unaware that her approach to teaching in attainment groups can lead to exclusion from mathematics. She seems also unaware about the tension between her figured world of fixed ability and the idea of inclusive teaching, and the potential impact of a nurturing approach on inclusion. An implication of this study is that it is important for teacher educators to work with teachers to explore teacher identity and their "big D Discourse" in order to support a more reflective enactment of their teaching practise for TPO and inclusion.

Irrational numbers in the teaching of the Pythagorean theorem: practical argumentation in a Lesson Study and Didactic Suitability training course

Viviane Hummes, Telesforo Sol, Alicia Sánchez, Adriana Breda and Vicenç Font

University of Barcelona, Spain;

vhummes@ub.edu; telesforo.sol@ub.edu; asanchezb@ub.edu; adriana.breda@ub.edu; vfont@ub.edu

This work investigates the role of the Didactic Suitability Criteria in the argumentation oriented towards action when introducing irrational numbers in the teaching of the Pythagorean Theorem in a teacher training course that combines Lesson Study and Didactic Suitability. We analysed the dialogues of the lesson planning stage of the Lesson Study cycle by means of an argumentative trajectory and the Didactic Suitability Criteria, also considering practical argumentation. We evidenced the conflicts between the cognitive and the epistemic suitability criteria in which teachers gave more importance to one criterion than another depending on the context. Epistemic suitability gives rise to considering a representative sample of problems for a partial meaning of the Pythagorean Theorem, and cognitive suitability promotes argumentation about which intended meanings can be achieved.

Keywords: Irrational numbers, pythagorean theorem, practical argumentation, lesson study, didactic suitability.

Introduction

Research in Mathematics Education highlights the need to consider students' previous knowledge in teaching and learning processes. This entails the teacher should know and comprehend students' previous knowledge and then decide what to do in the instructional process. Among some trends that regard the importance of previous knowledge, we focus on Lesson Study (Huang et al., 2019), which originated in Japan and later spread to other countries, and the Didactic Suitability Criteria (Breda et al., 2018), proposed by the Onto-Semiotic Approach (Godino et al., 2019).

In Lesson Study, implicit agreements between participants on the aspects that are positively valued emerge. These aspects can be reinterpreted in terms of the components and indicators of the Didactic Suitability Criteria. In Lesson Study, some of these components and indicators may emerge as consensuses from the reflection of the group of teachers. This justifies the inclusion of the Didactic Suitability Criteria in a training course involving Lesson Study. This phenomenon is the origin of proposals for teacher training which focus on the development of reflection on teaching practice by combining Lesson Study and Didactic Suitability Criteria (Hummes et al., 2019). In addition, analysis of teachers' reflections indicates that teachers engage in argumentation about the actions that they agree to undertake, which some authors call practical argumentation (Gómez, 2017). This argumentation occurs when the participant teachers try to find a consensus and explain their reasons as equals. The structure of this type of argument is of interest in our research.

This work is part of broader research whose objectives are designing and implementing training experiences aimed at developing reflection and teachers' argumentative competence in order to study: i) How they argue in their lessons; ii) What is their practical reasoning about the actions they decide to carry out in lessons; and iii) How Didactic Suitability Criteria relate to (teachers') arguments about their practice during the teaching and learning processes. In particular, this study focuses on an episode from a training course for mathematics teachers that combines the Lesson Study and the Didactic Suitability Criteria. It aims to analyse the argumentation oriented towards action when introducing irrational numbers in the teaching of the Pythagorean Theorem and the role of the Didactic Suitability Criteria in this argumentation.

Theoretical Framework

Lesson Study: This is the collaborative and detailed design of a lesson, its implementation and direct observation in the classroom, and its joint analysis after its implementation (Huang et al., 2019). A group of teachers and experts with a common concern about their students' learning gather, plan a lesson, and finally analyse and discuss what they observed in the implementation. Multiple iterations of this process bring the teachers many opportunities to discuss the students' learning and how the teaching influences this learning. A Lesson Study cycle should follow these stages (Lim-Ratnam, 2013): 1) study of the curriculum and goals, when participants choose content to teach and set the learning goals; 2) lesson planning, when participants set the objectives of the lesson and describe its development; 3) implementation and observation of the lesson, when they record the impact of the planning on the students' learning and collect data generated from the observation; 4) joint reflection on the collected data, when participants use the data from the observation to reflect on the implemented lesson, the students' learning and the previous planning.

Didactic Suitability: In the Onto-Semiotic Approach, the didactic suitability of an instructional process is the degree to which it meets certain characteristics that allow it to be described as suitable (optimal or adequate) to achieve an adaptation between the personal meanings developed by students (learning) and the institutional meanings intended or implemented (teaching), taking into account the circumstances and available resources (environment) (Godino et al., 2019). This is a multidimensional construct that consists of six suitability criteria: 1) epistemic criterion, to assess whether the mathematics that is taught is 'good mathematics'; 2) cognitive criterion, to assess, before starting the instructional process, whether what is intended to be taught is at a reasonable distance from what students know; 3) interactional criterion, to assess whether the interaction solves students' doubts and difficulties; 4) mediational criterion, to assess the adequacy of time and material resources used in the instructional process; 5) emotional criterion, to assess the students' involvement in the classroom; and 6) ecological criterion, to assess the adequacy of the instructional process to the educational project of the school, the curricular guidelines, and the conditions of the social and professional environment, among others factors (Godino et al., 2019).

Argumentation oriented towards action: In the Theory of Communicative Action, argumentation is defined as a "type of speech in which participants state the validity claims that have turned dubious and try to accept or decline them using arguments" (Habermas, 1987, p. 37). We focus on argumentation oriented towards action (or practical argumentation) and on the consensus that emerges from the reflection of a group of teachers on their own practice. Gómez (2017) defines practical argumentation as a “reasoning in social contexts directed to choose an action to solve a practical problem” (p. 215). The argumentative speech may be considered as a process, a procedure, and a product (Habermas, 1987). As a process, one may exclude any coaction and focus on the search for truth as an action directed to understanding. As a procedure, the discursive process of understanding is regulated as a cooperative work division between proponents (P) and opponents (O), where a validity claim (VC) that has become a problem is stated, examining with arguments whether this claim is recognized or not. In the case addressed here, some VC are discussed and the teachers can be distinguished, based on their reasons -supporting and providing argumentative strength (AS) to the VC, or trying to invalidate it (InvVC)- to recognise or not its validity. Finally, as a product, the argumentative speech is producing appropriate arguments that are convincing by their intrinsic properties and can be used to accept or refuse the VC. Arguments are the ways to obtain a common acknowledgment of the VC that the proponent states hypothetically, and through which an opinion can become a knowledge or an action. The argument trajectory (Ramos, 2006) is a tool that allows the elements of the argumentative speech mentioned above to be identified. In this study, we used an argumentative trajectory to analyse the participants’ practical argumentation.

Methodology

This is a qualitative-interpretive study. Eight mathematics teachers working in schools in the south of Brazil (students aged 11-18) participated in this research. They were graduated in mathematics and had three-to-fifteen-years of teaching experience. In addition, three of them had a master’s degree in Mathematics Education. The training program was planned as a face-to-face implementation, but it had to be restructured as a virtual implementation due to the COVID-19 pandemic. The sessions were conducted using Skype and were recorded with the participants’ permission. The training course followed these phases: 1) implementation of two complete Lesson Study cycles (two groups of four teachers, each group developed a cycle); 2) introduction of the Didactic Suitability Criteria as a tool to guide the teacher reflections; 3) new analysis of the implemented lesson and its redesign using these criteria. The first author led the training course and acted as a participant observer.

We identified different episodes of practical argumentation between the participants along the phases of the course. We also identified the role of the Didactic Suitability Criteria within the arguments given in each session, with different relevance. The analysis presented in this work can be reproduced for each of these episodes. However, due to a lack of space, we present the analysis of only one episode from the lesson-planning stage of the Lesson Study conducted by one of the groups. The participants chose the Pythagorean Theorem as the topic to be taught as it allowed them to implement the original lesson and its redesign for two different student groups (aged 14-15) at two different moments of the semester.

With the argumentative trajectory, we considered the three aspects of the argumentation in the episode: ‘process’, aiming to achieve ideal conditions for communication between participants; ‘procedure’, considering the teachers’ argumentations in the form of cooperative work division between proponents and opponents; and ‘product’, obtaining appropriate arguments to accept or not the VC about including irrational numbers in the teaching of the Pythagorean Theorem. In addition, the argumentative trajectory allowed the argumentation to be related to the components and indicators of the Didactic Suitability Criteria, in order to identify the role of these criteria in the argumentation oriented towards action about introducing irrational numbers in the teaching of the Pythagorean Theorem. The analysis followed some phases similar to those used by Ramos (2006): i) We reviewed the sessions to identify the episodes of practical argumentation between the teachers, meaning discussions between them about the decisions made to plan the lesson. ii) Once we identified the episodes of argumentation in the videos, we recognised the teachers' roles, the achieved consensus, the invalidated claims, and the reasons to invalidate them, using the constructs described in the theoretical section (P, O, VC, InvVC, AS) plus RMC (rationally motivated consensus), and CO (consensus by omission). iii) We made an argumentative trajectory to visualise the relation between VC, InvVC, and AS in the episode, and thus conclude with the RMC. We distinguished the participants as P or O, and identify who participated in the CO. Regarding the latter, some elements of the argumentation are implicitly expressed in the sessions. These elements were inferred in the argumentative trajectory from the general context where the episodes of argumentation occur. To do this, we reviewed the videos recorded during the first and second stages of the Lesson Study cycle several times. iv) We analysed the argumentative trajectory using the components and descriptors of the Didactic Suitability Criteria to identify the role of these criteria in the participants' argumentation. v) We used triangulation by experts to validate the obtained results.

Analysis

In this section, we present the analysis of an argumentation episode that occured in the planning phase of the Lesson Study cycle implemented by four participant teachers (P1, P2, P3, P4). In the first phase of the Lesson Study cycle, where learning goals were established, P1 suggested a problem about finding the length of the diagonal of a square of side one using the Pythagorean Theorem, aiming to include examples of triangles with irrational lengths, in addition to examples with natural lengths. However, at that moment, the teachers did not discuss this proposal. Nevertheless, in the phase of planning the lesson, the teachers considered presenting examples of right-angled triangles with irrational lengths. They suggested using the Pythagorean Theorem to identify the length of the diagonal of a square of side one. In the following lines, we present the argumentation episode developed by the teachers:

P1:	I think that this will be light for them [he refers to the Pythagorean Theorem as a relation between natural lengths in a right-angled triangle]. They will have problems when we talk about the square root of two, since […] students have a great difficulty understanding the irrational numbers and, when we make the square of side one, I think that it will generate certain difficulty. Don't you think so? (VC1).
P2:	But the idea was only showing that it also works for the square root, was it not? (InvVC1).
P1:	This is the idea. In this case, we should remind that the square of the square root of two is two. (AS1 to VC1).
P4:	They didn't learn that. (AS2 to VC1).
P1:	Then, as they have not seen that, there should be an easy way to verify… Did they not learn the notion of the square root of two in the number line last year? (AS3 to VC1)

P4:	We worked on the irrational numbers quite well. But what you said is true, they have difficulties accepting that the square root of two is a number. I doubt that they remember it. (AS4 to VC1)
P1:	[…] we could propose how a square of area two is. For instance, you have a square of side one, then the area is one. In order to obtain the area two, what must happen? If the square side is two, then the area will be four. Thus, they will have a notion that, in order to obtain an area two, the length of the square side should be a number between one and two […]. (AS5 to VC1)
P4:	I think that this is a wonderful idea when the lesson is face-to-face. (InvAS5 to VC1)
P3:	Because many times they see a root and get blocked. They do not even wait to see what you want to do. I think that we should do a previous class to delve into the content of roots. (VC2)
P4:	I think that, after learning the Pythagorean Theorem and really showing that it works, we could make a triangle with two sides one and try to find the third side. Then, I can mention that the square root of two is an irrational number and that length that we have just found is an irrational number. (VC3)
P1:	What about using the ruler and the compass to make, for example, a square of side one and using the compass to show the length of the diagonal on the number line? What do you think? (VC4)
P4:	I like it. (AS1 to VC4)

We identified proponents (P1, P3, P4) and opponents (P2, P4). The theses are: i) introducing irrational numbers with the Pythagorean Theorem applied to the right-angled triangle of cathetuses one; ii) the sample of problems cannot be extended due to a lack of previous knowledge and the classroom conditions.

Argumentative trajectory

i) P1 posed the problem of working on the Pythagorean Theorem with irrational lengths. (**VC1**) ii) P2 tried to invalidate VC1 returning to the initial proposal of just showing some examples of right-angled triangles with irrational lengths. (**InvVC1**) iii) P1 considered that it is important to bear in mind the properties of irrational numbers, specifically, the operations with roots. (**AS1 to VC1**) iv) P4 indicated that the students did not learn operations with irrational numbers. (**AS2 to VC1**) v) P1 tried to discover what the students know about irrational numbers. He said that they should find an easy way to verify the Pythagorean Theorem with irrational numbers. (**AS3 to VC1**) vi) P4 explained that she has worked on that, but she was not sure whether the students remember it. She confirms that students also had difficulties understanding that the square root of two is a number. (**AS4 to VC1**) vii) P1 proposed to remind the students that the square root of two is an irrational number, doing an approximation of the decimal expansion. (**AS5 to VC1**) viii) P4 argued that this would be a good idea if this were a face-to-face implementation. (**InvAS5 to VC1**) ix) P3 highlighted the need of doing a previous lesson about operations with roots to address the students' difficulties. (**VC2**) x) P4 only mentioned that the number found is an irrational number. (**VC3**) xi) P1 proposed that they could use the ruler and the compass to make a square of side one and show the irrational number that corresponds to the length of the diagonal, representing it on the number line. (**VC4**) xii) P4 said that she liked that idea. (**AS1 to VC4**) xiii) Participants achieved a rationally motivated consensus (**RMC**). P2 and P3 did it by omission (**CO**).

Participants continued discussing about the resources for the lesson. The following questions arose: How could they use the ruler and the compass in a virtual lesson? How will they record the lesson? Which should be the position of P4 during the recording with the resources?

Analysis of the argumentative trajectory from the perspective of the Didactic Suitability

i) P1 highlighted the students' difficulties during the learning of irrational numbers. He questioned whether "the intended meanings can be achieved", an indicator of the component "prior knowledge" of the cognitive criterion. ii) P2 proposed to present a situation with irrational numbers as the lengths of the sides of a right-angled triangle, without delving into the concept of irrational numbers and operations with them. P2 tried to maintain the idea of having a representative sample of problems within the same partial meaning of the Pythagorean Theorem. This is related to the indicator "for one or more partial meanings, a representative sample of problems is provided" of the component "representativeness of the complexity of the mathematical object" of the epistemic criterion. iii) P1 considered whether "the students have the previous knowledge necessary to learn the topic", particularly the knowledge on operations with irrational numbers. It is related to the component "prior knowledge" of the cognitive criterion. iv) P4, who implemented the lesson and knew the students, confirmed the students' lack of knowledge on operations with irrational numbers. The component "prior knowledge" of the cognitive criterion emerged again. v) When P1 asked if the students placed irrational numbers on the number line, he looked into the students' previous knowledge. Thus, the component "prior knowledge" of the cognitive criterion was present again. vi) P4 confirmed the students' difficulty understanding the square root of two as a number. This assertion also corresponds to the component "prior knowledge" of the cognitive criterion. vii) P1 proposed an activity to work on the idea of irrational number as a relation between the area of a square and its sides (particularly, he proposed the square of area two), searching for an approximation of the decimal expansion, as a way to review irrational numbers for the students. He tried to propose a task that included a relevant mathematical process. This is an indicator of the component "richness of processes" of the epistemic criterion. viii) P4 explained that the idea of P1 would be wonderful for a face-to-face lesson. Although she did not mention it, P4 implicitly refered to the "classroom conditions" and "teacher-student interaction". These are components of the mediational and the interactional criteria respectively. ix) P3 mentioned a possible aversion to the lesson, when the students see the roots of non-perfect square numbers. This idea is related to the component "emotions" of the emotional criterion. In addition, she proposed to do a pre-lesson activity to address the prior knowledge necessary to comprehend the mathematical object that would be taught. This proposal is related to the indicator "adaptation of the intended meanings" of the cognitive criterion. x) P4 proposed only to show that using the Pythagorean Theorem they could obtain an irrational number (in this case, the square root of two), without doing a mathematically rich process (a component of the epistemic criterion) or considering the students' lack of previous knowledge on irrational numbers (a component of the cognitive criterion). xi) P1 proposed the use of material resources (ruler and compass), a component of the mediational criterion. At the same time, he proposed an activity rich in mathematical processes (using the ruler to translate the length of the diagonal of the square on the number line). It is related to the component "richness of processes" of the epistemic criterion. This episode ends with the discussion about the means and resources for the lesson. Thus, both the mediational and interactional criteria were highlighted.

In this episode, the practical argument took place when the teachers considered an indicator of the epistemic criterion: a representative sample of problems must be provided. The group tried to find a certain balance between the epistemic and the cognitive criteria and, in this search, they resorted to other Didactic Suitability Criteria (mediational and interactional criteria). The group agreed to briefly introduce the square root of two as an irrational number after applying the Pythagorean Theorem to a right triangle with length one. This was, in a certain way, a reformulation of the initial proposal that triggered the episode. The consensus obtained depended on the relevance of the different didactic suitability criteria in the argumentative trajectory.

Conclusions

The episode of argumentation that we analysed occured in the lesson-planning phase. When the teachers were planning to work on the Pythagorean Theorem as a relation between the lengths of the sides of a right-angled triangle, they proposed to extend the sample of problems with tasks that included right-angled triangles with irrational lengths, in addition to tasks with natural numbers (Pythagorean triples). This generated an episode of practical argumentation about which actions to do, that evidences how the teachers gave importance to the students' knowledge of irrational numbers to teach the Pythagorean Theorem. Throughout the episode of argumentation, the teachers became aware of the students' knowledge through the validity claims that they made.

In order to answer our study aims, first, we could identify moments of practical argumentation in the course of Lesson Study and Didactic Suitability Criteria. As explained in the last section, the analysis of the argumentative trajectory from the perspective of the didactic suitability made evident the important role of the Didactic Suitability Criteria to argue either for or against a certain action. Didactic Suitability Criteria were essential to provide argumentative strength to the proponent. In terms of Toulmin's (Molina et al., 2019) model, the Didactic Suitability Criteria took the role of the warrant. An area of interest is why Didactic Suitability Criteria provide argumentative strength and are present even when they were not taught. Our interpretation is that this happens because the Didactic Suitability Criteria emerge from a wide consensus among the educational community.

Moreover, it is worth noting that some criteria that are recommendable a priori, such as working on the Pythagorean Theorem in a mathematically rich way or considering the students' previous knowledge, can be in conflict when they are applied to a certain context. Regarding the epistemic suitability, the sample of problems for a partial meaning of the Pythagorean Theorem (the relation between the lengths of the sides of a right-angled triangle) should be representative. The cognitive suitability fosters arguments about the intended partial meanings that are achievable and the students' previous knowledge. In this case, in the practical argumentation about introducing irrational numbers in the teaching of the Pythagorean Theorem, conflict arose between the cognitive suitability criterion and the epistemic suitability criterion. Then, the teachers focused on one criterion or the other, considering the specific context. We observed that the teachers who are in favor of extending the sample of problems, focus on epistemic suitability. While the teachers in favor of limiting the extension of the sample focus on cognitive aspects.

In the broader project, where this study is located, the main objective is to develop teacher reflection. In that sense, it is already known that teaching the Didactic Suitability Criteria to the participants improves reflection. In addition, with the design and implementation of the course that combines the Lesson Study and Didactic Suitability Criteria, it is expected to obtain data to analyse the practical argumentation in different stages of the course and, in this way, verify the influence of the combination of Lesson Study and Didactic Suitability Criteria in the promotion of teacher reflection as a professional competence. From the analysis carried out, our conclusion is that we could identify several moments of practical argumentation in which the Didactic Suitability Criteria had a relevant role. In our opinion, this occured because the training course implemented facilitates collective argumentation, among other reasons.

This paper investigates a professional development program's (PD) effect on classroom discourses. The PD was based on problem-based curriculum processing and intensive use of classroom discourse. The authors analyze seven pilot lessons of one of the teacher training's participants, providing an example of how a teacher with 20 years of experience in mathematics teaching, but using traditional teacher-centered methods, can apply the new approach in the classroom. Our analysis is based on a combined theoretical approach that starts from students' mathematical thoughts and examines the teacher's responses. We found numerous possibilities for starting classroom discussions building on students' thinking, and the teacher responded to most of them. Furthermore, the teacher's responses also included several invitations for students to classroom discourse, although these elements were almost absent before the PD.

Keywords: Professional development, problem-oriented instruction, student-centered teaching, class discussion.

Introduction

Based on the Hungarian tradition and inspired by the ideas of Tamás Varga in mathematics teaching (Varga, 1988), the second and third authors have developed a research-based professional development (PD) program. This program was piloted in 2018-2019, with four voluntary teachers as participants. One teacher's lessons are the basis for this paper, since the authors analyze the PD's effect on classroom discourses during the PD's lessons.

The PD program's two main basis points were problem-oriented curriculum processing and the systematic use of classroom discourses. Kónya and Kovács (2021) characterized the problem-oriented approach to learning mathematics by three attributes: (1) students analyze mathematical problem situations; (2) students critically adapt their own and their classmates' thinking; (3) students learn to explain and justify their thinking. This approach is very close to the idea of Roh's definition of problem-based learning: it describes a learning environment in mathematics, where problems drive learning (Roh, 2003).

Cirillo et al. (2014) believe that mathematics classrooms' discursive nature impacts students' identities as mathematical knowers and doers. Leatham et al. (2015) hypothesize that high cognitive demand tasks support the emergence of mathematically significant moments as possible starting points of mathematical discourses in the classroom. However, teachers' and students' proper reactions are crucial. Whether the active knowledge construction takes place in a discourse is decided by the teacher's reaction. Sfard (2003) points out "a productive mathematical discussion (…) turns out to be an extremely demanding and intricate task. The role of discussion coordinator is particularly difficult" (p. 375). Teachers tend to teach and make decisions by routine (Shavelson & Stern, 1981), and it is challenging to change this routine. One of the PD's aims was to break the teacher-centered pattern among practiced teachers and create more complex and precious whole-class discussions.

Therefore, this paper concentrates on two aspects: firstly, the possible starting points of classroom discussion generated by students' thoughts identified by Leatham et al.'s (2015) framework. The second focus is the teacher's reactions to these, analyzed by Sohmer et al.'s (2008) framework. With these tools, our research question is: *How does a problem-oriented professional development with additional focus on classroom discourses impact an experienced teacher's lessons with teacher-centered instructional habits?*

Theoretical frameworks applied for the analysis

A student's action is characterized as a *Mathematically significant pedagogical Opportunity to build on Students Thinking* (MOST) moment when it fulfills six criteria built on each other – each represented by a question (C1…C6) (Leatham et al., 2015), see Figure 1. "In their analytic process, the unit of analysis is an instance (…) Typically an idea unit is one conversational turn or physical expression (such as writing a solution on the board)" (Leatham et al., 2015, p. 92).

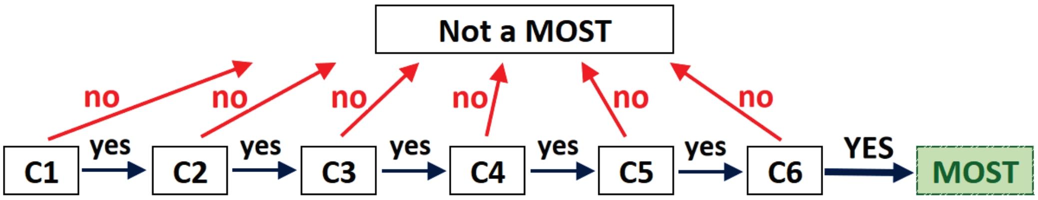

Figure 1: The MOST Analytic Framework

This framework was used to identify MOST moments in the videotaped and transcribed lessons. To find these moments, one should examine each student's utterances with six questions. These questions are built on each other, starting from the very basic point: whether the student's utterance contains understandable mathematical thoughts or not (C1, C2), then examining whether it is accessible for the students (C3) or whether it is the central goal of the lesson (C4). The fifth criteria (C5) can be described by the following question: Does the expression of the student mathematics seem to create an intellectual need (called opening) that, if met, will contribute to understanding the mathematical point of the instance? These expressions can classify into one of the following five groups: (a) a correct answer with novel reasoning, (b) an incorrect answer that involves a common or mathematically rich misconception, (c) a mathematical contradiction, (d) incomplete or incorrect reasoning, (e) why or generalizing questions. The sixth criterium (C6) is about the timing, whether it is worth taking advantage of the student's opening. Later, these criteria will be presented through an example.

Identifying MOST moments provide a quantitative description of a lesson, which can inform about the active and meaningful participation of the students. However, this framework does not provide information about the quality of the teacher's reactions. Therefore, the authors added Sohmer et al.'s

(2008) framework to analyze the teacher's reactions to the MOST moments. This framework seems to provide supportive information to assist teachers in making in-the-moment decisions about whether or how to react to those MOST moments. The authors found the combination of these two frameworks highly fruitful.

Researchers try to identify how some types of teacher interaction influence the following student's utterances to support teachers in activating students more effectively (Dahl et al., 2019). Sohmer et al. (2008) identified talk move as

> a turn at talk that (1) responds to what has gone before; (2) adds to the ongoing discourse; and (3) anticipates or ‘sets up’ what will come next. A talk move is inextricably tied to the context. It reaches beyond a single turn (p. 107).

They studied teachers who have been effective in using talk to promote learning. Six moves were identified that can be useful to model and to elicit academically productive talk: (1) revoicing students' utterances, (2) asking to restate someone else's reasoning, (3) asking students to apply their reasoning to someone else's reasoning, (4) prompting students for further participation, (5) asking students to explicate their reasoning and provide evidence, and (6) challenging or providing a counterexample.

The professional development program

The analysis of this research concentrates on a teacher with 20 years of experience in teaching mathematics. She joined the PD program voluntarily, out of an inner urge to renew her practice. The researchers visited her before the PD, observed her class, and discussed the teacher's professional view as a starting point. She used to prefer a teacher-centered way of teaching: explaining the new material, driving the students with direct questions, and rarely initiating open classroom discussions.

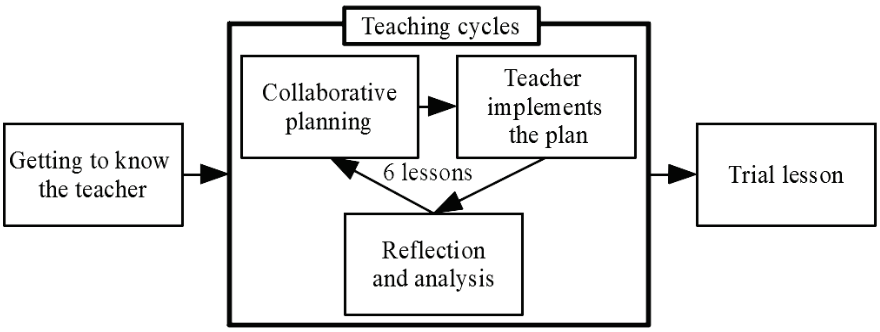

Figure 2: Scheme of the PD-program

In an opening workshop, the researchers explained the design of the program and the principles based on work by Varga (1988). The most important of them were the followings:

1. Problem-solving both alone and in pairs or small groups.
2. Improving students' oral and written communication skills encourage independent opinions.
3. Let students learn through experience and using heuristic strategies.

4. The teacher's role should include encouraging group discussions, planning classroom discussions, and implementing students' proposals into the flow of the lesson.
5. Differentiation and individualized treatment for each student.

After selecting the pilot lessons from the teachers' agenda, the researchers developed detailed lesson plans and provided all the teaching materials. These lesson plans explicitly contained reminders and advice on how to realize the principles of the PD. For example, there were time slots devoted to classroom discussions after solving a problem in small groups.

The teachers gave their opinions and suggestions and finalized the lesson plans. The teacher needed to feel that the lesson plan suited her at the end of the collaborative planning. At the end of the lessons, the teacher should reflect on it both alone and accompanied by the researchers.

The researchers organized six teaching cycles (three per semester during one year of the experiment) and concluded the year-long program with one trial lesson (Figure 2). During the planning for the trial lesson, the teacher had to come up with her own lesson plan.

The whole research process and focus are summarized in Figure 3.

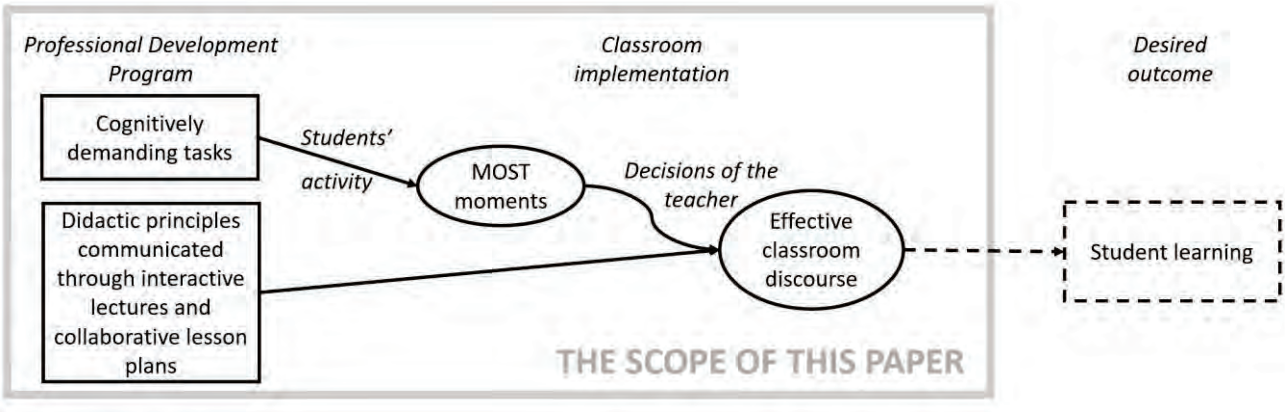

Figure 3: Scheme of the research

The process of analysis

Each 45-minutes lesson was videotaped and transcribed. Two researchers analyzed the transcripts independently and looked for moments where all the six MOST criteria appeared. In a disagreement, the three authors' consensus fixed the MOST moments. The transcripts of each lesson were investigated in the same way:

1. The authors separated those parts of the lesson in which the whole class discussion occurred and identified each observable student utterance according to Leatham et al. (2015).
2. All of these instances were coded according to the six MOST criteria.
3. Further distinctions between the MOST units were made according to the situation that caused it (see criterion C5) and assigned one of the above codes a, ..., e to each unit.
4. After gathering the MOST moments, the authors examined the teacher's response to these MOST moments in a new analysis process according to Sohmer et al.'s (2009) framework. Three categories emerge A) The teacher evaluates the student's action and tells the correct

answer if it was incorrect. B) The teacher starts a classroom discussion. C) The teacher does not notice the MOST moment.

5. Case B was further refined, determining the occurred talk move. In line with the work of Sohmer et al. (2009), the authors used the following codes: the teacher B1) revoicing the student's utterance, or the teacher asks a student for B2) restating someone else's reasoning, B3) commenting on someone else's reasoning, B4) further participating, B5) providing evidence or B6) providing counterexample. The traditional Initiation–Response–Evaluation pattern (IRE) completes the code system as B7.

We illustrate our coding system with an example.

Example - Class 9, fourth pilot lesson

Topic: Divisibility

Episode: Whole class discussion after finding all divisors of 54 in pair work. (Time: 35:49-36:16)

Student:	Can I write them as products? (He writes on the blackboard 1·54,2·27)
Teacher:	[Please use] semicolon…
Student:	(He corrects and writes 1·54;2·27;3·18; 6·9)
Teacher:	How did you know you had to finish here?

This activity is considered as mathematical problem instead of routine task because the student has to define the procedure itself. The teacher does not present the solution as usual, but it appears as the students' activity, as he uses the structure of products to identify all divisors of 54.

The two student manifestations were considered a single action because the teacher's interruption is mathematically insignificant. However, this interruption demonstrates the teacher's accustomed state of controlling everything. The authors classified this student action as a MOST moment because it meets the C1-C6 criteria:

C1. The student is concentrating on mathematical ideas and not offtopic themes.
C2. The mathematical point of the instance is to determine all divisors of a number and decompose it into two-factor products in all possible ways.
C3. The mathematical point is accessible to all students, but at that point not all students realized it as a helpful tool for the task.
C4. A deep understanding of the above procedure is one of the lesson's goals.
C5. A deeper analysis of the fifth criterion shows that this is the case (d), i.e., incomplete reasoning, as the student wrote the products in a logical order but did not verbalize the reason behind it.
C6. Finally, the timing is considered appropriate as all students were paying attention, and there were still nearly 10 minutes left in the lesson.

The teacher recognized the MOST moment and asked the student to provide evidence, i.e., to explain why the presented procedure is appropriate for finding all the divisors. Therefore, the authors coded the teacher action responding to the MOST moment as B5.

Findings and analysis

The emergence of MOST moments

The analysis found numerous MOST scenes that have emerged applying the problem-oriented lesson plans, which were considered satisfactory from the researchers' point of view (Table 1).

Table 1: The emergence of MOST moments

MOST category	a) Novel reasoning	b) Incorrect answer	c) Mathematical contradiction	d) Incorrect reasoning	e) "Why" question	Total
Occurrence during the 7 lessons	13	22	0	16	2	53

Most of the MOST situations in this research emerged from students' incorrect answers (42%), and "MOST" situations based on the student's novel approach or the student's "why" questions were less frequent while mathematical contradictions did not appear.

Teacher's reactions on MOST moments

The teacher identified the MOST scenes effectively (Table 2). The authors attribute this success to the teacher's 20 years of practice, in addition to the influence of the PD. Leatham et al. (2015) also support this view implicitly, as they stated that novice teachers could miss realizing when a MOST scene has developed more often.

Furthermore, 64% of the identified MOST moments do not end with a simple teacher evaluation but lead to a "talk move." The authors consider this to be the result of the PD's approach, as the teacher was aware of the importance of classroom discourse, which she almost neglected in her previous teaching practice.

Therefore, the PD's result is considered to be the realization of the importance of the MOST moments and the use of the appropriate talk moves in the teacher's reactions. In conclusion, the teacher started using the learner's initiative to guide the lesson.

Table 2: Teacher's reactions on MOST moments

MOST category	A (evaluation)	B (talk move)	C (unnoticed)	Total
Occurrence	18	32	3	53

The subtle structure of "talk move" reactions

The dominant "talk move" reaction was that the teacher involved others in the conversation (B4, 20 out of 32 talk moves, 62.5%), see Table 3. Thus, B4 has become an almost permanent behavior, especially in the case of novel reasoning by the students. However, the teacher has also used it when a more detailed explanation of the student's own thinking, i.e., elaboration (B5), would have also been adequate. Moreover, since the problem-based approach requires the learner to think critically about his/her thinking, encouraging this elaborative behavior would also have been part of the problem-based learning approach.

Table 3: The subtle structure of "talk move" reactions

MOST category	B1 revoicing	B4 participate	B5 elaboration	B6 counterexample	B7 IRE	Total
a) Novel reasoning	0	7	0	0	0	7
b) Incorrect answer	1	5	3	2	2	13
d) Incorrect reasoning	0	7	3	1	0	11
e) "Why" question	0	1	0	0	0	1
Total	1	20	6	3	2	32

Conclusions and pedagogical implications

During the PD's lessons, when the teacher got support from training, lesson plans, and collaborative lesson planning, numerous MOST moments mainly emerged from students' incorrect answers or incorrect reasoning. Furthermore, the teacher identified MOST scenes effectively. Most of them do not end with a simple teacher evaluation but lead to a talk move, supporting students' activity. Based on one previously observed lesson and the discussion on her professional view of teaching before the PD, the authors believe that this is the result of the PD's approach. Although further research is needed to prove this finding.

Based on the above result, the authors conclude that the PD is probably suitable to improve the amount and the quality of classroom discourse in an experienced teacher's lessons. It would be worth examining lessons after the PD to explore more about the PD's long-term effect.

It is worth to highlight that identifying mathematically valuable moments is insufficient. Teachers must also be aware of the importance of MOST moments and consciously apply potential talk moves. However, we still know little about how the implementation of talk moves unfold and what is needed to enable teachers to apply them effectively in practice. In connection with it, this paper also argues that the two joined frameworks were beneficial to examine how the demanding mathematics gets leveraged into productive discourse.

Initiating a community of practice amongst primary school mathematics teachers – trials and triumphs

Tarryn Lovemore[1], Sally-Ann Robertson[2] and Mellony Graven[3]

Rhodes University, Faculty of Education, South Africa;
[1]tarrynlovemoreIC@outlook.com; [2]s-a.robertson@ru.ac.za; [3]m.graven@ru.ac.za

This paper derives from the early phases of the first author's doctoral study. Eight primary school teachers at a school in South Africa's Eastern Cape Province were invited to be part of a community of practice in which strategies for using music to support the teaching and learning of fractions would be explored. Wenger's theory of community of practice guided the first author as facilitator in this collaborative space. Having immersed herself as a researcher in the school context, she began by inviting the participating teachers to interrogate and trial a series of integrated mathematics and music lessons designed by the authors. In this paper the authors analyse some of the early trials and triumphs of working within a community of practice.

Keywords: Community of practice, curriculum integration, primary school mathematics teachers.

Introduction

The first author has, as part of her doctoral research, initiated a Community of Practice (CoP) (Wenger, 1998) with a group of primary school mathematics teachers, all of whom teach at the same school in South Africa's Eastern Cape Province. The intended purpose for this CoP is to explore strategies for integrating music into the teaching of fractions to Grade 4, 5 and 6 students (children between the ages of 9 and 12). Initiating the CoP has, however, been compromised by a number of factors and the first author has had to make a number of adjustments to her initial research design choices. In this paper, the first author, together with her co-authors (the joint supervisors of her doctoral study), share their analysis of some of the initial data from this early phase of the study.

Researcher-teacher relationships are not new to education research, and much focus has been placed on the fostering of positive interactions. Initiating and working within a CoP is not without challenges. In the present instance, some of the challenges encountered are unique to the particular setting; some derive from the unprecedented current global Covid-19 pandemic situation; some are common to CoP platforms more generally (see for example, Pyrko et al., 2017). Many CoPs fail to "reach maturity" (Bouchamma et al., 2018, p. 91). Reasons for challenges noted in the literature include a lack of the appropriate means and strategies to initiate and develop a CoP, as well as difficulties encountered in ensuring that CoP members' needs are met in ways that sustain mutual engagement (Bouchamma et al., 2018; Pyrko et al., 2017). Our initial findings around some of the challenges, and some of the successes, we encountered in getting our particular CoP up and running, may, we believe, be relevant and helpful to other researchers working in similar CoP contexts.

Literature around national, regional and international bench-marking assessments point to low levels of mathematics achievement in South African schools. In writing about these concerning achievement levels, Venkat and Graven (2017) argued that inadequate support is given to South Africa's mathematics teachers in achieving curriculum aims and that this has contributed to a lowering of teacher morale. Spaull (2019) similarly noted that many South African teachers were found to lack confidence in their mathematics content and pedagogical knowledge which negatively impacted their morale. Such observations highlight a need to better support teachers, providing them with opportunities to enhance their competencies, and ensuring they have access to appropriate teaching and learning resources and associated strategies all of which might also then contribute to boosting teacher morale. The first author's setting up of the CoP thus represents one such initiative. It provides a forum through which to support her own ongoing professional development together with that of the participating teachers while simultaneously being able to interrogate task and learning support materials design decisions. For brief discussion of some of the first author's earlier work on the use of music to help strengthen her own Grade 5 students' fractional understanding, see Lovemore, Robertson and Graven (2021).

Literature review and theoretical framework

The South African mathematics curriculum (South Africa. Department of Basic Education [DBE], 2011) aims to develop deep conceptual understanding of mathematical concepts, as well as recognition of mathematics as an elegant and creative human activity. Furthermore, integration across subjects is encouraged. The authors recognised potential benefits of integrating music into mathematics lessons, which, as literature suggests, can contribute to increasing student motivation and participation, and decrease anxiety (see for example, Edelson & Johnson, 2003).

Wenger's CoP model (1998) was used to explore such integration strategies. A CoP is a space where professionals can share strategies, solve problems and learn from one another (Bouchamma et al., 2018; Pyrko et al., 2017). In particular, Wenger's CoP model interrelates the concepts 'community', 'identity', 'practice' and 'meaning' so providing participating teachers with rich opportunities to reflect critically on their teaching practices and resources. As Wenger (1998) explains, *community* refers to developing "relations of mutual accountability" (p. 81) where information and resources are shared responsibly in supporting members; *identity* reflects members' ways of talking about their role in the context of their community (for example, their professional confidence as mathematics teachers); *practice* implies action within a social context which, in turn, gives *meaning* through community members' shared experiences.

The first author, in her role both as researcher and as CoP facilitator (for the sake of simplicity, throughout the remainder of this paper, the phrase 'first author' will be consistently used), was mindful of the deficit perspective noted in literature where, all too often, teachers are viewed as objects rather than professional partners in research undertakings. Such a perspective makes teachers feel 'used' rather than genuine "research collaborators" (Makar, 2021, p. 440). Setati's (2005) distinction between research 'with' teachers and research 'on' teachers is useful, highlighting as it does the merit in creating reciprocal power dynamics between researcher-teachers whereby all benefit from the research interactions. Consistent with Horne and Makar's recommendations about designing a "win-win project" (2013, p. 769), teacher choice and empowerment needs to remain key throughout. Mutually positive relationships help ensure that all members of the group find the project significant to their own practice. This, as Horne and Makar (2013) note, requires planning a mutually agreed upon vision and values, maintaining mutual respect, valuing all members' input and practicing patience and perseverance. Challenges in sustaining a CoP (Bouchamma et al., 2018) notwithstanding, the first author hoped that once the CoP had got off the ground, participating teachers would want to continue in this collaborative space to explore further opportunities for curriculum integration even after her own withdrawal from the site. In our next section we outline key aspects of the methodological decision-making process.

Methodology

Guided, as noted, by Wenger's CoP principles (1998), the first author issued an invitation to eight practising mathematics teachers to explore with her music/mathematics integration strategies. The CoP first met in February 2021. The school at which all of these teachers are employed is a private one and well-resourced relative to many other schools in the country. The school's teaching and learning philosophy actively encourages its teachers to explore innovative teaching strategies, including more integrated approaches towards curriculum delivery. The school's principal welcomed the ideas informing the first author's proposed CoP, adjudging them as fully consistent with the school's commitment to the ongoing professional development of its teachers and he granted the requisite gatekeeper permission to approach the teachers accordingly. All eight teachers voluntarily gave their informed consent. The first author emphasized to them that she was researching *with* them as co-researchers (Setati, 2005). She emphasised too that the research would focus on teaching strategies and resources, not on individual student or teacher achievement.

The design of the broader qualitative, participatory design research study consists of three phases: (1) preliminary introduction phase, (2) collaborative phase, (3) evaluation phase. It is the first and second phases of initiating and maintaining the CoP that constitute the substance for the present paper.

Ahead of the preliminary introduction phase, the first author immersed herself in the school context to gain the kinds of autoethnographic insight (Du Plooy-Cilliers et al., 2014) that would help inform her researcher interactions with the CoP teachers. Although some have questioned the value of auto-ethnographic studies because of their interpretive and subjective nature, auto-ethnography provides a powerful mechanism for researchers to "self-interrogate" (Denshire, 2014, p. 834) their role within a research setting. The first author strove to consistently and critically evaluate her ongoing researcher/facilitator relationship and interactions with the CoP teachers. As a full member of the social group being studied (Anderson, 2006) she continues with her auto-ethnographic journey, spending full days at the school and observing classes, engaging in reflexive practice by writing entries in her reflective research journal during and after every CoP meeting. Reflective journals and field notes represent, as noted by Farrell et al. (2015), an important part of data collection in autoethnography

The preliminary introduction phase is now complete. It consisted of introducing the music-mathematics connection and sharing with the CoP teachers integrated mathematics and music activities. The second (collaborative) phase is still underway. Teachers have been invited to interrogate and adjust the suggested strategies and resources, to experiment with them, and to then reflect on what worked well or otherwise in their integration of music into their teaching of fractions. Via mainly focus group discussions and interviews, the CoP teachers have been providing the first author with valuable feedback data from their early trialling of the various strategies and resources.

Transcriptions of the audio-recorded CoP meetings, focus group interviews and electronic communication between the researcher and the teachers have been made. Data continue also to be collected via the first author's ongoing reflective research journal entries detailing reflections on critical moments, as well as on her verbal exchanges, both formal and informal, with the teachers. Together with the external data from the other participants, this self-reflection provides a means of triangulating the data.

Farrell et al. (2015) explain that thematic analysis in ethnography requires the researcher to "step back and think about the story" (p. 979), which may then result in the development of themes which describe the social interactions. The first author's transcribed field notes, reflective research journal and supplementary external data such as the CoP meetings and interviews, allowed for thick description (Maxwell, 2013) of some of the trials and triumphs experienced both by the CoP teachers and by the first author. The focus here is on identifying patterns and themes emerging from these transcriptions during these two phases of the study. Themes were identified deductively, based on Wenger's (1998) CoP model, by coding the data according to the four elements, *community* (C), *identity* (I), *practice* (P) and *meaning* (M). Patterns emerged from the data which allowed the authors to identify lessons around the trials and triumphs of initiating a CoP to trial novel integration strategies. These are discussed in our following section.

Discussion on preliminary findings – trials and triumphs

In this section, we share preliminary findings on, and insights deriving from some early trials and triumphs encountered by the first author in her working with the CoP. Before doing so, however, we note also that many aspects of the study have been, and continue to be, affected by the global Covid-19 pandemic. Disruptions included the school having to close for periods of time; some teachers being forced to isolate in quarantine; the need to introduce a blended learning approach. Such circumstances placed additional pressures on the participating teachers, and many planned CoP meetings had to be postponed, resulting in a break in momentum and affecting the first author's communications with the teachers. It also created additional time constraints.

Clear communication to maintain momentum

In facilitating the CoP, the first author found a lack of continuous communication delayed the CoP teachers' trialling of some of the strategies and resources. Weeks would pass between meetings and communication, and lines of communication became blurred. She noted in her reflective research journal, 'There is no clarity as to what communication channels to follow' [06/05/21]. The Head Teacher had, for example, suggested the first author communicate directly with the CoP teachers. The teachers, on the other hand, requested that arrangements should rather go through the Head Teacher. This challenge in communication threatened to compromise the 'community' aspect of the CoP (Wenger, 1998). Graven (2004) emphasizes the importance of access to other members in the community and a wide range of "ongoing activity" (p. 182) in order for a CoP to be successful. Finding time, however, in which all the teachers could meet as a group proved a challenge. Normal expectations on teachers, with the additional demands of blended teaching and learning due to Covid-19, meant that their time to meet were limited, leading to the first author deciding to rather be more of a physical presence at the school, something that had initially been suggested by the school principal. She made her visits to the school more frequent and regular. This provided opportunities for more informal ongoing discussion with CoP members. She found that the teachers responded more favourably to these informal, small group discussions, and welcomed opportunities to share their experiences around their trialling of the various integration strategies and resources. The less formal visits appeared to strengthen the first author's relationships with the teachers, and communication increased. Rather than waiting for the next scheduled, face-to-face meeting, teachers began to show a greater willingness to communicate with her via platforms such as WhatsApp and email when they had questions requiring immediate responses, or simply wanted to share a comment about something that had happened in a lesson. This development led to the first author making the research and ethical decision to continue these informal (individual, or small group) conversations alongside the CoPs more formal discussion sessions. They gave her an additional means of supporting the teachers. She observed in her reflective research journal: "I came to the conclusion that supporting Teacher P individually is ethical, as I do not want the study to cause additional pressure or anxiety for her" [28/05/21]. Key points arising from these informal exchanges were noted for subsequent follow-up at the scheduled whole group CoP meetings.

A further challenge the CoP teachers experienced was trying to fit the integrated lessons into their term plans. These were already under strain due to the school days missed because of Covid-19. The Head Teacher alerted the first author to this, during a Zoom meeting, "… something that the teachers are wrestling with … is to find time to fit in these lessons, over and above their weekly curriculum work" [02/06/21]. The first author realised that CoP members had not yet come to recognise the potential value of the integrated lessons as a time-saving mechanism for their teaching of fractions. Instead, they saw the integration ideas as an 'add on' to their existing workload. Data showed this to be an example of the teachers questioning the 'meaning' (Wenger, 1998) of the CoP goals, but the first author was reassured when some of the teachers acknowledged that, once they had become more confident in delivering their integrated mathematics-music lessons, this approach may indeed have represented a more efficient use of teaching time.

The fostering of equitable power relations

Makar's (2021) description of teacher-researcher collaboration resonated with the first author relative to roles within the CoP. She was aware of possible difficulties to do with differential power relations. In the introductory meeting she had emphasised to the CoP teachers that she intended for them to work together as a team of equals, interrogating and adjusting various ideas around integration strategies and resources. Early on, however, she noticed that teachers were experiencing concerns and challenges in trying to teach the initial suggested lessons to try to 'get it right'. She therefore re-emphasised Makar's point (2021) that there is no 'right' or 'wrong' way to carry out lessons, and that, as co-researchers, teachers were at liberty to adjust initial ideas around the design and teaching of a lesson. Recognising that her status as a researcher may inadvertently have made teachers feel somewhat disempowered, the first author reiterated in follow-up meetings the point about their status as co-researchers meaning that, far from following top-down directions from her, they were free to make their own choices as to how to tackle the lessons. Once they had accepted this point, and due, also, to the challenges limiting the frequency of scheduled CoP meetings, the teachers began discussing amongst themselves elements of their lessons and of the challenges encountered. They nominated Teacher P to communicate the substance of these discussions to the first author. Consistent with Wenger's CoP model, they appeared now to be developing a genuine community and embracing their identity as participants/ co-researchers. This data was interpreted as evidence that the CoP was succeeding in encouraging members to exercise greater autonomy over their decision-making. Reflecting on this in her research journal, she wrote:

> Perhaps this is a sign that the participants in the CoP are starting to work together and share common goals. I don't want to be prescriptive or top down in the CoP but rather facilitate the teachers to act. [06/05/21]

The creation of a safe space to trial and interrogate new ideas

During the introductory meeting, there was every sign of initial buy-in from the teachers. They appeared interested in finding out more about the novel idea of integrating music and mathematics. During the preliminary introduction phase, the teachers pro-actively made suggestions as to how they might adjust the resources to make the application of the lesson easier in their classes. Teachers discussing adaptations early on in the study, the first author noted as a positive element of the CoP, taking this as evidence of shared 'practice' and 'meaning' (Wenger, 1998). Keeping in mind a warning from Krajcik et al. (1998, p. 41), she remained aware, however, that challenges teachers face when trialling new strategies and resources may lead to "premature rejection" of such innovations. Cautious to avoid this happening, she spent time reflecting with the teachers on their challenges in teaching their mathematics-music integrated lessons. Some teachers, for example, expressed uncertainty about the second lesson which was based on Western Staff notation of music note values.

> Teacher K: I am starting to wrap my head around it. [21/05/21]
> Teacher D: I didn't feel like in my mind, I knew what I was doing. So that was my mistake. I think I did it fine, but in my mind I still– I wasn't 100% confident. [10/09/2021]

It was these sorts of aspects that the CoP teachers identified as challenging that led to the co-authors having to further grapple with the wisdom of using Western Staff notation. They adjusted the musical representations, stepping back from Western Staff notation (for example, two eighth notes: ♫) and instead, adopting a percussion representation of music beats per bar (using Xs to indicate claps), which, further along, could then be adjusted to reflect a number line. The following comments indicate that the teachers responded favourably to this adjusted musical representation, expressing greater confidence about being able to integrate the music into their fraction lessons:

> Teacher P: I'm really feeling more confident with that [the Xs representing claps] than with the music notes.
> Teacher D: For me, taking the notes out of it and that you say adding a set of claps makes a total difference. I feel more confident. [10/09/2021]

Seven months into the study, after many disruptions, a CoP meeting was held where Teacher K described to the other teachers how her own teaching of mathematics had evolved in response to her participation in the study. The first author recognised this as positively representing the collaborative intention that ideally informs a CoP's research focus and 'meaning'.

> Teacher K: I've changed the way I've taught fractions. Today we had to do a table on common fractions to decimal fractions to percentages. And for the first time ever, I've said, "Okay, but now this common fraction is five fourths –", because I've always just given them three fourths or two thirds…And then they were fascinated, because

> they said, "But then you can't get a percentage!" And I said, "You actually can. It's 125%." And then we had a very interesting conversation because of how you would use it; you can't get 125% for a test, but you can have 125% mark-up… Yeah, and I would never have thought to do that without that jumping/clapping exercise and talking about a fraction as a measure, rather than part of a whole…I think it's taught me how to teach fractions. [10/09/2021]

Conclusion

Analysis of the critical feedback from CoP members, together with first author's preliminary auto-ethnographic data suggests some key lessons which can support researcher-facilitators when trialling new strategies for teaching mathematics. Three key lessons were identified for this paper. A first key lesson is that clear communication channels are of utmost importance for maintaining momentum within a CoP. Immersing oneself in the CoP's school context provides opportunities for gaining deeper insight into the experiences of the teachers which not only helps build more meaningful relationships with the CoP teachers but also provides more time to support them via informal, small group meetings. This became particularly important given the additional time-constraints caused by Covid-19 circumstances. A second key lesson is that the potential for power inequities need to be countered to foster teacher-researcher teamwork and action essential for this kind of collaborative research endeavour. And finally, a third key lesson is that a CoP context has rich potential to act as an invaluable, supportive and empowering space in which not only researchers, but also teachers are able to reflect upon, interrogate, and adjust innovative strategies for enhancing teaching and learning, such as, in this instance, the integration of mathematics and music.

Identifying improvisation in the secondary mathematics classroom

Nick McIvor

University College London, Institute of Education, London, UK; nick.mcivor@ucl.ac.uk

This paper argues that improvisation is a common feature of expert mathematics teaching, but that the processes involved remain under-explored by the research community. Drawing on ideas from organisational theorists and improvisational theatre practitioners as well as educational writers, it proposes a framework for identifying and analysing the practice of improvisation in the secondary mathematics classroom. It then goes on to place a more clearly defined concept of classroom improvisation within a wider understanding of teacher expertise and suggests future directions of study.

Keywords: Secondary mathematics teaching, creative teaching, decision making, interactions.

Why improvisation matters.

'Good teachers think on their feet,' was the opening statement of Robert Yinger's 1986 paper presented at the AERA Conference that year (Yinger, 1986, p.263). He clearly regarded this as a self-evident truth, making no attempt to justify the claim beyond the assertion that 'few educators or researchers of teaching would deny this' (Yinger, 1986, p.263) and going on to use the term 'improvisation' on four separate occasions as he discusses the key skills that underpin successful, interactive teaching.

Yinger's discussion is entirely theoretical and does not focus on any particular subject, but his ideas were developed by Borko and Livingston (1989). They found that the 'expert teachers' of mathematics (identified as such by both school and county leaders) were very skilled at keeping the lesson on track while including the comments and questions of their students in the discussion whereas novices struggled to accommodate student input in their lessons. Borko and Livingston concluded that a key marker of maths teacher expertise is a capacity to improvise productively.

Berliner (1994) draws on a range of different sources including Borko and Livingston in an influential survey exploring the nature of teacher expertise more generally. He proposes eight characteristics that distinguish the 'exemplary performance' of expert practitioners including the practice of being 'more opportunistic and flexible in their teaching than are novices' (Berliner, 1994, p.161), and, like Yinger, repeatedly uses the term 'improvise' to describe this behaviour. Rowland, et al. (2003) choose the term 'contingency' in preference to 'improvisation' as one of the four pillars of 'The Knowledge Quartet', which they propose as a framework for understanding mathematics teacher knowledge, but are clearly describing a very similar phenomenon, echoing Yinger when they define it as 'the ability to "think on one's feet"', (Rowland, et al. 2003, p.98). More recently, Pinto (2017), explicitly linked expert mathematics teaching to jazz improvisation in title of his paper delivered at the CERME conference that year.

Improvisation appears to be a recurring theme in discussions of teacher expertise, including expert mathematics teaching, and the brief account offered above draws on a much wider body of work. Despite these frequent references, however, there are very few detailed descriptions of what improvisation might actually look like in the classroom, and still fewer suggestions about how teachers might develop their skills in this area. Borko and Livingston, for example, offer only a few, quite general indications of teacher practice, such as the post-lesson reflection by expert teacher 'Scott' who explains: "I sort of do a little and then they do a little. And then I do a little and then they do a little" (Borko & Livingston, 1989, p.484). This, seemingly casual approach to defining such a key concept is because Borko and Livingston are not primarily concerned with the practice of improvisation, but with the nature of mathematics teacher expertise. Specifically, they are trying to articulate the distinctive ways in which novices and experts conceptualise their mathematical knowledge and conclude that the experts have 'an extensive network of interconnected, easily accessible schemata' (p.485) which enable them to respond more quickly and productively than novices with less well-connected schemata. For Borko and Livingston, therefore, the capacity to improvise well is a pointer towards the structure of this expert teacher knowledge. The implication is that such schemata are a necessary condition for improvisational teaching; the question that remains unasked is whether it is also a sufficient one.

Borko and Livingston (1989) link the notion of improvisation to the metaphor of the teacher as a performer. Developing this line of inquiry, Barker and Borko (2011) explicitly connect classroom practice to a number of seminal texts on stage improvisation such as Spolin (1963) and Johnstone (1981). This is an appealing prospect, because improvisation for the stage is recognised as a teachable skill by drama schools and theatres across the world. If similarities between successful classroom and theatrical improvisation can be identified, well-established methods for developing improvisatory skills on the stage may offer a route for mathematics teachers to move towards expertise more rapidly. The remainder of this paper is devoted to a consideration of how this might be accomplished, offering a conceptual framework for re-examining existing literature and undertaking further investigation.

Identifying improvisation in existing Maths Education literature.

The near silence of Borko and Livingston (1989) with regard to the processes involved in improvisation has already been noted. A decade later, Remillard (1999) described improvisation as 'on-the-spot curriculum development' (p.331), claiming that the practice is central to the way in which textbooks and other curriculum materials are used in the classroom. In contrast to Borko and Livingston, Remillard's primary concern is on the effect this practice has on the way teachers use textbooks and other materials, rather than the way their knowledge is structured, but like them, her interest in the processes involved is secondary; she does, nonetheless, identify one broad category of improvisatory practice – that of 'task adaptation' (Remillard, 1999, p.328) – as an important feature of expert teaching and gives some thought to the way in which this accomplished.

Remillard situates improvisation within a framework of curriculum development comprising three 'arenas' in which teachers participate: the over-arching arena of 'curriculum mapping' which defines the organisation and content of the entire school mathematics curriculum and two distinct, subsidiary arenas of 'design' and 'construction' where the day-to-day decisions made by individual teachers take place (Remillard, 1999, p.322). In this conception, a central feature of the construction arena is 'improvising in response to students' (p.322), and although it is not her primary focus, Remillard offers some analysis of what she terms the process of 'task enactment', breaking it down into two distinct activities, first ‘*reading* of students' performances, that is, observing and listening to students in order to assess their understandings’ then ‘*improvising* in response’ (Remillard, 1999, p.329, author's italics).

Brown (2009), develops Remillard’s discussion of the way teachers improvise in their use of curriculum materials, explicitly associating the process with the way in which jazz musicians interact with a musical score. Drawing on of Yinger’s proposal that teaching can be seen as a ‘design profession’ (Yinger, 1986, p. 275), he describes this design process as one which treats ‘curriculum artifacts’ – textbooks, slides, worksheets and so on – as tools with which the teacher interacts. In Brown’s model, these interactions can be placed on a 3-point scale that characterises the level of teacher agency involved according to the way the artifact is used. The lowest level of agency is labelled ‘*offloading*’ (Brown, 2009, p. 24, author’s italics), which would be exemplified by a teacher simply issuing a worksheet without offering any guidance to pupils beyond that provided by the publisher. The next level is termed ‘*adapting*’ (ibid., p. 24) and involves the use of some existing artifact but involves the teacher making some adjustment to its original use in response to the needs of the class. It is worth pointing out that this kind or adaptation could potentially be planned prior to the lesson, distinguishing from highest point on Brown’s teacher-agency scale, which he identifies with the term ‘*improvising’* (ibid., p. 24). To be classified as falling into this final category, Brown envisages the teacher moving beyond the scope of the original artifact and devising their own spontaneous strategy.

Like Remillard, Brown’s focus is on the use of curriculum resources, but he also identifies three types of ‘teacher resource’ that have a significant impact on the way those curriculum resources are used, ‘a) subject matter knowledge, (b) pedagogical content knowledge (Shulman, 1986), and (c) goals and beliefs’ (Brown, 2009, p. 27). In terms of relating these concepts to practice, however, the discussion is largely theoretical and focuses on ‘The Design Capacity for Enactment Framework’ which the author proposes as ‘a starting point for identifying and situating the factors that can influence how a teacher adapts, offloads, or improvises’ (ibid. p. 27). While the notion of teacher-as-designer is an intriguing one, and Brown’s framework offers an indication of the factors that may be in play when a teacher is engaged in the kind of ‘on-the-spot curriculum development’ described by Remillard (1999), it offers little insight into the processes involved in classroom improvisation.

Any attempt to explore existing literature on classroom improvisation soon encounters the problem that the term is often deployed in studies that appear to be addressing quite different issues. Even the Borko and Livingston study which uses the term in its title is addressing the broader issue of expertise, while Remillard and Brown are concerned with the use of curriculum materials. To identify what is known about improvisation in the mathematics classroom, the first step is therefore to identify the terms in which it has been discussed in the past. In their systematic review of adaptive teaching in mathematics, Gallagher et al. (2022), use the term ‘Teacher Improvisation’ as one of several for their initial database trawl (although for some reason they ignore ‘contingency’). The mere fact that they have placed improvisation within the scope of their search shows that they are adopting a far broader understanding of ‘adaptation’ than the one proposed by Brown, and indeed some of the studies cited in that review seem to regard the terms ‘improvisation’ and ‘adaptation’ as virtually interchangeable. In fact, the Gallagher et al. review offers a useful collection of related terms for conducting a survey of improvisation-related research in Mathematics Education, including adaptive teaching, responsive teaching, unexpectedness, noticing and orchestrating.

Having established an approach to identifying the work that has addressed improvisation in the past, an even more fundamental question arises, namely: what do all these different concepts have to do with 'expert improvisation' as it is understood in the theatre? To answer that question a clear definition of improvisation is required alongside an account of what constitutes expertise in both the classroom and the theatre. The next section proposes a conceptual framework for understanding both ideas in these two very different settings, and perhaps surprisingly, starts in the office.

Improvisation and expertise in the office, on the stage, in the maths classroom.

Organisational theorists Crossnan and Sorrenti define improvisation as '*intuition guiding action in a spontaneous way*' (2002, p. 27, author's italics). They are concerned with behaviour in commercial settings which are very different from a secondary mathematics classroom, nonetheless, aspects of their theoretical framework shown in Figure 1 offer useful insights into how it might be possible to differentiate between spontaneous classroom actions that might be considered fully improvisatory and those which are to some extent prepared.

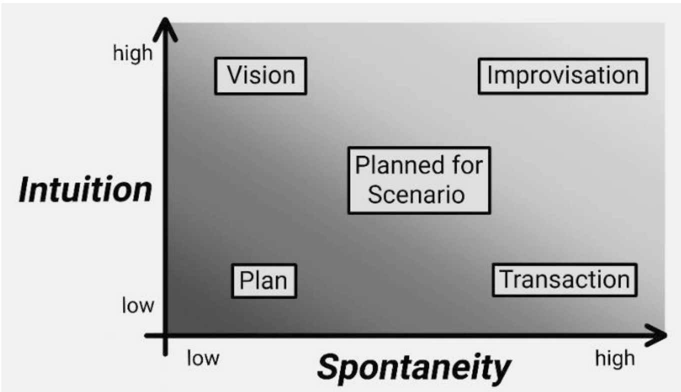

Figure 1: Adapted from Crossnan and Sorrenti (2002)

A key insight of this model is way it places planning and improvising at opposite ends of a spectrum, with the intermediate notion of 'planned for scenario' in between. The proximity of 'planned for scenario' to 'improvisation' in the diagram hint at the possibility that improvisation may be more accessible for teachers who have considered possible scenarios more thoroughly, as they are able to move easily into the semi-improvised region of working within anticipated contingencies, bringing improvisation within easy reach, but it is premature to read too much into what is, after all, a conceptual structure with no obvious scale. The other aspect of the structure which is of interest at this stage is the positioning of the 'transaction' category to describe 'spontaneous but not intuitive' actions. The Crossnan and Sorrenti model therefore allows for the possibility of actions which are spontaneous – in the sense of being immediate but not part of the teacher's formal plan – and yet not improvised. This distinction narrows the concept of improvisation being explored here from the wider category of 'adaptation' described by Gallagher, Parsons and Vaughn as 'any diversion from the lesson plan stimulated by some classroom event' (2020, p.1).

A drawback of Crossnan and Sorrenti's definition of improvisation is that it rests on two other concepts: spontaneity and intuition. Their understanding of spontaneity as acting 'in-the-moment' without time for serious forethought is clear enough, but their view of intuition as 'an unconscious process based on distilled experiences' (2002, p.28) is more elusive. The view taken here is captured in the aphorism: 'intuition and judgment – at least good judgment – are simply analyses frozen into habit' (Simon, 1987, p.63). Intuition is therefore seen as a rapid decision-making process rooted in prior learning which may be inadvertent or deliberate.

While organisational theory has provided a succinct definition, the practical appeal of improvisation is its supposed 'teachability', at least in the sense in which it is understood by stage performers. This raises the obvious question of how the improvisational performances that might win applause in a theatre relate to those that have the potential to support learning in a mathematics classroom. To address these difficulties, the first step is to move the 'theatrical' metaphor from the public setting of the stage to the relative privacy of the rehearsal room. This simplifies the analogy by removing the audience but leaves the teacher in the role of director and continues to situate the pupils as performers. The next step, therefore, is to move yet further from the metaphor of the stage, and rather than envisaging the classroom as a rehearsal space, view it as an 'improvisation workshop.'

One of the most influential figures in the development of improvisational theatre in the mid-twentieth century was the American, Viola Spolin. She talks at length of the 'workshop' (Spolin, 1963, p.18), as the space where performers can develop the skills they need before embarking on formal rehearsals. For Spolin, the key task of the workshop 'teacher' – and it is interesting to note how often she uses the term teacher – is '*giving problems to solve problems*' (Spolin, 1963, p.20, author's italics) through 'problem-solving games and exercises' (Spolin, 1963, p.9). The final step in mapping an improvisational performance to an improvisational mathematics lesson identifies the students as workshop participants the with the teacher adopting the dual role of 'workshop leader' (or 'game-chooser') and player.

To explain the connection between Spolin's notion of a 'problem-solving game' and the mathematics classroom, the key improvisational principle of 'accepting offers' is required. In improvisational theatre, an 'offer' is defined as 'anything that an actor does' (Johnstone, 1981 p. 97); to 'accept' an offer, another performer – or player of the game – must acknowledge that action and build on it, a strategy that is sometimes codified as the 'yes, and…' principle. The brief extract below illustrates this principle in action during a Year 7 class (11– 12 years old) in the autumn of 2020. To make sense of the exchange, the reader needs to know that the pupil has mistakenly interpreted the marker for '–6 degrees' on a temperature scale as 'negative four'.

1	Teacher:	How did you know that one's a negative four?
2	Pupil:	Because it's like, one line behind negative five.
3	Teacher	Yeah, we're at negative five and we've gone one down…
4	Pupil	…negative six!
5	Teacher	Negative six degrees, okay. Remember, when we're going in the negative direction, we're counting down the number line

In line 1, the teacher starts the game by making an 'offer' which involves questioning a pupil who has given an incorrect answer. In line 2 the pupil 'accepts the offer' by answering the teacher using the ambiguous term 'behind' and in line 3, the teacher uses a 'yes, and…' structure to accept the pupil’s offer while simultaneously clarifying the term ‘behind’ through what they say, and by moving their pen one unit to the left along the number line drawn on the board. In line 4 the pupil accepts the teacher’s offer and corrects their earlier answer, then in line 5, the teacher accepts the pupil’s new offer and builds on it by offering a more general description of what is meant by the word negative, again reinforcing their spoken words with actions, this time, walking backwards across their pre-drawn number line in a ‘negative direction’. The way in which the teacher responded, incorporating details of what the pupil had said in their responses provides strong evidence that their remarks were spontaneous rather than planned, and the ease with which the dialogue flowed, with no pause for deliberation, indicates that any decision-making process was intuitive. It is therefore argued that this exchange demonstrates genuine improvisation according to the definition being used here.

According to Johnstone, ‘good improvisers seem telepathic; everything looks prearranged. This is because they accept all offers made – which is something no 'normal' person would do’ (Johnstone, 1981, p. 99). Lines 2 to 5 demonstrate both participants immediately accepting each other’s offers, but the interaction seems rather brief to serve as an exemplar of expert practice. In fact, the offer-acceptance structure continues and is shown below

6	Teacher:	This is just a number line; it’s just a number line disguised a thermometer.
7	Teacher:	Negative six degrees.

At the end of line 5, the teacher had reintroduced the number line (which was discussed earlier in the lesson) and in line 6, they ‘accept their own offer’ taking the idea of the number line and relating it back to the thermometer on which the original question was based. Finally, in line 7, the teacher rejects their own ‘offer’ of the thermometer, and simply restates the correct answer offered by the pupil earlier, ending the improvised episode. Johnstone describes this kind of rejection with the rather pejorative term ‘blocking’ and regards it as something to be avoided, but in this instance, the teacher is using the tactic deliberately to end a diversion from an existing plan, judging that enough time has been spent on this particular question.

The discussion above highlighted several similarities between theatrical and classroom improvisation, but the exchange on which it is based also illustrates several key differences, one being the very different levels of knowledge possessed by the participants. In a workshop situation, it is reasonable to expect all those involved to be aware of the ‘yes and…’ principle, but this does not apply to a mathematics classroom. In a well-run class, the teacher can reasonably expect a pupil to ‘accept’ a direct question and ‘offer’ an answer, which is exactly what happens in line 2. The teacher is then able to incorporate the answer into their next statement. However, the next utterance by the pupil was not so much an offer as an inadvertent calling out of the correct answer, and it was only the skill of the teacher that allowed them to transform line 4 into an offer by responding instantly, accepting, and incorporating it into their next statement. Realising that they could not rely on the pupil to productively maintain the dialogue any longer, the teacher then elected to continue with the offer and acceptance structure in the form of a monologue for as long as they felt necessary. A second important difference between theatrical and classroom improvisation is its purpose: in classroom, it serves to draw in the student by including them in a learning dialogue that serves the teacher’s wider goal. This contrasts sharply with a workshop where the priority is to explore a situation until is mutually agreed that the scene has run its course. Given the different priorities of the classroom, ‘blocking’ by the teacher is legitimate strategy. It is therefore argued that the episode above shows expertise in theatrical improvisation re-interpreted for the classroom.

It is further argued that this brief exchange includes behaviours which are consistent with the account of expert teaching outlined by Winch (2017). In this model, successful learning is identified as ‘epistemic ascent’ (EA), which is explained using the following metaphor: consider a subject expert (who may or may not be an expert teacher) as someone with an overhead view of a room, that room represents the subject, and the view they have of every item within it and all the relationships between those items represents their knowledge. The novice is ‘gradually opening the door to that room, initially gaining partial glimpses of apparently unrelated items’ (Winch, 2017, pp. 80-81), and the process of EA is moving from the view of the novice to the view of the expert. To facilitate this journey among their students, the expert teacher must therefore understand ‘the kind of difficulty that they may be experiencing in learning’ (Winch, 2017, p. 137, author’s italics). To take the learner on this journey, the teacher obviously needs a thorough grasp of the relevant subject knowledge – metaphorically, an ‘expert’ grasp of where all the items within the room lie and the relationships between them – but Winch goes further, suggesting that the expert teacher needs the ability to switch between the perspective of the omniscient expert and that of the novice at will (2017, p. 81). The teacher response in line 3 could be explained by imagining the teacher making such a perspective-shifting move: ‘seeing’ how their pupil has (mis)read the number line, then moving rapidly to teacher mode and homing in on the point where they moved in the wrong direction from the correctly interpreted ‘–5’ marker. The speed of the pupil’s response in line 4 adds weight to this hypothesis.

Conclusion and next steps

This paper adopts Crossnan and Sorrenti’s (2002) definition of improvisation as ‘*intuition guiding action in a spontaneous way*’, going on to argue that the language of theatrical improvisation – in particular, the so-called ‘yes and…’ principle – offers an approach for identifying the practice in mathematics classrooms. It embeds these ideas within a wider understanding of teacher expertise and proposes a mechanism by the which the interconnected framework of knowledge referred to by Borko and Livingston and further explored by Winch might facilitate the practice.

The published evidence cited here is inevitably limited. Borko and Livingston's observations from 1989 are consistent with the view of expert teachers as skilled in perspective shifting, but a more detailed review of existing literature, starting with the terms noted earlier in this paper, needs to be undertaken to ascertain whether there is widespread support for this view. The empirical research described here is still sparser, and the few lines of classroom dialogue merely hint at the ways in which expert teachers might exercise their improvisational skills. More thorough investigation is clearly required. Nonetheless, the prospect of finding simpler ways to articulate, and ultimately teach others to productively engage in spontaneous classroom interactions continue to inspire this author to keep searching.

Entailments of questions and questioning practices in ambitious mathematics teaching

Reidar Mosvold[1] and Kjersti Wæge[2]

[1]University of Stavanger, Stavanger, Norway; reidar.mosvold@uis.no

[2]Norwegian University of Science and Technology, Trondheim, Norway; kjersti.wage@matematikksenteret.no

The work of teaching mathematics is complex and involves numerous problems and challenges for teachers to handle. Questioning is a slice of mathematics teaching that is both common and challenging. In this paper, we use the context of collective planning in a Norwegian professional development initiative as a space for investigating questions and questioning practices in ambitious mathematics teaching. Based on analysis of nine co-planning sessions, which were carried out over the course of two years, we suggest that questioning practices involve considerations of: 1) what types of questions to ask, 2) purpose of questions and questioning, and 3) timing of questioning. Based on our conceptual framework, we propose a fourth logical entailment relating to the positionality of students, and we suggest that further research is needed to explore this entailment.

Keywords: Questioning, planning, mathematics teaching, interactions.

Introduction

More than a century ago, in her seminal study of questions as a measure of effective teaching, Stevens (1912) investigated if the number of questions asked by teachers could serve as a proxy for efficiency in instruction. Interestingly, she found that it was also necessary to consider the quality of questions. Based on observations across different subjects, Stevens identified three elements of questioning that indicate quality: questions have to stimulate reflection, they must be adapted to students' experience, and questions must aim at moving students' thinking forward. Despite an increasing number of studies of teacher questions and questioning practices, Gall (1970, p. 707) introduced her review of research on the use of questions in teaching by stating that even though everyone agrees that questions are important in teaching, "researchers still do not know much about them. What educational objectives can questions help students to achieve? What are the criteria of an effective question and how can effective questions be identified?" As evident from the review of Gall, as well as from other reviews of research on questions and questioning in (mathematics) education, studies tend to highlight either how questions are used in the classroom (e.g., Gall, 1970), or what constitutes effective questions and questioning practices (e.g., Shahrill, 2013; Wilen & Clegg, 1986). In other words, studies often have a similar focus to the seminal study of Stevens (1912).

Following recent discussions in Thematic Working Group 19 (TWG19), this study attempts to shift focus from *what teachers do* to consider teaching as a *work to be done*. Instead of focusing on activities performed by teachers – and their effects on student learning — we follow Ball (2017) in our attempt to investigate what constitutes the special work of teaching mathematics, and we seek to explore and understand the entailments of this work. In particular, we focus on questioning practices, which constitutes a slice of the work of teaching. Whereas Stevens (1912) focused on questioning in recitation, we focus on questioning in discussions within the context of ambitious mathematics teaching when we approach the following research question:

What can be entailed by questions and questioning practices in ambitious mathematics teaching?

Our use of the word ‘entail’ indicates that something is logically involved or necessitated, and it points toward a view of teaching as work, which implies that it is something to be done, or task(s) to be undertaken (Work, n.d., para. 3). When we use the term ‘questions and questioning practices’, we follow Enright et al. (2016), who use the term with reference to a collection of practices that are carried out within the teaching profession.

Conceptual framework

This study draws on a conceptualization of teaching as instructional interactions that are collaboratively constructed between teacher and students around a particular content, and situated in broader environments (Cohen et al., 2003). Mathematics teaching can never be considered as transmission of content in isolation, but it is “co-constructed in classrooms through a dynamic interplay of relationships, situated in broad socio-political, historical, economic, cultural, community, and family environments” (Ball, 2017, p. 15). In addition, we draw on the notion of teaching as work, as described by Ball (2017) and Lampert (2010). Following their interpretation of the work of teaching, we consider teaching as a complex work that entails many demands and dilemmas that teachers must manage. A study of the work of teaching mathematics, in this sense, thus involves efforts to identify and understand these demands and dilemmas, rather than describing what teachers do and attempting to make sense of these actions.

Our study also draws on a conceptualization of ambitious mathematics teaching where students’ emerging mathematical thinking and sensemaking is at the forefront. Ambitious mathematics teaching aims at positioning students as sense-makers and provide equitable access to learning. To achieve these aims, ambitious mathematics teaching typically includes facilitation of mathematical discussions that elicit and build on students’ thinking (Kazemi & Hintz, 2014). The study draws on data from a larger project, called Mastering Ambitious Mathematics teaching (MAM). This project is organized around cycles of enactment and investigation, and it is inspired by similar projects in the United States (e.g., Lampert et al., 2013).

Methods

Thirty Norwegian elementary teachers participated in the project. In the cycles, teachers were divided into four groups. We analyze data from one group of eight teachers in the present study. The groups participated in 12 sessions over a period of two years, and nine sessions were organized around learning cycles that include the following phases: 1) *Preparation* that involved reading and watching videos; 2) *Collective analysis* guided by a teacher educator around principles and practices central to the instructional activity; 3) *Co-planning* of the instructional activity; 4) *Rehearsal* where one or two teachers tried out the activity with colleagues acting as students; 5) *Enactment* of the instructional activity by the same teacher with a group of students (age 11–12); 6) *Collective analysis* that included reflections on how the principles and practices had worked out. We anticipated that experienced demands and dilemmas would become most visible in the planning phase, so our focus here is therefore on the third phase of the learning cycles.

We analyzed nine co-planning sessions using Sportscode video analysis software, which allowed for direct coding on the videos. Initial deductive coding followed an adapted version of the discussion planning framework of Boerst et al. (2011). We then conducted inductive coding of the segments that were coded as *questioning* in the initial coding phase, with an emphasis on trying to identify tasks that are entailed in the work. Instead of asking what teachers did, and what they discussed in the planning sessions, we asked what kinds of problems, dilemmas, or decisions they were faced with. Three categories emerged from the inductive coding, and these are presented and discussed below.

Entailments of questions and questioning practices

In the following, we present excerpts from our data material to illustrate and discuss the proposed categories of entailments.

Considering type of question to ask

In the planning sessions, we observed several instances where the group engaged in discussion of what questions they could ask students. This is not surprising, as questions abound in mathematics lessons; when teachers want to guide students in a certain direction, they often try to use questions instead of teaching by telling.

In the second session, when the teachers planned an activity using quick images, they discussed the challenge of stimulating the students to identify a certain pattern. One teacher suggested that they could ask: "How can you use the 4 times table to get the first number? In other words, how can you get 5 as an answer when you have to use the 4 times table." Another teacher commented that this is hard for students, both to visualize and discuss. One of the teacher educators in the group interrupted,

TE1: Yes, but let's try to come up with a really good question that helps the students understand where we want to go, shall we? Because this is really where we are at, right. If we want them to discuss this, which we might not want to eventually, but if we want them to discuss this…

This was one of several instances where the teachers discussed how to use questioning to guide the students in a particular direction, which is a task that is entailed in the work. In this case, the teachers wanted to help the students discover the pattern of $4n + 1$. From the teacher educator's reference to "a really good question", and from the overall discussion, it appears that the aim here was to identify a particular question that could work as a prompt to stimulate exploration through discussion, rather than to check students' understanding, as in recitation.

Although the primary focus in this discussion seemed to be on finding the best question to ask, we notice that there is also an embedded focus on purpose. This leads to the next, and tightly related, kind of entailment that teachers are faced with in questioning practices.

Considering purpose of questions and questioning

Another entailment is thus to consider the purpose of questions and questioning practices. For instance, teachers can consider how to formulate a question to stimulate students' thinking. We noticed that this is also at play in the above discussion of the type of question to ask. In another session, the teachers discussed how they wanted students to discover connections between a string of tasks, but they hesitated to ask the students straight away if they could see any connections. One teacher reflected, “So, we want to tell them: I want you to consider these numbers now. Do you see any connection between them?” Then she added, “Is it wrong to be so direct about it?” The teacher educator affirmed that they could ask students directly if they could see any connections, but this challenge of how direct they should be, and what kind of questions they should ask, persisted.

As the teachers continued to discuss this, the issue of whether to use an open question came up.

T1:	When we say, in the context of 4000 divided by 160, we could ask: Do you see a connection with the previous task? 400 divided by 16.
T2:	Should we say that?
T1:	Well, if we say that, they have to consider it for a while, and then they will notice that both are multiplied by 10. And, what do you think happens there?
T3:	That is kind of more open. If you consider these expressions, what do you think about?

Although this appears to be another example of considering what type of question to ask, we notice an underlying challenge relating to purpose here. The task of deciding on a type of question to ask is thus entailed by considering the purpose of stimulating students’ thinking, which is important in ambitious mathematics teaching. Sometimes teachers consider using an open question to allow for more creativity and exploration, but, at other times, they might consider using a more closed and directive question to check on students’ understanding. This choice depends on the purpose.

Considering order and timing of questioning

A third entailment of questions and questioning practices relates to timing. In direct response to the discussion above, T2 asked: “But do you think we should say that first? Should we begin by asking if they see a connection, or should we let them think for a little while first, before we hook them on?” This points at two considerations that need to be made in questioning practices: one concerning the *order* of questions, and another concerning the *timing* in the sense of finding the exact right moment to ask a question. If the overall aim of an activity is to stimulate exploration, which is prominent in ambitious mathematics teaching, teachers might want to start by asking a more open question, before asking for connections more directly. T2 seemed to be conscious about this challenge. When one of the other teachers moved on without responding, he continued to press for reflections about this: “But should we ask them: Do you see a connection with the previous task? Or should we allow them to think a little bit on their own first, to see if someone actually discovers it … before we hook them on?” On the one hand, we notice that this comment is indicative of a challenge concerning the order of questions. On the other hand, there appears to be an entailed issue concerning timing, both with respect to timing of the questions in the overall trajectory of the class, but there is also an entailed challenge of how long to wait before providing the students with a more directed question.

The discussion of order and timing above relates to a situation that the teacher controls. Deciding what question to ask first or how long students may think before posing a more directive question, are both examples of issues that teachers can consider beforehand, as they plan the lesson. However, in a classroom with real students, unexpected situations often occur. For instance, a student might immediately come up with a solution that ends the discussion prematurely. This kind of situation was discussed in the third session, where the teachers planned an activity on quick images (see Figure 1).

TE1: What do we ask if this [pattern] comes up quickly?

T1: This relates to our previous discussion about how 9 can be represented in different ways. So it might be a good idea to bring up that one in addition, showing that they are almost similar. Perhaps put this [pattern] below the other one.

TE1: But what if someone says 3 times 9? Yeah, that was nice. Then the discussion is kind of over. What kind of questions do we ask then, in order to move on?

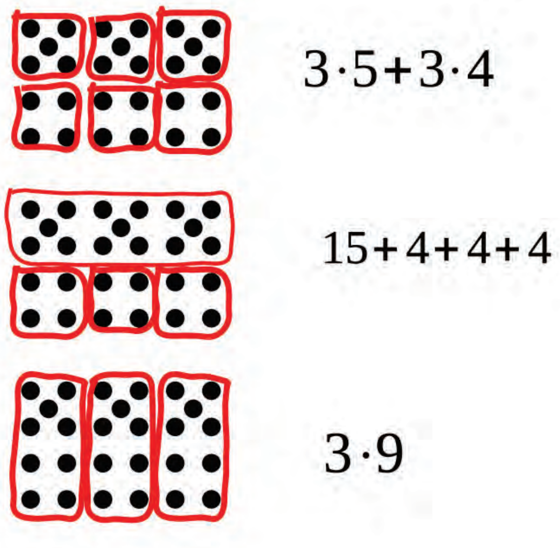

Figure 1: Reconstruction of some of the teachers' annotations on the quick images discussed

This question was followed by a pause in the conversation, indicating that it was considered a dilemma by the teachers. One of the teachers followed up, suggesting that they could prompt the students to explain their thinking, and show the others how they see the 9 in this representation. This suggestion corresponds with the literature on cognitively guided instruction (e.g., Carpenter et al., 2015), and points at eliciting students' thinking. The initial issue of timing in questioning is thus related to the more foundational question about purpose of questions and questioning practices.

Discussion

In her review of research on questioning, Gall (1970) emphasized the *type* of questions being asked, and Stevens (1912) focused on type of questions as well as the number of questions that were asked. Early studies of questioning in teaching had less emphasis, however, on the *purpose* and functions of questions, and they did not emphasize *timing* of teacher questioning. Yet, we can recognize some of these as underlying perspectives in many studies of teacher questioning. Another important difference between our study and other studies of teacher questioning is that most other studies focus on what teachers *do* – what types of questions they ask, what purpose their questioning has, and how their timing of questioning influences students' learning – and not on the entailments of the work of questioning. In the following, we discuss results from our study in relation to previous research, and in relation to our conceptual framework. Analyses of what teachers do often end up in evaluation of their performance, attempts to explain why they performed in a certain way, or in efforts to measure the effects of their performance on students' learning. As opposed to this, analysis of teaching as *work* tends to focus on understanding the complexity and entailments of teaching and its demands. Such analysis thus contributes to unpacking and conceptualizing the work of teaching, and it may also contribute to developing a much-needed professional language to describe this work.

Every review of questioning in teaching that we have seen involves a focus on types of questions that teachers ask. In her review of the use of questions in teaching, Gall (1970) notes that studies have used different taxonomies for classifying types of questions. She highlights Bloom's taxonomy as the one that "best represents the commonalities that exist among the systems" (p. 710). Later reviews, both in general education and in mathematics education, also highlight the importance of considering cognitive levels of questions (e.g., Shahrill, 2013; Wilen & Clegg, 1986). With respect to the instructional triangle, considering the type of question to ask relates to what is described in the triangle as interactions between teachers and students. In ambitious mathematics teaching, deciding on the type of question to ask is particularly important. Whereas use of questions might be appropriate to check on students' understanding, it can be challenging to decide on a good question to prompt discussion.

Considering the purpose and function is another entailment of questions and questioning practices, and Enright et al. (2016) unpacked this entailment in their attempt to develop a typology of questions by instructional function — also by applying the instructional triangle as conceptual framework. Whereas teachers in the context of planning would typically consider the purpose of questions and questioning, the entailments that teachers are faced with inside of the instructional interactions would often be more related to considering the functions of questions. Consideration of purpose and functions of questions would often be located along the axis of interactions between teachers and content, for instance when considering purpose in relation to the learning goal for the lesson. However, purpose and function of questions might also involve considerations around what types of interactions between students and content that teachers wish to facilitate. For instance, teachers might decide to use open questions or why-questions when they aim at facilitating a discussion, whereas more closed questions or what-questions might lead to recitation. Ambitious mathematics teaching aims at facilitating discussions that elicit and build on students' mathematical thinking (Kazemi & Hintz, 2014), and our analysis illustrates some of the challenges teachers are faced with when trying to build on students' thinking without being too directive. This balancing of drawing on students' thinking while at the same time leading a class toward a mathematical goal may constitute a dilemma.

Entailments of considering order and timing of questions might involve similar considerations as those teachers have to make in the context of purpose and function. One aspect of timing that has frequently been described in research on questions and questioning is wait time (e.g., Shahrill, 2013; Wilen & Clegg, 1986), and this was also visible in the planning discussions we analyzed. Considering what is the appropriate time to pose a question has been less focused on in previous research, but it is also something teachers need to consider when interacting with students. Our analysis also indicates that considerations of order and timing of questions and questioning might constitute a task of teaching that is particularly pressing in the context of ambitious mathematics teaching. As one of the teachers noted, a student might come up with a response that are perceived by the class to end the discussion, and the teacher is then faced with a considerable challenge of coming up with a follow-up question or prompt to move the discussion forward.

All three entailments of questions and questioning practices that we have identified thus appear to fit well within the instructional triangle, and we have discussed above how these entailments are particularly pressing in the context of ambitious mathematics teaching. What we did not observe in our analysis of planning sessions, and what we have not seen much of in other studies, are considerations around interactions with environments with respect to questions and questioning practices. Recent studies of the work of teaching mathematics that build on the conceptual frames of the instructional triangle have explored interactions with environment in terms of considering identity and positioning of students. For instance, in her discussion of what constitutes the mathematical work of teaching, Ball (2017, p. 17) states:

> Central to bear in mind is an inherent fact of teaching, namely, that teachers are always communicating, relating, and making sense across differences, including differences in age, gender identities, race and ethnicity, culture and religion, language, and experience. This important dimension of difference in identity and positionality means that a fundamental part of the work of teaching is being aware of and oriented to learning about and coordinating others' perspectives.

Thus, a logical entailment of questions and questioning practices would be to also consider identity and positioning. As can be seen from the quote above, such considerations tap into interactions with environments and is a fundamental — but often overlooked — part of the work of teaching mathematics. There are a couple of possible reasons why positionality did not emerge as a category from our analysis. On the one hand, it might be a feature of the project. The teachers in the MAM project engaged in cycles of planning and enactment in a context where they did not know the students. When planning the activities, they had to make assumptions about students, since they did not know what students they would encounter before the enactment phase. In a context when teachers do not know their students, they might not be expected to consider positionality, which requires knowledge of students and their identities. On the other hand, the lack of emphasis on positionality in planning of these instructional activities might also indicate a general lack of emphasis on positionality among (these) Norwegian mathematics teachers. If that is the case, it is even more important to emphasize this — both as a fundamental part of the work of teaching mathematics, and as a fundamental part of questions and questioning practices in mathematics teaching. We believe that considering *positionality* might constitute a fourth entailment of questions and questioning practices in mathematics teaching, and we call for future studies to investigate it. This is particularly important in the context of ambitious mathematics teaching, which aims at positioning students as sense-makers and provide equitable access to learning mathematics (Kazemi & Hintz, 2014). There is thus a need to explore what this might look like in questions and questioning practices.

Conclusion

Questions and questioning practices in teaching have been studied for more than a century. Whereas much research has focused on how teachers use questions and the effects of these questioning practices on student learning, we propose to instead focus on trying to understand what might be entailed in questions and questioning practices — considered as a slice of the professional work of teaching mathematics. From our analysis of teacher planning sessions, we identified three entailments that relate to considering what *types* of questions to ask, the *purpose* of asking questions, and the *timing* of questioning, which includes considering both the order of questions and deciding on the right moment to ask questions. In addition, we suggest that a fourth entailment is also involved in questions and questioning practices: considering *positionality* of students through questioning practices. This involves attending carefully to how teachers' questions and questioning practices can contribute to providing equitable access for all students and thus serve as part of an overall effort toward justice and inclusion — in school, but also in the society at large.

An investigation of teacher's practices when teaching mass measurement in grade 4 in Malawi

Liveness Mwale[1] and Arne Jakobsen[2]

[1]University of Malawi, Zomba, Malawi; lmwale@cc.ac.mw

[2]University of Stavanger, Stavanger, Norway; arne.jakobsen@uis.no

This paper reports on a study on teachers' practices when teaching mass measurement in grade 4 in Malawi. Data was collected from video recordings of three grade 4 teachers (two lessons each) who were purposively sampled to ensure they were teaching measurement of mass. The teachers' practices were analysed using the Mathematics Discourse in Instruction (MDI) framework. Findings of the study showed that the common teachers' practices included: having lesson plans with clear lesson goals, using similar examples and tasks throughout the lessons, involving learners in hands-on activities without providing the conceptual understanding of the tasks, and asking low level questions. We argue that teachers' practices when teaching mass measurement should focus more on developing learners' conceptual understandings of mass measurement.

Keywords: Teacher's practices, mathematics discourse in instruction, measurement, mass.

Introduction

Measurement of length, area and mass is a central part of primary school curriculum in many countries (e.g., Ministry of Education, Science and Technology [MoEST], 2006; National Council of Teachers of Mathematics [NCTM], 2020). Research on the teaching of measurement shows it is poorly taught in many countries and is focused on procedures rather than conceptual understanding (Clements, 2003, Irwin et al., 2004, Zacharos, 2006). Stephan and Clements (2003) have attributed this to curricular content, teachers' knowledge and instructional practices. Cheeseman et al. (2011) challenged the traditional-curriculum approach of using informal units for an extended period of time before introducing standard units of measure, and Zacharos (2006) showed that both students and teachers have difficulties in understanding the concepts of measurement.

While several studies have investigated the teaching of length and area measures, less is known about the teaching of mass measurement in primary school. For example, in our review of research reported in CERME11 (see Jankvist et al., 2019), we found 12 studies reporting on the measurements of length and area, but none reporting on the teaching of mass measurement. In addition, research about the teaching of mass measurement in the Malawi context is specifically lacking. This motivated us to investigate Malawi teachers' practices in the teaching of mass measurement. Measurement is one of the core elements of the mathematics curriculum in Malawi, from grade 1 through secondary school. For grades 1 and 2, the curriculum includes mass measurement using non-standard units, while in grades 3 and 4, learners are introduced to the standard units of mass and are taught how to measure mass in kilograms and grams (MoEST, 2006). The learning of measurement involves the use and understanding of procedures and the development of conceptual understandings. In the literature, these are commonly discussed in relation to length measurement (e.g., Battista, 2006; Lehrer et al., 2003) but can be transferred to other measurement concepts like mass.

According to Cheeseman et al. (2011) children need rich experiences involving the measurement of mass, especially in the early grades. Rich experiences are those in which learners are offered opportunities to engage in activities that lead to conceptual understanding in mathematics and challenge them to think and foster the communication of mathematical reasoning.

We describe teacher practices as what teachers do and say in a lesson. Teacher practices matter in mathematics lessons and determine what learners learn and the skills they acquire (Adler, 2017). This is particularly critical in teaching measurement and in early grades where learners depend on teachers to learn. The need to understand practice in the Malawian context motivated our research question:

What are teachers' practices when teaching measurement of mass in grade 4 in Malawi?

Literature review

McDonough et al. (2012) found that although measurement may look simple, insights gained from research into young children's concepts of mass measurement show that the learning of measurement can be complex. Some studies on mass have focused on learning in early grades. McDonough (2010) showed that children in the early years of school have informal knowledge of mass measurement. They develop this knowledge during outdoor play activities prior to formal schooling. Some acquire the knowledge of mass measurement from handling or weighing things at home (Spinillo & Batista, 2009). Cheeseman and McDonough (2013) reported that children's learning about measurement continues from experiences prior to school through formal schooling, where they are taught about attributes of measure including length, mass, time, area, angle, and volume. MacDonald (2010) found that children four to six years old have an awareness of the attribute of mass, as revealed in drawings of measurement situations. These and other findings reveal the importance of underlying knowledge and skills that early grade learners bring to the learning of mass measurement. These include informal knowledge of mass, handling or weighing objects and attributes of mass. Knowing learners' prior knowledge ensures that the teacher works towards building on what is already known and correcting misconceptions.

The teaching of mass in early grades involves measuring in both standard units and non-standard units. McDonough and Cheeseman (2015) found that in learning to measure, children develop other skills, such as how to use a balance scale, and develop understanding of foundational ideas, including awareness of the attribute, comparison and unit iteration. Other skills that learners develop in measuring mass are precision and origin (Lehrer et al., 2003, Sarama & Clements, 2009). Therefore, in teaching measuring mass in standard units, more skills and knowledge are developed in learners. These skills are used or applied in other mathematics topics and subjects like science.

Other researchers have pointed out the need for learners' conceptual understanding and reasoning when they are measuring in standard units. Wilson and Osborne (1992) found out that while the basic idea of direct measurement is simple, there are complex mental accomplishments within measuring that are often downplayed in typical lessons. Opportunities for children to reason, with the purpose of coming to understand foundational or key ideas of measurement, can be enhanced by task design and teacher actions when carrying out those tasks. This makes the teaching practice important as what teachers say and how they say it matters for children's learning (Adler, 2017).

Theoretical framework

This study used the Mathematics Discourse in Instruction (MDI) as its theoretical and analytical framework. The framework was developed from extensive research among poorly resourced schools in South Africa (Adler & Ronda, 2015). The MDI framework describes the lesson “bit by bit” meaning step by step, thereby analysing teaching shifts that take place in a mathematics lesson. This way of analysing the lesson was useful in this study as it enabled thorough understanding of the shifts in teaching practices and how each shift made mathematics available to learners.

In describing the framework, Adler and Ronda (2015) represents it diagrammatically as below:

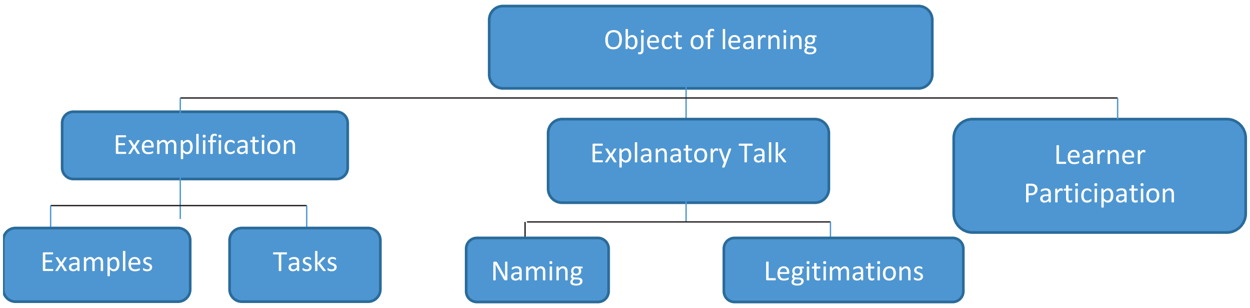

Figure 1: Constitutive elements of MDI (Adler & Ronda, 2015, p. 3)

The four constitutive elements of MDI are object of learning, exemplification, explanatory talk and learner participation. Object of learning is regarded as the lesson goal (that which students are to know and be able to do). In the diagrammatic representation above, Adler and Ronda (2015) separate the object of learning from the other components of MDI. The three components of *exemplification*, *explanatory* talk and *learner participation* are viewed as the key mediational means or cultural tools in a typical mathematics classroom instruction. These tools are used to achieve the object of learning. Exemplification which is further divided into *examples* and *tasks* is a common practice in mathematics teaching where lessons start with examples followed by similar tasks for learners' practice. Examples are categorized into three levels, from Level 1 to Level 3, depending on whether the selection of examples are similar, contrasting, or a combination of the two.

Explanatory talk involves communication by the teacher that takes place during the lesson. It is divided into *naming* (words used to name the mathematics being discussed) and *legitimation* (explanations of what is to be known and done in the lesson). Naming is also categorized into three levels: Level 1 meaning colloquial language is used, including ambiguous referents such as this, that thing, to refer to objects; Level 2 if some math language is used to name the object or component, or the string of symbols is simply read when explaining; and Level 3 if appropriate names of math objects and procedures are used. If non-math legitimation is used (such as visual cues, or metaphors relating to features), it is classified as Level 1 NM (nonmathematical); Level 2M (math) if a specific/single case, real-life application or purely mathematical explanation are used; Level 3M (math) if equivalent representations, definitions, or previously established generalizations are used but explanations are unclear or incomplete; and finally, Level 4M if it is a general full explanation.

Learner participation on the other hand allows learners to participate in the teacher's communication even if it may be in form of mostly listening to the teacher (Adler, 2017). It also involves their participation in answering questions. It is also categorized in three levels: Level 1 if learners simply answer yes/no questions or offer single words to teachers in the form of unfinished sentences; Level 2 if learners answer (what/how) questions in phrases/sentences; and Level 3 if learners answer why questions or present ideas in discussion, or the teacher revoices/confirms learners' questions.

Methodology

This study collected qualitative data from three teachers in three classrooms in two schools in Malawi. The teachers were purposively sampled to ensure that they were teaching mass during the time of data collection. Two lessons from each teacher were observed and video recorded. We used the MDI framework to analyse what the teachers were doing and saying in class to make the idea of mass available to learners. We sought consent from the District Education Office, Head teachers and teachers themselves to record the lessons. Teachers were free to withdrawal from the study anytime within the data collection exercise.

Findings of the study

Due to limited space, in this section we present one sample lesson in detail and its analysis using the MDI analytic framework. The title of this illustrated lesson was "Kulemera kwa Zinthu" meaning mass of objects. The teacher guide gave the following success criteria of the lesson: i) measure mass in kilograms (kg) and ii) measure mass in grams (g).

Following the MDI framework, the lesson was divided into five events, with a new event distinguished by a shift in activity. Below is a detailed description of the events with dialogue between the teacher and the learners.

Event 1: Measuring using non-standard units

The teacher carried a stone and a duster in her hands and asked learners to identify which one of the two was heavier than the other. The learners were able to identify the stone as being heavier than the duster. The activity was repeated using two stones of different sizes. The learners were able to identify the heavier stone, judging from the sizes of the stones.

Teacher	Which stone is heavier between Stone A and B?
Learners	Stone A.

Event 2: Measuring using unmarked simple balance

Learners were shown a simple balance and the teacher explained how it is used to determine which object has more mass than the other or if any two objects have the same mass.

Teacher	The balance tilts on the side where there is a heavier mass. That shows that one object is heavier than the other. When the two objects have the same mass, the balance does not tilt.

The teacher demonstrated how to measure two stones by putting them in bags and hanging the bags on the simple balance. The learners were able to identify the stone with a bigger mass. This activity was repeated using different objects such as duster, stones, books and pencils. Learners carried out the rest of the activities in pairs.

Event 3: Comparing masses of objects with a 1 kg packet of sugar

In this activity learners were comparing mass of an object with a 1 kg packet of sugar on a simple balance. The teacher put a stone in one bag and a packet of sugar in another bag and hung the bags on a simple balance. Learners were able to identify which one of the two had more mass than the other by looking at how the simple balance tilted. The learners repeated this activity using stones of different sizes and a chalkboard duster.

Teacher	Which is heavier between a 1 kg packet of sugar and a stone?
Learners	A packet of sugar.

Event 4: Introducing gram (g)

In this event, the class continued to compare the mass of 1 kg of sugar with various objects using a simple balance. The teacher was careful to choose objects that were less than 1 kg this time around. The learners were then informed that objects that were less than 1 kg are measured in grams. The learners identified items such as 500 g salt and 100 g baking soda that were present in class. The class was comparing masses of items in grams with the 1 kg packet of sugar using the simple balance. Similarly, the teacher put the 2 masses under comparison in bags and hung them on a simple balance.

Teacher	Which is heavier between a 1 kg packet of sugar and a 500 g packet of salt?
Learners	1 kg packet of sugar.

Event 5: The relationship between kg and g

The last event was for learners to establish the relationship between kg and g. The teacher showed that 500 g + 500 g = 1 kg by comparing two packets of 500 g salt and 1 kg packet of sugar on a simple balance. Learners identified the two sides of the simple balance as the same and concluded that 1000 g = 1 kg. The learners were later given the following three exercises to write individually in their exercise books: i) 250 g + 250 g + 500 g = ____ kg, ii) 3 kg = ___ g, and iii) 200 g + 500 g + 300 g = _____ kg.

Discussion

There were two lesson goals given by the teacher: i) measure mass in kilograms, and ii) measure mass in grams. These identified objects of learning were well captured in the lesson plan. Most of what happened in this class was direct comparison of masses of objects using standard and non-standard units. The common question by the teacher in the first four events was: Which is heavier between a stone and a packet of sugar? At this point, learners' judgement of "heavier than" was based on how the simple balance tilted. In event 5, learners were comparing known masses of items such as 1 kg of sugar and 500 g of salt.

The lesson intended to teach learners how to measure masses in kg and g. However, what happened in this class was mostly comparing and ordering masses of objects. According to Cheeseman et al. (2011), comparing, ordering and matching masses of various objects are important skills in mass measurement. They form part of the preliminary skills that children should acquire in measurement. However, more skills and knowledge of mass measurement need to be acquired in the early years of primary schooling.

The second element of MDI is exemplification and it consists of examples and tasks. Mathematical goals are supposed to be achieved through elaborated examples and given tasks. Since the lesson under discussion was mainly hands-on, we analysed the hands-on examples and tasks that the learners were given and the materials with which the children were engaged. However, when analysing the five events of the lesson, it was observed that the tasks were similar in terms of level of difficulty and demands for cognitive ability. The instructions for the tasks were the same and repetitive. Further, the tasks were set procedures in comparing the given masses. The lesson focused on teacher's instructions on how to compare different masses of objects. Conceptual understanding of the underlying idea of mass and measuring mass in standard units of kg and g was missing in the lesson.

The third element of MDI is explanatory talk. The MDI framework divides teacher explanatory talk into naming and legitimations. In this case, naming are mathematical terms used in the lesson while legitimations are explanations of mathematical ideas and procedures. The two are divided into three levels (low to high) depending on the teacher's use of mathematical language in the lesson. In terms of naming, we observed that the teacher mostly operated at Level 2 and 3 where she was able to use appropriate mathematical language to name objects, simple balance, 1 kg, 500 g masses, and measuring mass in kg and g among others.

In terms of legitimations, we observed that teacher talk was generally of Level 1 and 2. The teacher was giving explanations that were simple, single and isolated cases with real life examples. For example, she explained with the help of a simple balance that the mass of two 500 g salt packets is equal to 1 kg of sugar. The teacher's explanations were characterised by the use of unspecialised mathematics to name mathematical terms and compare masses of objects. In line with Adler (2017) reporting that what teachers say and how they say it matters in mathematics lessons, especially in early grades where learners depend more on teachers, we observed that the selection of tools of measuring mass affected the teaching and learning of the lesson.

The fourth element of MDI is learner participation. Learners participated in carrying out activities in measuring masses of various objects and in answering questions from the teacher. The MDI framework describes learner participation in terms of levels of answers provided by learners. It was observed that learners' answers were of both Level 1 (the yes/ no answers) and Level 2 (what, which and how answers). For example, the common question in this lesson was: Which is heavier between stone A and stone B?

Conclusion

This study collected and analysed qualitative data to find out teachers' practices in grade 4 when teaching mass measurement. Using the MDI framework, we divided the lesson into five events, in which each event was characterised by a shift in the activity. We analysed the three cultural tools of a typical mathematics lesson according to MDI; exemplification, explanatory talk and learner participation based on their level of complexity. The object of learning was also analysed to find out if the intended goal of the lesson was achieved.

While we only presented detailed data from one lesson, the study established that all the teachers had lesson plans with clearly stated lesson goals (success criteria); to measure mass of objects in kg and g. However, it was not clear whether learners achieved this intended lesson goal. In terms of examples and tasks, teachers used similar examples in different events of the lesson such that the examples looked like a repetition of what had already been done. The examples were teacher demonstrations of measuring in grams and kilograms. Most of what was called measuring in g and kg activities were direct comparisons of objects of known masses. Teachers' explanations followed the examples and tasks that they did in class with learners. These were mostly instructions on how to compare objects using simple balances.

Possible implications from using these identified practices in the teaching of measuring mass in grade 4 in Malawi is that some learners may not be able to measure mass of objects in kg and g by the time they finish grade 4 because the teaching of mass did not prepare them adequately with the measuring knowledge and skills. We also noticed that teaching is compromised by the lack of resources such as scale balances to use during the teaching of measuring mass. A final observation is that teachers' practices are determined by suggestions from the curriculum material. Therefore, improving curriculum materials would provide better guidance to teachers so they can better support learners to develop conceptual understanding of mass measurement.

„That is how you do it, when you justify something in math“: Learning opportunities with an unproductive sociomathematical norm

Edyta Nowińska

Universität Osnabrück, Germany; enowinska@uos.de

Promoting students' mathematical reasoning skills is a challenging teaching goal. This paper exemplifies that the construct "negative discursive activities" provides a useful theoretical perspective to capture characteristics of class discussions that might impair students' understanding of what acceptable justifications in mathematics are. By applying this construct to three episodes from mathematics lessons in Grade 7, an unintentional evolvement of a sociomathematical norm with potentially negative consequences for students' reasoning skills is reconstructed. The core purpose of this paper is to broaden researchers' understanding of interactions involved in the process of establishing sociomathematical norms.

Keywords: Justification, reasoning skills, discourse, sociomathematical norms, interactions.

Introduction

In this paper, *teaching* is considered as a continuous process, in which teachers establish and maintain a specific classroom culture of *doing mathematics*, where "doing mathematics" refers to students' activities when they learn and use mathematics in the classroom. According to this understanding of teaching, one goal of teachers' practices in the classroom is to support students' enculturation into the ways of speaking, working and thinking that are specific for mathematics. Teachers do it, among other things, through the negotiation of social and sociomathematical norms (Yackel & Cobb, 1996). Both kinds of norms pertain to normative or students' taken-as-shared interpretations of their mathematical activities in the classroom. They describe what learners are expected to do in certain situations, e.g. when presenting their solutions to others (Yackel & Cobb, 1996). Social norms refer to the expected activities in class discussions, whereas sociomathematical norms to their quality. Examples of a social norm can be *that* learners are expected to explain and justify their own answers. Sociomathematical norms, on the other hand, regulate *what* is an acceptable explanation or justification in their class. For example, they may specify that explanations must be comprehensible for others and that justifications must be based on actions performed on mathematical objects known in the class or on properties of these objects. Both kinds of norms are not simply imposed by teachers and accepted by students. Instead, they are negotiated through student-teacher interactions. In this process teachers play a crucial role as representatives of the mathematical community in a class. They legitimize certain aspects of learners' mathematical activities and sanction others by pointing them out as inadequate or incorrect.

Sociomathematical norms described in research literature are commonly associated with means that have a positive potential to support students' mathematical enculturation and their intellectual autonomy in doing mathematics, i.e. their ability to judge and decide in action on what is an appropriate cognitive activity in a given situation (Yackel & Cobb, 1996). Teachers can intentionally initiate the negotiation of these norms (McClain & Cobb, 2001). However, also negative, i.e. unproductive, norms can emerge unintentionally. Thereby norms are meant that might hinder the mathematical enculturation of students, their intellectual autonomy or their understanding of what they learn. To avoid such norms, the process of their development must be understood. In this paper, the construct "negative discursive activities" (Cohors-Fresenborg & Kaune, 2007) is used to shed light on this process. The paper exemplifies that this construct provides a useful theoretical perspective to identify activities and interactions in class discussions that might lead to an unproductive sociomathematical norm. This is the pragmatic purpose of this paper. The theoretical purpose is to broaden teachers' and researchers' understanding of the role of negative discursive activities in interactions involved in negotiating sociomathematical norms. Given the teachers' interest in improving teaching quality, this paper is also of practical relevance.

The insights presented in this paper result from our[1] reflection on a communicational pattern that we unexpectedly noticed when analysing instructional data from the perspective of a *metacognitive-discursive teaching quality* (Nowińska, 2019) in a broader empirical study (Nowińska & Praetorius, 2017). The following section explains the theoretical perspective that gave rise to these insights.

Metacognitive-discursive teaching quality

The construct *metacognitive-discursive quality* (Nowińska, 2019) has been developed to analyse how class discussions promote students' metacognitive skills, i.e. their ability to spontaneously and adequately regulate (plan, control and reflect on) their own cognitive activities and comprehension in learning mathematics (Cohors-Fresenborg & Kaune, 2007; Nowińska, 2019). This construct has its roots in theoretical considerations (Flavell, 1979) and empirical findings (Veenman et al., 2004) indicating that metacognitive skills improve students' learning in mathematics. Furthermore, it also considers the social context of learning in the classroom, in particular its role in constructing students' shared understanding of what they learn in the classroom (Iiskala et al., 2011). Metacognitive-discursive quality encompasses characteristics of class discussion that are considered favourable to improve the process and the effects of learning mathematics in the class by promoting students' metacognitive skills. One of these characteristics is that teachers provide students with opportunities to engage in *metacognitive activities*, e.g. to *plan* how to approach a given question, task or problem, *control* the validity of answers and solutions generated in class discussions, and *reflect* on their own understanding of what they learn. Another characteristic is that teachers promote students' *discursive activities*, in particular they support students in making their own cognitive and metacognitive thoughts comprehensible to others. That is necessary to construct a shared understanding of the mathematics discussed in the class. The term *discourse* refers thereby to a class discussion, where the participants make an effort to provide precise, extended explanations and justifications and to build on or elaborate previous contributions from themselves or others. They link their contributions to previous questions or comments, provide a justified agreement or disagreement on other contributions, paraphrase what has been said in order to avoid a misunderstanding. These are examples of *discursive activities*. *Negative discursive activities*, on the other hand, refer to activities that might impair or even hinder a discourse, and consequently also students' shared understanding

[1] References to *our* and *we* are to a mathematics research team in the study presented in (Nowińska & Praetorius, 2017).

of the mathematics discussed in the class. Examples of these are: (NDa[2]) providing unclear or fragmentary statements/argumentations or (NDb) statements in which it is not clear what is meant, (NDc) providing inappropriate (with an uncommented substantial change to what was said) summaries or repetitions of what was said, (NDd) uncommented change of the reference point or of the meaning of the issue discussed, (NDe) using false logical structure in an argumentation, and (NDf) asking a sequence of different questions or (NDg) asking a leading question. A metacognitive-discursive teaching quality is characterised by teachers' and students' efforts to prevent negative discursive activities from impairing their communication in the class.

Analysis of negative discursive activities and their effect on the learning process

The instructional data analysed in this paper consists of three consecutive episodes selected from one of four lessons on locus lines videotaped in Grade 7 in Germany. The following task is discussed in this lesson: "The perpendicular bisector of chord ($\overline{BC}$) of a circle with the centre A passes through point A. Justify why." The episodes are chosen for this paper as representative examples of communicational patterns observed in all four lessons, where the students learned examples of locus lines (e.g. a perpendicular bisector and an angle bisector) and used their properties to justify relations between geometrical objects. One goal of doing mathematics in this lesson series is to foster students' reasoning skills and promote their understanding on how mathematical statements can be justified by drawing conclusions from statements accepted as "true" or "given", or justified before (deductive reasoning). Based on tasks that require this kind of reasoning, the teacher created opportunities for students to learn what is an acceptable justification in mathematics. At the end of this lesson series, however, the students were not able to decide in action what to focus on in order to provide a correct justification without asking the teacher if their answers are what the teacher wants them to say. Analysing class discussions in these lessons from the perspective of metacognitive-discursive quality allowed us to identify a communicational pattern based on negative discursive activities. This pattern might have led to the development of one *unproductive sociomathematical norm* of what are acceptable mathematical justifications in this class. It seems plausible that this norm contributed to the problem observed in students' understanding of correct justifications.

In the following, the three lesson episodes are analysed from the perspective of the negative discursive activities. The analytical work was done by two researchers in mathematics education who were trained to code metacognitive, discursive and negative discursive activities using the category system published in Nowińska (2019). Afterwards, it will be explained how these activities might have led to an unintentional evolvement of the unproductive norm.

Episodes from the class discussion

According to the teacher in the observed class, the learners know the definition of a perpendicular bisector (The perpendicular bisector of a line segment $\overline{AB}$ is the locus of all points that are equidistant from points A and B.) and two properties of it (P1: The perpendicular bisector to a line segment is a line which meets the segment at its midpoint perpendicularly. P2: All points that lie on the

[2] The codes given here for negative discursive activities will be used to code these activities in lesson transcripts.

perpendicular bisector to a line segment $\overline{AB}$ are equidistant from A and B.). Since in this context the term “locus line” is defined as a set of all points, whose location is determined by one specified condition, one more property of a perpendicular bisector can be concluded (P3: Every point that is equidistant from A and B belongs to the perpendicular bisector of the segment line AB.).

Although a justification required in the given task can be reduced to three steps (1., 4. and 5. in the following argumentation), its logical structure is quite complex.

1. The perpendicular bisector of $\overline{\mathrm{BC}}$ consists of *all* points that are equidistant from B and C.
   [Reference to the definition of a perpendicular bisector as a locus line (or to the property P3)
2. Points B and C of the chord $\overline{\mathrm{BC}}$ belong to the circle line with the centre A.
   [Reference to the definition of a chord of a circle.]
3. Points B and C are equidistant from point A.
   [Conclusion from 2. with a reference to the definition of a circle line as the locus of all points with the same distance to the centre of the circle.]
4. The centre A of the circle is equidistant from B and C.
   [Conclusion from 3. with a reference to a property of the distance between two points.]
5. The centre A of the circle belongs to the perpendicular bisector of $\overline{\mathrm{BC}}$.
   In other words: The perpendicular bisector of $\overline{\mathrm{BC}}$ passes through the centre A of the circle.
   [Conclusion form 1. and 4.]

Episode 1: The teacher starts the discussion by constructing a circle with the centre A, a chord $\overline{BC}$ of this circle and the perpendicular bisector of $\overline{BC}$ using GeoGebra and asking the following question:

Teacher:	The perpendicular bisector passes through the centre of the circle. (…) Is that always the case? What do you think?
Karen:	I think so because I mean it’s called perpendicular bisector[2]. (NDa)
Teacher:	Mhm. Lea
Lea:	I would also say that it always passes through the centre of the circle, because it is a circle as well, and is equidistant to every uhm to every point, the centre of the circle. (NDa)
Teacher:	Mhm. Tom
Tom:	And the line that passes through the centre of the circle always lies in the middle of point B and C, I mean the one that passes through to the right … so then that’s automatically the centre, because uhm… (NDb)

In Episode 1, negative discursive activities, which turned to be typical for class discussions in all lessons videotaped in this class, can be identified. Karen’s answer refers to the name “perpendicular bisector”, which in German is associated with a middle (Mittelsenkrechte (Ger.) = perpendicular to the middle (Eng.)). She uses the word “because”, but she does not explain how the argument “it is called a perpendicular bisector” is to be used to justify the observed relationship. Her answer can be regarded as an *unclear, fragmentary statement/argumentation* (NDa). Lea, on the other hand, refers to an appropriate argument – to a property of a circle. However, likewise Karen, she does not explain how this argument can be used to draw the conclusion that the perpendicular bisector passes through the point A. Her answer has the form of an *unclear, fragmentary statement/argumentation* (NDa) too. Tom’s contribution consists of broken sentences. Based on them it is difficult to reconstruct his reasoning. Therefore, for the teacher and for the classmates is may by *not clear what exactly he wants to say* (NDb). The negative discursive activities observed in this episode may indicate that the students lack an adequate understanding of what are precise, acceptable justifications. As a consequence of these activities it might be difficult for the classmates to grasp logical relations between the given arguments and the relationship to be justified.

Coding the learners' contributions as negative discursive activities does not mean that their reasoning is fundamentally wrong or irrelevant for the intended argumentation, nor does it mean that perfectly articulated justifications are expected there. These codes are used to mark parts of the discussion that clearly indicate opportunities for the teacher to explicitly negotiate with the students what acceptable justifications are. Instead, the teacher implicitly accepts the contributions ("Mhm.") without challenging the students to explain their reasoning.

Episode 2: Following Tom's answer from Episode 1, the teacher asks:

Teacher:	Have you noticed what those, who have answered the question, actually have done? What have they paid attention to? How have they justified their opinion, their view? What kinds of arguments have they used? Felix. (NDf)
Felix:	Because the circle is round, and B and C are always the same distance away from A. And then uhm that's where that comes from. (NDd)
Teacher:	Mhm. Exactly. Right. One argument is the one about the circle. There has been another argument, or another justification, that has been brought up. (4 sec) Ines.
Ines:	I also think it's the case, that it always passes through the centre, because… The perpendicular bisector divides the lines into right angles, so to speak, and that is why that is, I think, that it's always like that. (NDb)
Teacher:	Mhm, what do you say to Ines? (15 sec) Where in the circle do you have right angles?
Ines:	Well, I mean, if you … if you divide a circle in four equal sized halves, you get four right angles, that's what I meant. (NDb)

The teacher tries to make students' answers from Episode 1 explicit objects of the class discussion. In doing so, she *asks a sequence of different questions one after the other* (NDf). This may impede a clear course of the subsequent class discussion and is therefore to be coded as a negative discursive activity. Each of these questions does definitely have the potential to initiate students' reflection on the logical structure of the arguments mentioned in Episode 1 and to explicitly negotiate the meaning of an acceptable justification – of *what* a justification is based on and *how* it is used. However, the subsequent reactions indicate that this potential is not productively used.

Felix seems to refer to Lea's answer, but he *changes the meaning of her argument* (NDd). Lea named a property of the point A, whereas Felix describes a property of the points B and C. He does not make a mistake here, but he shifts the focus of attention from the centre of the circle to points B and C on the circle line. This activity has the consequence that even more argumentation steps would be needed to justify the relationship in question (see steps 3.-5. in the argumentation). Since Felix responds to one of the teacher's questions about the arguments mentioned by others, his utterance is not a new unclear and fragmentary utterance/argumentation. The teacher explicitly expresses her acceptance of the given answer. She stresses the reference point of this argument ("the one about the circle") and suggests that another relevant argument can be found in Lea's and Tom's answers. Her statement has the potential to initiate students' reflection on their own understanding of their classmates' arguments. Unfortunately, Ines does not directly respond to the teacher's contribution. Instead, she expresses her own reasoning. In doing so, she *changes the reference point of the conversation without any comment* *on this change* (NDd). This activity might impair the clarity of the discussion. Furthermore, in her first answer Ines refers to the results of actions on objects that cannot be interpreted unambiguously ("the lines [divided] into right angles"). Therefore, there is a risk that for the teacher and for her classmates *it is not clear what exactly she means* (NDb) there. Particularly, she does not make it clear which "lines" she refers to. Her answer is the only one, where the teacher asks for clarification. Unfortunately, also in her second answer Ines refers to the results of actions on objects that cannot be unambiguously interpreted ("the circle [divided] into four equal sized halves"). Consequently, it might still be *unclear for others what she means* (NDb). Thus, in Episode 2, the teacher explicitly accepts justifications based on imprecise arguments "about the circle". Implicitly she does not accept justifications based on ambiguously described mathematical objects or actions. As far it is left to the learners themselves to interpret how the accepted argument can serve as a justification for the relationship described in the task.

Episode 3:

Teacher:	(…) Ines wanted to link the circle and the perpendicular bisector, their properties. And you guys also mentioned the properties of the circle before. Lea did it first and Felix just picked it up again. So, what you did is that you looked at the properties of the circle. The points B and C of the circle are always equidistant to A. And you also used another argument. You also linked the circle and the perpendicular bisector, just like Ines tried to do again just now. What did you say and what did you use about the perpendicular bisector? (4 sec) You also used these in your statements, maybe you weren't even aware of it, again the properties of perpendicular bisectors used. Which ones? (5 sec) Eva. (NDc, NDg)
Eva:	Every point on the perpendicular bisector has uhm is equidistant uhm to B and C.
Teacher:	Mhm, exactly. That is what you used. Sometimes you didn't even say that directly because we have always talked and known about that in class. And so that is what you used: B and C are equidistant to the perpendicular bisector and the centre of the circle is equidistant to both points as well. And that is what you linked to justify, that the centre of the circle A has to be on the perpendicular bisector. That's actually a useful strategy or that is how you do it, when you justify something in math, that you take different properties of different objects and try to link them and to look for connections. (NDe, NDc, NDa)

The teacher's comments in Episode 3 indicate a typical feature observed in all four lessons videotaped in this class. She interprets Ines' contributions in Episode 2 as an attempt to "link" the properties of the circle and those of the perpendicular bisector. Ines mentioned both concepts, but clear attempts to "link" them cannot be observed in her statements. Therefore, a part of the teacher's comment can be regarded as *a summary with a substantial change to what was said* (NDc) and to what can be interpreted unambiguously with regard to the learners' reasoning. The "links", i.e. the logical relations between the properties of the circle and those of the angle bisector, are not made explicit at any point in the class discussion. This would be, however, necessary for the students to understand the logical structure of the intended justification, and to construct a shared understanding of how arguments are to be used to provide an acceptable justification.

Since no student answers the teacher's question "What did you say and use about the perpendicular bisector?", the teacher changes it to a *leading question* (NDg) about "Properties of the perpendicular bisector". In her second comment, the teacher points out that the pupils did not explicitly mention this property. Despite this fact, she does not specify the expected chain of arguments and the conclusion derived from this property, nor does she clarify the logical structure underlying the intended justification. In her second contribution, she suggests that since this property is a part of the knowledge shared in the class, it did not need to be explicitly mentioned. This comment might cause the learners to feel not obliged to express their reasoning precisely and in a way that can be understood by others.

The argumentation given by the teacher in her second comment in Episode 3 indicates a *false logical structure* (ND3e). The teacher should have used the property P3 instead of P2. P3 describes conditions that must be fulfilled for a point to belong to the perpendicular bisector. P3, on the other hand, describes properties of points that are known to belong to the perpendicular bisector. This comment is not to be understood as a negative discursive activity just because it includes a mistake. The reason for coding it as a negative discursive activity is that this mistake makes it more difficult for others to understand how the teacher generates her justification based on the mentioned properties of mathematical objects. Moreover, the teacher's comments *differ from what the students actually said* (NDc). No student said that B and C are equidistant to the perpendicular bisector. Since this argument is not relevant for the intended argumentation, this comment must be regarded as an *unclear and fragmentary statement/argument* (NDa). For the learners, it might be unclear how the arguments mentioned by the teacher should be "linked" together to form an adequate justification. Consequently, the learners must find their own interpretation of the statement "that is how you do it, when you justify something in math, that you take different properties of different objects and try to link them together and to look for connections". One possible interpretation, supported by the way how the teacher provides the final justification, is that of linking together as collecting properties of mathematical objects given in a geometrical representation; for an acceptable justification, the arguments on which a justification is based must refer to unambiguously described mathematical objects or actions.

Conclusion

The negative discursive activities identified in the three episodes occur in all four lessons videotaped in this class and create a pattern with the following regularities: (1) The students make an effort to provide justifications based on their knowledge about mathematical objects given in a particular geometrical representation, but their justifications lack precision with regard to the language and logical structure. (2) The teacher usually does not comment on students' imprecise answers nor does she provide comments that could help the students improve their reasoning. Instead, she implicitly accepts arguments and justification despite their negative discursive character. Only if students' contributions refer to ambiguously described mathematical objects, the teacher asks for a clarification. In doing so, she implicitly negotiates the boundaries of what is an acceptable justification. (3) The teacher inaccurately summarizes the students' contributions. There she gives an answer to the question under discussion without referring very precisely to the learners' previous answers. Her explanations support the interpretation of justifications as collections of arguments related to mathematical objects.

Since the regularities occur in all four lessons, the students seem to have it as a rule that the teacher "summarizes" their contributions and gives the expected answer or solution. This is evidenced by the fact that they often try to guess what the teacher expects them do say (e.g. "Do you mean this?") and do not question the teacher's "summaries". Their behaviour can be interpreted as acting according an unproductive sociomathematical norm. According to this norm, acceptable justifications are collection of properties of clearly named mathematical objects. This norm promotes activities and interactions that are unproductive in the sense that they impair students' understanding of mathematical justifications and their reasoning ability.

The paper has demonstrated that negative discursive activities can be used to capture interactions in class discussions that might lead to unproductive sociomathematical norms. In class communication negative discursive activities cannot be completely avoided and this should not be an idealistic teaching goal. Moreover, not each negative discursive activity necessarily implies negative consequences for students' understanding. The consequences depend on whether teachers accept these activities or rather sanction them and use them as learning opportunities to negotiate ways of thinking and talking that are specific for mathematics. In the first case, there is a risk that unproductive sociomathematical norms emerge. The negative norm identified in this paper indicates a challenge for teachers' educators to make teachers aware of consequences that negative discursive activities might have for students' learning and to enable teachers to productively deal with these activities.

Teaching beyond the mathematics of the moment

Evi Papadaki and Irene Biza

University of East Anglia, Norwich, UK; P.Papadaki@uea.ac.uk, I.Biza@uea.ac.uk

In this paper, we showcase a method of identifying opportunities during the lesson where the communicational patterns go beyond the mathematics of the moment, namely beyond the boundaries of the curriculum. Drawing on the literature around Horizon Content Knowledge and building on the Theory of Commognition, we look at a lesson from one teacher and study instances where her communication with the students goes beyond the mathematics of the moment. Our analysis identifies three types of opportunities (manifested, potentials of the discussion and potentials of the task). Further analysis of manifested opportunities indicates that intersubjectivity is a characteristic of the discourse of the teacher at the mathematical horizon.

Keywords: Discourse, mathematical horizon, teaching practices, mathematics.

Introduction

This paper reports on preliminary results from the first author's doctoral study that aims to explore in-service mathematics teachers' discourse that goes beyond the boundaries of the curriculum, what is described by Ball and Bass (2009) as "the larger significance of what may be only partially revealed in the *mathematics of the moment*" (para. 17, our emphasis). The importance of this idea has been described in the literature in connection to teacher actions in response to students' contributions and towards addressing students' learning needs (Ball & Bass, 2009). However, the boundaries of the curriculum, even more going beyond them, are not always identifiable. Initially, this study, in its effort to describe such boundaries, was inspired by Ball and colleagues' idea of the Horizon Content Knowledge (HCK), one of the mathematical domains of the Mathematical Knowledge for Teaching (MKT) model for teacher professional knowledge:

> an awareness – more as an experienced and appreciative tourist than as a tour guide – of the large mathematical landscape in which the present experience and instruction is situated. (Ball & Bass, 2009, para. 17)

HCK is theorised to influence, among others, teaching practices related to noticing and evaluating mathematical significance in what the students are saying, foreseeing and making connection across educational levels and disciplines and evaluating opportunities (Ball & Bass, 2009). So far, several studies drew on the idea of the HCK with variations in the use and the narratives about the 'horizon' metaphor (see also Papadaki, 2019). Evidence of the role of the HCK in the quality of teaching relys on these different uses and narratives of the 'horizon' metaphor. In our work, we argue that bridging the gap between an all-encompassing mathematical knowledge for teaching and teaching practices aiming to enrich the learners' experience of mathematics as a subject, could lessen the reliance on the metaphor. To this aim we propose a discursive approach to the "horizon" embedded in the communicational patterns of the classroom. Specifically we draw on the commognitive theory (Sfard, 2008) to address the theoretical and methodological question: *How can we identify opportunities during the lesson where the communicational patterns go beyond the mathematics of the moment?*

Theoretical background

To study the communicational patterns in the mathematics classroom, we use the *Theory of Commognition* (Sfard, 2008). According to this theory, a discourse is signified by four elements: *word use*, *endorsed narratives*, *visual mediators* and performed *routines*. Thus, mathematical discourse is the type of communication signified by specific word use (e.g., 'circles'), visual mediators (e.g., diagrams, symbols), endorsed narratives (e.g., theorems, definitions) and routines (e.g., calculating angles). Learning of mathematics is conceptualised as change in learners' discourse (Sfard, 2008). Tabach and Nachlieli (2016) define teaching as "the communicational activity the motive of which is to bring the learners' discourse closer to a canonic discourse" (p. 303). In this study, the canonic discourse is the Mathematical Discourse[1] of the class which is confined by the curriculum. The role of the teacher in mediating changes is vital. The *Mathematical Discourse for Teaching* (*MDT*) model (Cooper, 2016; Mosvold, 2015), an adaptation of the MKT, provides a basis to study teachers' discourses shifting the attention to word use, narratives, visual mediators, routines and "the kinds of mathematical activities that are valued" (Cooper, 2016, p. 21).

MDT consist of two main Discourses that could be viewed as a way to partially distinguish between mathematical narratives situated in the social context of the classroom (Mathematical Discourse) and pedagogical narratives situated in the context of teaching mathematics (Pedagogical Content Discourse). The two Discourses are distinguished into six sub-Discourses. One of them is the *Discourse at the Mathematical Horizon* (*DMH*), which is described as "patterns of mathematical communication that are appropriate in a higher grade level" (Cooper & Karsenty, 2018, p. 242). In our work DMH spans across the Mathematical and Pedagogical Discourses and regards the recognition of mathematical as well as pedagogical significance in students' work beyond the mathematics of the moment by addressing, for example, issues of content (e.g., 'what should be learnt') and access (e.g., 'who should learn').

So far, the MDT has been used in the context of teachers' professional development (e.g., Cooper, 2016; Mosvold, 2015). However, in our work we aim to identify and analyse aspects of DMH in lesson observations, where Mathematical and Pedagogical Discourses are intertwined in teaching actions. To this purpose, we encompass recent developments of the Theory of Commognition. We are interested in identifying teaching practices, seen as routines performed by the teacher in the mathematics classroom, that go beyond the expected Mathematical Discourse of that classroom. Attending to the mathematical elements of the communication between teacher and students could provide evidence about mathematical aspects of DMH. To account for pedagogical aspects, we adopt Nachlieli and Elbaum-Cohen's (2021) view that teaching practices could be considered as objects of Pedagogical Discourse. Furthermore, to investigate situations in which the communication between the teacher and her students makes or does not make sense at both ends, we use the notion of intersubjectivity, namely "an action that makes sense from the perspective of two discourses – the learner's and the expert's–which may be incommensurable" (Cooper & Lavie, 2021, pp. 8–9).

---

[1] Here, the term 'Discourse' denotes community established patterns of communication while 'discourse' is used to refer to the individualised version of that communication between the interlocutors.

Data and methods

The study is conducted in England and participants are secondary school mathematics teachers, their students and teacher educators. In England, schools develop a program of study following the guidelines of the curriculum for Key Stages 3 and 4 (KS3, ages 11 to 14 and KS4, ages 15 to 16) and the specifications of the qualification provider the school collaborates with. Thus, what students are expected to learn each year varies across schools. Mathematics teachers prepare their lessons using resources available on the internet, textbooks or their school's repository. Data of lesson observations consist of an audio recording of the lesson and notes produced by the first author during the observation and revised shortly after. The notes include recreations of the writings on the board, the slides used by teachers and accounts of their actions during the lesson. The lesson was transcribed, we also produced a factual account summarising the lesson. The data collection process complies with the code of ethics of the University of East Anglia.

The analysis of the data consists of four phases. First, we created a template to study teacher's contributions by dividing each lesson into sections according to the actions of the teacher (e.g., talking to groups of students, introducing a task, initiating a whole class discussion etc.). Second, all sections were coded in relation to the mathematical objects (e.g., angles) and/or practices (e.g., measurement of angles) accounting for the discursive elements (word use, visual mediators, narratives, and routines) identified in each section. By comparing the codes with the topic of the lesson, as identified by the teacher and the specifications of the curriculum, we eliminated the sections that were directly related to what the students are expected to learn during the academic year. We regarded the remaining sections as opportunities to engage in communication beyond the mathematics of the moment and proceeded analysing them further. Thirdly, we categorised the identified opportunities in three groups: *potential of the task* (the mathematical object or practice is not made explicit during the lesson, it is only attributed by the analysis), *potential of the discussion* (the mathematical object or practice is made explicit in the lesson but is not addressed by the teacher), and *manifested* (the mathematical object or practice is made explicit and addressed by the teacher during the lesson). Finally, we revisited the opportunities proposed in the third phase to identify deviations or alignments in teacher-students communications from the intersubjectivity perspective.

Exemplification of the analysis: The lesson of the 'nine-point circle'

Here, we draw on one lesson of a newly qualified mathematics teacher, Liz (alias), and her 11-year-old students. The students are in Year 7, the first year of lower secondary education. Liz designed the lesson by combining resources available on the internet and the school's repository. For her lessons, Liz shares slides on the interactive whiteboard. At the beginning of the lesson we discuss here, Liz invited the students to calculate the value of an angle in a composite shape. Figure 1, depicts the main task of the lesson that consists of four parts (1, 2, 3 and 4). The common characteristic of the parts is a circle with nine equally spaced points on its circumference. Liz referred to this shape throughout the lesson as "the nine-point circle". In part 1, the students were asked to identify all the different triangles with one vertex on the centre of the circle and the others on two of the nine points and calculate their angles. In part 2, they were asked to find a way to calculate the angles in a triangle with all the vertices on the circle. In part 3, the students were asked to find their own triangles by joining three points on the circle and work on their angles. Finally in part 4, Liz asked the students to calculate the angles ACB and ADB and tell her if they notice anything. By the end, Liz pointed out that the observation made in part 4 was related to one of the 'circle theorems' included in the highest band of their qualification requirements (GCSE, acquired at age 16).

In this lesson, we identified four opportunities to engage in communication beyond the mathematics of the moment. Two of them were categorised as *manifested* ('auxiliary lines' and the 'Star-Trek lemma'), one *potential of the discussion* and one *potential of the task.* In the following sections, we present the opportunities alongside the curriculum expectations.

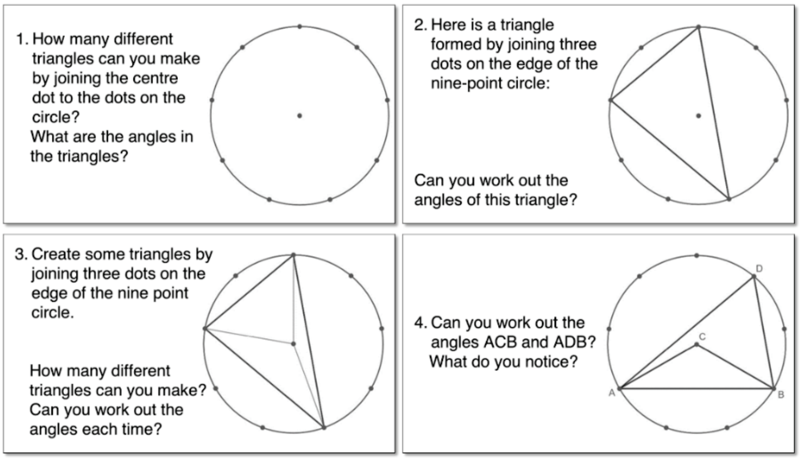

Figure 1: A recreation of the main task of the lesson

Manifested opportunities to go beyond the mathematics of the moment

Auxiliary lines: The completion of the main task, requires drawing auxiliary lines (i.e., additional lines) in order to divide the inscribed triangle in part 2 appropriately and calculate its angles. The process of drawing auxiliary lines was used by Liz as an approach to tackle an open problem.

Liz: Yeah. Right. [slide of part 2 on the board] So, I've got a slightly trickier question for you now. So here is a triangle formed by joining three dots on the edge of a nine-point circle, nine-point circle [points towards the diagram]. However, this time it doesn't go through the centre. Can you work out the angles of this triangle?

The process of drawing additional lines is not new to students at this age. As part of their primary and secondary school education, the students are expected to use auxiliary lines for the purposes of calculating the area of composite shapes or identifying a line of symmetry. Highly attaining students are also expected to learn to use auxiliary lines when proving certain theorems, in known situations, at the end of KS4, but not at Year 7. Also, this task requires the students to explore unfamiliar to them situations where auxiliary lines are necessary. Similar uses of auxiliary lines are observed in more of Liz's lessons suggesting that engagement with this process was not an one-off event.

Initially, Liz prompts the students to explore possible ways of tackling the problem. The students try to measure or estimate the angles of the given triangle. Five minutes later, she addresses the class:

Liz: […] it's taken him [student A] quite a long time to ask me a really, really good question. But, I think I should share it with everybody. He said, can I split it up into other triangles.

Student B: Oooh.

From a commognitive perspective, drawing auxiliary lines to modify the triangle in an appropriate way is a routine. For student A, the initiation of this routine is prompted when other routines failed. However, he requested Liz's approval before moving on. For other students the initiation was prompted by the teacher:

Liz:	Yeah, I'm not going to tell you the answer. I'm going to show you the clue. So, this is the clue. [draws three line segments from the centre to the edges of the triangle]
Student C:	Oh.
Liz:	[…] if you can split it into other triangles and using the triangles where we can where we can start. We know some facts, don't we? An isosceles triangle is nice. I'm not trying to find three unknown angles now, am I? I know that two are the same. […] plus we did all that work beforehand.

Here the procedure is presented to the students as a "clue". The use of the word could signify a step to a direction that was previously hidden from the students who are now invited to follow this clue to complete the task. The use of the phrase "split up into other triangles" and the absence of words like 'draw', 'line segment', that are usually present in formal geometric proofs, indicates that the discussion is mediated by the specific drawings of the task (Figure 1). We interpret the use of these words as evidence of intersubjectivity. For the students, this task is a new situation where they need to draw additional lines to solve a problem - similar to what they are doing when they are asked to calculate the area of a composite shape. While for Liz, this is a routine towards the modification of a shape in order to use properties established in earlier stages of a task. This routine is not part of the canonic discourse (Tabach & Nachlieli, 2016). Liz presents the students with a broad spectrum of situations that promote the routine of auxiliary lines beyond the requirements of the curriculum of Year 11. The instance presented here illustrates her teaching practice of providing gradual support to her students, of expanding the applicability of the routine and of establishing this process as conventional in geometric reasoning. Evidence of this practice were observed across Liz's lessons.

<u>The Star-Trek lemma:</u> Liz uses the 'nine-point circle' to introduce her students to a theorem about angles in circles also known as the Star-Trek lemma:

The angle subtended by an arc at the centre is twice the angle subtended at the circumference.

Liz presents the last part of the main task (part 4, Figure 1) as a challenge to the students:

Liz:	So, I'm going to give you one last challenge, which is to take a look at this. [Liz puts up the slide with part 4 of the task]. And you're going to need to start calculating the angles and see if you notice anything. So, I'd like you, actually we can start from, we've got a starting point, haven't we? We know this angle here.

According to the curriculum, the Star Trek Lemma, named after the resemblance of the logo of the popular series, is one of the theorems that only highly attaining students are expected to learn to prove and apply during KS4. According to the school's program of study, Liz's students might come across circle theorems in Year 11 (age 16), subject to their grades until then, but not at Year 7.

The analysis shows that with the help of the nine-point circle and building upon the previous parts of the task, Liz and the students have an opportunity to go through the main ideas of the proof of the Star-Trek lemma despite not having yet engaged with algebraic routines and relevant terminology (e.g., arc, subtended, etc). Throughout the lesson, Liz and the students communicate using the words 'angle', 'triangle', 'circle' and 'point' or 'dot'. The new narratives about angles can be negotiated through routines and other narratives endorsed in previous lessons or earlier parts of the task. In the lesson students engage with simple algebraic routines based on the visual mediator of ‘the nine-point circle’ in comparison to the proof of the lemma seen later in KS4. Table 1 illustrates our reconstruction of the narratives observed during the lesson (left column) alongside a canonic proof of the lemma seen in KS4 (right column). To produce the reconstructed narrative, we collated parts of the recording and the notes in a way that corresponds with the steps of the proof.

Table 1: Reconstruction of narratives observed in lesson (left) and a canonic proof seen in KS4 (right)

The nine-point Circle task	A proof of the Star-Trek Lemma
 [Spliting the shape into the triangles ACD, ACB and CDB.] **Liz:** Two sides when I'm going from the centre point out to the edge of my circle, that line there is exactly the same distance as that line there. DCA=160º [task 1/angles around a point] ADC=10º because the triangle is isosceles. ACB=120º BCD=80º [task 1] CDB=50º because the triangle is isosceles. ADB=60º **Student**: Mmm, Double!	 Draw AB and the radius CD. On the diagram angle ADC=x and CDB=y. Therefore, ADB=x+y Angle CAD=x because the triangle ACD is isosceles, CA=CD radius of the circle. And DCA=180º-2x (i) Also, angle DBC=y because the triangle DCB is isosceles, CB=CD radius of the circle. And BCD=180º-2y (ii) ACB+DCA+DCB=360º because angles around a point sum up to 360º. From (i) and (ii): ACB+180º-2x+180º -2y=360º⇔ ⇔ACB=2x+2y ⇔ ⇔ACB=2(x+y) ⇔ ⇔ACB=2ADB

The students are not yet familiar with advanced algebraic routines, such as rearranging algebraic equivalences with more than one variable. However, with the mediation of ‘the nine-point circle’ Liz and the students negotiate the Star-Trek lemma and its proof, using an example where the angles can be calculated. Students are familiar with routines such as using angle facts to substantiate their actions or naming unknown angles towards their calculating. Additionally, drawing auxiliary lines was introduced in part 2. The action above led Liz to conclude:

Liz: […] this angle here [centre] will always be double the size of that one there [circumference].

Phrases like “this angle here” and “that angle there” act as placeholders for missing words that the students might come across in the future. Liz is aware of the words but does not name them to her students. Yet, the constructed narrative make sense both from the perspective of Liz, as an application of the Star-Trek lemma, and to the students, as an observation that can be confirmed following the steps of the task. Also, she uses the word “always” to signpost the generality of the argument. The task and Liz’s actions gear students towards constructing a narrative about the two angles by the end of the lesson. Actions beyond the mathematics of the moment are seen here as she engages students with mathematical content that students might see in the future in ways that are accessible to them.

Potentials of the discussion and the task to go beyond the mathematics of the moment

We also identified potential opportunities where the discussion could go beyond the mathematics of the moment but were not addressed by Liz. In part 3, the students are asked to create as many different triangles as they can by joining three points on the ‘nine-point circle’, during a specified time. An opportunity that emerged regards the total number of the different triangles:

Student: Miss, do you have us drawing thousands of triangles?
Liz: Are there thousands of triangles to find?
Student: Yeah… [Liz moves on]

Later, Liz makes the following comment during the whole class discussion:

Liz: There are, I believe there are about thirty-six different triangles that you can make out of this. There are lots. But we're running out of time, so I can't show you and I can't load up the the document I wanted to show you.

Time limitations and technical difficulties seem to be the reason why this opportunity did not materialise despite Liz’s intentions. Determining the exact number of different triangles relies on observations about congruent shapes which is part of the students’ compulsory education, as well as elements of problem solving and combinatorics that go beyond the mathematics of the moment.

Finally, one opportunity we observed emerging from the task is to use the same visual mediator, the ‘nine-point circle’, to introduce more circle theorems e.g., exploring the angles of cyclic polygons. As mentioned earlier, circle theorems, including cyclic quadrilaterals, could be mentioned in KS4.

Discussion and Conclusion

The analysis yielded opportunities to engage in mathematical conversation beyond the mathematics of the moment. Some of these opportunities were taken (manifested) and others were missed (potentials of the discussion and the task). Using intersubjectivity, we discuss opportunities that materialised during the lesson, to identify the elements of the teacher communicational patterns at the Mathematical Horizon. The teaching actions exemplified here, regard Liz inviting her students to endorse intersubjective narratives (the Star-Trek lemma with word use and routines which are accessible by the students) or to perform intersubjective routines (auxiliary lines prompted by teacher’s ‘clues’). We observed Liz and her students using words, endorsing narratives and perform routines that make sense from both teacher and student perspectives through the mediation of the ‘nine-point circle’. Liz’s expectation is that students, with her support would utilise known routines to justify their arguments mathematically. Our observations are in line with nested routines and ritual-enabling opportunities to learn as stepping stones for the students to enter a new discourse (Nachlieli

& Tabach, 2019). The missed opportunities identified here indicate that the communication might be constrained by factors such availability of time and resources or teacher's priorities.

The data reported here, illustrate a theoretical frame and a method of analysis to account for teaching situations where the communication goes beyond the boundaries of the curriculum. We consider the opportunities discussed here as evidence of DMH and, thus, contributes to the work on how DMH is conceptualised and investigated in research. The identification of opportunities (manifested and potential) can be utilised to determine what facilitates or hinders the opportunities to go beyond the mathematics of the moment. What, for example, does stop teachers to act upon students' contributions that have potential for a discussion that goes beyond the mathematics of the moments? How could these discussions be beneficial to students? These are the next steps of our work on the analysis of data collected from teachers (interviews and class observations) and teacher educators (interviews). In our work, our attention is on teachers: we study their narratives and how they react to student contributions. We note, however, that this study does not explore connections between DMH and students' learning. Finally, what we discuss here is connected to our own horizons as mathematicians and mathematics education researchers. Therefore, further research and collective work will give a nuanced view of DMH and its implications in teaching and teacher professional development.

Acknowledgment

Using roles and positions to foster explorative talk in mathematics

This article is part of the Theatre in Mathematics project (TIM), where we use drama and roles to involve students' actively in their learning of mathematics. In this article, we report on the use of roles in group work in mathematics. The data comes from one group of six students that were given roles to use during joint task solving, and the analysis is based on transcriptions from the lesson. In this particular group, two of the students enacted the role of the curious very actively. We find that these two ask almost all the questions. Looking further into it, we find four types of questions that are most frequent: requesting answers and claims, requesting explanation, requesting evaluation and clarification, and requesting argumentation. The last three types are essential parts of explorative talk, and we conclude that our study has illustrated how an active role of curios can move the discussion forward in ways similar to explorative talk. This study is an example how the teacher can shift the focus from teacher questioning to student questioning in the mathematics classroom.

Keywords: Positioning, interactions, roles, explorative talk.

Introduction

Our experience from the classroom indicates that many students rarely participate in discussions in mathematics. There are several reasons for this, ranging from some students taking a dominant position that makes other students passive to students lacking sufficient self-confidence in mathematics to dare to express themselves in the classroom. The background for this project was to explore whether we could change the classroom discourse by giving the students different roles and positions, and if this could lead to a more exploratory talk in mathematics and if more students will be actively involved in the mathematical discussions. This included a shift in focus from searching for the correct answer in mathematics to discussion, argumentation, and in-depth explanations.

Both Mortimer and Scott (2003) and Mercer and Wegerif (2002) describe different types of classroom discourse. Mortimer and Scott (2003) suggest four communicative approaches, where one is preferable (the interactive-dialogic approach) as it gives room for several points of view and allows several persons to participate. In the same way do Mercer and Wegerif (2002) present three types of talk where one is preferred. In explorative talk, all partners actively participate, opinions are sought, and decisions are jointly made. This means that the interactive-dialogic approach and explorative talk both emphasize participation and openness to different ideas. Through positioning theory, we might explain and understand why not all classrooms look like this. We can even use positioning theory as a mean to change the classroom towards the ideals of Mortimer and Scott (2003) and Mercer and

Wegerif (2002). In this article, we report from a European project called Theatre in Mathematics (TIM), where we use positions, roles, and drama to create classroom discourses characterized by active participation, openness for ideas, and a clear focus on questions, challenges, explanations, and arguments. Our research question for this article is: How can assigned roles and positions, particularly the curious role, foster a more interactive and explorative talk in mathematics? To answer this question, we needed a framework capable of describing student interactions on a turn-by-turn basis. As we could not find one that suited, we developed one based on literature.

Theory

Mortimer and Scott (2003) suggest a model that describes teacher's communicative approach along two dimensions (table 1). The first is the authoritative-dialogic dimension, which refers to whether only one point of view (authoritative) or more than one point of view (dialogic) is paid attention to. The second dimension is the interactive-non-interactive dimension that separates between approaches that include or exclude people from participating.

Table 1: Communicative approach (Mortimer & Scott, 2003, p. 35)

	INTERACTIVE	NON-INTERACTIVE
DIALOGIC	A Interactive/Dialogic	B Non-interactive/Dialogic
AUTHORITATIVE	C Interactive / Authoritative	D Non-interactive / Authoritative

The result is four different communicative approaches, where the interactive-dialogic approach, which opens for several points of view and includes participants, is preferred. Another one is the interactive-authoritative, where the teacher allows students to participate, but there is only one point of view. This has apparent similarities with the IRE pattern (Initiation-Response-Evaluation) (Cazden, 1988; Mehan,1979), as the students typically are allowed to answer questions and tasks but rarely allowed to introduce other points of view by initiating new ideas or evaluating.

While Mortimer and Scott (2003) present a model for a teacher's communicative approach, Mercer and Wegerif (2002) look at the dialogue per se and suggest three general types. The first is *the cumulative talk* in which each interaction builds on the prior one, in a positive and supportive way, but also uncritically. Repetitions, confirmations, and elaborations characterize cumulative talk, and only one idea is heard. The second is *the disputational talk* which is characterized by disagreement and individual decision making. Even though multiple ideas are heard, there is no genuine attempt to understand each other. Instead, it is characterized by assertions and challenges, and the participants are trying to win the discussion. The third is *the explorative talk*, where the participants engage critically but constructively, and multiple ideas are accepted and even wanted. It is also typical that suggestions are offered, justified, and challenged. It is characterized by making knowledge publicly accountable and making reasoning visible as part of the talk. While explorative talk is preferred by Mercer and Wegerif (2002), the characteristics of Mercer's categories are further explained and nuanced by Sjåstad (2018). A central argument that Sjåstad (2018) argues that all three types of talk have some positive sides. For example, the cumulative talk might be consensus-based or explanatory, and particularly the latter has potential for learning even though only one idea is discussed because the idea through discussion is modified. Also, disputational talk may be argumentative or true disputational, and the first has potential for learning even though they do not try to agree because their ideas are substantiated (Mork, 2006; Sjåstad, 2018).

However, how do we identify the different types of communicative approaches or talk? One way to do so is to study the discourse on a turn-by-turn basis. Scholars have developed a wide range of concepts describing different types of interactions, and some have also developed frameworks. One such is the inquiry co-operation model by Alrö and Skovsmose (2004), suggesting eight types of interactions that both teachers and students use: *getting in contact, locating, identifying, advocating, thinking aloud, reformulating, challenging, and evaluating*. Another framework that separates teachers' and students' interactions is suggested by Drageset (2014, 2015), which describes four main types of student comments: *(mere) answers to mathematical questions, explanations, initiatives, and evaluations.* Such frameworks, and their concepts, are helpful when trying to characterize different types of communication in the classroom, based on a turn-by-turn analysis.

While it is well established that a turn is dependent on the prior turn (Linell, 1998), communication is more than responding to prior turns. For example, some students never talk even when invited in by the teacher, while others tend to dominate any discussion. This might be explained by using positioning theory. According to Harré and Van Langenhove (1999), people have preferences that guide their position in social settings and discourse. Also, taking a position could affect other positions, so positioning may not be taken freely but instead a negotiation. Such positions, and positioning of others, could be intentional sometimes and unintentional at other times. For example, if one student position herself as a helper for those who do not understand during group work, this is also a way to position someone else as needing help. Also, if one or two positions themselves as a solver of a task, this might exclude or passivate others.

Roles relate to positions. Roles are a central part of any drama, and even though roles are used in many ways (Drageset et al., 2021), two key factors separate roles in drama from positions. One is that roles include fiction, while positions do not. The other is that you are always aware of playing a role, while you are not always conscious of your positioning and how this affects your surroundings. At the same time, there are apparent similarities as it is possible to choose both a role and a position deliberately, and it is possible to change to another role or position deliberately. In the TIM project, we use limited roles (which we call role categories) to make students aware of possible positions they can take in the classroom and give them experience in taking them and changing between them. One such role category is the curious, a role where you ask questions until you understand, sometimes rather insistent. It is well known that asking questions may be a scary thing to do as one might be seen as dumb, but when you are given the role of curious, you are asking because it is your task. Another role is the skeptic that tries to find other solutions or challenge ideas. We also use the role of authority, where this is a democratic authority that requests arguments and explanations and several points of view before deciding. Furthermore, we use a mediator that tries to find common ground for a joint decision. Then we try to establish these roles as positions in the classroom by giving students roles and encourage them to use the given position in the discussion around the math problems.

To study the dialogue, we have built an analytical framework based on the above theory. The starting point was a limited search for concepts that could describe student interactions in a group-work setting (without teacher participation). Then we grouped the concepts in different ways and arrived at seven quite distinct types of student interactions (see table 2). The framework was also adjusted during the analysis.

Table 2: Analytical framework describing seven main types of student interactions

Code	Description	Developed from
Answers & claims	These are answers to questions and might be correct, partial, or wrong. No explanation or argument is given. Often part of a flow of questions and answers, which is typical for cumulative talk.	(mere) answers to mathematical questions (Drageset et al., 2021) Cumulative talk (Mercer & Wegerif, 2002)
Argumentation	Argumentation is focused on why something is correct or beneficial, or logical.	Advocating (Alrø & Skovsmose, 2004)
Challenges	Challenges break with the flow, present a new idea, or opposes a presented idea. This is an essential part of explorative talk if it leads to arguments or explanations but might also create a disputational talk if challenges are met with challenges and no arguments or explanations.	Challenging (Alrø & Skovsmose, 2004) Explorative talk and Disputational talk (Mercer & Wegerif, 2002)
Evaluation & clarification	Evaluating is an assessment of any of the other codes, typically related to correctness or logic. It might also be about clarifying, typically seen in reformulating.	Evaluation (Alrø & Skovsmose, 2004) Explorative talk (Mercer & Wegerif, 2002) Reformulating (Alrø & Skovsmose, 2004)
Explanation	Explanations are focused on what is done, or has to be done, to reach an answer, typically chronologically.	Explanations (Drageset et al., 2021)
Questions	Questions about what, how, and why. It is typical for an explorative talk that students take initiatives and ask questions.	Initiatives (Drageset et al., 2021) Explorative talk (Mercer & Wegerif, 2002)
Suggestions	Suggestions are an initiative to a way of solving a task, often related to thinking aloud. These typically will be followed by arguments or explanations.	Thinking aloud (Alrø & Skovsmose, 2004) Initiatives (Drageset et al., 2021)

Method

This article builds on data gathered as part of the Theatre in Mathematics (TIM) project financed by Erasmus+ and partners from Italy, Norway, Greece, and Portugal. The aim is to develop a mathematical teaching methodology that involves students actively in their mathematics lessons by using drama techniques. The methodology builds on two approaches. One approach uses process drama, where the participants take on specific characters or roles in a story. This is a form of drama where there are no fixed lines, but the participants instead interpret how the role or character would act in the different situations of the story. The other approach is called Mathemart, where theatre workshop techniques that include mathematical games and performative activities are used to explore a particular mathematical topic. These activities aim at creating a trusting atmosphere where mistakes are not stigmatized but instead considered elements of a creative process.

The data reported in this paper comes from a lesson in a tenth-grade class with 25 students and their teacher. The students have used role categories since they were in grade 8. In this lesson, they were given a set with nine problem-solving tasks to complete in groups (five to six students) in 60 minutes. The tasks covered statistics, relations between metrics, physics and variables, geometry, equations, and functions. An example is how to make and analyze diagrams that show how many apprentices there are in different educational programs. Another is to find the relations between density and volume in a practical situation. The students had worked on the tasks on their own before the group session. Each group of students was given three different role categories to be used during the work with the tasks: authority, curious, mediatorial. One can see the curios as a role that cultivates what Mercer and Wegerif (2002) call explorative talk, while the mediator cultivates the cumulative talk. Arguably, an authoritarian role could be seen as cultivating disputational talk, but we seek to create a more democratic authority that listens to all before deciding, hence supporting both cumulative and explorative talk. The working process of each group was video-recorded, and a desk microphone captured their speech. For this paper, one group of six girls was chosen as a case study because two students were playing curios in a very active way.

The group discussions were transcribed, and the analysis was done using NVivo, where we first coded all student turns into the seven categories from table 2. Then we identified one group where two of the students were actively playing the role of curios and looked further into this. In the second step we coded the two girls' questions based on what they asked for (of the six other categories), to characterize how they used their role to include others in different ways. The analysis of turns was supported by observation of non-verbal communications seen in the video.

Findings

The group consisted of six girls, one being an authority, three being curios, and two mediators. First, we categorized all turns related to table 2 (See table 3). The first analyzes showed that two of the three students who had a role as curious asked 90% of all the questions in the group. The girls in the role of curious were aware of their roles as questioners. One of them even asks at the beginning of the lesson: Should I ask questions, even though I know the answer? We decided to analyze in more detail the type of questions they asked.

Table 3: Amount of each type of turn for each girl, named by their role category

Categories	Sum	Girl 1 (curious)	Girl 2 (curious)	Girl 3 (curious)	Girl 4 (mediator)	Girl 5 (mediator)	Girl 6 (authoritarian)
Argumentation	3	1	0	0	0	2	0
Evaluation/clarification	76	28	9	3	10	19	7

Explanation	48	12	5	0	3	21	7
Suggestion	35	9	8	0	4	13	1
Question	88	55	18	3	1	4	7
Answer/claim	52	13	11	4	5	12	7
Challenge/initiative	32	15	2	0	0	6	9

In the analysis below, we looked for the qualities of the questions in terms of the type of response they asked for. This means that we coded the questions of these two active curios based on what they asked for (using the categories of table 2). Figure 1 highlights the type of questions the two girls asked. The category challenge/initiative are excluded as we only found one example of that kind.

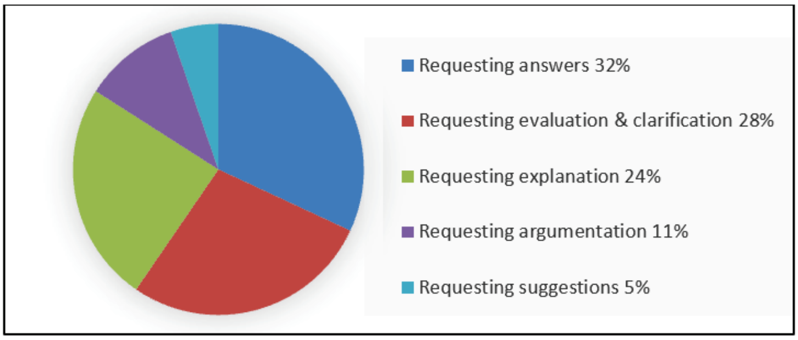

Figure 1: Type of questions in the percentage of all questions

There were four types of questions most frequently asked by these two curious girls. The first, *requesting answers and claims*, could be questions such as “how long was that (line between A and B)?”, “are they all of equal length?” and “what is the formula?” Such questions are essential to create progress and get something on the table to discuss or work on. At the same time, they just request what Drageset et al. (2021) call (mere) answers without any explanation. When such questions and (mere) answers go on with confirmations and no elaboration, it is a typical cumulative pattern described by Mercer and Wegerif (2002).

The second, *requesting explanation*, could be questions such as “hmm, how do we find the average then?” and “how do we construct that (an angle of 120 degrees)?” These questions focus on revealing what was or could be done to reach an answer, often step by step. Such questions and explanations are typically about elaboration, and if these explanations are mostly accepted without further questions, they might be explanatory as part of a cumulative talk. On the other hand, when questions are further worked on or challenged, they might form a basis for Mercer and Wegerif’s (2002) explorative talk.

The third, *requesting evaluation and clarification*, could be questions such as “What if there were no number in the middle, what if so? (talking about the median)”. While these questions request an evaluation, they also typically request clarification of detail, or what Alrø and Skovsmose (2004) call reformulation, which is vital to move the process or understanding forward. Such questions form an essential part of an explorative talk (Mercer & Wegerif, 2002) since clarifications and evaluations form the basis for further developing each other’s ideas.

The fourth, *requesting argumentation*, could be questions such as “Why did you do that?” and “Why is it so that we can add and divide?” These questions could be separated from explanations as they request a logical explanation or advocating (Alrø & Skovsmose, 2004) for a reason and not just a chronological explanation of the steps that lead to the answer. Such questions are an essential part of an exploratory talk, but when they are rhetorical with no genuine interest in the answers, they belong more to Mercer and Wegerif's (2002) disputational talk.

Overall, girls 1 and 2 moves the mathematical talk forward with their different types of questions. When one question is asked, suggestions and explanations are often followed up by additional questions, requiring elaboration and involvement from several students. Since both multiple students and multiple points of view were accepted, the conversation in the group is characterized by having an interactive-dialogic approach (Mortimer & Scott, 2003). One example of how girls 1 and 2 move the talk forward is this, where they support and elaborate on each other's questions:

Girl1:	Which education programs have more apprentices than the average for all education programs? What must be done then?
Girl2:	Then we must find the average
Girl1:	Of all of them?
Girl2:	Yes. How do you do that then? I have forgotten
Girl1:	Hmm, how do you find the average here then?
Girl6:	You add everyone, and then you divide by the number.
Girl1:	Lovely, and then once we have done that, then we find out which ones are over?
Girl2:	Yes, which one is more than average?
Girl1:	Why is it so that we can add and divide? Why is it like that?

The students' discussion can be seen as negotiations about understanding where meaning is constructed together. It is not necessarily the correct answer that gets the most attention, but rather the process that leads to the answer. The students build on each other's input, which is a characteristic of cumulative talk. At the same time, the conversation shows elements from an exploratory talk where statements are being challenged and required for further explanations. The situation above can also be characterized as a dialogical interaction (Mortimer & Scott, 2003). The students are open to each other's ideas, and they build on the suggestions that emerge. They do not respond by pointing out errors but ask for further argumentation and explanation when they do not understand.

Although not all the girls were equally active orally, for example, the third girl who had the role of curious, the video shows that even the students who did not contribute with many statements were involved. They responded with *yes*, *no*, and other statements of support such as *hmm*, and visual expressions such as nodding their heads. Questions, explanations, and clarifications given by some of the students in the group seemed to contribute so that all students became actively involved in the mathematical discussions, some with an active role as listening more than talking.

Discussion and conclusion

This article reports from a study of how assigned roles and positions, particularly the curious role, can foster a more interactive and explorative talk in mathematics. Our findings show that the discussion in the group we studied is characterized by both cumulative talk and explorative talk (as defined by Mercer & Wegerif, 2002). Cumulative talk is most clearly seen when the curios request answers and claims and when they request explanations without using the explanation further. At the same time, almost two thirds of the questions request explanations, evaluations, and arguments. Such questions help to shift the focus from the search for mere answers to inviting peer students to focus on reason. These are signs of explorative talks, and these questions are so frequent that this group discussion is more explorative than cumulative. Further, the questions from girl 1 and 2 invites the other students to share their ideas, which means that the discussion is also characterized by dialogic and interactive communication, as defined by Mortimer and Scott (2003).

These findings illustrate how roles in mathematics, where we especially highlight the role as curious, can influence the mathematical talk towards a more interactive and explorative talk. This is done by requesting explanations, evaluations, and arguments, and in this way inviting other students into the discourse while simultaneously shifting the focus from finding mere answers towards reasoning. More generally, this article illustrates how the teacher can change the emphasis from teacher questioning to student questioning in the mathematics classroom.

Cognitively activating lessons: A Nordic comparative study

Jóhann Örn Sigurjónsson

University of Iceland, School of Education, Reykjavík, Iceland; johannorn@hi.is

Keywords: Instructional quality, cognitive activation, classroom observation.

Cognitive activation

Although frameworks differ somewhat in exact conceptualization, there is a general agreement that instructional quality is a multidimensional construct (Croninger et al., 2012; Grossman et al., 2014). Cognitive activation has been established as one of "three basic dimensions" of instructional quality, along with individual learning support and efficient classroom management (Kunter et al., 2013). Furthermore, cognitive activation is among the dimensions of teaching most often represented in both mathematics-specific and content-generic frameworks for analyzing instructional quality (Praetorius & Charalambous, 2018). In an analysis of 12 frameworks, Praetorius and Charalambous (2018) concluded that cognitive activation consists of three aspects of teaching practice: (1) the teacher's selection of challenging tasks and use of mathematically rich practices, (2) facilitation of students' cognitive activity, and (3) supporting students' meta-cognitive learning from cognitively activating tasks.

The aim of this study is to compare the differences and similarities in cognitive activation in mathematics instruction between Iceland and the other Nordic countries.

Method

The study is a part of a larger research initiative, *Quality in Nordic Teaching* (QUINT), whose vision is to investigate instructional quality in the Nordic countries using video-based classroom observations. The sample consisted of ten mathematics classrooms from each country: Iceland, Denmark, Sweden, and Norway. In each classroom, three to four consecutive lessons were video-recorded and scored on a four-point scale by trained observers in the mathematics-adapted Protocol for Language Arts Teaching Observations (PLATO; see Grossman, 2019). For this study, specific lessons were identified where the teacher offered students rich opportunities for cognitive activation by considering the PLATO scores for *intellectual challenge* (IC) and *classroom discourse* (CD). In lessons where IC is at a high level, the teacher provides students with activities where analytical thinking is required by explaining, justifying solutions or reasoning. In lessons where CD is at a high level, the teacher provides students with opportunities for mathematics-related talk and the participants in the discussion expand on each other's ideas. The "top two" lessons in these elements from separate classrooms from each country were selected, for a total of eight cognitively activating lessons from eight separate classrooms.

Results

Analysis of data is ongoing as of this writing. In figure 1, a scatterplot visualizes the average scores across classrooms in IC and CD where chosen lessons have been highlighted.

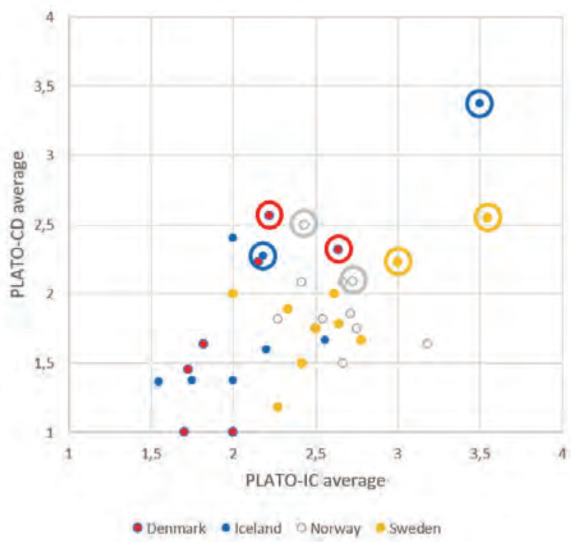

Figure 1: Scatterplot of average scores in IC and CD across classrooms in the four countries with classrooms highlighted from which lessons were chosen for further analysis

It is worth noting that average classroom-level scores only tell a small part of the story. Ongoing analysis of the chosen lessons will shed further light on which aspects of cognitive activation were manifested in classroom interaction and resulted in the high scores, such as choice or implementation of tasks, activity structures or other teaching profiles. The results will address to what extent the lessons may fit the notion of a "Nordic model" of instruction.

Socio-mathematical norms regulate whole-class discussion

Christina Svensson[1] and Richard Wester[2]

[1]Malmö University, Malmö, Sweden; christina.svensson@mau.se

[2]Lunds kommun, Lund, Sweden; rickard.wester@lund.se

This study identifies existing socio-mathematical norms through student and teacher responses in mathematical activity in grade eight in Sweden. The data consist of one video observed research lesson, and the analyses contribute to methodological identification of socio-mathematical norms through student responses and connected teacher activity during dialogues. Through these dialogues, the study identifies how students and the teacher expressed aspects of mathematical knowledge in their responses based on socio-mathematical norms in this classroom.

Keywords: Mathematical reasoning, socio-mathematical norms, student responses.

Introduction

Socio-mathematical norms (SMN) are jointly agreed upon between teachers and students in the mathematical classroom, constituted through participation (Cobb, 2002). SMN are common cognitive and social structures that frame what is communally valued by the classroom community (Cobb, 2002). These are shaped and reflected by cultural traditions that emerge specifically in mathematics classrooms through the configuration of activities. Focus is directed towards what knowledge is rewarded during the learning process (Yackel & Cobb, 1996). What distinguishes a mathematics classroom from another is the structure of classroom norms, not their existence or absence (Yackel et al., 2000). According to Yackel and Cobb (1996), the teacher has a significant role in suggesting SMN, which the students can collectively accept. For example, the teacher can do so based on the type of solution and arguments from students (McClain & Cobb, 2001), which influences the type of mathematical knowledge to be valued in the activity.

Some previous studies have identified limitations where social classroom norms limit the establishment of SMN when the focus is more on how teachers or students should behave democratically in an activity (Fredriksdotter et al., 2021; Kazemi & Stipek, 2001), instead of promoting discussions or arguments for which a mathematical model is best suited for the task (Cobb & Yackel, 1996b). SMN frame both the knowledge and structure for interaction (Cobb & Yackel, 1996a). However, sometimes the teacher will intend to gather short student responses with a character of correct answers. Responses like that contrast with occasions where the student response is more comprehensive, containing conceptual understanding and elegant reasoning (Kilhamn & Skodras, 2018).

Methodologically it is challenging to detect classroom norms. These are often indirect and implicit but somehow obvious to participants through their participation in practice (Cobb, 2002). Different perceptions of existing norms may coexist within the classroom (Cobb & Yackel, 1996b). One way to methodologically detect classroom norms is when teachers and students explicitly discuss expectations (Cobb, 2002; Wester, 2015). Another opportunity to identify SMN occurs through participants' reactions when existing norms suddenly get challenged (Cobb, 2002). These reactions will be indicators when existing norms are broken. The current study will contribute to identifying SMN through video observation of interactions between students and teachers in a mathematical teaching activity. Instead of methodologically using teachers' intentions to promote SMN (Wester, 2015), this current study elucidates student response through dialogical patterns in the classroom community of practice aiming to identify SMN. We address the following research question: How can student response and connected teacher activity be used to identify socio-mathematical norms (SMN)?

Method

We analysed a whole-class discussion (50 min) to answer this study's research question. To capture students' responses and connected teacher activity, the students were video-observed during a whole-class discussion in a grade 8 classroom in Sweden (one teacher and 25 students). The video observation was transcribed verbatim and analysed by the two authors. We have used an abductive approach during the analysis of empirical data and use of the framework (see Table 1). First, we divided the whole-class discussion into parts based on dialogue patterns. Each pattern consists of the students standing in front of the class discussing their own solutions to a given task (see Figure 1). Students' responses in the discussion, together with the related teacher activity, form the unit of analysis. By studying several dialogue patterns in the whole-class discussion during the same lesson, the opportunity for detecting how SMN directs and influences the mathematical teaching activity regarding the structure of the whole-class discussion increases. According to Kilhamn and Skodras' (2018), framework dialogue patterns are illustrated in the operationalising approach (see Table 1).

In operationalisation, different characters of reasoning are elucidated, and these have been inspired by Hjelte et al. (2020). Reasoning can be characterised as either general or domain-specific for mathematics (Hjelte et al., 2020). General reasoning is like a logical chain attempting to reach a solution, using necessary mathematics regardless of domain. Domain-specific reasoning belongs to a specific mathematical domain. Hjelte et al. (2020) suggest the following mathematical domains in research-based studies: *Spatial reasoning*, *Informal Inferential Reasoning*, *Additive, multiplicative and distributive reasoning*, *Algebraic reasoning*, *Proportional and covariational reasoning*, *Quantitative reasoning*, and *Transformational reasoning*. Different types of reasoning may be connected to each other and form a network of reasoning.

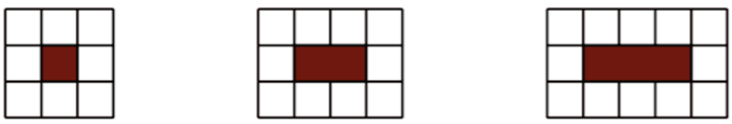
The operationalisation of the framework also focuses on different characters of mathematical knowledge as procedural or conceptual, based on Yackel and Cobb (1996), concerning SMN. Procedural knowledge focuses on solving the already constructed mathematical calculation structures, while conceptual knowledge means that the student knows mathematical concepts and their relations between each other (Yackel & Cobb, 1996). Knowledge is valued as SMN in category LC through the operationalisation procedural, while conceptual understanding is valued as SMN in category HC.

Table 1: Operationalisation of Kilhamn and Skodras' (2018) framework according to student response and associated SMN

Level of response	Student's response associated to SMN
F Factual	An accepted answer related to the task or to teacher's questions. No attempt at descriptive or explanatory response. Ex: Name, identify, repeat, recall known facts or procedures, "correct" answers wanted. (often short answers, including yes/no)
LC Low-level Conceptual	The descriptive response values procedural knowledge (Yackel & Cobb, 1996) containing expressions of step-to-step solutions and may contain general reasoning (Hjelte et al., 2020)
HC High-level Conceptual	The explanatory response values conceptual knowledge (Yackel & Cobb, 1996) and is based on domain-specific reasoning (Hjelte et al., 2020).
E Evaluative	Apply and evaluate domain-specific reasoning (Hjelte et al., 2020) in relation to mathematical content containing in specific task. Different domain-specific reasoning forms a network for explanation.

Ethical procedures of informing participants of their rights to refuse to participate and obtaining verbal and written consent for their voluntary participation were followed using Swedish guidelines for research (Vetenskapsrådet, 2017). Furthermore, the collected data were anonymised and coded to protect participants' confidentiality, and the researchers had no teaching or grading role for the students involved. In addition, the names of the participants and other sensitive data were removed from the stored data, and these data were secured in a safe locker to avoid unauthorised access.

Eva and Ali put white tiles around flowerbeds as the pictures shows.



Figur 1 Figur 2 Figur 3

3. How many white plates are used in figure n?

4. How long will the flower bed (dark tiles) be if they have 158 white tiles to lay?

Figure 1: Task

Result

Analysis of this whole-class discussion reveals the following lesson sequence of dialogue patterns based on the operationalised framework: F-F-**LC-LC-HC**-LC-F. Three dialogue patterns are emphasised (bold) to answer the research question: How can student response and connected teacher activity be used to identify socio-mathematical norms (SMN)?

Dialogue 1 (student's response level LC)

66	Teacher:	We will stick to problem 3 (How many white plates are needed in figure n?) Namely the formula (point to the formula that the students wrote on the board: 2 * n + 6) and then I take problem 4 (How long will the discount be if they have 158 white tiles to put?) which was also to find out how many or which figure how many blacks what discount is it that has 158 tiles around it and then we have student A and student B, welcome.
67	Student A	We have taken 2 times n plus 6 (read out what is written in the formula 2 * n + 6 on the board for the teacher).
68	Teacher.	How have you used this since, in task number 4 where what have you done?
69	Student B	2 was the difference, after all, any number plus 6 (rename the formula for the teacher).
70	Teacher.	How have you used this since how have you done to calculate, ie which figure you are looking for?
71	Student A	We took 2 times 54 plus 6.
72	Teacher	Hm
73	Student A.	It will be 158 minus 6 it was the edges and then 152 divided by 2 and it will be 76.

The teacher (line 66) begins by inviting students to the board and asks them to focus on parts 3 and 4 in the task (Figure 1). Through the introduction (line 66), the students explicitly request no specific student response. Still, it is up to the students themselves to interpret what is expected of them when they stand by their solution at the board. Student A responds by reading out the expression for the formula without mentioning the answer to part 3 in the task (line 67), which constitutes a limited student response. The situation that, as a student, sometimes occurs at the board is not new for these grade eight students. Students have support for their interpretation of what is expected of them at the board based on previous similar experiences, which follows prevailing classroom norms for the situation and similar contexts. Pretending that the students' responses do not contain the direct answer to the task may mean that the students have interpreted that the teacher is looking for something other than just the answer to part 3 in the task, of which the indication of the formula becomes their attempt at what can constitute an acceptable response (level F).

The teacher follows up students' short responses by asking a more investigative question (line 68), aimed at part 4 in the task, which the students also did not answer with their short response. This how-to question has the potential for student responses at higher levels than F. Student A's response continues as before by repeating the formula in different ways (line 69 and line 71), although the formula alone still does not answer the teacher's consecutive how-questions (lines 68 and 70). The student's response remains at level F.

Only when the teacher (line 72) does not provide the expected feedback on the given student response (based on the formula), do the students develop their responses to a description at the LC level. Student A describes how they arithmetically worked their way to answer part 4 in the task. LC level because the student in their response expresses different steps in their calculation against the answer. In their arithmetic description, the student also names a geometric representation (the edges of the figure) to support the calculation. Therefore, we cannot answer whether these students are able to make an explanatory response at the HC level or if the students' interpretations of the norm system prevent them from providing an explanatory response.

In writing, the students show the way to the answer on the board and orally express what they value is most interesting and of the highest mathematical quality (the formula). These responses show how these two students interpret prevailing SMN. Since the teacher is repeatedly not satisfied with the students' responses, the students finally succeed in changing the content in their responses (line 73). Based on its arithmetic calculation, the steps to the answer are described (level LC), and no further teacher questions are then asked.

Dialogue 2 (student response level LC)

80	Teacher:	Now there are two solutions left that do not do exactly the same […] can you come up and tell?

Already in the introduction (line 80) of dialogue 2, the teacher expresses that one should compare two different solutions. This teaching document challenges the accounting students to develop their response since they have different solutions that must be compared in an investigative way.

83	Student C:	May I draw?
84	Teacher:	Yes
85	Student C:	Ok, then we'll see (draw a rectangle and another rectangle inside) if you have, so to speak, the whole figure here, i.e. 158, (draw around the inner rectangle) then you take minus 2 and you get (draw again) you get the cubes. And then you get 156 which is this and that (shows in the drawing) then you divide by 2 so you get 78 and 78 is then this one down as well (shows in the drawing) and since we knew there was one on each side (shows in the drawing) instead of taking it minus 2 you know yes it is the solution (aimed at the teacher).
90	Teacher:	(fills in more the four boxes in the middle) these are the discount in the middle and this is what you want to find out so C removes this and that piece (point to the boxes next to the right and left of the discount) to remove them simply and then he has left the top row and the bottom row (points in the rectangle) and then he divides them by two and then he only gets one row (points to the bottom row) but that row is two pieces longer still than the one in the middle so then he takes minus two again. Are you in? Turns to the class and then you did a formula of this (turns to student C).

Contained in the introduction (line 80) of dialogue 2, the teacher expresses that one should compare two different solutions. This teaching document challenges the accounting students to develop their response since they have different solutions that must be investigated. Student C asks if it is ok to draw (line 83). After the teacher's approval to draw, the student enters a dialogue with the teacher using some verbal caution and then tries to describe the chosen calculations based on a drawn picture. Through general reasoning, the student uses, without verbal expression, concepts in the mathematical domains geometry (perimeter) and algebra (Figure n). Based on the student's response, there are possible conditions to end up at the HC or E level. However, expressions in students' responses are not explanatory and contain domain-specific reasoning. Instead, this student's response is a step-by-step description, strengthened through the drawn picture, of the path to the task solution (level LC).

In line 93, the teacher once again verbally expresses the student's description of the solution based on the picture. For the context, the teacher possesses more functional language than the student, and the teacher's revoicing of C's description becomes more accessible to the listening students.

However, in terms of content, the teacher's narrative is on the same level as the student's (level LC) as it intends to explain the path to the solution. As the content of the teacher's responses remain at the LC level, the prevailing SMN in the internship community are confirmed for the context.

Dialogue 3 (student response level HC)

D: accounting student, Ex: students in the class.

97	Teacher:	[...] can you tell us how that formula came to be?
100	Teacher:	Look at what you have done (point to the formula $Y = (1n + 2) * 3$ and student D looks) 1n plus 2.
101	Student D:	In order to …
102	Teacher:	What is 1 and why 2?
103	Student D:	Hm.
104	Teacher:	Can you tell others what he did? (turns to the class)?
105	Student E1:	2 is probably the difference between the different ones.
106	Student E2:	n is well that in the middle.
107	Student E3:	n is well the figure plus ...
108	Student E1:	not always.
109	Student E2:	Now we'll find out in the middle.
110	Student D:	Wait n is it (points to the flowerbed in the middle, the four coloured squares in the rectangle) plus 2 is equal to it (points to the bottom row) and
111	Student E2:	Why multiplied by 3?
112	Student E3:	Y is the whole set.
113	Teacher:	Yes exactly, he has taken the middle plus the edge pieces (points) and so he has called it y. So he puts someone else's letter. One row is (points) and taken it three times, there are three rows, but after doing that you have to remove what is in the middle to get what is around.

In line 97, student D is asked to unpack the formula they have formulated. Since the student cannot answer the question, it is reformulated by the teacher (lines 100 and 102). When the student is still unable to formulate a response (line 103), the teacher (line 104) turns to the whole class and asks them to investigate what is identified in the formula. This teacher's action breaches norms that open the norm system for investigative conversations. This invites interactions from students who have previously only listened and not been involved in the dialogue. Student D and some listening students then formulate a joint understanding of the formula (lines 105–112). As a collective unit, they unpack the formula and express the meaning of the parts in words. Each of the individual students' responses contains short responses and statements. Through joint interaction in the investigative conversation, the short contributions together explain domain-specific reasoning in algebra reasoning and spatial reasoning. In the common dialogue (lines 105–112), there is a knowledge of mathematical content based on spatial reasoning linked to numbers (numerical), which are allowed to meet algebraic reasoning about the variables and constants of the formula to create a common relational understanding of what the formula expresses. Despite students' mathematical knowledge, their verbal response does not contain expressions of reasoning and mathematical ideas. Instead, the students express different statements about how different parts of the formula can be interpreted in their responses. It does not become an open dialogue about which mathematical ideas and mathematical reasoning are behind the various statements. Instead, statements that are not met during dialogue with alternative statements are silently accepted. Therefore, the common student response remains on the HC level. Both the students' knowledge and the teacher's activity – to encourage students into exploratory conversations – contain the potential for HC and level E. However, there is a lack of support in the SMN for students' responses to be able to reach level E in this situation.

Also, in this episode, the teacher sums up the discussion by re-telling and verbalising the jointly expressed opinions by the students. The teacher thus responds to students' responses at both the LC and HC levels.

Discussion

Through an operationalised framework (Table 1), it becomes possible to categorise students' responses in the dialogue patterns. The level of student response and connected teacher activity is used to identify the prevailing SMN. Based on an analysis of each dialogue pattern, a lesson sequence for the whole lesson is possible. In the current lesson sequence (F-F-LC-LC-HC-LC-F), F and LC levels became the most common student response. This means that prevailing SMN supports dialogue patterns at the F and LC levels through this classroom discussion but lacks support in SMN for both the HC and E levels. However, one dialogue pattern still ends at the HC level during this lesson. This exception happened when the current teacher opened up the prevailing norm system for that moment. After this particular dialogue pattern, the following dialogue patterns once again returned to the normative for F and LC levels. This then saw the identification of the F and LC levels around the mathematic knowledge valued in the activity (McClain & Cobb, 2001).

A complementary methodological way to identify SMN can be done through potential norm breaks. According to Cobb (2002), another way to identify SMN are manifested through participants' reactions when existing norms are challenged. In dialogue 1, the teacher's action (line 72) challenges students' perceptions of their existing valued response. Instead of the students becoming frustrated at expressing the algebraic formula once again (level F), the teacher's activity leads to the students developing a response containing a description of the calculation steps (level LC). In dialogue 2, the student explicitly asks the teacher for permission to break existing SMN about valid representations (line 83). This student's response aims to precede that there will be no reactions to the drawing. This student response leads to be descriptive or explanatory and contains reasoning. In this episode, the student response still ended up at the LC level by being descriptive and containing general reasoning (Hjelte et al., 2020). In dialogue 3, the teacher insinuates norm break (line 104) by challenging the prevailing SMN to change temporarily. This teacher activity made it normative for other students to become temporarily involved in a joint explanation activity. Through the mentioned potential norm breaks, we will receive similar SMN as we would when analysing through the framework (Table 1).

The operationalised framework contains four "levels" of student responses, and these levels in our approach are somehow considered misleading. This is because they are more about four different structures, with different teaching intentions linked to different SMN due to classroom community of practice (Cobb & Yackel, 1996a). From this point of view, we will consider the analysis through the framework as non-normative for teaching, rather a contribution to developing and challenging teacher practice. Based on the findings in this research study, our implications for practice indicate that SMN impact and even regulate the opportunities for developments in the mathematical community of practice. Therefore, implications for practice will be to contribute through this framework teachers' professional learning development about their own teacher practice according to deeper insights in different SMN. We suggest further research in this area, with the aim to contribute to professional teaching-learning development. Such research could also contribute to further elaboration of the operationalisation of the framework and analysis through the framework according to SMN.

What to do or what to learn – on communicating learning goals

Jorryt van Bommel, Marie Nilsberth, Anna Nissen, Michael Tengberg and Michael Walkert

Karlstad University, Sweden; jorryt.vanbommel@kau.se; marie.nilsberth@kau.se; anna.nissen@kau.se; michael.tengberg@kau.se; michael.walkert@kau.se

This paper reports the results from a large-scale video-observation study where 127 mathematics lessons were coded with regard to the way teachers communicated learning goals. Four consecutive lessons were collected in 35 classrooms (grade 7, students age 14) in Sweden. The PLATO-manual was used to code the lessons with a four-grade scale. The results show that teachers mostly communicate vague or inferred learning goals. Tasks are in line with these (inferred) learning goals and the teachers give clear instructions to students regarding what to do. Throughout lessons, teachers seldom refer back to the learning goals. However, half of the teachers occasionally express more detailed learning goals and relate the content of the lesson to a learning outcome.

Keywords: Learning goals, video-observation study, lower secondary school, interactions.

Introduction

> So, the coming lesson we will work from page 64 and work through task 83 to 94. For task 93 and 94 you might need a calculator which you can find in the cupboard here in front of the class. Don't forget to explain your calculations! Now let's get started.

When a teacher gives instructions such as the one above, students are given clear instructions on what to do and can immediately start working on the tasks. What is to be done has been clarified, but what is to be learned is vaguer. Further, no discussion is initiated on how or why students are expected to learn this. Research on instructional techniques in all core content areas has found that explicitly linking classroom activities to learning goals helps students understand the purpose of the instruction and make them feel motivated to engage with the ideas (Baker et al., 2002; Banilower et al., 2010; Spinath & Steinmayr, 2012). Further, clarity and explicitness of learning goals help students to create a context in their learning (Spinath & Steinmayr, 2012).

The situation presented above describes a rather common lesson start as observed in a large-scale video-observation study in grade 7 (14-year-olds) in Sweden (Tengberg et al., 2021). This LISA-study (Linking Instruction and Student Achievement) aims to capture different aspects of teacher instruction, in which the way teachers present their learning goals is one such aspect. In this paper data from the LISA-study will be presented with a specific focus on learning goals. It aims to answer the following question: To what extent and in what detail are learning goals communicated across lessons and classrooms in Swedish 7th grade mathematics?

Previous studies

Detailed and clearly communicated learning goals influence students' learning achievements (Hattie, 2009; Boden et al., 2019; Locke & Latham, 2002, Reed, 2012). Further, clear learning goals can motivate students (Spinath & Steinmayr, 2012) and clarify what is expected as an outcome of the lesson (English & Steffy, 2001; Hattie, 2009). Communicating learning goals enables both students and teachers to see connections between previous lessons and the current one but also to see connections between activities and instruction within a lesson (Vaughn & Bos, 2010).

Within a Swedish context, Hemmi and colleagues (2019) found that Swedish teachers, when working with Finnish curriculum materials, expressed their goals vague and implicit. This is in line with previous studies in Sweden (c.f. Boesen et al., 2014). In an interview-study, Fauskanger and colleagues (2018) found that Norwegian teachers preferred goals focusing on the content and supporting student learning. Yet, observing teachers' instructions on a large scale is relatively uncommon in the Nordic countries. In Sweden, a limited number of observation studies have been conducted either led by The Swedish Schools Inspectorate (2009), or as an evaluation of a nationwide mathematics professional development program (i.e., The Boost for Mathematics, Matematiklyftet) dedicated to the improvement of the teaching of mathematics (Ramböll, 2016: Österholm et al., 2016; 2021). One of the outcomes revealed that while lessons are often structured in terms of planned activities, they seldom start with a presentation of goals and purposes of the lesson, and teachers seldom leave time for reflection or evaluation of what was learned at the end of the lesson (Österholm et al., 2016; 2021).

Since the importance of communicating clear learning goals to students has been discussed and has been the subject of professional development initiatives in Sweden, this element deserves special attention. Also, the Swedish goal-oriented curriculum (Swedish National Agency for Education, 2011) pleads for an attention to communication of learning goals in class.

Background – the LISA-study

The LISA-study aims to capture the quality of teaching of different subjects in the Nordic countries. This article focuses on mathematics taught in Sweden. LISA uses an observation protocol (see below) to explore the quality of teaching. In Sweden, we observed 35 classrooms, taught by 31 teachers at 15 schools. Each classroom was video-recorded for three or four consecutive lessons in the middle of the school year, which resulted in 127 video-recorded mathematics lessons.

To obtain a representative sample and to match the national distribution, the schools were stratified according to different variables such as the schools' locality (urban/rural), the percentage of immigrant students; achievement level; the organization of the school (public/charter). Also, age, gender and qualifications of the teachers included in the sample varied which provided a fair and diverse representation of mathematics teachers in Sweden (for a more detailed description, see Tengberg et al., 2021).

Method

Video observations

In the present study, two cameras and two microphones were used to capture the teaching. One camera in the back of the class, capturing the teacher, and one in front of the class, capturing the students. The teachers wore a microphone so all their talk could be recorded. Another microphone was placed in the middle of the room to capture students' speaking. Students who did not want to be video-recorded were seated on one side of the classroom, and the cameras were adjusted in order not to capture that part.

Four consecutive lessons were recorded in order to enable reliable information and to capture enough variation of teaching practice, this choice was led by findings from previous studies (cf. Kane & Staiger, 2012). However, the question of how many lessons that are needed to capture a teaching phenomenon (like clarifying and communicating learning goals) has been raised by several researchers (Cohen & Goldhaber, 2016; Ho & Kane, 2013) and consensus has, so far, not been obtained.

Each lesson was divided into segments, 15 minutes each, constituting the unit of analysis. If the last minutes of a lesson did not make up a whole segment, these minutes were either included in the previous segment (if the segment was shorter then 7,5 minutes) or added as a new segment (if the segment was at least 7,5 minutes long). When analyzing a lesson, a division into smaller units, following the different stages of a lesson is advisable (Clarke et al., 2006). These stages correspond to the structural level a teacher adopts to a lesson and often follows 15-minute segments.

Observation protocol

The protocol for language arts teaching observation (PLATO) was used to code the video recorded lessons. It was first designed for observing lessons in language arts (Grossman, 2015) but has been used in other subject areas as well. For mathematics the observation protocol has been revised, which has resulted in qualitative criteria similar to those used for language arts, but valid for mathematics. In specific, the PLATO-element *purpose* attempts to focus on whether or not the learning goals are clarified, and if coherence is established between the tasks, activities and the learning goals. By doing so, the quality of instruction is coded on a four-grade scale. In the example at the beginning of this paper, no specific learning goal was communicated. However, an implicit goal (connected to the mathematical content of the exercises) can be inferred. This would score a '2' according to the PLATO-manual. General instructions like "Today we will learn about linear functions" would also score a 2 (Figure 1). If a teacher would communicate a more specific learning goal such as "Today we will learn more about the slope of a linear function in relation to the values a and b in the formula", this could result in a score of '3'. In order to score a '4', there should also be evidence that the students are aware of the purpose or that the teacher or the students refer back to the purpose during the segment. Each segment is coded separately and only for what is present during the segment. However, if a teacher or students refer back to a purpose that was presented more specifically during a previous segment, the coding will take that level of specificity into account in the later segment in order to score a '4'.

1 **Provides almost no evidence**	**2** **Provides limited evidence**	**3** **Provides evidence with some weaknesses**	**4** **Provides consistent strong evidence**
There is no clear learning goal in the class or the learning goal is not related to the development of mathematical knowledge or skills.	There is a learning goal communicated or inferred, that is connected to the development of mathematical knowledge or skills. The goal takes the form of a general topic or activity (e.g., "Today we will learn about linear functions", or "Now we will work on our division"). The lesson's activities may not align to the learning goal.	There is a clearly communicated, specific, learning goal that is connected to the development of mathematical knowledge and skills. The lesson's activities align to and target the specific learning goal. The teacher makes clear how the lesson will support students' development as users of mathematics.	There is a clearly communicated, specific, learning goal that is connected to the development of mathematical knowledge and skills. The lesson's activities align to and target the specific learning goal. There is evidence that students are aware of the purpose. The teacher or students refer back to the purpose during the segment. Teacher makes clear how lesson will support students' development as users of mathematics

Figure 1: Scoring criteria of *Purpose* in mathematics (adapted from Grossman, 2015)

Reliability

Video observations enable repeated analysis to capture important details and patterns to greater extend then observations in classrooms (Borko et al., 2017). Further, they enable joint coding. In the present study, around 40% of the data were scored jointly by two raters, in order to obtain and monitor reliability. The observers were all certified PLATO-raters. Certification was obtained after a four-day course and a test in which .80 reliability per item had to be obtained.

To obtain a reliability of .80 on PLATO, at least five lesson segments should be observed (Cor, 2011). In our study we have an average of 12,7 observed segments per teacher, with a minimum of 7 segments.

Ethics

The principals of all schools were contacted first after which our request for participation was forwarded to the teachers. Teachers and students were informed about the aim of the research and how the data would be used as well as their rights as participants. Questions could be asked prior to data collection. All participating teachers, students, and guardians of students signed an informed consent. As stated, students who did not want to participate were seated on one side of the classroom so they would not be captured on video. The research was conducted in line with Swedish guidelines on research ethics (Swedish Research Council, 2017).

Results

Learning goals per segment

Of all 403 segments, 358 segments scored a ‘2’ (89%) on the four-grade scale. Often this was due to the fact that teachers only described the topic to work with in a broad way (e.g. “algebra”, “functions”, “fractions”), but on some occasion teachers would also refer back to previous lessons and just state that “today we will continue from where we ended yesterday”. Thus, they would not make it clear how the lesson would support the students’ development of mathematical competencies. Just as in the introductory example, teachers frequently instructed students on what to do “work from page 64 and work through task 83 to 94. Don’t forget to explain your calculations”, but did not explain why or what they were supposed to learn during the lesson.

One might assume that communicating goals would mostly occur during the beginning of a lesson, like in the following example (scoring a 3 or a 4): “We start with today’s schedule. The goal is to be able to calculate part of whole and to be able to simplify and reduce fractions”. Indeed, of the 41 instances where a score at the high end (3 or 4) was observed, 23 were observed in the first segment (Table 1). This means that, even when only the scores of the first segments of each lesson are included, still as many as 103 out of 127 segments (81%) scores a ‘2’. One could also argue that the goal of a lesson can be communicated at other stages of the lesson: for instance, at the end of a lesson. Looking at final segments, high scores of *purpose* occurred ten times out of 127 in the last segment of the lesson, which means that in just below 8% of the last segment of a lesson, teachers would come back to previously stated (implicit or explicit, vague or detailed) learning goals: “To sum up, todays lesson was about (…)”. There were in total four segments where no learning goal at all was communicated. One instance occurred in a lesson where a fifth segment was recorded (thus a lesson of consisting of more than 127,5 minutes), the other three segments occurred during one single lesson, indicating that no learning goals were communicated that lesson.

Table 1: Scores on Purpose divided over start, middle and closure of the lessons

Score	First segment	Middle segment(s)	Last segment	Total
1	1	1	2	4
2	103	140	115	358
3	21	6	8	35
4	2	2	2	6
Total	127	149	127	403

Learning goals per teacher

If we look at the different teachers and see in what way the scores were divided, we can see that the majority of teachers scores a mean value at or close to 2,00 (Mean 2,11; SD 0,38). Of all 31 teachers, 16 scored only on the low end (score 1 or 2), the other 15 teachers scored both at the high and the low end (scores ranging from 1 to 4). These teachers, who scored distinctly higher than 2,00 on average, communicated their goals more explicitly and in more detail. On rare occasions, this was done through utterances like: “at the end of the lesson you are expected to be able to (…)” or “yesterday we dealt with functions with one unknown, today we will continue and you will learn how to handle functions with two unknows or variables”. The scores on the high end require that the learning goals are in some way connected to a learning outcome, which could for instance be through exit tickets where students were to write what they had learned during the lesson.

Summary

We set out to answer the research question “To what extent and in what detail are learning goals communicated across lessons and classrooms in Swedish 7th grade mathematics?” and found that learning goals are typically implicitly stated and addressed in a vague way. Half of the teachers, express their learning goals more explicitly and, on rare occasions, learning goals are revisited by the teacher at the end of the lesson.

Discussion

The present study aimed to contribute to previous literature about learning goals through analysing how the purpose of the lesson is communicated in class, in specific in 35 mathematics classes in Sweden. The results showed that learning goals in lower secondary mathematics instruction are often implicitly stated, which is in line with the findings of Hemmi and colleagues (2019). Also, in a study including LISA data from all Nordic countries, similar results were found with a large number of segments scoring a ‘2’ (Selling & Klette, 2021). Their study also examined if the goals were focusing on content or competencies and found that most often content was addressed. If competency goals were included, these addressed procedures rather than conceptual knowledge.

A lack of clarity and detail can lead to a difficulty for students to perceive coherence within a lesson (Vaughn & Bos, 2010). In the present study, we found that even when instructions indicate some kind of coherence (e.g., when teachers say “Today we will continue from where we ended yesterday”) the connection between previous lessons and the current one might nevertheless be unclear. Also, the outcome of a lesson might be unclear for students, as no guidance is given regarding to what they are supposed to learn during the lesson. As there were few deliberately planned closures of lessons, learning goals and learning outcomes were very seldom reflected upon.

In light of the goal-oriented curriculum in Sweden, where it is considered to be important for students to understand what they are expected to accomplish for a specific grade (Swedish National Agency for Education, 2011), implicit goals in class do not offer students such an awareness (English & Steffy, 2001; Hattie, 2009). A critical note to our choice of method (video observations) is that a phenomenon like communicating learning goals might be observable elsewhere, and not only through the teachers’ communication captured on the video-recordings. For instance, detailed plans that explain what students are expected to do are often available for students on digital platforms, and in such plans, learning goals might be more explicitly stated. Furthermore, when giving feedback to students, teachers might indicate more explicitly what an expected learning outcome might be, related to detailed learning goals (Hattie, 2009). PLATO includes feedback as an element, and the analysis of that element might reveal some more insights on the communication of learning goals. The implicitness and vagueness of the orally communicated learning goals do not have to imply that students are not aware of the more detailed ones. During the observations we saw that students were constantly working on their tasks (measured in the PLATO-element ‘time management and behaviour management, for more details, see Tengberg et al., 2021). Students ask relevant questions and teachers replied accordingly, seemingly in line with specific learning goals.

In sum, we argue that since communication of learning goals influences the students’ learning achievement (Hattie, 2009; Boden et al., 2019; Locke & Latham, 2002, Reed, 2012), the results of this study could suggest that the students in half of the classrooms (with teachers scoring at the high end) might be affected in a positive way, whereas the other half of the students (with teachers only scoring on the low end) might obtain lower results. The next step will thus be to link teachers’ instruction to student achievement as our data enables us to do so.

TWG20: Mathematics teacher knowledge, beliefs, and identity

Introduction to TWG20: mathematics teacher knowledge, beliefs, and identity

Rationale

The TWG 20 had 28 papers and 8 poster presentations. Due to the high number of participants, we had to split the group into two subgroups, A and B. We had 5 parallel paper sessions for each subgroup and one all group poster session. Like all other CERME TWGs, we used Padlet to share materials and reflections that were visible to both subgroups. The final session has been an all group discussion on the main crucial points discussed along the work developed. The discussions occurred around four main themes: (i) teacher knowledge and research – including the specificities of prospective and in-service teachers; (ii) teacher beliefs and identity; (iii) teacher knowledge and reflections and (iv) collaborative knowledge development. The discussions revealed the need to perceive and study teachers' beliefs, identity, teaching practice, emotions and teacher knowledge has a complex system, and the need to design (and to deepen in how to do it) and research collaborative professional development dynamics for teachers taking into account cultural context.

Here, instead of presenting what has been discussed in each one of the presented papers we opted for a more holistic approach: we present some of the main ideas and questions raised in collective discussions and at the end of TWG20 work, hoping that pursuing finding answers to such questions would lead us to advance to new paths and bring possible insights and approaches also to be discussed in the next CERMEs. For doing so we address the four main themes and conclude with some open questions and provocations for (possible) future work.

Teacher knowledgeand research

Research on teachers' knowledge seems to have assumed naturally the existence of different teachers' knowledge models with all its diversity and focus on particular specificities of the knowledge considered. In both CERME9 and CERME11, there was an effervescence of model development. The focus was on their use for a deeper understanding of teachers' knowledge in various contexts and on various topics. The discussions developed in TWG 20 during CERME 12 revealed a research shift of attention from the knowledge teachers (don't) have to the knowledge teachers use to teach mathematics which lead to the "superman/woman teacher" idea and on how to deal with it.

The ideas, theoretical discussions and methodological viewpoints emerged can be summarized as:

- the role of teacher knowledge frameworks – discussing the importance of the different teachers' knowledge models and knowledge conceptualizations and their use in and for research;
- research tools that "serve" both educators and researchers – focusing on the intertwined way of perceiving how the research tools can (should) be employed in both contexts (for teacher education and for doing research in and for teacher education);
- the need to pay attention to the specificity of teacher knowledge This problematic emerged associated to the large amount of research supposedly being done focusing in teachers' mathematical knowledge that can be carried out similarly with students from the school level those (prospective) teachers are (will be) teaching.

Some of the emerging questions are:

(a) What are the differences amongst prospective teachers and practice teachers in terms of content knowledge? Are we "taking care" of prospective teachers as teachers or as "older" students? And do we consider them in the work we do?
(b) The focus of attention in teachers' knowledge research has been mainly (in TWG 20) in prospective teachers, do we need to shift this focus and what are the affordances of and for doing so?
(c) What are the differences amongst these groups in terms of mathematical and pedagogical knowledge and what are the implications of the research being done and of the conclusions obtained?
(d) When doing research in prospective teachers, are we looking at the transition from student to teachers? What can we learn from that transition?

Teacher beliefs and identity

The themes of beliefs and identify have been addressed mainly in an intertwined manner to other issues. Teachers' beliefs, identity, teaching practice, emotions and teacher knowledge seem to represent a complex system, in which each dimension informs the others in a direct or indirect manner. The discussions carried out on these themes during TWG20 can be synthetized around three main ideas:

(a) the importance for prospective teachers and in-service teachers of collectively discussing and reflecting on core teaching practices for the development of their identity and their knowledge;
(b) different definitions and conceptualizations of identity allow for the study of different aspects of teacher (learner) identity and change;
(c) the relationship between teacher beliefs, culture and traditions: culture and traditions represent factors which inform beliefs.

Teachers’ knowledge and reflections

Reflection is transversal to teachers’ practices and thus, related with all the teachers’ cognitions (and not only). A set of discussion went around reflecting on the relationships involving enactment of teacher knowledge on:

(a) student thinking – associated to the research being done using student productions as a reflective tool and the analysis of students’ assessment items for investigating teachers’ knowledge;

(b) online environment – choosing and implementing tasks for online learning environment, the (dis)advantages of each one of the tasks and its types and the knowledge involved and required;

(c) developing measurement items – metacognitive aspect of developing measurement items to measuring teachers’ knowledge and the different dimensions of knowledge being measured.

In this space of discussions, also influenced by experiences during the pandemic period, the online practices emerged in an interconnected explicit manner and some questions related worth mention:

(i) What kind of practices allows teachers to improve themselves for online learning environment and what knowledge is involved?
(ii) What does it mean to have a strong mathematical knowledge for teaching online? In what terms it differs from other contexts of teaching?
(iii) How can different teacher knowledge models – considering or not explicitly technology – can be used for practical and methodological research purposes?

Collaborative knowledge development

The cultural dimension emerged strongly during the TWG meetings last CERME and TWG20 participants addressed it again during this CERME. There is the need to continue considering the international audience we have in the TWG and its cultural diversity in order to make explicit the particularities of the context research occurs. It will allow also the findings to be important to such a broader audience, and allowing, thus, contributing for the broader picture of improving the quality of research and its impact.

Some questions and reflections that emerged were:

(a) How to design and research collaborative professional development for teachers taking into account cultural context?
   (i) the need to a productive middle way between ‘anything anywhere’ and ‘nothing nowhere’ – the two ends of trying to implement anything anywhere or not implementing due to cultural factors are not beneficial;
   (ii) the need for comparison and exchange between professional development programs in different local contexts for further understanding of both local contexts and important aspects in implementation and the research being done;
(b) How to describe and/or analyze a cultural context that is useful in research relating to professional development?

(i) the need to consider that the awareness of culture/context might not be enough leading to the need to be explicit in how and what ways the specificities of the cultural context and considered and impact on the research being done;
(ii) the need for precise terminology for describing what was actually taken into account in the research being done so it can be also meaningful to a broader audience and impact on the more global level.

These questions were framed with the background of "*direction with potential*", thinking on the research being done and its intertwining with teacher education and professional development programs – both with prospective and practice teachers. In that sense in a transversal manner to the discussions there were to topics of cooperation, comparison and extension of these professional contexts and the tasks involved both in micro, local and global levels of practices.

Transversal ideas and new emerging questions

The structure of the work carried out during TWG 20 was designed to move from the discussion of the specific papers presented (which can be perceived as case studies) to the elaboration of a set of possible new trends for research on teachers' knowledge, beliefs and identity in initial and continuing education contexts.

In doing so we have been able to frame new possible paths and inquiry questions that have, indeed guided some of the research being done afterwards and which reflect the problematic themes from this community. Some of these transversal ideas to all the discussions refers to:

(a) a more concrete and explicit focus of attention in the connections and relationships between research and teacher education, emerging from: (i) the diversity of roles each one of us assume as researchers, teacher educators, and teachers; (ii) the research tools conceptualized and employed – e.g. tasks for data collection and its intertwined required relationship with teacher education;
(b) a specific aim of considering the impact of what we do (in research) in what it's expected to be done in the future – in terms of public policy about teacher education.

Some of the emerging open questions are related to:

(i) How researchers will manage zooming in on knowledge for teaching specific topics within a cultural context while zooming out of teacher knowledge models?

(ii) How can we balance the role of cultural context in conducting research and implementing teacher education with developing common understanding from research results?

(iii) What does it mean to have a "sound mathematical knowledge" allowing students to understand (online or not)? How can this be improved?

(iv) How can we (researchers, educators) address, utilize and examine different definitions of identity?

(v) How should we look into the system of teacher knowledge, identity, beliefs with lens of situated learning?

Teacher Practicum in Turkey at the Time of Pandemic

Fatma Aslan-Tutak[1], Berna Sena Civan[2] and Arife Şahin[3]

Mentoring in pre-service teacher education is defined as a process in which mentor teachers assist the professional development of pre-service teachers. In this study, teacher practicum at the time of pandemic is examined through supervisor and mentor practices. This study aims to unveil how the practices of the two stakeholders in Turkey, and their interaction with each other in the context of teaching practicum evolved during Covid-19 pandemic. The sample of the study was 2 supervisors and 4 mentor teachers from Istanbul who worked with secondary school preservice mathematics teachers. Data was collected by using interviews with supervisors and mentor teachers. The findings of the phenomenology analysis showed that the adaptation of the interaction of stakeholders emerged to be in three categories; i) discontinuity of practicum due to practicum school online teaching policy; ii) online micro-teaching at university as practicum; iii) online teaching at high school courses.

Keywords: Mentoring, teaching practicum, secondary school preservice teacher education.

Introduction

In line with the fast changing world, education has an important role to shape nations' generations who are capable of overcoming the challenges. Therefore, the quality of education is important for countries in order to raise qualified citizens who make their counties much better. The most essential component of education is teachers and raising effective teachers is the first step of education for students. Because, "the quality of teachers determines the quality of education" (Jan, 2017, p.50) and the quality of teachers are determined by the quality of the continuum of teacher education. Teacher education is a life-long learning and preservice teacher education is the first step of it. The most essential part of preservice teacher education is teaching practice because teaching practice gives opportunities for preservice teachers to transform their theoretical knowledge into practice (Azkiyah & Mukminin, 2017). During the practicum process, mentees need guidance and support. The people who are responsible for providing such support and guidance are supervisors-instructors of mentees in the teacher education program and mentor teachers-collaborating teachers from practice schools.

Understanding the practicum process is difficult because it should be evaluated in terms of opinions of three stakeholders, university supervisors, mentor teachers and mentees. When the research studies about teacher practicum are examined, it can be seen that there is a limited number of studies to examine the practicum process in terms of the relationship and collaboration between three stakeholders. Because of the Covid-19, understanding these relationships has gained more importance to provide effective teacher practicum for mentees. Thus, the purpose of this study is to contribute to the literature on how the practices of the triad stakeholders in Turkey, and their interaction with each other in the context of teaching practicum evolved during Covid-19 pandemic.

Even if the importance of teacher has started to increase, many people think that anyone who has such content knowledge can be a teacher (Darling-Hammond, 2000). According to Shulman (1987), being a teacher, and skills that teacher must have are underestimated. Being a teacher contains within itself many roles, responsibilities, knowledge, and skills. Even if content knowledge is an essential to be a good teacher, it is not the only component of teaching because it just forms the “what” part of teaching. Teachers should also have pedagogical knowledge to be qualified to “how” s/he will teach the content.

Knowing how these skills and knowledge can be got as much as important knowing which skills and knowledge are necessary to be a teacher (Darling-Hammond, 2006). According to Shulman (1987) and Darling- Hammond (2000), preparation is an important step for getting these kinds of skills and knowledge because teaching can be learned. Therefore, teacher education has a significant role to raise qualified teachers.Teacher education is not short-term learning, it is a life-long learning. Therefore, it is not true to say that each teacher who graduates from undergraduate teacher education program completes their teacher education. Undergraduate teacher education program is just the first step of the teacher education process, and it has a great role to shape preservice teachers’ lives as a teacher.

Preservice teacher education and practicum

Due to the fact that preservice teacher education is the first step of teacher education, planning and applying the preservice teacher education is important to raise qualified teachers for countries. Even if each county may have its own preservice teacher education program, preservice teacher education has generally two parts to prepare students teachers as a teacher. One part constitutes the theoretical side of preservice teacher education and the second part constitutes the practical side of preservice teacher education.Even if theoretical knowledge is necessary, it is not sufficient to be a teacher. According to Munby et al. (2001), knowledge of teaching can be acquired and improved by the preservice teachers’ own teaching experience. Therefore, preservice teachers should have opportunities to apply their theoretical knowledge into practice (Azkiyah & Mukminin, 2017; Zeichner, 2009; Nguyen, 2020) to build a bridge between theory and practice.

In Turkey, recently, the Ministry of National Education and the Council of Higher Education made regulations on pre-service teachers' practices, the partnership between universities and schools and revised the roles of pre-service teachers, mentors and supervisors (MEB, 2018). Based on these regulations, mentees are expected to take subject-matter courses and teaching methods courses and to experience teaching in practicum schools. Universities are responsible for providing teacher candidates with the courses of subjects and teaching methods. In the field experience, both universities and partner schools have responsibilities for teaching practices of teacher candidates. Especially, mentoring provided by mentor teachers who are the supporters of teacher candidates at practicum schools plays a significant role in the development of teacher candidates' knowledge and skills on teaching.

There is a limited number of studies that focused on triad stakeholders in teacher practicum in Turkey. One of the studies of Yılmaz and Bıkmaz (2020) aims to examine the mentors' needs within the context of Classroom Teacher Education from the perspectives of supervisors, mentors and mentees.

According to findings, each stakeholder stated that mentors had a need for their roles and responsibilities to be clearly stated, which confirms Curran's and Goldrick's (2002) argument that mentoring should be based on clearly stated objectives. Moreover, Yılmaz and Bıkmaz (2020) emphasized that even though the mentor training program was built on a collaborative approach, in practice, mentoring diverges from being a collaborative effort. Even though the literature suggests investigating mentor teacher practices for area specific studies, the pandemic created an unexpected crisis on teacher education. In Turkey, schools were closed for a long period of time which required preservice teachers to finish their senior year practicum with emergency solutions. This study aims to investigate how mentors and supervisors of preservice secondary school mathematics teachers adapted teacher practicum while conducting emergency remote teaching in Turkey.

Methodology

In order to investigate the experiences of two stakeholders, mentors and supervisors, at the time of pandemic in 2020 for teacher practicum, phenomenology design is used. In the context of teacher education, in order to examine preservice teachers' learning processes it was necessary to examine the interaction between these stakeholders. In order to do so, data was collected from the two stakeholders by the end of teacher practicum semester, Spring 2020. There are only two secondary school mathematics teaching programs in Istanbul. Researchers contacted both of these programs and reached mentor teachers (n=4) of their practicum schools and supervisors (n=2) in order to conduct individual interviews. In the semi-structured individual interviews both groups of participants were first asked about pre-pandemic practices of teacher practicum. Then they were asked to talk about their experiences of practicum after all high schools and universities were closed and continued education as emergency remote teaching. Both stakeholders were also asked about their relationship with others during the adaptation of practicum at the time of pandemic. These interviews transcripted and coded for themes.

Findings and Discussion

Findings from two supervisors (one from two universities) and four mentor teachers showed that the pre-pandemic interactions among stakeholders were consistent with each other in terms of how they interacted. The interaction was evident, carefully planned and regulated by both universities and the Ministry of Education. Both parties mentioned these regulations and how the Ministry of Education requirements really regulates mentee preservice teachers' practices but not providing much direction for supervisor-mentor interactions.

One expected finding was the limited direct interaction between these two stakeholders. Supervisors and mentors interacted through the mentee preservice teachers. Their answers for elaboration of the interaction revealed the nature of interaction in two categories; i) cooperation or ii) collaboration. When mentors' practices were limited with Ministry of Education requirements (mentees to do six-hour weekly observations, four teaching practices) the interaction became at cooperation level. For some supervisor-mentor pairs, there was clear differentiation from others in terms of how they interacted beyond the regulations. These supervisor-mentor interactions were extended from mentee evaluation into deliberate communication and visits for topics other than specific mentees. For such cases, stakeholders collaborated with extended share of interest and resources.

As the Turkish government decided emergency curfew, all schools were closed by March 23rd, 2020. After one week of emergency spring break, schools started emergency remote teaching. In addition to the online synchronous teaching, the Ministry also provided TV broadcasting. Meanwhile universities started emergency remote teaching. But it brought a great challenge for teacher education because mentees could not complete their internship. Most of them were able to attend only one third of the internship. Due to curfew, the Ministry waived all the requirements, asked supervisor and mentors to evaluate mentees based on the work during face-to-face education, before curfew.

We found that, when the Ministry of Education waived all practicum requirements as an emergency reaction, the adaptation process was directed by supervisors' priorities for teacher education rather than mentors' practices. This may imply how stakeholders positioned themselves for teacher education during the pandemic. Findings also revealed three types of adaptation: i) discontinuity of practicum due to practicum school online teaching policy; ii) online micro-teaching at university as practicum; iii) online teaching at high school courses as practicum.

In this presentation, authors will discuss these adaptation types which provide insights to how stakeholders considered new normal in teacher education by relating them to pre-pandemic practicum interactions and also how it may transform teacher practicum for the following years.

How teachers' knowledge and didactic contract evolve when transitioning to student-centered pedagogy – the case of project-based learning

Tuval Avishai[1] and Alik Palatnik[2]

[1]The Hebrew University of Jerusalem, School of Education, Israel; tuval.avishai@mail.huji.ac.il

[2]The Hebrew University of Jerusalem, School of Education, Israel; alik.palatnik@mail.huji.ac.il

Despite project-based learning (PBL) benefits, its use when teaching mathematics is not as common as expected, partly because of the required changes in teachers' role and knowledge. In this case study, we map and characterize the changes undergone by one teacher while transitioning from teacher-centered instruction to PBL. This transition was accompanied by a teacher community where the teachers experienced authentic real-life problems from the tech industry as learners, then led project-based learning in their 9th-grade classrooms. The findings indicate a development in the content knowledge, the pedagogical content knowledge, and the general pedagogical knowledge of the teacher and demonstrate the formation and implementation of an up-to-date didactic contract between her and her students. Recommendations include integrating the topics of teacher's knowledge components and didactic contract in teacher training for PBL.

Keywords: Teachers' knowledge, teacher community, didactic contract, pedagogical content knowledge, project-based learning.

Introduction and background

Project-based learning (PBL) is a teaching method known throughout the world for several decades, and there is extensive knowledge and literature on its characteristics and advantages (e.g., Condliffe et al., 2017; Thomas, 2000). It is rooted in Dewey's (1938/1963) educational ideas stating that learning is a social activity and emphasizing the effect of real-life situations, students' choice of context, and ways of learning. The projects allow students to work relatively autonomously, over extended periods of time, with a tangible product created by the students at the end (Thomas, 2000). When students perform PBL in mathematics, they implement strategies such as reducing the complexity of the problem, searching a simple model, and moving from the specific case to generalization (Halverscheid, 2005). In PBL of mathematics, students engage in problem solving, decision making, and investigative activities (Palatnik & Koichu, 2017).

Despite these advantages, PBL is not a common practice in math classes as one might have expected, partly because the planning and the implementation in class are challenging (Thomas, 2000). Being student-oriented and constructivist, PBL challenges teaching practices and learning methods and thus requires a significant change in the work of teachers and students. PBL requires a modification in teachers' role from director to a facilitator of learning and requires them to tolerate ambiguity and higher levels of noise and movement in the classroom (Condliffe et al., 2017). These challenges suggest the need for new models of professional development and teachers' training geared to the specific characteristics of this teaching method to provide teachers with the tools and skills they need to successfully implement PBL in class (Barron et al., 1998).

The purpose of this study is to begin building a conceptual, cultural, and organizational framework that will enable PBL based on real-world industrial problems to be widely implemented in schools. The motivation is based on the aforementioned characteristics of PBL contributing to the development of students' independence, strengthening their sense of ownership of knowledge, and encouraging learning out of curiosity (Thomas, 2000), and on a perception that tackling real-world context problems leads to higher-order thinking processes, integration of critical thinking, and improvement in communication and reflection (OECD, 2018).

Given the importance of the teacher's role and the need to rethink and refine this role while implementing student-centered pedagogy (Condliffe et al., 2017), we chose to focus our research on teachers and the changes that occur when transitioning from teacher-centered instruction to PBL in mathematics. Based on the second author's experience in implementing PBL (Palatnik & Koichu, 2017; Palatnik, 2022) as well as on Brousseau, 1997; Condliffe, 2017 and Thomas, 2000, we hypothesize that this transition creates changes in the teachers' knowledge, as well as changes in the nature of the interaction between the teacher and her students. To map and characterize these changes, we conducted a multiple case study of teachers who, for the first time, used real-life context PBL in their classrooms. This report describes the case of one of these teachers, Sarah.

Theoretical Framework and Research Questions

As mentioned, our study aims to identify and characterize the development of the teacher's knowledge when transitioning to teaching mathematics using PBL and to map and describe the changes in the nature of the interaction and the set of mutual expectations between the teacher and her students as a result of this transition. Thus, we acknowledge Shulman's categorization of teachers' knowledge (1986) and recent developments in the field (e.g., the Mathematics Teacher's Specialized Knowledge (MTSK) model, Carrillo-Yanez et al., 2018). However, as our study focuses on the professional development of mathematics teachers within a learning community and the enactment of new knowledge in class, we sought a more dynamic theoretical framework that will emphasize the knowledge flow between various layers of teachers' knowledge. Hence our theoretical framework draws on the Refined Consensus Model of PCK (Carlson & Daehler, 2019) for science teachers' practice. Their model describes the *flow* of knowledge from the outer circle of *collective* PCK (cPCK) of peers, teacher educators, researchers, and mathematicians to the *personal* PCK of the teacher in question (pPCK), and then on to *enacted* PCK (ePCK), which is "the unique subset of knowledge that a teacher draws on … during the planning of, teaching of, and reflecting on a lesson" (Carlson & Daehler, 2019, p. 82)

When the teacher shifts to student-centered pedagogy, students become more responsible for learning. Hence, we incorporate into the theoretical framework of this study the notion of didactic contract—the set of reciprocal obligations and mutual expectations between the teacher and the students (the theory of didactic situations, Artigue et al., 2014; Brousseau, 1997).

In terms of the theoretical framework, our research questions are:

(1) Which components of teachers' knowledge develop when transitioning from teacher-centered pedagogy to PBL in a real-life context?

(2) What changes does the didactic contract between the teacher and her students undergo due to this transition?

The context of the study – Practimatics program

The study is a pilot study accompanying "Practimatics", a novel program that brings industry system engineers, mathematics education researchers, and mathematics teachers around one table. The program relies on three elements: new mathematical content – tech-related real-world problems, new pedagogy – PBL, and a dedicated teacher community. During the program, we exposed the teachers to several real-life industry-based mathematical problems that were processed by the research team. The mathematical content needed for the inquiry was consistent with the 9th-grade Israeli curriculum (Pythagorean theorem, linear and quadratic equations and functions, the ratio, etc.) In addition, the tasks allowed the students to combine algebraic and geometric content, which is not usual for regular curriculum tasks. The milk container problem (see below) was chosen based on these considerations. The teachers who participated in the program and their 9th-grade students had no prior experience in PBL. As mentioned, a key element in the program was establishing a teacher community led by the research team. The community incorporated means to facilitate PBL implementation, as mentioned in the literature. Namely, it provided initial training, allowing teachers to experience project-based learning as learners (Condliffe et al., 2017), supported and accompanied the teachers through networking and training (Kokotsaki et al., 2016), was a safe meeting place for them to draw emotional support and conduct peer dialogue on the various projects (Tsybulsky et al., 2019), and provided teachers with explicit models of possible student learning trajectories before they enter the classroom (Barron et al., 1998). The first author of this paper is one of the community leaders and is a high school math and physics teacher. His background as an electronics engineer who worked extensively with systems engineers for over a decade before becoming a teacher helped create a common language between the program participants – teachers, engineers and researchers.

The original problem in the described case study

The students' projects originated from "TetraPak", a revolutionary pyramid-shaped milk container presented in the 1950s by a group of engineers and entrepreneurs (Figure 1a). The students were asked to create a model of such a container using as much as possible from an A4 paper sheet and to present it along with calculations and justifications.

Figure 1: TetraPak pyramid-shaped milk container and a diagram from one of the student projects

Methodology

Our method is an instrumental case study, exploring the issue over time with detailed, in-depth data collection involving multiple sources of information. In this paper we present the case of the teacher Sarah, whom we perceive as a typical case of an experienced teacher with no acquaintance and no prior experience with PBL or any other form of inquiry-based pedagogy. Sarah was very cooperative, verbal, and informative, and she was eager to share with us the nature of the interaction in her classroom, which made her a valuable informant. Data included transcriptions of seven 1:30 hr. community meeting recordings. We used inductive coding when analyzing Sara's account of her experience implementing the new teaching method. Both writers read the transcripts together, associating each teachers' expression with the categories based on our theoretical framework and our hypothesis: subject matter knowledge, pedagogical content knowledge, pedagogical knowledge, didactic contract. We created and examined a new category in cases where an expression did not fit any of these categories. We then cross-referenced data from additional sources: observation of Sarah's class, questionnaires, and documents collected in the field (Sarah's notebook, WhatsApp, and email correspondence), and compiled the account of Sarah's case.

Findings

Sarah teaches at a six-year religious high school for girls in central Israel. At biweekly community meetings, Sarah spoke in detail about PBL implementation in her class. Her students worked on a project that originated from the milk containers problem for about four and a half months. The mathematical content of the projects was mainly geometry (see example Figure 1b) and, in particular, the properties of the pyramids. Starting with reference to the didactic contract, we describe the findings in chronological order as possible to account for the gradual change. All descriptions and entries were made in Hebrew and translated by the authors of this article.

Formation of an up-to-date didactic contract between the teacher and her students

Already at Sarah's first meeting with her students, at which she planned to present only the structure of the program without delving into mathematics, she decided to introduce them to the problem of the milk container. At a learning community meeting, she explains why:

Sarah: Because…. well…, the audience demanded…it was as if they were curious and they said: "no, no, give us the problem now." So, of course, I said OK. Luckily, I prepared in advance.

Four months later, Sarah looks back at the beginning of the process and recalls how the students had to adapt to the new pedagogy and to the clauses of the updated contract with the teacher:

Sarah: …they never worked that way. These students did not even know what it means project-based learning…They are so used to learning in a specific way, to have all knowledge and information 'thrown' on them. It is really like a new language they had to learn.

During the following lesson, in which the students tried to build pyramids using rolls of paper, they asked why one should study this subject, which is not in the curriculum. Sarah replies:

Sarah: There is a reason for that, but wait, you will see soon. That's why I want you to try to look for the subjects yourself... In this program, you will learn on your own, and you will be able to teach me.

She builds on the students' questions to reveal another aspect of the new didactic contract as she tells them: "learning in this program will be different; responsibility is on you now." At the end of the lesson, when the students' attempts to create pyramids were unsuccessful, they asked her to reveal the answer. Sarah insisted they keep trying at home. According to Sarah, the students were surprised. Up to this point, in such situations, students were used to receiving solutions to the problem from her. Sara's actions and students' surprise indicate the start of redesigning the didactic contract—students' responsibility for learning and ability to deal with initial failure as part of mathematical inquiry.

Note, Sara's persistence in not revealing the answer is not arbitrary. She learns to be a learning facilitator to her students (PCK related to PBL). One of the elements of facilitation discussed lengthily in the community was that the teacher needs to avoid revealing the answer to motivate students to complete the inquiry. Thus, through community sessions and WhatsApp group, an element of the *collective* knowledge regarding the implementation of PBL in mathematics becomes part of Sarah's *personal* knowledge. When she acts in class applying this knowledge in the specific situation with specific students, this knowledge becomes *enacted* PCK (we elaborate on this later on).

A few weeks after the start of the project, a student told Sarah that she did not understand what she wanted from her in this project. Sarah was stunned because this was their fourth meeting already. As the project progressed, Sarah found herself constantly explaining to students what she expected of them. Indeed, the didactic contract should be re-clarified repeatedly for students and the teacher.

The final part of the project was an event held at the Hebrew University, in which the students presented their work and answered questions of prospective teacher program students. One of the questions concerned the way of learning. In the words of Ella, one of the students:

Ella: Learning this way was much more interesting because in regular math classes, you often study subjects you are less connected to, that interest you less. But when you choose the subject on your own, out of curiosity, you always have more motivation to learn, discover, and solve.

The student demonstrates the contrast between her motivation and interest during regular math classes and those during the project, highlighting another facet of a didactic contract for PBL: student choice of a problem.

Development of Sarah's pedagogical knowledge

Throughout the project, we witnessed the development of Sarah's pedagogical knowledge in aspects related to PBL, including ways to motivate and recruit students and ways to deal with procedural and social challenges in the working groups in her classroom. For example, at the fourth community meeting, she shared her opinion about the low pace compared to conventional pedagogy, and the teacher's need to be prepared widely for more than just the intended content:

Sarah: It takes a lot of time. It took me at least double the time I planned...I learned that one should be very flexible and be prepared not only for the specific lesson, right? You need to be ready for more.

At the seventh community meeting, she referred to the ways she has to prepare for a PBL session:

Sarah: So what you (members of the learning community) are saying here is that even if I give them this question in class, I should not try to solve it on my own beforehand.

These two excerpts illustrate bilateral knowledge exchange between *enacted*, *personal* and *collective* pedagogical knowledge of teachers. Sara's understanding of PBL planning and implementation includes now notions of teacher's flexibility regarding students’ projects and acting as a research partner of her students.

In yet another session, she shared her thoughts about encouraging low-motivated students who are stuck. Her pedagogical knowledge is challenged here:

Sarah: On the one hand, I can turn to them now and ask, but on the other hand, I wonder maybe it's supposed to come from them? Because if I'm the one asking, then ...well... I have to think, what's better.

However, two months later, she already has a solid opinion regarding ways to engage students:

Sarah: Explain to them the goal, show them the whole process so they can understand what's planned, so they have a sense of belonging. If you want students to feel a sense of belonging, you must share.

After enacting new pedagogy of PBL for a relatively long time, Sarah contributes her insights to collective pedagogical knowledge—sharing the goal and the process creates engagement.

Development of Sarah's content knowledge and pedagogical content knowledge

During the project, Sarah had to acquire new content knowledge. She learned some of it on her own, while in some cases, she relied on the community, as in the following example: Sarah tells the students tried to understand the pyramid volume formula by building a physical model. They managed to put six pyramids into a cube, as seen in Figure 1b, but not three pyramids. Sarah says:

Sarah: Maybe it came out by chance, but to really insert three pyramids into a cube, you cannot... I mean in volume, yes, but not in shape, not in dimensions.

In response, a discussion in the community begins as to whether it is possible to physically insert three pyramids into a cube. The program mentor demonstrated with the help of GeoGebra how it could be done, and Sarah now refers to her own lack of expertise in using GeoGebra:

Sarah: You see, say I would like to show them such a thing, (but) just looking it up... it would take me forever.

This example demonstrates how collective PCK becomes personal. Now Sarah knows it is possible to insert three pyramids into a cube, and she saw a new tool that allows visual illustration. The new knowledge she acquired here will most likely serve her in the future when teaching similar topics, thus becoming enacted PCK.

In a different case, Sarah seeks help from the community to bridge another content knowledge gap. She raises a question in the community's WhatsApp group regarding the characteristics of right pyramids and their heights. One of the community leaders replied without revealing the answer, in a way that encouraged Sarah to investigate and expand her knowledge on her own, while at the same time demonstrating how to communicate with students in PBL.

Discussion and conclusions

This study examines the case of an experienced teacher with no acquaintance and no prior experience with PBL and analyzes the development in her knowledge while transitioning to student-centered pedagogy. As mentioned in the literature, transitioning to student-centered pedagogy presents challenges and difficulties to teachers, as they require to adapt to new roles. This study brings empirical evidence of these challenges in the context of tech-related PBL and of the process of overcoming these challenges and developing relevant knowledge with the help of a teacher community. For instance, Sarah and the other teachers in the community realized that planning needs to be modular and flexible, much beyond a specific lesson, and must rely on broad mathematical knowledge, so they would be able to cope with surprises that arise from student inquiries. Teachers learned how to motivate and engage students in inquiry-based learning. They witnessed the power of learning through curiosity and experience and the notion that "breaking down the isolation of the classroom and designing performance opportunities in which students present to outside audiences can be a powerful way to support learning" (Barron et al., 1998, p. 285). Moreover, our findings demonstrate that PBL summons interpersonal situations and challenges that influence learning progress and requires teachers to develop and apply mediation skills. These insights and nuances regarding the implementation of PBL were new to Sarah and therefore represented an expansion of her knowledge.

In line with Brousseau's theory of didactic situations (1997), transitioning to student-centered pedagogy requires a new didactic contract between teachers and their students. Our study brings empirical evidence to the implementation of such a contract. Throughout the entire project, Sarah finds ways to convey her new set of expectations and re-clarify them when students lack understanding of these expectations. This movement back and forth in students' understanding of the expectations from them and the teacher's need to re-clarify the clauses of the contract is in line with Artigue's notion of an “appropriate didactical contract and the difficulties attached to the progressive negotiation of such a contract” (Artigue & Blomhøj, 2013, p. 804). From the teacher's knowledge perspective and in line with the RCM-PCK model (Carlson & Daehler, 2019), the whole notion of didactic contract, its formation, and the ways to convey and clarify it to the students represent a knowledge flow from the outer circle of community's collective knowledge to Sarah's personal and enacted knowledge.

Applying the RCM-PCK model in science to mathematics education, we demonstrated the flow of knowledge between the community leaders, peers and the teacher's personal knowledge and the development in her subject matter knowledge, pedagogical knowledge, and PCK. The case study exemplified that the notion of didactic contract and the need to redesign it when implementing PBL is a development of pPCK, thus suggesting a theoretical connection between this element of the TDS with a model of teachers' knowledge. Further research is needed to characterize these connections and how the formation of multiple didactic contracts by teachers in the community will enhance cPCK. Sarah's awareness of these developments and processes and her willingness to share and expand her knowledge helped her to implement PBL in her classroom successfully. We therefore recommend incorporating the subjects of didactic contract and the RCM-PCK model of teacher professional knowledge in mathematics teacher PD programs.

In this paper we inquire about the knowledge of the meanings of probability of preservice primary and secondary school teachers from Slovakia and Spain. At the end of their training on this content, we wonder about their conceptions of randomness and how they quantify its uncertainty. From the results obtained through a questionnaire filled in by 89 preservice mathematics teachers of Primary and Secondary in both countries and the interview to some of these informants, we highlight that they associate randomness mainly to future events and drawing experiments; they show knowledge of the classical meaning of uncertainty and little acquaintance with the subjective meaning. Besides, they seem to separate uncertainty from probability assignment.

Keywords: Probability, uncertainty, preservice teachers, Primary and Secondary School.

Introduction

Compared to other topics in mathematics, probability is especially difficult to understand. Unlike logical reasoning, which deals with statements which are either true or false, probabilistic reasoning deals with events for which there is no complete certitude. The intuitions underlying concepts of probability, such as dependence or fluctuations, are usually obscured by mathematical counting methods. These reasons, among others, make this a particularly difficult content item for both students and teachers, as Batanero *et al*. (2004) and the references therein, point out. These authors note that one aspect of teacher training concerning probability on which special emphasis should be placed is epistemological reflection on the concepts to be taught. We concur, and stress that understanding the inherent nature of probability should be one of the main goals in teaching the topic.

Probabilistic contexts can be understood from different perspectives. One major approach is the classical approach, which imposes the need for objective mathematical rules to explain random processes; in addition, the epistemic approach sees probability as the degree of personal belief about the ocurrence of an event, which is dependent on the information available, and constrained by theoretical decision rules. These two major trends can be included among what many authors have called the different perspectives on, or meanings of, probability, which also include the classical, frequentist and subjective approaches, among others (Batanero et al., 2016).

In our approach, following the Mathematics Teachers' Specialised Knowledge model (MTSK, Carrillo et al., 2018), teachers' knowledge of the different meanings of probability is located in their Knowledge of Topics (KoT). Numerous researchers have highlighted that, in order to offer students a richer learning experience, it is important for teachers to develop a broad understanding of the range of meanings of mathematical objects (e.g. Martín-Fernández *et al*., 2019; Thompson, 2016). In the case of the probability theory, realizing that uncertain situations can be described in terms of probabilistic models is especially significant. Ultimately, from the teachers point of view, we think that probability should be identify as the main mathematical tool for dealing rationally with uncertainty in daily life contexts.

This work is a descriptive exploratory study which focuses on the knowledge of preservice primary and secondary school teachers from Slovakia and Spain at the end of their training on probability. The research questions are: What are their conceptions of randomness, and how do they quantify uncertainty? In other words, our goal is to explore to what extent preservice teachers consider probability as a measure of uncertainty or of partial information.

Theoretical framework

We are especially interested in the subjective interpretation of randomness and its use in decision-making, as a way of teaching inferential reasoning. This approach is based on the probability theory initially presented by Ramsey (1926) and De Finetti (1937) and developed by authors such as Jeffrey (1965) and Savage (1967). Under this theory, randomness is associated to any observation or experimentation for which the observer has no total information or certainty. That is, randomness is a property not related to a situation, but related to the judgement of the subject that observes. That judgement translates in conditions governing a set of personal preferences so as to obtain coherent behavior in uncertain situations. Informally, such preferences and coherence refer to actions and consequences depending on the uncertain events considered. Technically, those concepts are defined inside the axiomatic for decision theory and based on concepts such as betting and Dutch book.

From the subjectivist point of view, probability is seen as a model for partial information, or uncertainty, of the decision-maker. This means that, e.g., two physicians could assign different coherent sets of probabilities (in fact, for possibly different diagnoses) and consider treatments and consequences in different ways according to their personal judgement.

As any other mathematical problem, random contexts can be modeled by different approaches inside the probability theory, the main two being the classical one, based on equiprobability and counting methods, and the decision theoretical one, based on personal information and coherence axiomatic. Their implications in statistical education are discussed in (Batanero et al., 2016).

These approaches are related, though. The axioms for coherence have been shown to be equivalent to Kolmogorov’s, which means that the usual rules of the calculus of probability are coherent, and, inversely, a coherent assignment of probability satisfies the usual properties, for instance, that the probability of the union of disjoint events is the sum of their probabilities. Additionally, the classical interpretation of probability, which assigns equal probability to the elementary events, is a particular case of subjective assignment, when we consider conditions such as the symmetry of the results of an experiment or lack of information. Similarly, the acceptance of conditions that guarantee the limit frequency as an adequate assignment of probability for a given event is a subjective choice, relative to the subject that is mathematically modeling the problem. Finally, the subjectivist interpretation implies that our own assignment of probabilities can change when updating our knowledge. Both prior and posterior assignments must follow coherent consequential rules, equivalently to the relation between conditional probabilities and the Bayes rule.

Several authors mention that preservice teachers are unfamiliar with different meanings of randomness and probability and that they need to be aware of these approaches, because they influence their students' reasoning (e.g., Chernoff & Zazkis, 2011; Batanero, 2016). That is why, in this paper, we focus on the meanings that preservice teachers attribute to randomness and its measure as mentioned above. More specifically, we explore the preservice teachers' conceptions of uncertainty in relation to certain daily situations, and how they quantify it. We locate this knowledge as distributed among knowledge of notions of uncertainty (KoT – definitions, properties, and their foundations), situations that this knowledge models (KoT – phenomenology) and calculation procedures for quantifying this knowledge (KoT – procedures). This is consistent with Di Bernardo *et al*. (2019) and the references therein, where subjective knowledge about probability and knowledge of connections between different meanings was divided into: knowledge of definitions, properties and their bases (intra-conceptual connections between different meanings); knowledge of procedures (calculation of probabilities); knowledge of representations; and knowledge of phenomenology (modeling a situation from the appropriate meaning).

Methodology

Our informants were 89 preservice mathematics teachers (PSTs), in Spain and in Slovakia. The Spanish group consisted of 43 preservice teachers at the University of Huelva, who had completed a course on statistics and probability as part of their degree. Both the classic approach to probability and a preliminary introduction to the subjective perspective had been covered during the course. The Slovak group of informants consisted of 46 preservice secondary school teachers (grades 5-13) from Pavol Jozef Šafárik University in Košice. All the Slovak PSTs had passed the compulsory classes in statistics and probability. During those courses, they were exposed to the classical definition of probability, and worked with the Kolmogorov axioms. The subjectivist view was not directly dealt with on that course. The training of both groups of students in probability has not been equivalent, neither in depth (greater in the case of the preservice Slovak secondary teachers) nor in that the preservice Spanish primary teachers have received some notions of subjective probability (idea of uncertainty and its relation to decision-making). Both groups have in common that they have received their last course on probability. Our goal is to explore whether differences in training and context are reflected in differences in their understanding of probability as uncertainty.

The information was collected through a questionnaire with four sets of questions. We analyze in this paper the first two (Table 1). The first question focused on the concept of randomness in a variety of situations including the result of a lottery taking place both in the past and the future, a social or economic index in the past, the location of a historical event, and a weather forecast. For each situation, we then asked for the PSTs' personal estimation of the probability of specific events.

In the case of Spain, the questionnaires were completed in the training classroom, while in Slovakia the questionnaires were completed online due to COVID-19 restrictions. One group of Slovak PSTs (13 participants) was explicitly asked to explain precisely the thinking behind their responses at the end of each question. A few days after they finished the questionnaires, they had a group discussion in which some of the PSTs explained the reasoning for the answers given in the questionnaire.

Once the data for each country had been collected, they were analyzed by the corresponding country team. Later, they were jointly analyzed by all the authors of this work. The main aspects of this analysis are: the students' conception of randomness, the assignment of probabilities and the coherence of this assignment. In Table 2 we point out how we analyzed each of these aspects, and explain them with more detail in the Section Results.

Table 1: Questions for information gathering

Task 1	Task 2
Indicate if you think that the following situations are random (A) or non-random (N), according to your current information. A: ( ) Next week's result of the 1st prize in the National Lottery. B: ( ) Last week's result of the 1st prize in the National Lottery. C: ( ) The birthplace of Alexander the Great. D: ( ) The temperature in Bratislava/Málaga tomorrow at noon. E: ( ) The Euribor index at close of business yesterday. F: ( ) The proportion of primary school pupils diagnosed with attention deficit disorder in 2019 in Slovakia/Spain.	Indicate your estimation of the probability that each of the following statements is true. Assign the numerical values that you consider appropriate according to your current information. (a) Next week the 1st prize in the National Lottery will be the number 89342. (b) Last week the 1st prize in the National Lottery was the number 89342. (c) Alexander the Great was born in Greece. (d) The temperature in Bratislava/Málaga tomorrow at noon will be between 18°C and 20°C. (e) The Euribor index closed down yesterday. (f) The proportion of primary school pupils diagnosed with attention deficit disorder in 2019, in Slovakia/Spain, is greater than 5%.

Table 2: Process of analysis

Aspect	Research question
Conception of randomness	Is randomness associated with uncertainty or partial information, as opposed to situations where the exact probability can be calculated? (KoT, notion of randomness –*definitions, properties and its foundation*) Task 1: Comparison of events A,B vs C,D,E,F
	Is randomness assigned to past / future events? (KoT, situations that randomness models – *phenomenology*) Task 1: Comparison of events B,C,E,F vs. A,D
Assignment of probabilities	To which events is a subjective probability assigned, and to which a value obtained by Laplace's rule? (KoT, calculation procedures –*procedures*) Task 2: Analysis of the students notes
Coherence (in decision making)	Is probability assigned only to the events associated with random contexts? Task 1 and Task 2: Comparison of corresponding events – focusing on non-random contexts with probability within the interval (0,1)

Results

Conception of randomness

Within this aspect, our goal was to identify the contexts that are believed to be random or nonrandom in the students conception. Two kinds of contexts were stated in the assertions of the Task 1: drawing experiments (A,B) vs. daily life events (C,D,E,F), and events occurring in the past (B,C,E,F) vs events in the future (A,D). Both groups of students agree on what they consider random, as can be seen in Figure 1, where each bar represents the percentage of respondents who regard the situation as random.

The situation described in item A is a random draw, the prototypical context for exemplifying probability in introductory courses at school – and was consequently universally considered random, as expected. The situation described in B, identical to that of item A but formulated in the past, shows a decrease in the assignment of randomness to about 65%. Events C, D, E and F were identified as nonrandom by most PSTs. The contexts of these situations do not offer the possibility of using combinatorics or frequencies, except perhaps for the context based on the weather, which has a slightly higher proportion. Moreover, neither the Spanish nor the Slovak PSTs had received the appropriate training for solving such tasks, nor had Slovak PSTs been introduced to subjective probability. In the Table 3, we associate the results of Task 1 for the past contexts (items B, C, E and F).

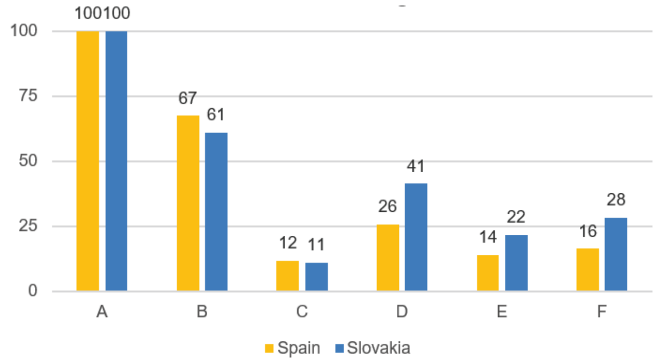

Figure 1: Proportion of answers (in percentage) which consider situations A-F as random

From the Table 3, we can see that 10 out of 43 Spanish PSTs (shaded orange) and 14 out of 46 Slovak PSTs (shaded blue) considered all past contexts as nonrandom. However, if situation B is excluded (a draw – usually connected with randomness) we get 28 out of 43 (18 + 10 shaded orange) Spanish PSTs and 23 out of 46 (14 + 9 shaded blue) Slovak PSTs. These numbers make up at least 50% of PSTs in each of the countries. Five PSTs from the group of 13 PSTs in the Slovak sample that commented on their answers argued that the situation is nonrandom because it happened in the past. The other argument was that a past situation is not random at all, since it is either true or false.

Table 3: Consideration of randomness for the past contexts.

		E – R				E – nR				Total
		F – R		F – nR		F – R		F – nR		
		ESP	SVK	ESP	SVK	ESP	SVK	ESP	SVK	
B – R	C – R	0	0	0	1	3	2	1	1	8
	C – nR	0	0	5	6	2	9	18	9	49
B – nR	C – R	0	0	0	0	0	1	1	0	2
	C – nR	0	1	1	2	2	0	10	14	30
Total		0	1	6	9	7	12	30	24	89

Assignment of probabilities

Two main methods of assignment of probabilities used by the PSTs emerge: the classical calculation from equiprobability and personal reasoning based on their previous knowledge.

For events A and B, a significant number of the PSTs in both countries assigned a probability based on the rules of combinatorics and classical calculus of probability: 33 out of 46 Slovak PSTs for event A, and 16, for B; 20 out of 43 Spanish PSTs for event A, and 12 out of 29 who assigned a probability less than 1, for event B. For the 13 PSTs in the Slovak sample who commented on their answers, a few of them tried to use Laplace's rule for the events C and D (4 PSTs in C, and 2 in D), but the corresponding values were chosen according to subjective considerations. For instance, the *"number of countries at that time"* was used for counting probability in event C, or *"according to the weather forecast, I expect that tomorrow's temperature will be between 15 and 20, so the probability will be 3/5"*, for event D. No Slovak PST used Laplace's rule in connection with events E and F. However, in situation F, two PSTs explained their answers in a way which combine estimation with personal experience, e. g.: *"5% means that every 20th child has been diagnosed with attention deficit in 2019, which is too many in my opinion. In my class we had nobody with such a condition", "If we have 800 thousand pupils 5% means 40 thousand pupils at approximately 2000 schools, that is 20 such pupils at one school – it is too many"*. During the discussion with the 13 Slovak PSTs after the questionnaire filling, 2 PSTs stated that the Task 2 was too challenging: *"Task 2 makes no sense to me. I don't know what to do"; "It was a big problem for me"*. In some of PSTs' explanations, we could explicitly identify assignment of subjective probability: *"First, I tried to find some relevant number in a question about Alexander the Great. Then, I decided that he was either born in Greece or not, so I assigned a probability of ½. I used the same logic in the subsequent questions"*. Spanish PSTs made similar remarks for events they do not have any information about.

Coherence

Finally, the third aspect is related to the coherence of the answers. For each case, the following four possible options can occur: the situation can be considered random or not, and the probability assigned to the specific event can be 0 or 1, indicating certainty, or a number within the interval (0,1), indicating uncertainty. Table 4 shows the coherence state for each pair.

Table 4: Probability assignment and random situations.

	Random	Nonrandom
Probabilities within the interval (0,1)	coherent	incoherent
Probability equals 0 or 1	may be coherent	coherent

From the perspective of our research question, it is most interesting to look at incoherence and therefore to display how many PSTs assigned probability within the interval (0,1) to events in the situations described formerly as nonrandom. We can see that this incoherence is quite common among our informants (see Figure 2).

Conclusions

From the results of our study, we conclude that: 1) regarding the situations associated to randomness (KoT -*phenomenology*), past events seem to be considered mostly as non-random, with the exception of when they are linked to a kind of draw, in which case, especially among the Spanish PSTs, it is mostly considered as random; 2) regarding the assignment of probability ((KoT- *procedures*), the PSTs have little experience in using a subjective or any other approach, even though it can be very useful in daily life. It seems that PSTs do not consider that kind of reasoning to be within the scope of mathematical modeling; and 3) regarding coherence, the results may reflect a narrow use of the concept of randomness (KoT- *definitions, properties and its foundation*), which does not include situations of uncertainty. Although the probabilistic language can be used to make statements about uncertainty, randomness as a mathematical model is not used in daily contexts.

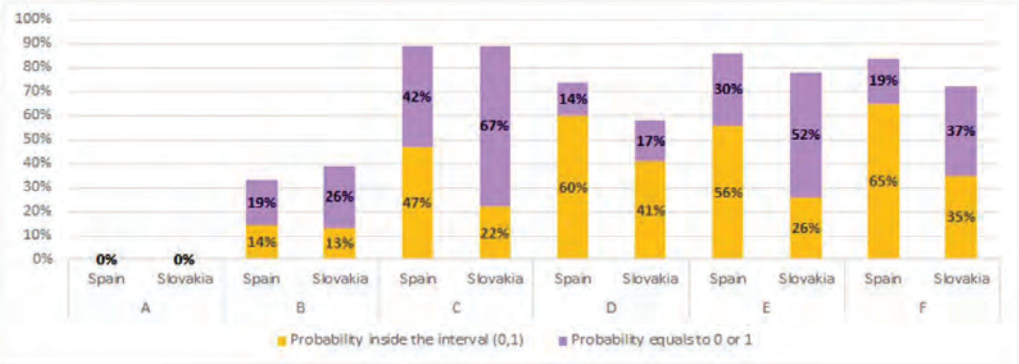

Figure 2: Probability assignation to events in contexts considered non-random

Therefore, PSTs' conception of randomness is not as deep and complex as might be desired. It enables them to use probability as a tool to inquire about contexts where Laplace can be utilized. This may be influenced by the fact that "Laplacian definition is echoed in today's textbooks" (Chernoff & Zazkis, 2011, p. 16). However, out of this box, most of the students do not develop a coherent probabilistic reasoning. Their knowledge of situations that can be modelled by uncertainty is restricted. They seem to be familiar with the classical meaning and do not consider the absence of information as uncertainty, although they use subjective arguments to justify their probability assignments. Contrastingly, they seem to separate uncertainty from probability assignment.

These results indicate that an axiomatic formation in probability, exclusively linked to the classical meaning (Slovak PSTs) leads to a limited knowledge of the topic, both in terms of the notion itself, as well as procedures and situations related to it (KoT – definitions; procedures; and phenomenology). On the other hand, a brief introduction to subjective probability (Spanish PSTs) does not seem to affect such knowledge. It seems that the knowledge of the PSTs is barely expanded in relation to that of secondary school students and does not acquire a specialized profile.

Multiple authors suggest activities for students which comprise subjective probability (e.g. Borovcnik & Kapadia, 2017; Martignon & Krauss, 2009) . The reason consist on large presentation of subjective probability in daily-life. On the other hand, to this time, subjective approach is rarely represented in national curricula. Moreover, our results show that PSTs who received their last course on probability have not developed KoT concerning probability properly, and they are not well-prepared to teach subjective approach to probability. If we want to include subjective probability in the curriculum, then it is necessary to develop their KoT in this area. One possibility is to include activities and tasks as it is suggested e.g. in Di Bernardo *et al.* (2019).

Preservice teachers' knowledge on area measurement

Sofía Caviedes[1], Genaro de Gamboa[1]and Edelmira Badillo[1]

[1]Autonomous University of Barcelona, Faculty of Education, Barcelona, Spain; sofia.caviedes@autonoma.cat; genaro.degamboa@uab.cat; edelmira.badillo@uab.cat

This study aims to characterise elements of specialised knowledge of a group of pre-service teachers using procedures related to the comparison and rearrangement of surfaces when solving area tasks. For this purpose, emphasis is placed on the subdomains of knowledge of topics and knowledge of the structure of mathematics. The written justifications and procedures that pre-service teachers used to solve two area tasks are analysed. The results indicate that when tasks condition the strict use of procedures related to the comparison and rearrangement of surfaces, written justifications supporting the procedures become more rigorous. These rigorous justifications appear, exclusively, when pre-service teachers mobilise specific geometric properties and principles, either implicitly or explicitly.

Keywords: *Area measurement, knowledge of the topics, knowledge of the structure of mathematics.*

Introduction

Area measurement has been identified as a problematic topic to both students and pre-service teachers (PST). The literature shows that students' difficulties related to the limited variety of procedures for solving area tasks are also evident in PST (Baturo & Nason, 1996; Caviedes, De Gamboa & Badillo, 2019; Chamberlin & Candelaria, 2018; Hong & Runnalls, 2020; Murphy, 2012). Hong and Runnalls (2020) show that PSTs have difficulties for accepting the conservation of area in non-prototypical figures, as they do not have numerical values to compare the areas of the triangles with the same base and height but different kinds of shapes, so they prioritise visual estimation without reasoned justification. The same authors emphasised that understanding the ideas behind area conservation would enable a better understanding of formulas for PSTs, helping them develop procedural fluency; based on the acquisition of the initial concepts. Similarly, Caviedes, De Gamboa, and Badillo (2019) point out that PSTs have a limited repertoire of strategies to solve area tasks, prioritising formulas rather than geometric procedures (procedures related to the comparison and rearrangement of surfaces) that may simplify a solving process.

This study assumes the specialised nature of mathematics teachers' knowledge in the sense of Carrillo et al. (2018) since it allows a first approach to characterise aspects of knowledge about specific mathematical concepts. In this context, we pose the following research question: *What specialised knowledge about area measurement do PSTs mobilise when solving tasks that require using geometric procedures?* Thus, we attempt to characterise elements of knowledge of topics (KoT) and knowledge of the structure of mathematics (KSM) in a group of PSTs when solving two tasks that require the use of geometrics procedures.

Theoretical framework

Amongst different possible ways of perceiving teachers` knowledge we consider the Mathematics Teachers` Specialised Knowledge -MTSK- (Carrillo et al., 2018). The MTSK model studies, mainly, the knowledge at stake in teachers' practice, but recent studies consider that it is possible to assume the MTSK model as a reference of the desirable components of a teacher's specialised knowledge, and as a consequence, as a first approximation of what PSTs should know for their future practice (Policastro, Ribeiro & Fiorentini, 2019). The MTSK conceptualisation is conceived as a theoretical and analytical tool to better understand teachers' knowledge specificities and it has been shown that MTSK model could be useful in conceptualising tasks for accessing and developing knowledge of procedures, representations and connections in certain concepts (Policastro, Mellone, Ribeiro & Fiorentini, 2019). Specifically, we are interested in two subdomains of knowledge - Knowledge of Topics (KoT) and Knowledge of the Structure of Mathematics (KSM). KoT includes teachers' knowledge of definitions (i.e., what is area mathematically speaking?); properties and their principles (i.e., the role of each element involved in solving an area task); the phenomenology or contexts of use (i.e., comparing and reproducing shapes; measuring, or sharing fairly); procedures (i.e., knowing how, when and why using certain procedures), and representations (i.e., the geometric, numerical and algebraic representations involved in solving area tasks).

The KSM refers to teachers' knowledge of connections, considering four categories: simplification connections and complexities connections, auxiliary connections, and transversal connections. For instance, knowing that the area of an unknown figure can be calculated by decomposing the area into known figures, such as triangles, rectangles, and-or squares is a simplification connection because figure decomposition can be a precursor to formulae; knowing that the area of a scalene right triangle can be calculated using Heron's formula is a complexity connection, because it involves more advanced mathematical knowledge, also considering the perimeter; knowing that the procedure of iterating units of measurement, lined up in rows and columns, can evoke the measurement procedure involving multiplying number of rows by the number of columns, is an auxiliary connection because it uses one procedure to introduce a different one; and knowing that an area model can be used as a basis for working on fractions and algebraic operations is a transversal connection since the concept of the area can relate different mathematical contents. Due to the scope of our work, we focus only on knowledge of auxiliary connections.

Method

The study is situated in an interpretative paradigm with a qualitative approach (Bassey, 1990) and is part of broader research that seeks to characterise the specialised knowledge about area measurement in a group of PSTs. Data collection was carried out in the first term of the 2020-2021 school year. The participants were non-randomly selected, and they were 70 PSTs studying the third year of the Primary Education Degree at the Autonomous University of Barcelona. The PSTs had previous instruction on different procedures for measuring areas as part of their study program. Content analysis is carried out (Krippendorff, 2004) using two of the subdomains of the MTSK model: The KoT and the KSM. The MTSK defines, for each of these subdomains, specific categories. For the KoT, we consider representations, procedures and justifications, properties and principles, and intra-conceptual connections. For the KSM, the auxiliary connections. In each category there are indicators which have been constructed by the authors based on a previous study (Caviedes, De Gamboa & Badillo, 2020). The MAXQDA software is used to facilitate the process of assigning indicators to the PSTs responses.

Instrument and procedure

A semi-structured open-ended questionnaire (Bailey, 2007) was designed to be completed individually. The PSTs were asked to justify each procedure in writing. To solve the tasks the PSTs could use manipulative material (cut-outs as an annex to the questionnaire), as well as measuring instruments (ruler, square, protractor). The questionnaire consisted of 8 tasks and was structured as follows: three tasks responding to contexts of equal sharing, and comparison and reproduction of shapes (Tasks 1, 2, and 3); two measurement tasks (Tasks 4 and 5); one task to classify statements and one task to define the concept of area (Tasks 6 and 7); finally, one task to analyse students' responses (Task 8). In Tasks 1, 2, and 3 the use of calculations and measuring instruments was prohibited. The questionnaire was administered by the subject teacher in online format due to the COVID-19 health contingency. The official language to administrate and to answer the questionnaire was spanish and the translation was executed by a professional translator. The validation of the instrument considered external research experts, in-service and pre-service primary school teachers.

The PSTs had one week to answer it and send it in pdf or word format. In order to answer our research question, the analysis of the resolutions to Tasks 2 and 3 is presented (Table 1).

Table 1: Tasks proposed to the PST group

Task statement	Graphical representation of the tasks
TASK 2: Camila is making a ceramic mosaic with different colours. To finish her mosaic, she needs to cover a rectangular space, but she doesn't have any ceramic pieces with that shape. **What can Camila do to cover the missing space in her mosaic? Justify your answer.**	 (Adapted from Puig and Guillén, 1983)
TASK 3: Using the shaded surface of Figure (T) as a reference: **Which of the following figures has a shaded surface equivalent to Figure (T)? Why? Justify your answer.**	 (Elaborated by the authors)

Methods of analysis

Since we have not found any studies detailing the KoT and KSM indicators of area measurement, these have been constructed based on the results of a previous study that allowed for the construction of an epistemic configuration of area concept (Caviedes, De Gamboa & Badillo, 2021). From this epistemic configuration we define the KoT indicators to focus on the analysis of the PSTs' responses to the tasks. Each indicator was adapted to the categories that the MTSK model proposes for KoT (representations, procedures and justifications, properties and principles, and intra-conceptual connections) and allowed a deductive coding of the PST responses, with the support of MAXQDA software. The indicator corresponding to the KSM (auxiliary connections) emerges from the analysis of PSTs' responses to the questionnaire (Table 2).

Table 2: Categories of specialised knowledge

Categories of KoT and KSM	Indicators
Representations (R)	(R1) W*ritten:* use of adjectives such as "equal", "thinner" "wider", "double", "half" "a quarter" related to surfaces. (R2) *Manipulative:* use of physical objects or dynamic geometry software. (R3) *Geometric:* use of convenient decompositions to compare and-or estimate surfaces quantities.. (R4) *Symbolic:* use of the R^+ set to compare two or more surfaces, for counting units or adding up areas.
Procedures (P) and justifications (J)	(P1) Compare two or more surfaces directly by total and-or partial overlapping. (P2) Compare two or more surfaces indirectly by cutting and pasting. (P3) Decompose in a convenient way, graphically or mentally, two or more surfaces. (P4) Carry out movements of rotation, translation and superimposition of figures. (P5) Measure areas as an additive process by counting units and-or sub-units that cover the surface. (J1) The act of comparing two or more surfaces by placing one shape over another is useful for establishing equivalence and/or to include relationships

	(J2) The mental act of cutting the two-dimensional space into parts of equal area as a basis for comparing areas. (J3) The act of changing the shape of a surface does not change the area of the surface, as the figures can be decomposed and reorganised while keeping the same "parts".
Properties (Pp) and principles (Pr)	(Pp1) Use of conservation (Pp2) Use of accumulation and additivity (Pp3) Use of transitivity (Pr1) Use of the fact that a parallelogram that has the same base as a triangle, both placed between the same parallels, has twice the area of the triangle. (Pr2) Use of the fact that the triangles placed on equal bases and between same parallel are equal. (Pr3) Use of the fact that two polygons are congruent if their sides and angles are respectively equal or congruent. (Pr4) Use of the fact that every polygon can be broken down into triangles. (Pr5) Use of the fact that every triangle is equidecomposable from a parallelogram.
Auxiliary connections (Cau)	(Cau1) Use of a procedure or concept to introduce a new procedure or concept.

Results

Figures 1, 2 and 3 show examples of resolutions of PST 2 and PST 39, who mobilise specialised knowledge from the KoT and KSM subdomains. These resolutions are considered representative of PSTs' set that evidence mobilization of these subdomains, as these are the type of resolutions that allows for the emergence of different indicators from PSTs' resolutions. Figure 1 shows indicators of KoT in Task 2.

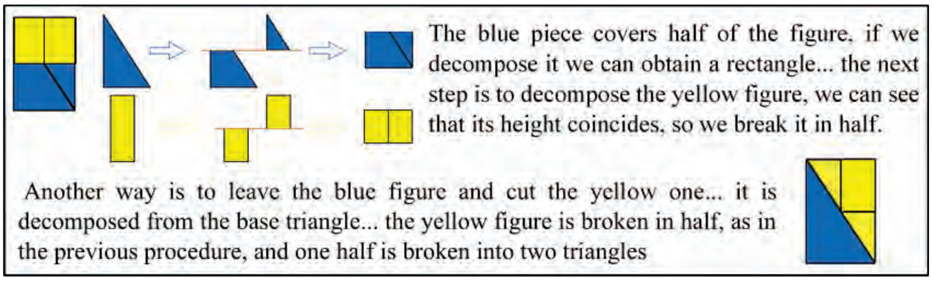

Figure 1: PST 2 resolution for Task 2

PST 2 uses written representations (R1) in her justifications, evidencing use of (J1) and (J2), as she superimposes the surfaces, as well as breaking them, in order to compare them. When breaking surfaces and rearranging their parts, she makes use of (J3). PST 2 uses manipulative representations (R2) to make visible decompositions and reorganizations of figures; and geometric representations (R3) as it compares surfaces indirectly (P2) and decomposes the surface in a convenient way (P3). In addition, she performs rotation and translation movements of the parts (P4), in order to check that both the triangle and the rectangle correspond to half of the piece that needs to be covered. PST 2 also shows an implicit use of the transitivity property (Pp3), while she compares between the surface to be covered and those represented by the pieces. Furthermore, PST2 shows an implicit use of the properties of accumulation and additivity (Pp2) and conservation (Pp1), as PST2 recognizes that figures can be decomposed and recomposed into other figures, while retaining the same "parts". Finally, it is possible to infer that PST 2 recognizes that a triangle is equidecomposable to a parallelogram (Pr5); that is, that a triangle can be decomposed into a finite number of polygons and form a parallelogram (and vice versa), conserving the area. Similarly, she implicitly recognises that a parallelogram with the same base and height as a triangle, both placed between the same parallels, is twice as large as the triangle (Pr1).

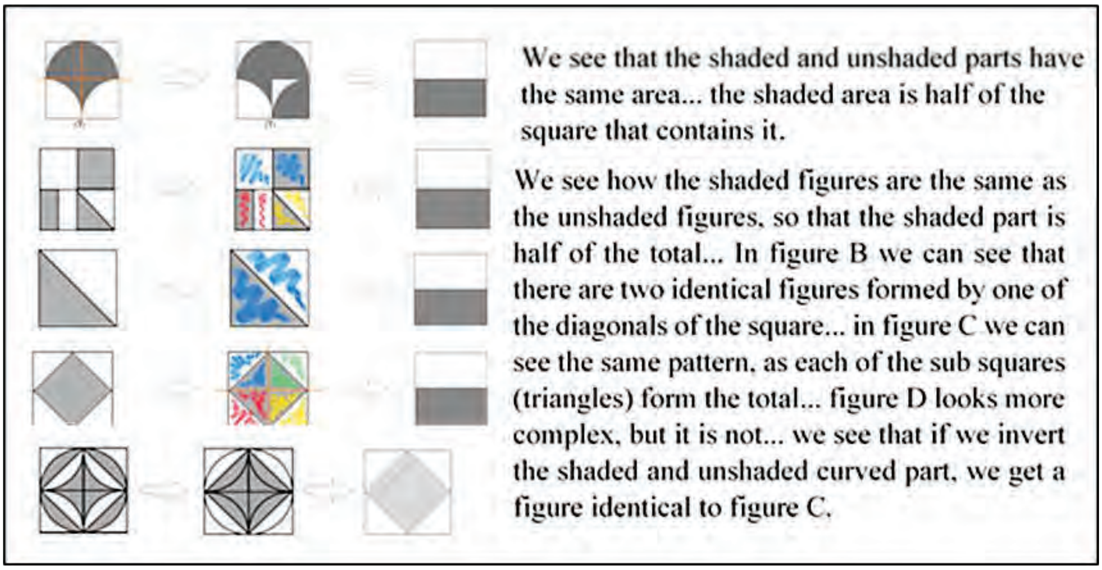

Figure 2: PST 2 resolution for Task 3

Figure 2 shows indicators of KoT knowledge in Task 3. It can be seen that PST 2 uses written (R1), manipulative (R2) and geometric (R3) representations, as she decomposes each of the figures in a convenient way (P3) and performs rotation and translation movements (P4) to verify and illustrate, manipulatively, that each of the figures is equivalent to the model figure. Thus, PST 2 manifests an implicit use of the properties of accumulation and additivity (Pp2) and conservation (Pp1), as she rearranges the shaded surfaces into rectangles that represent half of the square containing them. The property of transitivity (Pp3) is made explicit when PST 2 says that "if Figure D is equal to Figure C, and Figure C is equal to the model, then Figure D is equivalent to the model." PST 2 recognizes that triangles placed on equal bases and between the same parallels are equal (Pr2) and that every polygon can be decomposed into triangles (Pr4).

It is inferred that the PST 2 also makes use of (J2) which indicates that the mental act of cutting two-dimensional space into parts of equal area serves as a basis for comparing areas; and of (J3), since the PST 2 recognizes that changing the shape of a surface does not change the area of the surface.

Figure 3 shows indicators of knowledge of the KoT and KSM of PST 39 in Task 3. The PST 39 uses symbolic representations (R4) in a fractional register; that is, she uses fractions to compare the shaded area of each of the figures, and sets the shaded fraction relative to the total area. PST 39 also shows knowledge of addition of fractions with different denominators and simplification of fractions, showing an auxiliary connection (Cau1) to this concept. By rearranging the parts, PST 39 implements the procedure of surface decomposition (P3) and rotation and translation movements (P4). In this sense, it is inferred that PST 39 recognizes the properties of conservation (Pp1) and accumulation and additivity (Pp2). In turn, the comparisons made between the figures are associated with the property of transitivity using (Pp3). The procedures allow us to infer an implicit use of (J2), since PST 39 recognizes the usefulness of cutting the two-dimensional space.

T= $\frac{1}{2}$ of the figure. We can rearrange the bottom parts and fit them into the upper corners.

A= $\frac{1}{4}+\frac{1}{8}+\frac{1}{8}=\frac{1}{4}+\frac{1}{4}=\frac{1}{2}$

B= $\frac{1}{2}$ of the figure

C= $\frac{1}{2}$ of the figure

D= $\frac{1}{2}$ of the figure. D = C

Figure 3: PST 39 resolution for Task 3

Due to the geometric nature of the tasks, the results showed that PTSs solve Tasks 2 and 3 mostly using geometric type representations (R3) that are materialised through convenient surface decomposition procedures (P3), or the use of rotation, translation, and superimposition movements of figures (P4). These procedures, in turn, are supported by some of the properties as the mental act of cutting the two-dimensional space into parts of equal area serves as a basis to compare areas (J2); or that changing the shape of a surface does not produce changes in its area, since the figures can be decomposed and reorganized while retaining the same "parts" (J3).

The resolutions presented in the analysis show the way in which the PSTs mobilise knowledge about the different categories of the KoT and KSM, but do not allow us to identify the tendency of PSTs at the time of solving the task. For this reason, we consider it appropriate to show the frequency of each of the categories mobilised by the PSTs. Table 3 details this frequency and it can be seen that only 11 PSTs establish auxiliary connections (KSM), which are linked to KoT and associated with knowledge about fractions. Thus, knowledge about fractions is made explicit through the use of convenient surface decomposition procedures (P3), or the use of rotation, translation and superposition of figures (P4). Moreover, this type of knowledge is associated with a context that requires establishing equivalence or inclusion relations between different surfaces, linked to the properties of conservation (Pp1), transitivity (Pp3) and accumulation and additivity (Pp2). In this way, the relationship between KoT and the establishment of auxiliary connections becomes clear.

Table 3: Categories of specialised knowledge mobilized by PST (N=70)

Code	Frequency	Code	Frequency
P3	57	R4	13
Pp3	57	P2	11
Pp2	57	Cau 1	11
Pp1	57	R2	6
P4	56	Pr1	3
R3	56	J1	3
J3	56	No response	3
Pr5	56	Pr4	3
J2	53	Pr3	2
Pr2	51	P1	2

Discussion and final remarks

This study focused on the characterisation of PST's knowledge related to the topics and the structures of mathematics, according to the MTSK conceptualization. Results show a relation between descriptive answers that do not justify what is done and why it is done with the lack of use of geometric principles. As it can be seen in the examples presented in the above section (Figures 1, 2 and 3), PST 2 and PST 39 were able to justify and support the procedures they were using based in some of the geometric principles, such as: two polygons are congruent if their sides and angles are respectively equal or congruent (Pr3); every polygon can be broken down into triangles (Pr4); and a parallelogram that has the same base as a triangle, both placed between the same parallels, has twice the area of the triangle (Pr1). However, these principles are not mentioned in most of the PST's resolutions and written justifications, revealing a gap in their KoT and a link between the lack of this kind of knowledge and descriptive answers. Regarding KSM, the auxiliary connections that emerge from the PSTs responses showed a close relationship between knowledge about fractions and the use of procedures, properties and representations of a geometric nature. Although some research highlights the difficulties of PSTs in accepting area conservation (Hong & Runnalls, 2020), in the present study the use of this property is implicit in the justifications and-or procedures used and PSTs do not present major difficulties. This may be due to the time PSTs had to solve the questionnaire, or to the geometric nature of the tasks themselves, since by restricting the use of calculations and measuring instruments, PSTs are forced to use procedures of a geometrical nature.

The indicators proposed for the KoT subdomain serve as a reference of what PSTs should know for their future practice (Policastro, Mellone, Ribeiro & Fiorentini, 2019), as they allow detailing different representations, procedures and justifications, properties and principles underpinning area measurement. This could provide hints for PSTs trainers on how to propose tasks to promote the mobilisation of specialised knowledge, gradually increasing the indicators of knowledge to be developed. The need for further research seems evident, specifically in both at enriching the conceptualisation theoretically and in conceptualising tasks for developing a deeper knowledge on area measurement processes. It can also be seen that there is a need to explore the potential of MTSK model as a tool for promoting and developing an understanding of area measurement in relation to different kind of connections and in relation to other sub-domains of knowledge that have not been considered in this study.

[3]Autonomous University of Barcelona, Spain; edelmira.badillo@uab.cat

The goal of this study is to categorise transformations of existing problems performed by preservice primary teachers (PPTs). For this purpose, we propose to PPTs from Autonomous University of Barcelona (Spain) to transform two multiplicative problems from two primary school textbooks. Following a content analysis, we carry out a deductive-inductive coding process of the problems posed, establishing as main categories the four main elements of a problem proposed by Malaspina (2003). We describe the categorisation of the context transformations in detail and illustrate its four subcategories. The results highlight the abilities of PPTs to perform context transformations that encourage the engagement of potential solvers in the problem situation.

Keywords: Teacher education, professional competences, problem posing, problem solving.

Introduction

There is a broad consensus about the potential of problem solving as an approach to teaching mathematics, which promotes a deep understanding of mathematical knowledge and the development of mathematical abilities. Therefore, students should approach mathematical problems, being the teacher's responsibility to select the mathematical tasks to be faced by his or her students. Although the ability to formulate problems has been studied in mathematics education research (e.g. Kilpatrick, 1987), the focus has been mainly on students' formulation processes, requiring greater attention on teachers' ability and capacity to propose problems (Crespo, 2003).

We understand that proposing school problems is a professional competence of mathematics teachers in the sense of Weinert's competence (2001), meaning the development of cognitive abilities and motivational and volitional aspects to allow teachers to deal with problems of different nature. In particular, the professional competence of formulation of school problems (Carrillo, et al., in press) is seen as the teacher's ability to propose problems to their students, with the intention of encouraging the construction of mathematical learning. This competence is expressed by three skills: creating, selecting, and transforming problems. We focus on the latter skill, concretely the research question we address here is: how do PPTs transform existing mathematical problems? The aim is to categorise the transformations of multiplicative problems from school textbooks performed by PPTs. We select problems from textbooks as they are a didactic resource widely used by teachers for teaching and learning mathematics in the classroom (Fan, et al., 2013; Hadar, 2017).

Next, we present our theoretical view on problem formulation and transformation, as well as the four main elements of a problem (Malaspina, 2013). Then, the design and qualitative methods of data analysis are introduced. Finally, we describe the categorisation of the context transformations and conclude with reflections on the results and their implications on the PPTs' training.

Theoretical framework

Problem posing has a plural nature. It can be conceived as a professional activity inherent to mathematicians when they create problems for the development of the discipline. It can also be seen as a learning dynamic at different levels of schooling, aimed at promoting a deep and relational understanding of mathematics (Kilpatrick, 1987). Likewise, as a professional activity of mathematics teachers, focused on proposing problems to their students as learning tasks (Milinkovic, 2015). Formulating mathematical problems demands creativity (Silver, 1994), since it requires taking a proactive attitude towards mathematics, coordinating different mathematical elements in the construction of word problems. Therefore, it is a complex and cognitively demanding activity (Silver, 1994). Depending on the nature of the mathematical content, posing a problem could require a greater proficiency on specific abilities, such as visualisation in the case of geometry.

In the case of teachers' training, problem formulation is considered a powerful tool for understanding mathematical and didactical knowledge (e.g. Tichá & Hospesová, 2013). Moreover, problem formulation has been used as a tool to develop professional competences, such as sensitivity to students' mathematical thinking (Xu, et al., 2020). However, teachers' ability to propose problems to their students has received less attention (Crespo, 2003). This ability has multiple ways of being expressed in professional contexts (Carrillo, et al., in press), for instance, the transformation of existing problems (Milinkovic, 2015; Lavy & Hourigan, 2019). From a professional perspective, transforming a problem involves modifying one or more elements of the word problem with a didactic intentionality that may have an impact on the problem solving process (Lavy & Bershadsky, 2003).

The professional competence in the formulation of school problems is transverse in nature to the teaching activity itself. During the preparation of a lesson, a teacher can create, select, or transform problems when designing tasks for the students. For example, Lavy and Bershadsky (2003) propose transforming geometry problems using the "What if not...?" strategy. On the other hand, during a lesson, in response to a student's intervention, a teacher may decide to propose a problem to focus reflection on certain mathematical knowledge. Finally, at the end of a lesson, a teacher may reflect on some possible transformations of the problems proposed to the students, either for future courses or to propose similar problems in following lessons.

Malaspina (2013) suggests that a word problem can be broken down into four main elements: information, i.e., the elements provided explicitly or implicitly in the word problem; problem context, which can be either extra-mathematical or intra-mathematical; problem requirement, usually expressed as a question, which determines the goal to be achieved; and mathematical environment, understood as the mathematical elements useful for solving the problem. In this study we assume that transforming a problem implies changing at least one of the main elements. We consider that the information of a problem is transformed when some mathematical elements (numerical, algebraic, graphical, ...) of the problem are eliminated, added, or changed for others. In the case of the context, a transformation occurs when the situation related to the written word problem is totally or partially changed, extended or eliminated. Likewise, transforming the requirement involves changing, extending, or eliminating the explicit or implicit demand of the problem. Finally, transforming the mathematical environment implies changing the mathematical area useful for approaching the resolution of the problem. For example, when multiplicative problems are changed to others that are intended to be solved through elements of additive structures, or when problems focused on exact division are modified to include a possible remainder. The transformations of different elements entail the coordination of the information eliminated and added with the existence of a solution, as well as the consistency between the different expressions of a mathematical element and the element itself (Wessman-Enzinger and Tobias, 2020, Montes, et al., in press).

Methodology

We design a written protocol addressed to PPTs with four tasks involving the transformation of multiplicative problems from two primary school textbooks widely used in Spain. We restrict the mathematical content to multiplication and division because this crucial content at primary school has already been introduced to the participating PPTs during a previous course. We collect 67 written protocols solved individually by PPTs in the third year of the Primary Education Degree of the Autonomous University of Barcelona (Spain) in 2020-2021. For each task of the protocol, participants proposed one or more modifications to the given problems. We identify one or more transformations in each modification. For example, a PPT can extend the context (context transformation) and eliminate a numerical element (transformation of information) in the same modification. In total, the data consists of 186 modifications, 93 for the first problem and 93 for the second. Here, we present methods and results related to the analysis of the modifications proposed in the first task, which suggests modifying two word problems to promote the mathematical learning of the contents identified (Figure 1). Both problems correspond to the structure of isomorphisms of measures, where the proportion between two measurement spaces is established (Vergnaud, 1983). The first problem belongs to equal groups situation where the total number of elements is unknown. The second is a quotative division problem where the number of sets is unknown. Both problems have an extra-mathematical context with visual models of multiplication and division.

<table>
<tr><td colspan="2">Modify the following two word problems to promote the understanding of the mathematical content you identify. For each modification, indicate in the table: the type of transformation; the reason why you perform it; and the contribution to the students' mathematical learning.</td></tr>
<tr><td>Problem 1: Bruno has 10 boxes with marbles. Each box contains 5 marbles. In total, how many marbles has Bruno? </td><td>Problem 2: Lola has 30 bracelet beads. She uses 5 beads to make each bracelet.  Lola makes … bracelets.</td></tr>
</table>

Figure 1: Word problem of the first task of the protocol

Within a qualitative methodology, we conducted a content analysis in two phases: preparing and organising (Elo & Kyngäs, 2008). The aim is to describe the transformations proposed by PPTs as the result of a deductive-inductive coding process of each modification.

Preparing stage. In this stage, we familiarised with the whole data and established each modification as the unit of analysis. We also determined the central categories of coding: information, context, requirement, and mathematical environment (Malaspina, 2013). Then, we drew inspiration from the data and question codes proposed by Lavy and Bershadsky (2003) to create, a priori, some codes that were refined in the following analytical stage.

Organising stage. We begin the coding process by creating new emergent codes that are refined by comparing, contrasting, and abstracting codes across larger and larger samples of the data. The process is carried out in three rounds with the following structure: first each researcher codes the same sample, then a list of codes is agreed upon by the three authors and, afterwards, each researcher analyses an extension of the initial sample using the new codes. We record the agreements adopted in the joint discussions, which focus on the delimitation of the meanings of each code, the conditions of occurrence and the grouping of codes in each of the main categories. The final codes express the element transformed and the specific action to transform it, considering three actions: changing an element for another of the same class, extending an element, and eliminating one of the problem elements. This leads to descriptive codes such as changing to another extra-mathematical context or eliminating the context. Once a stable code set is established, we count the frequency of each code in the whole data. For each main category, we calculate the percentage of modifications incorporating at least one transformation from that category. As a result, we find that 77,9% of all the modifications incorporate transformations of information, 73,2% of them contain context transformations, 51% requirement transformations, and 15% mathematical environment transformations.

In this paper, we focus on the four emerging subcategories of context transformations. To highlight the nature of each subcategory, we illustrate each variant with some PPTs' modifications along with excerpts from their justifications.

Context transformations

We find that 73.2% of the PPTs' modifications incorporate some context transformation of the problem. In Table 1 we present the four emerging subcategories that constitute the context transformations, along with their frequency in the data.

Table 1: Context transformations subcategories and their frequencies

Context Transformations			
Extending the context	Changing the written expression	Changing to another context	Eliminating context
73	48	13	2

Context extension is the most frequently occurring transformation of context in the data. It refers to changes in which the word problem is expanded by adding characters, actions, descriptions, or relationships to the original context. These transformations seek to improve the comprehension and access of primary students to the problematic situation presented to them. Hence, the new problems are more realistic and closer to primary students' experiences or contains more detailed descriptions of certain information given in the problem. For instance, in the modification of the PPT UAB1.37 (Figure 2), the story that frames the problem is set in a scenario known to primary students- the school -. Also, the characters and actions introduced facilitate the identification of the student with the main character –making boxes with marbles to give to friends–. UAB1.37 states that simulating a situation close to a primary student's daily life can motivate him or her to solve the problem.

UAB 1.37 Modification:

Bruno has bought 10 boxes to give to each classmate. In each box he wanted to put some marbles, the same amount for all of them! Bruno has already made Joan's box and it looks like this:
Can you tell how many marbles he will need to make all the boxes?

Justification:

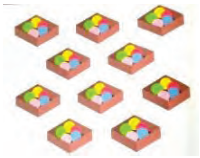
It is a situation that the student can easily find in his daily life, therefore, it gives meaning to the problem. For the student's learning, it motivates him/her to carry out the problem.

Figure 2: Modification and justification of UAB1.37

In contrast, elements of the visual model –quantity and colour of the marbles in each box– are described in greater detail in the UAB1.4 modification (Figure 3). Therefore, the word problem remarks the multiplicative unit, clarifying the elements that make it up, and suggesting a more detailed mental image in the primary student.

UAB1.4 modification:

Bruno has a green ball, a red ball, a green ball, a pink ball and a blue ball in a box. If he has 10 identical boxes, how many balls does Bruno have?



Justification:

Change in the word problem. Longer and more explicit word problem so that students have a better comprehension in reading and understanding it.

Figure 3: Modification and justification of UAB1.4

Changes in the writing of the context are micro-transformations of text segments of the word problem, such as changing the subject of a sentence that entails a change of the main character of the story in which the context is framed (Figure 4). These transformations are based on a social vision of language with the potential to transform sociocultural and affective aspects. For example, UAB1.25 changes the gender of the main character in response to a change in socially established gender roles. On the other hand, UAB1.2 changes the subject to the second person singular which places the reader as the main character of the story. As UAB1.2 explains in her justification, the context is more relevant to a potential solver and encourages his or her immersion in the problem

UAB1.2 modification: You have 10 boxes with marbles. Each box contains 5 marbles. How many marbles do you have in total? 	UAB 1.25 modification: Marcos has 30 bracelet beads. To make a bracelet he spends 5 beads. How many bracelets will he be able to make with the beads he has?
Justification: Change in the writing of the word problem. From 3rd person singular to 1st. With this change we make the problem more relevant to the student and his context.	Justification: Change the main character of the exercise to male to reinforce an image of equality.

Figure 4: Modifications and justifications of UAB1.2 and UAB1.25

Less frequently, we found *changes to another* extra-mathematical *context* (in no case was there a change to an intra-mathematical context) that implied a change in the scenario, objects, subjects or actions of the original context, i.e., a change in the phenomenon mathematised in the problem. Mostly, the new context poses a scenario and actions familiar to elementary school students, such as eating at school in the problem proposed by UAB1.7 (Figure 4). On other occasions, we find changes that incorporate references to other mathematical contexts such as measurement in the problem posed by UAB1.63 (Figure 5).

UAB1.7 modification: In the school's dining room, there is only space for 10 tables. At each table there can be a maximum of 5 students. How many students can eat at the same time in the dining room? Can the whole class eat together? 	UAB1.63 modification: Each bracelet beads measures 2 centimetres. If my bracelet has 5 beads, how many centimetres does it measure? 
Justification: The word problem is a bit more contextualised; the exercise allows students to place the use of mathematics in their lives. A second question is added to show such contextualization.	Justification: This change allows to work on measurement units, which is an important concept that is usually forgotten in the first years of primary school.

Figure 5: Modifications and justifications of UAB1.7 and UAB1.63

Finally, we found only two modifications with the *context eliminated*, i.e., the written word problem is deleted. This transformation appears together with a change of requirement. Either the execution of a mathematical operation is demanded, or the word problem is demanded from the graphical or symbolic-algebraic elements given. This is the case of UAB 1.3, who proposes: "show them the operation they have to perform, 30:5, and explain to them that they have to invent a word problem".

Final reflections

This study is part of a broader research project whose final goal is to characterise the professional competence in the formulation of school problems. Specifically, we are interested in the transformation of existing problems. First, we focus on describing and categorising the transformations that PPTs perform. Here, we present the analysis and preliminary results of this first step. We have illustrated how PPTs, when transforming existing problems, mostly focus on extending, changing, or eliminating elements related to the information and context of the problems rather than transformations focused on the requirement or the mathematical environment.

Regarding context transformations, we have identified four subcategories that describe different types of context transformations that result from extending or changing the context, introducing subtle changes in the writing of the word problem, or eliminating the context. With the first three types, the PPTs mostly encourage the immersion of the primary student in the problem and, to a lesser degree, the transmission of education in human values (such as gender equality) or the combination with other mathematical contexts (such as measurement). It should be noted that we only found two transformations in which the context is eliminated and the word problem itself is demanded. From our perspective, this fact supposes a call of attention on the need to train PPTs in problem posing dynamics as a type of classroom instruction (Silver, 1994; Malaspina, 2013).

It must be assumed that if students are to solve problems, their teachers must be active agents in the selection and generation of tasks focused on problem solving. Therefore, this line of research should result in the design of formative tasks for PPTs to develop and systematise their abilities to transform existing problems as the initial step on the route to create entirely new problems (Leavy & Hourigan, 2019). It seems promising to base these tasks on the adaptation and transformation of textbook problems, given their very wide use in Primary Education (Hadar, 2017). This will require transcending the cognitive perspective we assumed here about the professional competence to pose school problems, taking into account volitive and motivational aspects, in order to ensure a whole development of the competence.

Towards a dialogic analysis of mathematical problem-solving knowledge for teaching in a lesson study group

Stéphane Clivaz[1], Sara Presutti[1], Valérie Batteau, Luc-Olivier Bünzli and Audrey Daina

[1]Lausanne University of Teacher Education, UER MS & 3LS, Lausanne, Switzerland; stephane.clivaz@hepl.ch; sara.presutti@hepl.ch

This paper presents the construction of the analytical framework of an ongoing research about the development of teacher mathematical knowledge for the teaching of problem solving in a lesson study process. After presenting the context of the research, the article overviews previous research about lesson study and mathematical knowledge for teaching, about mathematical knowledge for teaching problem-solving and about teachers' dialogue in order to introduce the two dimensions of our analytical grid: the knowledge dimension and the dialogue dimension.

Introduction

Mathematical knowledge necessary for teaching has attracted a lot of attention in mathematics education. The same tendency is exhibited in problem-solving, seen from the students' point of view and, more recently, the collaboration in teacher professional development. In our research, the teaching of problem-solving is studied from the point of view of the development of teachers' professional knowledge in a collaborative process. In this paper, we present the context of our study and the analytical framework that we are currently developing, as well as our research questions.

Context and method

Our research is part of the ongoing research of the Lausanne Laboratory Lesson Study (3LS, n.d.) which studies the work of several lesson study (LS) groups in the French-speaking part of Switzerland. We are currently analysing the work of a LS group composed of eight grade 3 and grade 4 teachers from the Lausanne region and two facilitators. The two facilitators consist of a mathematics educator (the first author of this contribution) and a teacher from the institution who participated as a member of a previous LS group in mathematics. From 2018 to 2019, this group has completed three LS cycles with the question: "how to teach grade 3-4 students on how to solve mathematical problems". The fact that the teachers will be in a (professional) problem-solving situation about problem-solving teaching is coherent with Ball and Cohen's (1999) suggestion that professional development programs should situate teacher learning in the types of practice they wish to encourage. The data from these three cycles are analysed using Transana (Woods, 2002-2021) to encode video recordings which are integrated with the transcripts. The first cycle discussed in this article, includes eight meetings that lasted for about 90 minutes each and two research lessons. Interviews with the two facilitators were also analysed as a way of data triangulation. Since other research of our team used the same type of data (e.g. Batteau, 2017; Clivaz & Ni Shuilleabhain, 2019), the obtained results show that this type of data is thorough, systematic, reliable and authentic regarding the perspectives and practices of participants.

The research interests of our research team are two folded. The first series of questions is about the mathematical knowledge related to problem-solving which teachers use during this LS, the second series aims to describe the types of interactions related to the construction of this mathematical knowledge and, ultimately, to describe how the mathematical knowledge is constructed in a LS group. In order to do so, we will present some findings of the previous studies and the analytical frameworks which is currently being developed by our research team.

Lesson study and mathematical knowledge for teaching

Jugyou Kenkyuu, literally lesson study (LS), was born in Japan in the 1890s. It was popularised in the 2000s following international TIMSS comparisons (TIMSS Video, n.d.) and the comparison between mathematics education in Japan, Germany and the USA that Stigler and Hiebert (1999) presented in *The Teaching Gap*. Thanks to the efforts made to promote LS, and in particular to the work of Lewis, who contributed to formalising and popularising LS in the USA (Lewis, 2002, 2015; Lewis & Hurd, 2011), LS was initially introduced in the USA as a professional development approach to improve US mathematical classroom teaching and learning (Yoshida, 2012). As a mode of professional development, LS has developed all over the world and has attracted the interest of many researchers in educational sciences, particularly in mathematics education (see, e. g. among the most recent international edited books, Huang et al., 2019; Quaresma et al., 2018).

LS starts from an area of difficulty in teaching and learning identified by a group of teachers. Teachers analyse the targeted learning, study the mathematical concept, consult the various teaching methods, study articles from professional journals and other resources. This study allows them to plan a lesson together. This lesson is implemented in the classroom of one of the group members. Other teachers observe the lesson in real-time and analyse its impact on students' learning. The group may decide to plan an improved version of the lesson to be conducted in another teacher's classroom and the loop begins again. The results of the work are disseminated, both in the form of a detailed lesson plan for future use by other teachers and also in the form of articles in professional journals.

LS groups are usually led by an experienced teacher or trainer, called a facilitator, who "keeps the conversation moving and fair. Involves all participants. Follows an agreed-upon agenda" (Lewis & Hurd, 2011, p. 124). While in Japan LS is sometimes facilitated by the group members, it almost always involve one knowledgeable other who provides feedback after the research lesson and sometimes another knowledgeable other who can draw attention to key elements during the planning phase (Watanabe & Wang-Iverson, 2005). In countries where LS is developed (particularly in Japan), the role of supporting professionals participating in the group as facilitators and that of occasional external experts is well defined. In contrast, these two roles are often assumed by the same person or are confused in places where LS is starting to take root (Clivaz & Takahashi, 2018).

Mathematical Knowledge for teaching problem-solving

Most of the research about problem-solving have considered the student’s point of view (for a survey on the state-of-the-art, see Liljedahl et al., 2016). A few authors have considered the teachers’ point of view and Mathematical Knowledge for Teaching (MKT, Ball et al., 2008) framework to characterise the knowledge teachers use to teach problem-solving. Wake and his colleagues (Foster et al., 2014; Wake et al., 2014) have attempted to broaden MKT to include mathematical process knowledge and pedagogical process knowledge, by rewriting with ‘concepts and processes’ instead of ‘content’ of the MKT categories (Foster et al., 2014, p. 3.98). The focus on the process and not only on the knowledge is undoubtedly noteworthy. Nevertheless, during our data analysis, we realised that the specificity of the knowledge for teaching problem-solving is not only of it being a process. Similar insights were found in the work of Chapman (2005, 2012, 2015). In her conceptualisation, Chapman (2015) distinguishes six categories of Mathematics Problem-Solving Knowledge for Teaching, divided into Problem Solving Content Knowledge and Pedagogical Problem Solving Knowledge (Figure 1). All these categories are influenced by the teacher's Problem Solving Proficiency and by his/her Affective Factors and Beliefs. In the line of Chapman's findings, for the purpose of bridging the MPSKT to the MKT categories, we propose the following graphical representation of this categorisation (Figure 1).

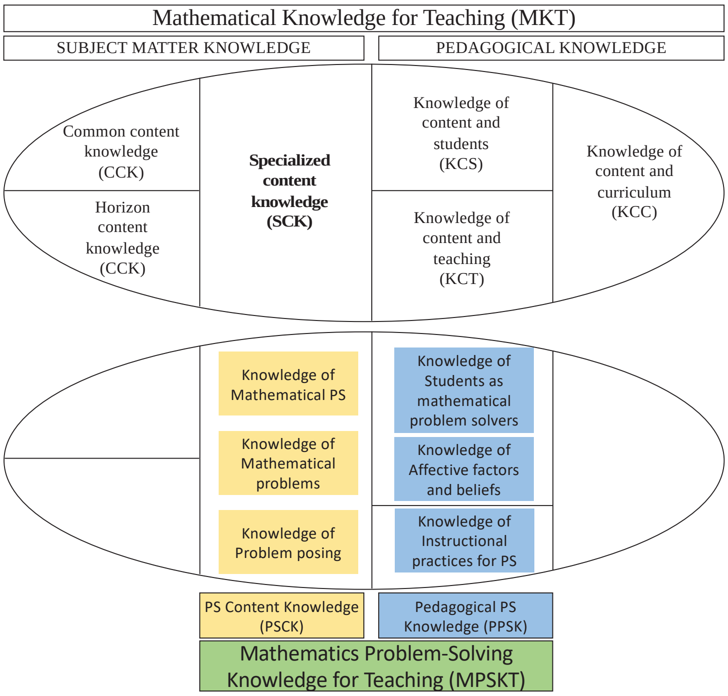

Figure 1: MKT and MPSKT. MKT upper uncoloured part of the figure is from Ball et al. (2008), MPSKT coloured categories are from Chapman (2015). Graphical representation of the coloured categories is by the authors of this paper

Lesson study and teachers' dialogue

It is with the objective of accurately describing how teachers' knowledge is constructed or evolves and, more generally, to better understand what happens between actors within an LS process, that we have been led to focus on discourse analysis in a sociocultural perspective. This perspective is rooted in the work of Vygotsky (1962, 1978), for whom the acquisition and use of language transforms children's thinking. One of our first inspirations was driven from the work of Vermunt and his colleagues (Vermunt et al., 2019; Vrikki et al., 2017; Warwick et al., 2016) who categorised the dialogic processes in LS groups in order to find statistic correlations between certain dialogic features and teachers' meaning-oriented learning in LS. With these categories being too broad for a comprehensive analysis, we were led to study the work of a sister group within the Cambridge Educational Dialogue Research group (CEDiR, n.d.), the Scheme for Educational Dialogue Analysis (SEDA, Hennessy et al., 2016) group. Rooted in the work of Alexander (2008) about dialogic teaching and of Littleton and Mercer (2013) about interthinking, this SEDA group produced a comprehensive grid to analyse classroom dialogue in problem-solving situations. The grid and the method come from an “inductive-deductive cycle that allowed to distil out the essence of dialogic interactions and operationalise them in the form of a new systematic indicators for these productive forms of educational dialogue” (Hennessy et al., 2016, p. 17). The grid and the method seemed to be a good choice to serve as a basis for the construction of a grid of systematic indicators able to capture the forms of professional dialogue within a professional development process. Nevertheless, adaptations have to be made to SEDA scheme to take into account our research context as well as previous research on teacher learning in LS.

Comprehensive research on LS groups and the fact that they appear to have an impact on teachers' professional knowledge often focuses on the essential role of facilitators (e.g. Bjuland & Helgevold, 2018; Lewis & Hurd, 2011; Lewis, 2016) and possible knowledgeable others (e.g. Seino & Foster, 2020; Takahashi, 2014). While many studies mention the importance of these roles and give examples of facilitator interventions or mention statements by teachers saying how important this role is to them, qualitative studies describing precisely how this role allows teachers to build professional knowledge are rare to date.

For our part, in our previous research, we examined the evolution of the trainer's role in terms of knowledge sharing in a series of LS (Clivaz & Clerc-Georgy, 2020) and showed which MKT teachers use during the LS process (Clivaz & Ni Shuilleabhain, 2019; Ni Shuilleabhain & Clivaz, 2017). Nevertheless, interactions within the group, in particular between the facilitators and the teachers, are yet to be explored.

The Construction of the LS Interaction Analysis Grid

In this section, we will describe our grid for analysing interactions as the result of a process that is both deductive and inductive. This grid currently focuses mainly on enunciative modalities but will be linked in the rest of our research with MKT and issues related to the topic of problem-solving.

Composed of 33 codes grouped into 8 entries, the SEDA grid (Hennessy et al., 2016; SEDA, n.d.) had to be adapted from students’ mathematics problem-solving classroom situation to teachers’ professional problem-solving discussion. We started from the SEDA grid, using the same codes every time it was possible and adapting them when necessary. After a one-year coding work, and team discussion of the coding, we were able to set up, in an inductive way, our grid for analysing the interactions within a LS. This required a fairly radical adaptation of the original grid, as we had to take into account our particular context as well as the actors and their intentions.

The process of the modification of the SEDA scheme lies beyond the scope of this paper, but we will highlight here the two main modifications related to the type of exchange in a LS professional dialogue which differs from a students’ dialogue in a classroom situation. The first modification is related to the two SEDA categories “B-built on ideas” and “R–make reasoning explicit” which were close. For example, in our data, it was almost impossible to distinguish “B1-Build on /clarify others' contributions” and “R1–Explain or justify another's contribution”. We therefore merged these two categories into “R – Answer, develop”. Since the Question-Response type of exchange among teachers was often present in our data, the codes for the R category were symmetrised with those of category Q - Prompting development or reasoning (categories Q and R in Table 1), both entries being specified into clarification-justification-hypothesising categories. The second modification is the adaptation of the “connect” category, due to the observation that group participants often make reference to incidents or episodes of the LS cycle or to other teaching experiences (categorie C in Table 1). This observation has already been illustrated in the analysis of the work of a different group (Ni Shuilleabhain & Clivaz, 2017) and we can relate it to the cumulative principle of Alexander (2018) “which underpins enquiry and knowledge growth in academic communities as well as classrooms, ensures that discussion is genuinely dialectical yet builds on what has gone before, advances understanding and is not merely circular” (p. 566).

Lesson study dialogue analysis

The first unit of coding of our analysis is the conversational turn, which allows us to first, code the identity of the speaker. Our LS Dialogue Analysis (LSDA) has 30 codes (33 for SEDA) which are clustered into 6 categories (8 for SEDA) that allow us to characterise interactions within the LS. Each code is characterised by indicators, assuring a good validity of the consensus coding (see Table 1):

- Categories E, Q, R, P and G allow us to highlight a dynamic of talk. Each turn is coded;
- Category C allows us to show what is being used as a reference in the conversational turn. This enables us to be aware of the connections that are made during the exchanges. In this case several turns are coded as a group.

The categories for LSDA are presented as follows in Table 1.

Table 1: Categories of codes for LS Dialogue Analysis

Category	Features
E – Express or invite new ideas	This category marks the entry of a new subject into the discussion, a new idea, an observation. Distinction between invitations to formulate new ideas and expression of a new idea is made.
Q – Arouse development or reasoning	This category is used with the next category R to code a series of exchanges around a subject. The Q-coded turn involves reference to a previous input. The three possible purposes of the Q-coded turn are, to better understand a factual statement or to understand the reasons for a previous statement or to consider other possibilities or hypotheses.
R – Answer, develop	This category has three possible purposes: to provide clarification and explanation, to give a justification, to develop other possibilities or hypotheses.
P – Position or coordinate	This category is used to indicate a turn intended to mark one’s stance or to coordinate ideas in relation to previous exchanges. It may involve synthesising ideas, evaluating different perspectives, challenging an idea or taking a position, approving.
G – Guide	This category is used to indicate a turn intended to guide the course of interaction by encouraging dialogue, by verbalising the rules of communication in order to promote discourse, by proposing an immediate action, by proposing an action in the future, by taking an expert position, by providing feedback, by focusing.
C – Connect	This category is used to show what a series of exchanges refers to. It might refer to: • the content of a past discussion episode • the research lesson (past or future) • one’s teaching experience • one’s personal experience • a theory or to mathematical principles • the LS process (at a meta level) • believes about teaching and learning • the learning trajectory of participants • the mathematical task

Towards an analytical framework

The ongoing coding of our transcribed LS meetings allows us to have three levels of coding:

1) Identity of the speaker
2) Dynamic of talk (categories E, Q, R, P, G) and the topic to which the series of utterances are connected (category C)
3) The category of MKT/MPSKT and the problem-solving proficiency and the affective factors and beliefs expressed by the participants.

We illustrate these three levels of coding, only with one intervention because of space constrain.

T2: Because when you discover [the problem], actually, it's not... it's complicated, you mix everything up, but if you separate it into four questions, you have the answer, so you have to find [the four questions].	1) Teacher 2 2) R: Give a justification, go further, develop 3) Knowledge of mathematical prob.
F2: Yeah, you have to split the problem up.	1) Facilitator 2 2) P: Take a stand 3) Knowledge of mathematical prob.
T4: That's it, and for them to be able to split it up like we do,... I find it interesting	1) Teacher 4 2) R: Give a justification, go further, develop 3) Knowledge of Students as mathematical prob. solvers Knowledge of mathematical prob.
T7: And I think that there's also the cover story of the problem… that's not easy	1) Teacher 7 2) E: Express a new idea, make an observation 3) Knowledge of prob. posing

These three levels and the relationships among them allow us to operationalise our question about the construction of MKT and MPSKT during LS. Level (3) will illustrate the categories of MKT or MPSKT observed in the dialogue. It will also allow us to provide some answers to the questions about the links between one teacher's problem-solving proficiency and his/her MPSKT, and about the links between one teacher's affective factors and beliefs and his/her MPSKT. The type of intervention (2) linked to the identity of the speaker (1) will lead us to determine the specific dialogic role of each facilitator and of each teacher during the phases of the LS process, to answer the questions: Are the facilitators mainly in charge of bringing up the mathematical knowledge? Is it the facilitators' role to develop mathematical knowledge or is it a shared responsibility? Are these roles evolving along the process?

Conclusion

The development of teacher mathematical knowledge about the teaching of problem-solving in a collaborative setting is a complex process. Developing a framework to analyse this process has proven highly challenging for our team, and we consider this framework as a first result. Our data analysis is still ongoing, and we hope that this analysis will bring some fine-grained description of how teachers construct knowledge collaboratively during a lesson study process.

Integration of two theoretical lenses to analyse the potentialities of a practice-based task in fostering pre-service mathematics teacher specialized knowledge

Annalisa Cusi[1] and Francesca Martignone[2]

[1] Sapienza University of Rome, Italy; annalisa.cusi@uniroma1.it

[2]University of Eastern Piedmont, Italy; francesca.martignone@uniupo.it

This paper presents an a priori analysis of a practice-based task designed to be implemented in the context of primary school pre-service mathematics teacher education. We integrate two different theoretical lenses aimed at describing teachers' practices and knowledge. By means of our analysis, we highlight the potentialities of the task to promote the goals of the educational program and to point out pre-service mathematics teacher specialised knowledge.

Keywords: Pre-service teacher, MTSK model, meta-didatical praxeologies, practice-based tasks, mathematics teacher specialised knowledge.

Background

This paper focuses on a specific task that was designed to be implemented in the context of pre-service mathematics teacher education. As Liljedahl et al. (2009) stressed, pre-service mathematics teachers (in the following, PMTs) live a unique experience within their educational paths, since

> they are both student and teacher, and through the constant shifting between student and teacher they are given the opportunity [...] to recast their initial (pre-conceived) beliefs about what it means to be a teacher, what it means to teach, what it means to learn, and even what it means for something to be mathematics (Liljedahl et al., 2009, p.29).

Researchers in the field of mathematics teacher education have stressed on the importance of focusing on practice-based approaches to mathematics teachers' professional development (Ball & Cohen, 1999), which aim to connect the ongoing professional development of teachers with the actual work of teaching. We think that these approaches could be particularly effective in the case of PMT education, since they could foster PMTs' reflections on teaching practice, filling the gap due to their lack of real classroom experience (Cusi & Morselli, 2018). In fact, by focusing on tasks aimed at fostering "activities that are situated in and organized around components and artifacts of instructional practice that replicate or resemble the work of teaching" (Silver, 2009, p.245) – the so called practice-based tasks. These approaches foster the development of a "useful and usable knowledge that builds mathematics teachers' capacity for the kinds of complex, nuanced judgments required in mathematics teaching" (Silver, 2009, p. 246). Therefore, teachers need to acquire and develop both subject matter knowledge and general pedagogical knowledge for teaching, but, as already highlighted in the 1980s by Shulman (1986), teachers' knowledge is characterised by the combination and amalgam of content knowledge and knowledge about teaching, students and curricula. This characteristic knowledge is defined by Shulman as "pedagogical content knowledge (PCK): "the particular form of content knowledge that embodies the aspects of content most germane to its teachability" (Shulman, 1986, p.9). Starting from Shulman's studies, different models to describe mathematics teachers' knowledge have been developed in the last decades: for example, the Mathematical Knowledge for Teaching - MKT model (Ball, et al. 2008), the Knowledge Quartet (Rowland, et al., 2005) and, more recently, the Mathematics Teacher's Specialised Knowledge-MTSK model (Carrillo-Yañez et al., 2018). In our study we referred to the MTSK model to describe some aspects of the specialized knowledge of PMTs. Teachers used/needed specialized knowledge to do their work and this specialized nature of their knowledge is linked to teaching:

> Our starting point is the assumption that in order to carry out their role (including lesson planning, liaising with colleagues, giving lessons and taking time to reflect on them afterwards) the teacher needs specific knowledge. We associate this specificity with mathematics teaching (Carrillo-Yañez et al., 2018, p. 239).

In this paper we present a specific type of practice-based task and we analyse the PMTs' specialised content knowledge that can emerge. The task combines the design of fictional classroom discussions representing virtual dialogues between a teacher and his/her students with the explicit request of justifying this design by means of specific theoretical lenses introduced during the teacher education courses. The activities fostered through this kind of task represent a fundamental component of a methodology for PMT education aimed at fostering PMTs' reflective practices (Jaworski, 2004), by actively involving them in the analysis of practice through the theoretical lenses provided by research (Cusi & Malara, 2016; Cusi & Morselli, 2018). To develop the *a priori* analysis of this type of task (in the following, FCD task, acronym for "fictional classroom discussions task"), we will integrate different theoretical lenses that are presented in the next section.

Analytical framework

The analytical framework is constituted by two main components. The first component is the Meta-didactical transposition (MDT) model (Arzarello et al., 2014). Based on Chevallard's Anthropological Theory of Didactics (Chevallard, 1985), this model was born to describe and analyze the evolution of mathematics teachers' and didacticians' practices within institutional contexts, when they are jointly engaged in professional development programmes or collaborative research projects (Arzarello et al., 2014). We use the term didacticians as "people from the university with knowledge of research and theory in the didactics of mathematics, interested to work with teachers to promote better opportunities for mathematics learning in classrooms." (Jaworski, 2012, p. 623).

In tune with Chevallard's framework, the MDT model focuses on the notion of praxeology, a tool to model the human activities developed within institutional contexts. A praxeology is structured in two main levels (García et al., 2006): the *praxis* or *know-how level*, which includes the task, or a family of tasks, and the techniques used to face the task; the *logos* or *knowledge level*, which includes the "discourses" developed to justify or frame the techniques for the task. The MDT model distinguished between: *didactical praxeologies*, which refer to tasks related to the knowledge to be taught and the technique being recognized and justified within a specific institution; and *meta-didactical praxeologies*, which focus on teachers' and didacticians' meta-level reflections on contents to be taught and corresponding didactical praxeologies (Arzarello et al., 2014). We chose to refer to the MDT model since: (a) it focuses on the role played by the meta-level reflective practices developed by communities of teachers and didacticians involved in professional development programs or collaborative research projects; and (b) it acknowledges teachers and didacticians' reciprocal influences when they work together in such contexts.

The second component of our analytical framework is aimed at describing PMTs' knowledge. We have chosen to use the interpretive lenses drawn from the MTSK model (Carrillo-Yañez et al., 2018) in order to describe the mathematics teacher specialized knowledge. This model is suitable for the analysis we want to develop since it focuses on the knowledge that teachers may use/need for the analysis and design of educational activities. We chose the interpretative tools provided by this model to understand and interpret teachers' praxeologies focusing on knowledge level. The starting assumption of the MTSK model is that teachers need specialized knowledge to fulfil their role. Therefore, knowledge developed and implemented for teaching is considered specialized. Inspired by Shulman's (1986) studies, the MTSK model distinguishes between mathematical knowledge (MK) and pedagogical content knowledge (PCK), both of which are considered as sub-domains of the teacher's specialized knowledge. The MTSK model describes three sub-domains of mathematical knowledge: Knowledge of Topic – KoT (e.g. knowledge of definitions, properties, procedures, representations, and applications of mathematics); Knowledge of the Structure of Mathematics – KSM (e.g. knowing how to connect activities in different domains of mathematics); and Knowledge of Practices in Mathematics – KPM (e.g. knowing how to prove, justify, define, make inferences and inductions, give examples and counterexamples). Pedagogical Content Knowledge is divided into three sub-domains: Knowledge of Mathematics Teaching – KMT (e.g. knowledge of theories of mathematics teaching or knowledge of teaching resources, materials and technologies, but also knowledge of strategies for introducing and representing contents and concepts, etc.); Knowledge of Features of Learning Mathematics – KFLM (e.g. knowledge of theories of mathematics learning or knowledge of the way in which pupils interact with mathematics); and Knowledge of Mathematics Learning Standards – KMLS (e.g. knowledge of expected learning outcomes and teaching goals in different school segments). The MTSK model in addition to detailing these subdomains of Mathematical Knowledge and PCK explicitly highlights the centrality of teachers' beliefs about mathematics and mathematics teaching-learning.

In the study presented in this paper, we integrate the theoretical lenses belonging to the MDT and MTSK models to develop an *a priori* analysis of a specific FCD task. The *a priori* analysis is performed in order to highlight the potentials of the FCD task in: (a) fostering the educational goals of the professional development programme within which the FCD task has been implemented; and (b) bringing out, consolidating and developing different aspects of PMTs' specialized content knowledge. As regards (a), we refer to the MDT model to frame the educational context in which this task has been implemented, characterizing, on one side, the praxeologies that guided the didacticians' design of the task and, on the other side, the praxeologies that PMTs have to activate in order to face the task. As regards (b), we use the MTSK model to characterize the different aspects of PMTs' specialized content knowledge that can arise when PMTs face the FCD task.

An example of FCD task

The example we present in this paper refers to the context of primary school PMT education. The FCD task on which we focus has been implemented within a 48 hours course for PMTs enrolled at the first year of the master-degree course “Primary education sciences” at Sapienza University of Rome. The course, named “From arithmetic to algebra. From algebra to arithmetic” was aimed, in tune with the studies presented in the background section, at making PMTs develop reflections, in an integrated way, on specific mathematical contents, mathematical processes and on specific pedagogical aspects of mathematics teaching-learning. The main mathematical contents, on which the course was focused, are: the use of algebraic language as a thinking tool; the different meanings of the equal sign; the construction and interpretation of mathematical representations and tools (such as tables, diagrams, graphs…); the study of sequences, relations and functions. As regards the mathematical processes, during the course PMTs had to opportunity to experience and reflect on generalization, argumentation, problem solving and posing. Finally, the main pedagogical aspects of mathematics teaching-learning that were discussed are: the possible approaches to early algebra; the use formative assessment in mathematics; the design of laboratorial activities; the role of the teacher in guiding classroom discussions. All the reflections, in tune with the MDT model, were always developed by referring to institutional aspects, such as the National Guidelines. PMTs faced different FCD tasks during the course together with other kinds of practice-based tasks that involved PMTs in the role of future teachers (classroom tasks, analysis of students’ written answers, and videos from real teaching experiments) and other laboratorial activities that involved PMTs in the main role of learners (activities focused on numerical explorations, conjecture and proof and on problem solving). The FDC tasks we are going to analyse was carried out at the end of this course. PMTs, at that time, had followed two other courses focused both on mathematics and mathematics education, for a total number of 100 hours.

The example of FCD task for PMTs analysed in this paper (Figure 3) requires to: (1) design an excerpt of a fictional classroom discussion, focused on a specific task for students (Figure 1), starting from a collection of six real students’ written answers (the translation of two of these answers is presented in Figure 2); (2) organize the discussion by selecting the students’ answers to be discussed, grouping them according to their characteristics and identifying the order in which to discuss them; (3) justify the choice made when designing the fictional classroom discussion, making explicit reference to the theoretical constructs introduced during the course.

Giovanni and Francesco have prepared a game for us, by constructing this three-floors pyramid. Complete the pyramid, explaining how you reasoned to identify the numbers to be put in the empty bricks.

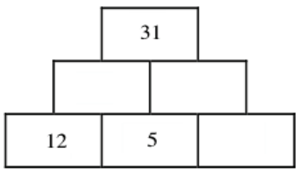

Figure 1: The task for students on which the FCD task is based

The task for students (Figure 1) is part of a sequence of tasks. During the work on the previous tasks, the students have already discovered the relationships between the numbers on the bricks that constitute a mini-pyramid (a pyramid of three bricks), that is “the number on the brick at the top of each mini-pyramid is the sum of the two numbers on the bricks at the base of the mini-pyramid”.

	We first made this pyramid: 17 / 12 5 Then we made the second pyramid. Since there were not two bricks [*they mean that they do not know one of the numbers at the base of this mini-pyramid*], we searched for the number to find out 31. We unified 14 with 17 and the result was 31. Then we made 14-5, which is 9; so, we finished also this pyramid: 14 / 5 9
	In the first line we found out the number 31. Then we formed the same number in the other two [*lines*].

Figure 2: Translation of two of the real students' written answers on which the FCD task is based

The translation of the text of the FCD task (except the problem in Figure 1 and the real students' written answers in Figure 2) is presented in Figure 3.

> Some students of a 2nd grade class have faced the following **problem** during a laboratorial activity.
>
> (*Here the text of problem in Figure 1 is inserted*)
>
> These are the **real answers** written by six of these students.
>
> (*Here the six students' written answers are inserted – two of them are in Figure 2*)
>
> **Design, by referring to the theoretical lenses introduced during the course, an excerpt of a fictional classroom discussion starting from these six students' answers.** Within the excerpt of the fictional classroom discussion, insert both the teacher's and his/her student' hypothetical interventions.
>
> The **aims of the discussion** are:
> (a) to compare the different argumentations proposed by the students;
> (b) to collectively reflect on strategies and mistakes;
> (c) to collectively construct representations aimed at making these strategies explicit.
>
> With these aims in mind, choose how to organize the phases of sharing and reflections on these written answers. For example, you can choose to discuss only some of them, to change the order in which to present the written answers, to group the answers according to the foci of the reflections you want to develop during the discussion.

Figure 3: Translation of the text of the FCD task

During the course different kind of data have been collected: the PMTs' written answers to the FCD task (that is the fictional classroom discussions they designed and the justifications of this design), videos of collective discussions between the didactician and the PMTs, PMTs' final reflections on their experience within the course (with a focus on each activity in which they were involved).

A priori analysis of the FCD task

The data collected during the course could be analysed at different levels: (1) the level of the *a priori* analysis of the FCD task as a tool for PMT education; (2) the level of the analysis of the excerpts of the fictional classroom discussions designed by PMTs and of the ways in which this design was justified referring to the theoretical tools introduced during the course; (3) the level of PMTs' reflections on the role played by their work on the FCD task in their professional development. In this paper we focus on the first level of analysis.

In this paper show an *a priori* analysis of the FCD task presented in the previous paragraph. We frame the activity on FCD tasks by using the theoretical lenses presented in the analytical framework. We refer to the MDT model to characterize the different practices, developed by the didacticians and the PMTs, in relation to this FCD task. First of all, we focus on the *praxeology of the didactician* who have conceived and designed the FCD task within an educational program for PMTs of primary school. This praxeology is related to the *task* of making PMTs experiment the activity of design of classroom discussions starting from students' answers. The adopted *technique* consists in the FCD task design itself. The *logos component* of this praxeology is constituted by the theoretical references that frame the educational program and support the justifying discourses behind the choice of focusing on methodologies for teacher education aimed at fostering PMTs' reflective practices. In relation to this, a fundamental element of the logos component is represented by the research studies focused on the role played by theory as a tool to support practice. As concerns the *praxeologies developed by the PMTs* in their role as authors of fictional classroom discussions, the *task* to which these praxeologies refer is that of designing a classroom discussion focused on a specific task for students and on specific students' written answers. The *technique* to face this task is characterized by different processes that have to be realised: the analysis of the task for students, the analysis of the students' written answers and the identification of the possible interventions that the teacher and her students could make during the classroom discussion. The *logos component* is constituted by the different theoretical lenses shared with PMTs during the whole course. It must be added that the didacticians' choice of the task for students on which the FCD task is focused (Figure 1) and the aims of the classroom discussion to be designed make PMTs direct their attention also on specific aspects related to different mathematical and pedagogical contents faced during the course (for instance, the role of argumentation in mathematics, early algebra, formative assessment…). Other elements could also be part of the logos components of PMTs' praxeologies, such as the PMTs' (mathematical and not mathematical) previous knowledge and their beliefs about teaching and about the mathematical content on which the task for students is focused. In order to analyse which aspect of specialized content knowledge might emerge when pre-service teachers face this task, we use the MTSK model. In the analysis of the task for students, the students' answers and the possible discussion about them, PMTs can use their KoT about: the properties of natural numbers and operations; the additive relation; the procedural/relational meaning of the equality symbol. With regard to KSM, their knowledge about relations among number sets and about pre-algebra should emerge. The role of examples and counterexamples in the production of hypotheses in arithmetic problems and the possibility of using different possible arguments are part of KPM. The task could make the PMTs deeply reflect on different and effective representations that can be used to work with students to explore numerical relations or artefacts and meaningful activities concerning problem solving (KMT). The different procedures that students might carry out or students' possible errors as well as the difficulties in producing arguments can be framed in the KFLM domain. The examples of students' answers (Figure 2) are useful for the development of shared reflections on students' argumentative processes and on the arithmetic relationships they can identify. It is important to be aware that the pyramid task aims not only at implementing computational schemes but, above all, at fostering problem solving and argumentation processes. These processes are key issues in the goals for the development of competences written in Italian National Guidelines (Standards) that PMTs have to know (KMLS). This detailed analysis of PMTs' mathematical knowledge and pedagogical content knowledge allows us to enhance the MDT model with regard to the description of the *logos component* of PMTs meta-didactical praxeologies.

Conclusion

In this paper we have presented a specific practice-based task – the FCD task – designed to be implemented within courses for PMTs. By integrating two different theoretical lenses, we developed an *a priori* analysis of the FCD task aimed at highlighting the potentialities of this kind of task in terms of promotion of both the educational goals of the course within which it was implemented, and development of PMTs' specialised content knowledge. In particular, the MDT model enabled us to reflect on the meta-didactical praxeologies activated by the protagonists of the educational process under scrutiny: on one side, the praxeologies that guided the design of the FCD task by the didactician; on the other side, the praxeologies activated by PMTs during their work on the FCD task. The MTSK model constituted the lenses through which we deepened the characterization of the logos component of the PMTs' praxeologies, by focusing on the specialised content knowledge that could emerge and be consolidated by means of the examined task. We detailed, for each of the subdomains of the MTSK model, what knowledge can emerge when PMTs face this task.

The results of our analysis could have both practical and theoretical implications. At the practical level, by highlighting the potentialities of FCD tasks, our analysis confirmed the effectiveness of the criteria that guided the design of this kind of tasks: focusing on meaningful mathematical problems (to foster the activation of mathematics teachers' specialized knowledge); asking to design fictional classroom discussions starting from students' real written answers (to promote PMTs' reflections on aspects related to different mathematical and pedagogical contents faced during the course); asking to justify the fictional classroom discussions' design by referring to specific theoretical lenses (to better trigger PMTs' reflective practices). At the theoretical level, our analysis shows that the integration of the MDT and the MTSK model was effective in highlighting both the educational aims connected to the design of FCD tasks and the possible results of the implementation of such tasks in terms of potential emergence of PMTs' specialised content knowledge.

In this paper we focused only on the *a priori* analysis of the FCD task. As a further step of our study, we will focus on the different data collected during and after the implementation of the FCD task to perform other levels of analysis in which we will continue to interweave theoretical lenses from the MDT and MTSK models.

Mathematics teacher educators' thinking about mutuality in teaching

Stakeholders agree that the mathematical education of teachers needs to focus on mathematical knowledge for teaching, but the practice-based nature of this knowledge poses challenges for mathematics teacher educators — for understanding it, developing tasks that maintain its integrity in practice, and teaching it to teachers in ways that meaningfully support their learning to teach. We know little, however, about how mathematics teacher educators conceptualize the teaching that knowledge is to support. Our analysis reveals that thinking develops from a view of teaching as straightforward, where aspects can be treated in isolation, to a view of it as requiring focused attention while maintaining mutual regard for the whole. This difference has implications for how mathematics teacher educators understand specialized mathematical knowledge and for how to support their understanding and teaching of it.

Keywords: Mathematical knowledge for teaching, teaching, teacher educators.

Introduction

At present there is little doubt about the importance of specialized knowledge for teaching mathematics. Scholars have invested in supporting mathematics teacher educators (including, mathematicians, education specialists, instructional coaches, teacher leaders, and others) to develop their understanding (Even & Ball, 2009). As mathematics teacher educators are a diverse group with disparate backgrounds and uneven expertise and experiences, such work is often challenging and showcases how these differences might matter (Lloyd & Chapman, 2020). Specifically, the practice-based nature of mathematical knowledge for teaching together with uneven understanding of teaching creates challenges in the work that impede progress. A more detailed and systematic unpacking of mathematics teacher educators' thinking would help professional development efforts, however, currently we know very little about how mathematics teacher educators think about teaching or how this thinking connects to their understandings of specialized mathematical knowledge.

Theoretical Background and Research Design

For several years, the research group in which we work (based in the United States) has conducted workshops that seek to develop mathematics teacher educators' understanding of the mathematical demands of teaching. The current study is part of a larger project designed to support mathematics teacher educators' engagement in collegial development of instructional tasks for teachers that address mathematical knowledge for teaching (Ball et al., 2008). We conducted a dozen four-day workshops of approximately 30 participants each. Participants applied as teams that were composed of individuals from different professional settings engaged in the mathematical education of teachers in their local area. Workshops began with a basic introduction to mathematical knowledge for teaching, task writing, and the mathematical demands of attending to justice, where teaching is understood as management of the interactions among teacher, students, and content, occurring in immediate and broader social environments (Ball, 2018; Brousseau, 1970-1990/2002; Jaworski, 1994), and justice is understood as an essential feature of professionally responsible teaching (Ball, 2018). Moving between whole-group and small-group work, we introduced participants to tools for developing tasks with most of the time spent on writing and reviewing tasks.

For this study, we asked, how do mathematics teacher educators think about teaching? Throughout, our focus was on differences that might matter for their thinking about mathematical knowledge for teaching. We selected 12 participants to interview, with varied demographics, professional affiliation, and experience with the ideas. Approximately one third were affiliated with university mathematics departments, one third with schools of education, and one third were in public primary and secondary schools. Roughly half of the participants had over ten years of experience teaching, and the majority were white women. (All names are pseudonyms.) Although this is a small sample, sampling was purposeful across roles and experiences, and differences in thinking (which is our focus) likely reflect differences in the wider community. We collected extensive pre-workshop applications and post-workshop surveys, including responses to specialized content knowledge tasks with detailed explanations. Our guided interview protocol was designed for multiple purposes: to gather feedback on the workshop, to gain insight into participants' understandings, and to inform future development efforts. Interviews were conducted via video conferencing, recorded, and transcribed. Open-ended questions probed four topics: (i) reasons for applying; (ii) what they learned and found useful; (iii) perspectives on a video clip of a workshop discussion; and (iv) thoughts about the mathematical-knowledge-for-teaching needs of mathematics teacher educators. The interview was not designed solely to elicit views of teaching, but teaching was a focus of the workshops and each section of the protocol touched on teaching directly and indirectly. Analysis focused on the interviews but also used applications, surveys, and observations to inform and test interpretations.

To investigate participants' thinking, we used a conceptual analytic approach (Erickson 1986). Our approach was empirically grounded, coordinated different perspectives, and was driven by practical concerns and logical analysis. Analysis involved cycles of attuning initial conceptualizations, relevant literature, and available data with a focus on local meaning and an assumption that what people say is sensible from their perspective. We identified units of text in tandem with coding — selecting text that focused on the evidence for the code and was enough context to stand alone as evidence. We wrote memos, developed a codebook, and coded for salient distinctions in thinking from direct viewing recordings of interviews, and when uncertainty or inconsistency occasionally arose, we re-watched, explored different interpretations, imagined from the participant's perspective, and set aside to revisit later. We developed codes from sections of a subset of interviews until they could be used consistently and then applied and documented them for the full set. Our focus was on interpretive power, with attention to subjective coder reliability when reconciling our independent coding.

Analysis and results

Our analysis reveals a fundamental distinction in mathematics teacher educator's thinking about teaching — that it develops from views of teaching as *straightforward, where one gives attention to an aspect of teaching but with little regard for other aspects*, to views of it as *involved*, *where, while giving attention to an aspect of teaching, one maintains regard for other aspects and the whole, with* *a sense of mutuality*. By *aspect* we mean a focused slice of teaching. By a sense of *mutuality*, we mean regard for the comprehensive interactions of teaching and learning, including the influence of broader social environments and the need to contend with complexity by specifying practice at a finer grain size (Ball & Forzani, 2009; Grossman & McDonald, 2008), while also considering its character as dilemma management (Lampert, 1985).

We coded units of text conveying: (i) regard for only a single aspect of teaching with no regard for other aspects; (ii) mutual regard for mathematics content and student thinking, but where these alone are privileged; and (iii) mutual regard other than this limited purview, for instance, additionally considering classroom culture, students' developing identities, or the pace and remaining time for a lesson. Viewing an aspect of teaching without regard for other aspects is common in the general public but is likely rare among mathematics teacher educators (as in our data). Instead, the second code is prominent, where teaching is considered in ways that foreground mutual regard for mathematics and student thinking to the exclusion of other aspects. Frameworks drawn from mainstream mathematics education shape, or at least reinforce, this thinking. Fuller mutual regard combines experience and more theoretically grounded consideration of the complex nature of teaching as situated human interaction.

As an example of thinking about teaching as straightforward, consider Claire, a white graduate student in mathematics education, with three years of secondary mathematics teaching experience. She describes interpreting and classifying student thinking as an independent task teachers need to do. She talks about not needing to know students' backgrounds or identities and how this can be a distraction. She acknowledges that teaching can seem complex, but in her view, teachers manage complexity by focusing on "narrow pieces" of teaching in isolation.

> *Instead of thinking about like okay there are forty individual approaches in this classroom, there are reasonably like three or four ways my students might be thinking about that, and … based on these [students'] comments, we can try to put students into this model that we already have of how a student is thinking.*

Her comment suggests that understanding and making good use of idealized conceptual models of how students are thinking is the crux of the work in this situation, in almost complete isolation from consideration of other aspects of teaching. From this perspective, interpreting students is less an attempt to grapple with students' ideas on their own terms, and more about considering them in relation to pre-existing conceptions of content as conceived by the teacher. This view conveys that teaching is about being aware of and understanding these conceptions of content and using them to assess students and manage the presentation of mathematics going forward.

Such an understanding is limited. It reduces the work of interpreting student thinking to one where human beings and their interactions are not the primary focus, but abstract conceptions are. Content is given primacy here above all other aspects of teaching, which obscures and distorts essential mathematical work required for the multiple and interrelated concerns in teaching. In this view, we lose sight of how a student might feel when they are the subject of this kind of classification (what if the assigned classification is incorrect?) and the impact such classification might have on future interactions and the subsequent mathematical trajectory of the class. We also miss how certain conceptions (even if accurately assigned and skillfully used in service of content goals) might be viewed as less mathematically advanced by peers and potentially reinforce stereotypes that undermine a productive learning environment. In this way, the central purpose of such an activity shifts away from understanding students or making sense of complex human interaction and toward unpacking abstract conceptualizations of content. Additionally, as teachers often interact with students across cultural and racial differences, their perceptions, unless actively interrogated and disrupted, are likely to impose norms of dominant groups that harm marginalized students.

Despite all of this, Claire trusts that care and good intentions will sufficiently address other aspects of teaching. She has an abiding regard for mathematics and teaches prospective teachers how, for example, to set clear objectives, yet she treats this and other pedagogical tasks as separate matters that do not come into play when classifying student thinking. For Claire, the pedagogical tasks that make up teaching can each be learned relatively independently and used straightforwardly.

A second form of constrained thinking about teaching prioritizes two concerns, mathematical goals and student thinking, with these treated as interdependent but as so primary that exclusive attention to them is given. For example, when debriefing the workshop discussion from the institute, Teresa (a Latina instructional coach with over 10 years of teaching experience, whose focus is the professional development of elementary teachers) explains:

> *The hardest part that we see teachers work with is making connections, helping students connect these different ideas ... What I appreciate about this video is that it makes it real time … it's almost asking teachers to write exactly what questions or what they would say to actually bring together Aniyah and Katherine's work and build on the mathematical thinking that is there to reach this goal.*

This comment highlights mutual consideration of student thinking and mathematical goals, and how their navigation requires thinking through and attending to the details of what a teacher needs to say and do. She describes Stein et al.'s (2008) five practices for leading a productive discussion as the essence of teaching — a dance between mathematical content and student thinking. When she focuses on mathematical issues, student thinking is near at hand, and when she scrutinizes student thinking, she keeps mathematical goals in mind. Relevant mathematical knowledge for teaching in this view is fundamentally shaped by the mutual consideration of student thinking in conjunction with content goals. In the quote above, Teresa expresses the need to help teachers formulate what they might actually say because she sees that specificity is needed to size up whether and how to probe student thinking in a way that maintains mathematical goals. In her interview these two aspects of teaching are often privileged — to the exclusion of others.

Another example of our second code is the following from Andy, a white high school teacher with two years of teaching experience and a graduate degree in mathematics. He talks about how challenging it is to hear the parts of student contributions that are mathematically correct and see how to leverage these to advance mathematics. For Andy, this is the heart of skillful, experienced teaching. As did Teresa, he emphasizes the challenge of evaluating student responses in real time.

> *Getting over that fact that this is so crazy, this student has one seventh, and this student is looking at fourths, and to get to the point of where their fractions are coming from … you know, you have*

five minutes basically in real time … while you're trying to manage all the other behavior issues and the other things going on in the classroom.

From his overall response, we hear Andy describe the need for mutual, interdependent regard in the work of bridging student thinking and mathematical goals, but his reference to "other things going on" posits these as independent tasks that need to be carried out simultaneously, but do not require substantial coordination. Andy does not, for example, note how the real-time nature of this moment shapes the kinds of responses that might be available to a teacher, or say how particular responses to behavior might exclude certain children from the mathematical work, both relevant concerns that significantly impact the mathematical knowledge demands of this situation.

The quotes from Teresa and Andy suggest a view of teaching as coordinated attention to mathematical goals and student thinking, but without mutual regard for other aspects, such as for students' identities, classroom culture, materials available, and practical time constraints. Such a conception of teaching does bring genuine regard for a dual attention to mathematics and student thinking but does not attend much beyond that. Indeed, in this view, teaching is still principally about content, whether student-generated or prescribed by curricular and disciplinary goals. While this conception might consider interactions between students or student ideas as mathematically relevant, they are seemingly only so if they are in service of immediate content goals — to the exclusion of other possible goals of teaching (e.g., development of a longer-term mathematical trajectory, encouraging individual and collective participation, human improvement, empathy, disrupting status hierarchies, or social change). Such a view of teaching continues to idealize content away from context and again misses important mathematical work in the interactions among the environments surrounding instruction and the multiple interacting components of the instructional triad. For example, work concerning student identity development is intertwined with and inseparable from mathematically relevant questions such as who should get to speak next, what content might be useful to surface, which examples can reasonably be done in the remaining class time, or what examples are likely to elicit unconventional responses. Mathematics teacher educators who see mathematical objectives and student identity development as isolated and disconnected concerns miss how one can shape the other. It is worth noting that this limited view of teaching is evident in much mathematics education research and many mathematics-education programs, where learning theory and mathematics are often central and integrated but other issues are treated as separate, e.g., classroom management, time management, moral and civic education, and social (in)justice.

Our third code identifies mutuality that goes beyond regard for mathematical goals and student thinking. As an example, Naima (a black curriculum specialist and professional development facilitator with six years of teaching experience and a graduate degree in public policy) focuses on interpreting students' contributions and using them together to advance instruction, but she also stitches regard for other aspects into her comments. Discussing the mathematical content and the collective trajectory of the class, she comments about carefully choosing who should speak, with reference to each student's strengths and growth, how they are positioned, and the overall classroom culture. She attends to all parts of the instructional triad. Naima routinely focuses on a specific concern yet maintains a sensibility for teaching as complex interactional work, inserting brief asides to other aspects of teaching and offering examples that situate her specific point in an overall picture.

The participants in our study were recognized professionals. They were connected enough to hear about and attend a national workshop. The majority of our codes were of this third type (Figure 1).

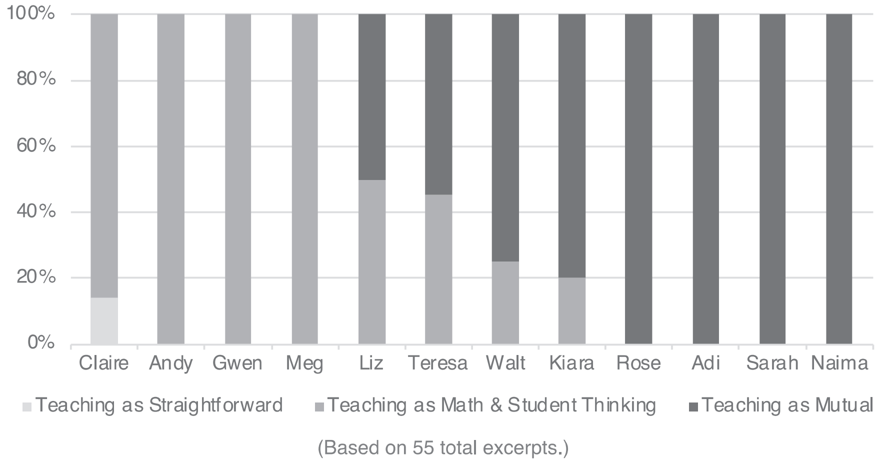

Figure 1: Percents of coded units for each way of thinking about teaching for each participant

Some participants consistently spoke of teaching as requiring mutual regard, while others did not. These two groups are visible at the two ends. The middle four were mixed. For instance, Teresa described how attention to justice issues in the workshop was making her realize she was leaving significant parts of the work implicit in her work with teachers, not only related to justice but to other mutual considerations. She reflected that, in her focus on orchestrating a productive discussion, "the characters, for lack of a better word, the little people, the kids have been absent."

> *I didn't realize how powerful it is to actually paint that context and paint the picture of who is that student with that voice. Like, as a classroom teacher I think I did attend to that, like I understood who kinda- like when you're working with an equalizer board in music, there are times where I need a tone, somebody's voice, and I was- I felt like I was in tune with that. But I didn't realize how to make that visible and explicit to teachers as they think about how they do that with their students. And now I found it seems like a simple solution, tell the whole story. Paint the picture, tell who this student is so that it is part of how they are making their decisions when they have this much time to think about it … I think is my biggest aha! Like make it visible- it can't be something you hope they think to consider in the moment.*

For Teresa, attention to justice issues became an inroad that extended her constrained thinking about teaching as navigation of dynamics only between mathematical objectives and student thinking to navigation involving a much fuller set of dynamics at play in the human interactions of teaching and learning. Similar to Teresa, the three other participants in the middle of Figure 1 all have frames that constrain their thinking about teaching (limited views of mathematics, of what is interesting or important, of students, or of teaching), but also have experiences that allow them at times to take up pedagogical concerns with fuller mutual regard.

Conclusion

The distinction we have unpacked here matters. It is likely a source of miscommunication and misunderstanding among mathematics teacher educators; it reflects something fundamental about the development of mathematics teacher educators' thinking about teaching; and it also has implications for their understanding of specialized mathematical knowledge. Understanding of teaching as straightforward constrains the work that is visible and considered mathematically relevant. Consequently, such a view inhibits understanding of specialized mathematical knowledge. The tendency to idealize or abstract out of context in service of content goals distorts the purposes of teaching and severs its connections to the realities of practice. It reframes a situated activity as one that is almost entirely cognitive. Our analysis suggests that in the absence of a well-developed understanding of teaching, existing orientations and sensibilities get imported to fill the void. For mathematics teacher educators, viewing teaching through a cognitive or content lens is probably a natural step given the backgrounds and training these individuals likely bring to the work. It is perhaps no surprise then that the practice-based nature of specialized mathematical knowledge often creates difficulties for mathematics teacher educators. Writing tasks for teachers that are authentic to practice is difficult when one's understanding of practice is limited.

In addition, understanding how mathematics teacher educators think about teaching can be used in the service of professional development. In a larger study that makes use of the mutuality distinction, we found that it aligns with thinking about specialized mathematical knowledge as practice-based or resource-based, and with thinking about justice as fundamental or optional (Hoover et al., 2022).

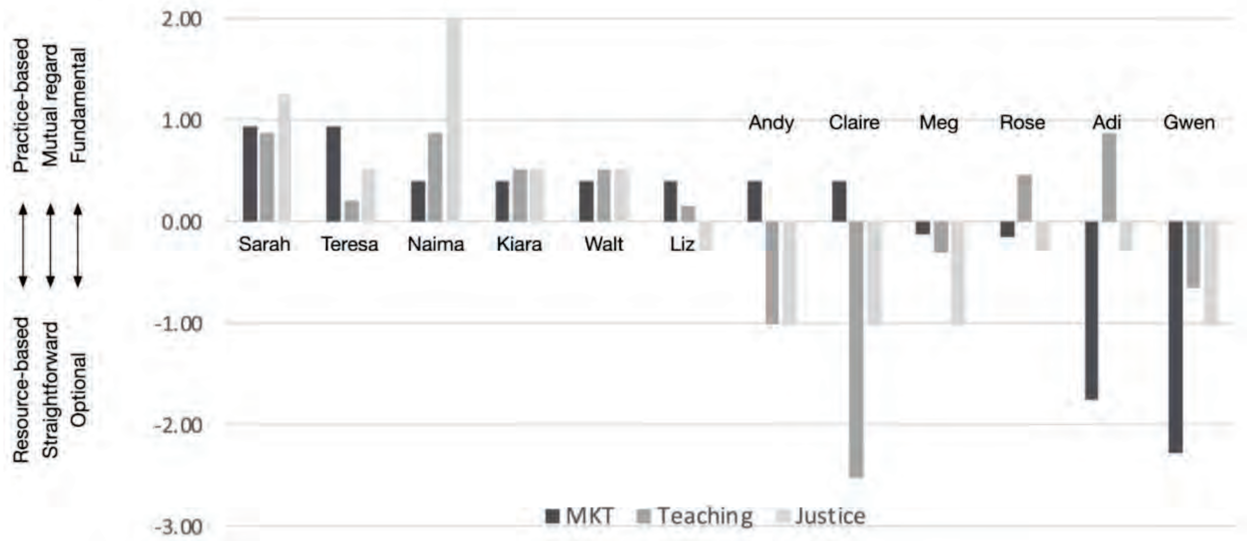

Figure 2: Profiles of the extent to which participants think of mathematical knowledge for teaching as practice-based, teaching as mutually involved, and justice as fundamental and consequential

Deeper examination suggests several clusters of participants with distinctive characterizations that might benefit from more focused professional development that takes alignment (or misalignment) into account. For example, understanding that a mathematics teacher educator thinks of teaching as straightforward allows professional development to be tailored to push on the boundaries of that view and might help them to see the practice-based nature of specialized mathematical knowledge.

While other scholars have described dynamics akin to mutuality, using different language, in different contexts, our analysis is significant in several ways. Conceptual distinctions are significant for specific purposes, and this distinction matters for how mathematics teacher educators work, including how they think about specialized mathematical knowledge, the tasks they write, and the mathematical opportunities they provide to teachers. We recognize that our analysis is more suggestive than definitive, that our language for and elaboration of the concept of mutuality is limited, and that our data draws primarily from mathematics teacher educators working in a U.S. context, but it offers a starting point. Important questions to address are the composition of skillful regard for mutuality and whether attention to mutuality matters for teachers as well as for mathematics teacher educators.

Using the Knowledge Quartet to quantify the appropriateness of present and absent Mathematical Knowledge in Teaching

Arjen de Vetten

Leiden University, ICLON Graduate School of Teaching, the Netherlands; a.j.de.vetten@iclon.leidenuniv.nl

Keywords: Classroom observation techniques, statistics education, statistical inference.

Introduction

The purpose for teachers acquiring mathematical knowledge for teaching (MKT) is to use this in their classrooms. Research on teachers' MKT, therefore, also needs to measure their mathematical knowledge in teaching (MKiT). The Knowledge Quartet (KQ) framework is designed for such situations (Rowland, Huckstep, & Thwaites, 2005). The KQ comprises four dimensions: foundation, transformation, connection, and contingency, each consisting of four to seven aspects (see knowledgequartet.org). Using the KQ, Weston (2013) suggests to quantify the presence and appropriateness of MKiT. However, she does not quantify the appropriateness of the *absence* of MKiT. Building on Weston's method, we also analyze whether the absence of particular aspects of teacher knowledge is appropriate. The research question is: What does the quantified use of the KQ framework reveal about the appropriateness of present and absent MKiT?

Methods

Using a multiple case study, we applied the KQ in the context of a teacher college intervention that aimed to improve the PSTs' MKT of informal statistical inference (ISI; De Vetten, Schoonenboom, Keijzer, & Van Oers, 2018), which can be defined a generalization, based on data, expressed with uncertainty. Part of the intervention was to teach an ISI lesson. We observed three of the 21 participants, Alfred, Celine and Demi (pseudonyms) teaching their 3rd to 5th classrooms. The PSTs taught a lesson, called "What is the most frequently used word in a stack of children novels?" The lesson was modelled at teacher college and was laid out in a lesson plan. The analyses are based on transcripts of video recordings of the classroom interactions. The unit of analysis was a teaching situation, constituted by a fragment of whole class discussion that concerned one substantive topic. Within each fragment the PSTs' actions were analyzed from the idea that these actions "could be construed to be informed by a trainee's mathematics content knowledge or […] mathematical pedagogical knowledge" (Rowland et al., 2005, p. 258). The coding process followed the approach of Weston (2013). First, for each fragment the presence of each of the 20 KQ codes was coded (present versus non-present). Second, the appropriateness of the (non-)presence was evaluated (appropriate versus inappropriate). Present teaching actions were coded as appropriate when these teaching actions helped to attain the learning objectives (p-a), and as inappropriate when they hindered the attainment of the learning objectives (p-i). Absent teaching actions were coded as appropriate when absence did not hinder the attainment of the learning objectives (np-a), and as inappropriate when they were essential to move the lesson towards attainment of the learning objectives (np-i). Coding was discussed with a second coder until consensus was reached. Six out of 20 KQ codes were present in at most one fragment and were excluded from the analyses. These concerned, for example, procedural codes, which are not relevant for the conceptual nature of ISI, and codes related to lesson design issues, which are not relevant for lessons not designed by the PSTs. The analyses involved tabulating the presence and appropriateness codes and searching for patterns.

Results and discussion

Table 1 shows the results of the analysis. It shows, for example, that Alfred and Demi were not aware of the purpose of the lesson in 27 to 28% of the fragments. Another result is that inappropriate (absence of) teaching actions often concern the failure to correctly interpret or respond to students' conceptual input, and to provide correct conceptual explanations of the content. Lastly, the use of mathematical language was largely absent from the lessons, apart from Alfred and Demi defining a sample. This is not surprising given that ISI is informal by definition and stimulates the use of context language. The above examples thus show how quantifying the presence and appropriateness of teaching actions helps to overall impression of PSTs' MKiT. Qualitative analyses could provide more depth to these results.

In this paper we present a study regarding a professional development course for primary and lower secondary teachers designed in the frame of a model of Mathematical Teachers' Specialised Knowledge (MTSK) conceptualization. In particular, taking inspiration from the subjectivist approach to probability, the teachers are involved in a context of betting games facing the problem of quantifying the degree of confidence of an event. We will focus on some steps of a collective discussion emerged in one of the meetings analysing them by the MTSK frame. Starting from this analysis we discuss the implications regarding the use of this kind of settings for developing teachers' knowledge in the field of probability.

Keywords: Probability, subjectivist approach, Mathematic Teachers' Specialised Knowledge.

Introduction

In the last years the topic of Probability has become an increasingly central topic in the national and international curriculum around the world (Batanero et al., 2016). Also, the research in mathematics education is giving much more attention to this topic, focusing both on the pupils and the teachers (e.g., Ireland & Watson, 2009; Chernoff & Sriraman, 2014). Some studies (Franklin & Mewborn, 2006; Chick & Pierce, 2008) point out that teachers' training in the field of probability is not enough to enable them to deal with challenges posed by the work with pupils. Several teachers present difficulties similar to their students' ones in managing basic concepts (Prodromou, 2012). Moreover, their pedagogical content knowledge in probability appears to be not appropriate (Batanero et al. 2004) and they seem to have scarce experience in conducting experimental activities with students (Stohl, 2005). In this view, Batanero et al. (2016) have highlighted the necessity of leading research on the components of teachers' knowledge and of designing materials for teachers' professional development concerning probability.

In this paper we propose an analysis regarding a professional development course (PD) for primary and lower secondary mathematics teachers. This PD was designed referring to the subjectivist approach to probability (de Finetti, 1931) and to the model of Mathematical Teachers' Specialised Knowledge – MTSK (Carrillo et al., 2018). In particular, the PD has the aim of challenging the teachers' mathematical knowledge and allowing them to invest in designing meaningful activities and contexts for teaching probability. The simulation of betting games has been the background for this specific PD and one of the games explored was the one related to betting on the sum of the two faces outcoming when rolling a six-sided dice.

In this study we discuss how the autonomous creation and modification of quotas, together with the debate about the associated decisions and the stabilization of quotas, have activated in teachers processes of qualitative and quantitative refinement of the degree of confidence, associated to each possible event. This discussion aims at answering the following question: Which element of specialised Knowledge on the Topic (KoT) of probability is possible to trace in teachers facing the problem of quantifying “quotas” in a context of betting game? These elements could be revisited in a perspective that allows the construction of a probability measure to be rooted on a subjective choice (de Finetti, 1931).

Theoretical framework

Teachers’ knowledge plays a crucial role in students’ learning process (e. g. Ball, Hill & Bass, 2005; Boyd et al., 2009; Nye, Konstantopoulos & Hedges, 2004). For this reason, the research interested in teachers’ knowledge has been an emerging focus of attention in the last years and, in this scenario, different approaches were designed and explored in order to help understanding the specificities of such knowledge. In particular, the MTSK’s model was proposed to catch better the complexity and the specialised nature of this teachers’ particular knowledge. It comprises two main domains: Mathematical Knowledge (MK) and the Pedagogical Content Knowledge (PCK) in which three subdomains are considered.

KoT’s sub-domain (Knowledge of Topics) concerns mathematics content itself and refers to the teachers’ knowledge related to definitions and notions about each specific mathematical topic, its own set of properties, the intra-conceptual connections between the single items’ content of the topic and the understanding of its foundation and history. KoT refers to a mathematical specialised knowledge as it comprises the teacher mathematical knowledge situated in the context of practice and thus it is a knowledge only required for the task of teaching mathematics. It is composed by a set of categories: procedures; definitions; properties and foundations; phenomenology and applications; intra-conceptual connection. This subdomain includes teachers’ knowledge on different representational systems about the specific mathematical topic and the different meanings connected with the procedures related to that topic. According to the MTSK model a sound KoT allows teachers to manage mathematical procedures in an aware way and to master the meanings connected to the different procedures. Mathematical epistemological aspects, and so all the forms of explorable examples in a real context or in connection with other disciplines, characterise the category of phenomenology and application, useful to contextualise a problem and a situation.

In this vision, in the field of probability, it’s important to understand which the kind of specialised knowledge is that a teacher needs to have and which the sub-domains are where these knowledge can be located. Specialised knowledge of probability is identified in this paper with the words "KoT - category name" to simplify the reading.

It is desirable that a teacher has a strong KoT that involves, among other things, the fact that probability needs to be seen not only in the classic probability’s vision, but also with the frequentist and subjectivist approach. These three kinds of approaches are linked to each other (KoT - intra-conceptual connection). It is also relevant that the teacher should have a knowledge of the definition and the meaning of probability, which allows to know the potential of each approach.

Let’s take the example of the "dice game", that it is also the context of the discussion that we will analyse later, and consider the problem of the quantification of the degree of confidence of events “sum of faces of two six-sided dice” (KoT - phenomenology). This issue can be faced using all the three approaches of probability (KoT - definition, properties and foundation).

The classical approach to probability sees the probability’s measure like a fraction between the number of favourable cases of a given event E and the number of all possible cases of a given event space (KoT - definition). Thus, according to the classical approach, in Figure 1 are reported, with the black colour, the probability’s measures associated with each sum (listed in green and unpacked in orange and blue) of the problem (KoT - procedures) presented in this paper.

					6+1

Figure 1: probability’s measures associated with sum from 2 to 12

In the frequentist approach, if an experiment is repeated in the same conditions for a considerable number of times (KoT - phenomenology and application), the relative frequency of an event is considering a first reasonable valuation of the degree of reliability of the occurrence of the event itself (KoT - definition, properties and foundation). With “relative frequency” is meant the ratio between the number of occurrences of an event (meaning the number of times that an event happens, that can be "how many times the sum 6 came out of the dice") and the number of accomplished proves (that can be “the number of times we roll the dice”). By the increasing of the number of experiments or accomplished proves (potentially for an infinite number of times), the value of the frequency tends to the theoretical value of probability, that is the value given to the classical probability (law of large numbers- KoT - definition, properties and foundation).

The construction of the probability theory from a subjectivist point of view has emerged from the intention to give to the probability’s meaning a psychological basis. In particular, the probability of an event is a quantitative measure of the degree of confidence based on the judgment that events occur (KoT - definition, properties and foundation). In this perspective, what really matters isn’t the concept *"what I foresee, will happen, because I foresaw it*” but, instead we should focus on the question “*why do I foresee that this event will happen?"* (de Finetti, 1931). The answers to the query “why different degrees of confidence can be attributed to different events” are various: reasoning based on sensations, on statistical analysis or on assessments that rely on the combinatorial calculation. Based on the subjectivist approach, the definition of probability P of an event E can be given supposing that a bookmaker is obliged to accept bets on a certain number of events, including the event E (KoT - phenomenology and application).

The bookmaker (B) has the authority to decide the price p that a bettor (G) has to pay to bet on some events at stake and to collect the amount 1 if the event E verifies. G has the authority of deciding to pay the price related to the chosen event in order to collect 1 or to pay S times that price ($p \times S$) to collect, in case of victory, S times that amount 1 ($S \times 1$).

If G decides to bet on the event E, B collects the price $p \times S$ from G who, if the event E is verifies, collects S. Let's indicate this situation as *pro E bet*. In de Finetti's frame another possibility is provided: if G decides to bet against the verifying of E, B will be obliged to pay $p \times S$ to G if the event E doesn't verify (G-wins), or to collect $(1 - \text{p})\text{S}$ if the event E verifies (G loses). In this way, G is forcing B to play money on an event using the prices set by B. Let's indicate this situation as *cons E bet*.

Regardless of the opportunity to build the definition of subjective probability, however, it seems useful to take into account that, according to this approach, the probability is *"the mathematical theory that teaches to be coherent"* (de Finetti, 1931). In a betting game contest, probability is the measure of the "degree of confidence values" to be attributed to events in order to "not enable competitors to win with certainty" (de Finetti, 1931).

Context and Method

The research presented in this paper is part of a PhD project that the first author is developing with the focus on mathematical teachers' specialised knowledge in the field of probability. For this project of research, a PD was designed and implemented and it involves primary school teachers and lower secondary school teachers together with their pupils. The analysed PD, which took place last year for a total of 12 meetings; it involved 8 teachers, 4 of primary school and 4 of lower secondary school. The teachers of the PD have a very different educational background and so their background in stochastics is very heterogeneous. The second part of the PD was interrupted due to the COVID-19 pandemic. The purpose of the PD was to make explicit the specialised mathematical knowledge around the deepening of the probability construct, starting from the de Finetti (1931) vision about subjectivist approach.

An initial part of the meetings was used to develop and expand the teachers' KoT. For this purpose, from the beginning teachers were put in a situation of game immersion. The game consisted in betting on the sum of the two faces outcoming in the six-sided dice's roll (both white) and in establishing the quotas to be allocated to each possible sortie (sums from 2 to 12, including). The quota is commonly understood as the multiplication factor that is applied to the player's bet to determine the amount that the same player will be entitled to collect if the bet event E occurs. The challenge with the teachers was to establish quotas so as to be coherent to de Finetti's vision (1931) in order to *"not enable competitors to win with certainty"* (de Finetti, 1931).

The setting of the classroom has been arranged in order to have two gaming stations using the game board depicted in Figure 2 that was designed and built for this PD. Some teachers were given the role of bookmaker (those who set quotas), while the other teachers were given the role of bettor. Taking turns, each teacher played both roles in the game. During the betting sessions, the teachers had the opportunity to identify elements in the dynamics of the game and so to rethink the criteria with which they chose the first quotas and, possibly, to modify them.

BET MONEY											
SUM OF THE VALUE OF TWO SIX-SIDES DICE'S FACE	2	3	4	5	6	7	8	9	10	11	12
QUOTES											
POTENTIAL WINNINGS											

Figure 2: Game board to bet

The purpose of KoT phase's meetings, was to study the dynamics, created in the group of teachers, to analyse the idea of probability that an adult has and how this idea of probability is managed and used. All the discussions were recorded and transcribed. For this study, we propose the analyses of some excerpts of the discussion that took place during the fourth meeting. In order to comment and discuss the choices of bookmakers and bettors, in this specific meeting teachers were involved in a simulated game session, that provided the possibility, for the first time, to do *pro E bet* but also *cons E bet*.

For privacy reasons we will use pseudonymous for the teachers' names.

Analysis and discussion

After remembering the *pro E bet* modes and explaining the dynamics of the *cons E bet*, each teacher took some time to set the quotas for each event and to share them with the group.

In this paper are reported, in Figure 3, the productions of Alba (in red), of Giorgio (in pink) and of Mirco (in violet) – in the order in which the quotas are shown in the figure, respecting chronologically the sharing's order of the teachers with the working group.

SUM OF THE VALUE OF TWO SIX-SIDED DICE'S FACE	2	3	4	5	6	7	8	9	10	11	12
ALBA'S QUOTES	10	9	8	6	5	5	6	5	7	8	9
GIORGIO'S QUOTES	4	5	6	8	8	8	8	8	6	5	4
MIRKO'S QUOTES	36	18	12	9	7,2	6	7,2	9	12	18	36

Figure 3: Representation of teachers' quotes

Mirco fixed the quotas symmetrically, using the inverse of the classical probability measure. The quotas set by Alba and Giorgio are very different: Alba chose to assign higher quotas to less probable events (this choice entails an higher profit in a less probable event) and lower quotas to more probable events (KoT - phenomenology and application). Giorgio wrote the quotas using a contrary criterion. But during the simulation of the game and the related discussion, Giorgio realised that his quotas earned less money to the bettor who risked more and vice versa (KoT - phenomenology and application), so at the very first part of the discussion he said:

Giorgio: My reasoning upstream was like Alba's one, but I was wrong writing the numbers.

Alba: If a person thinks about the law of large numbers and calculates all the ratio between favorable cases and possible cases, it should be a Gaussian that peaks on the “sum 7”. Because “sum 7” has more combinations, so quotas need to be symmetrical around this point (referring to “sum 7”). If I wanted to give “symmetrical quotas”, I would really choose quota five to “sum 7”, quota six to “sum 6”, quota seven to “sum 5” ...

Alba, more qualitatively than quantitatively, employed a criterion which is consistent with her classical probability’s knowledge (KoT - definition, phenomenology and application).

The meeting led to the need to create an “ideal” and “unrealistic” simulation game, in which it is possible to roll the dice a very big number of times, and so, to rely on the law of large numbers. Ciro is the educator who mediated the discussion:

Alba: Let’s say I have to play 36 times; I play 36 times.
Ciro: A million times.
Alba: Let’s imagine rolling the dice 36 million times. Let’s consider 36 rolls: I’m extrapolating the 36 rolls from the case of the million. So, out of 36 rolls: the “sum 2” comes out one time, the “sum 12” comes out one time, the “sum 7” comes out six times. Now, what should I do? In 36 rolls I decide that I bet all 36 bets only on one sum. Let’s do the math!

Alba referred to the frequentist approach of probability (KoT - phenomenology and application) to create the "ideal" and "unrealistic" situation described above. Moreover, Alba quantified the “big number of times” with the number "36 million" and normalised this number to “36 rolls” using, in a non-explicit way, the combinatorial calculation with which it is possible to unpack 36 total possible combinations by summing the faces of two six-sided dice (like in Figure 1). The knowledge about the frequentist definition of probability allowed Alba to use the classical definition of probability to predict what would happen with frequencies (KoT - intra-conceptual connection), since supposing an infinite number of throws the relative frequency tends to the classical value of probability.

Paola: If the bookmaker, in this situation, wants to ensure a certain gain, he must choose quotas lower than the probability value. In this sense, if “sum 2” has 1probability out of 36, the quota must not be 36, but must be lower.
Alba: Quota 35 would be enough to make him earn.
Paola: Yes, the bettor would lose a coin.

In this example, in the situation previously normalised by Alba, for 36 rolls the bettor plays *pro “sum 2”* using each time 1 coin and paying 36 coins in total. Ideally, the "sum 2" event occurs once out of 36 launches and the bettor wins 35 coins. He pays 36 coins, winning only 35. The bookmaker earns 1 coin.

Giorgio: But are we talking about the previous game where you couldn’t bet *cons E*?
Ciro: Why are you saying that?
Giorgio: Because in a situation like this, the first thing I would do is pointing *cons “sum 2”*.

Giorgio remembered that there was the possibility to play *cons E* (KoT - phenomenology and application). With this move, the bettor would reverse the results of the "ideal" bet. If the bettor bets 36 times *cons "sum 2"*, at the end of the 36 rolls, he wins.

Ciro: Using what Giorgio said: so, is the bookmaker at risk? How does the bookmaker respond to this move?
Paola: So, I have to put higher quotas.
But the bettor can always bet in both ways.

At first Paola, not explicitly, seemed that she had changed idea radically: previously she proposed to use “quotas lower than the probability value”, then she was proposing to use quotas higher than the probability value. At the same time, she verbalised this "idea’s change", Paola realised that, even doing so, the bettor could overturn the situation, once again, betting *pro E* for 36 times.

Mirco:	And so, this situation is impossible to be solved.
Ciro:	If you use lower quotas?
Alba:	You lose.
Ciro:	If you use higher quotas?
Mirco:	You have to use equal quotas.
Ciro:	Equal to what?
Paola:	To 36 (referring to the “sum 2”).
Ciro:	Yes, quotes equal to the inverse of the probability value.

It is significant that Mirco said that it wasn’t possible to solve that situation: he was the one who - we remember it - from the beginning used the inverse of the probability value to choose his quotas (Figure 3). In this discussion we could appreciate the collective knowledge development in constructing a criterion for establishing quotas (KoT - phenomenology and application) in order to ensure that none of the competitors would win with certainty (de Finetti, 1931).

Conclusion

The goal of this research is twofold: on one hand we tried to develop an innovative educational approach to the topic of probability; on the other one we attempted to identify useful elements for experiences of teachers’ professional development. In particular, taking inspiration from the subjectivist approach to probability (de Finetti, 1931), we designed a particular PD for primary and lower secondary teachers involving them in a betting game context in which they had to quantify the degree of confidence associated to each possible event of the game. The analysis of the excerpt of the discussion showed how the refinement process of the degree of confidence associated to each possible event by the teachers involved both qualitative and quantitative aspects: qualitative, because teachers gave meaning to their knowledge; quantitative, because they used, especially at the end of the process, their knowledge of the classical and frequentist probability definition as a tool to make conscious choices. The actual mathematical systematisation of the subjectivist approach to probability, and in particular the results proving its consistency with the other two approaches to probability, is a fascinating piece of Mathematics and it entails many mathematical formal and complicated structures and techniques. With this study we are not proposing that the subjectivist definition of probability should be explicitly taught during PDs for teachers in service and students at school, but we are exploring its potentiality as educational innovative paths for teachers and students – to avoid proposing not trivial probability activities. In this episode emerges that a betting game like that described above (which follows an idea by de Finetti’s) actually generates a dynamic that leads to the coherent construction of a probability measure based on the choices of the players. This provides a strategy for teachers to design educational paths where a (classical or frequentist) definition of probability is not given a priori, but it is established starting from the degree of confidence expressed by learners. In this case, the probability measure can be given as the reciprocal of the quote. In this perspective, in the second part of the PD we fostered and challenged teachers to design didactical paths of probability for their students, taking inspiration from the experience lived during the PD and the knowledge that it developed. In further studies we will address also these parts of the research.

In this paper we describe a pre-service teacher professional development program based on Meta-Didactical Transposition model. We focus on the encounter between the praxeologies of researchers/teacher educators and pre-service primary teachers. We show how specific tasks for teachers and information provided by a standardized assessment database (GESTINV) can be used to establish a link between Italian National Evaluation System and pre-service teacher professional development. We present some aspects of mathematics specialized knowledge that pre-service teachers declare to be improved during the educational program. Pre-service teachers' reflections on their specialized knowledge are framed into MTSK model.

Keywords: Teacher education, pre- service primary teachers, teacher knowledge, MTSK model, standardized tests.

Introduction

The use of standardized tests in mathematics for both international surveys (such as PISA and TIMMS) and national evaluations of school systems is widespread, and the results of these tests are also often disseminated in the press and commented on by policymakers and researchers (Doig, 2006). In order to not confine these data to the ranking of students, schools and nations it is essential to develop the dialogue between standardized assessment and educational research (De Lange, 2007). The Standardized Assessment data can also become effective and usable tools for improving teaching and learning processes. Our study fits in this stream of thought; in particular, we will show educational potentials of Italian Standardized Assessment by using theoretical tools to interpret the quantitative data they provide and the macro phenomena that emerge from the complexity of educational systems (Bolondi et al., 2019;, Ferretti, & Bolondi, 2019). Quantitative data should be interpreted and intertwined with a qualitative analysis of tasks. This is possible by means of an encounter between Standardized Assessment, mathematics education research and teacher education. In this paper we present an example of pre-service teachers' professional development that profits from data collected by the Italian National Evaluation Institute for the School System (INVALSI). We will show how to create a link between the Italian National Evaluation System and pre-service teacher professional development programs in order to improve mathematics teaching school practices. In our study we argue how the analysis of standardized assessment results should impact the improvement of the teaching and learning of mathematics. We have been working for many years in this perspective and we have carried out educational projects using data from INVALSI tests as an object of reflection for teachers (Martignone, 2017; Ferretti et al., 2018; Ferretti, et al., 2020, Santi et al., in press). It must be stressed, however, that this use of INVALSI tests is favored by the fact that in Italy the framework of INVALSI tests is closely linked to the National Guidelines and it takes into account the research in mathematics education. In this paper we describe some teacher education activities carried out during a pre-service primary teacher professional development course. During a university course teacher educators/researchers shared with pre-service teachers some theoretical tools in order to conduct an a priori qualitative analysis of tasks from INVALSI tests. As final reflections, after the introduction of the Mathematics Teacher Specialized Knowledge model - MTSK Model (Carrillo-Yañez et al., 2018), the educators/researchers asked pre-service teachers about which aspects of mathematics specialized knowledge the course activities brought out and developed

Theoretical framework

Mathematical knowledge lives in the institutional dimension where mathematical objects emerge from socio-cultural activities shared by individuals belonging to one or more institutions. The development of mathematics, teaching and learning of mathematics and mathematics teachers' education are characterized by the dialectics between the personal and institutional relation to knowledge (Chevallard, 1985). The Anthropological Theory of Didactics (Chevallard, 1985) conceives human activity as a praxeology, which is made up of a set of tasks that drive the practice (praxis), the techniques that allow individuals to solve the problems, and the knowledge and discourses (logos) that ground the techniques. To describe and interpret the practices of mathematics educators/researchers and those of teachers who are engaged in teachers' education activities, in our study we use theoretical lenses from Meta-didactical Transposition Model (Aldon et al., 2013; Martignone, 2015). The teacher professional development program described in this paper can be seen as an instantiation of the Meta-Didactical Transposition model. In regard to the institutional dimension, the teacher education process involves the Italian Ministry of Education via the INVALSI institute, Italian Schools and Universities. Researchers/teacher educators and teachers share didactical praxeologies and reflect on them. Researchers bring to the fore tasks and techniques related to the epistemology of mathematics and mathematics education studies. As we will show in the next paragraph, the shared praxeology is linked to the analysis of mathematical and pedagogical issues in INVALSI tasks about rational numbers, but not just this. Theoretical lenses for reflecting on mathematics teacher specialised knowledge are shared and discussed. In specific, the MTSK model (Carrillo-Yañez et al., 2018) was introduced. MTSK model distinguishes between mathematical knowledge (MK) and pedagogical content knowledge (PCK), both of which are considered as sub-domains of the teacher's specialized knowledge. As concerns the MK, are part of the Knowledge of Topic (KoT) the knowledge of definitions, properties, procedures, representations, etc. The knowledge about how to connect activities in different domains of mathematics is part of the Knowledge of the Structure of Mathematics (KSM). As knowledge of Practices in Mathematics (KPM), we can identify, for example, the knowledge of how to prove, justify, define, make inferences and inductions, give examples and counterexamples. Also Pedagogical Content Knowledge is divided into three sub-domains. The Knowledge of Mathematics Teaching (KMT): knowledge of theories of mathematics teaching or knowledge of teaching resources, materials and technologies, but also knowledge of strategies for introducing and representing contents and concepts, etc. The Knowledge of Features of Learning Mathematics (KFLM): knowledge of theories of mathematics learning or knowledge of the way in which pupils interact with mathematics. The Knowledge of Mathematics

Learning Standards (KMLS): knowledge of expected learning outcomes and teaching goals in different school segments. The MTSK model in addition to detailing these subdomains of Mathematical Knowledge and PCK explicitly highlights the centrality of teachers' beliefs about mathematics and mathematics teaching-learning. For this reason, in our opinion, MTSK model is suitable to be used by teachers to explore, reflect, discuss on what they think/believe about their specialized knowledge developed during the education program. Therefore, in our study we show that MTSK model can be used by pre- service teachers to reflect on their knowledge during a teacher education program. The interpretive lenses provided by MTSK model have become part of the logos of shared meta-didactical praxeologies. Moreover, the MTSK model becomes a theoretical object shared between researchers and teachers to reflect on tasks and practices. Following MDT model, in our teacher educational program the researcher/teacher educator play the role of broker (Rasmussen et al., 2009) who belongs both to the community of mathematics experts and to the community of the teacher education program. The broker facilitates the sharing of knowledge and practices from one community to the other by drawing on boundary objects (Bowker and Star, 1999). Boundary objects are meaningful tools, ideal or material, in both the communities and they put them in touch, although with different nuances and uses that characterize their respective praxeologies. Boundary objects can be material artefacts, digital technologies, mathematical procedures etc. In our teaching education programs the database of INVALSI tests, GESTINV, acts as a boundary object between communities of researchers and future teachers. GESTINV (www.gestinv.it) is a structured database containing all the data of the INVALSI standardized assessments from the 2008 surveys of all surveyed domains. In detail, it contains 2121 items from the INVALSI mathematics tests. There are more than 25,000 registered users in GESTINV and an average of 200 accesses per day. These data, together with its structured information in line with the theoretical framework of INVALSI tests, promote Gestinv as a tool to be implemented in the design of teacher education models (Ferretti et al., 2020). There are many ways in which the database can be used; different forms of research can be carried out within it (National Guidelines, scholastic year, school grade, content, percentage of correct/wrong/invalid answer). In our research, GESTINV plays an important role in providing teachers and researchers with an interactive tool to access a wide range of information and feedback concerning the processes of learning and teaching mathematics. In particular, the results of the INVALSI tests highlight and quantify relevant macro-phenomena, which can be interpreted according to the methods and results of research in mathematics education. By means of specific tasks for teachers the information provided by GESTINV can be used to establish the link between the data of the standardized assessments and pre-service teacher professional development (PTPD), assuming the role of boundary object. In this paper we show some teachers' a-posteriori reflections on specialized knowledge emerged and developed in the analysis of INVALSI tasks selected by means of GESTINV. The pre-service teachers use theoretical lenses from MTSK model to state which aspects of specialized knowledge are improved at the end of the PTPD program.

Methodology

In this paper we show some activities carried out during a pre-service primary teacher professional development university course (conducted in presence in 2019). This course lasted 40 hours and each activity consists of the following phases:

Introduction. The teacher educators address the mathematical contents selected for the educational activity from an epistemological and didactic point of view and they also present GESTINV. The teacher educators share with future teachers' possible interpretative tools and research results that can be useful in the analysis of INVALSI tasks and data. As we already stressed INVALSI tests' theoretical framework is linked to the National Guidelines and also for this reason the macro-phenomena emerging from the INVALSI tests are meaningful for the analysis carried out with future teachers.

Analysis of an example. The teacher educators analyze an example of INVALSI tasks selected by using GESTINV.

Group activity. The teacher educators ask teachers to analyze INVALSI tasks on specific topics. Teachers work in subgroups of a maximum of 4/5 people. They choose mathematical contents with reference to the Italian National Guidelines of primary school. They should identify one or more learning difficulties. The small group activity takes place in line with the characteristics of a Community of Inquiry in the sense of Jaworski (2006). The group activity aims at the construction of a multimedia product, an artefact, the design of an activity for the students, etc. that highlights the reflections, beliefs and convictions of the future teachers involved.

General discussion. The subgroups present their productions to the whole group. Each presentation is discussed in order to highlight beliefs and convictions, address doubts, difficulties and unclear contents. Then teacher educators presented and discuss with teachers the MTSK model.

At the end of the course, we administered an open-ended questionnaire to the pre-service teachers in which they were asked if and how, in their opinion, the activities carried out during the course had increased their knowledge by referring to each sub-domain of the MTSK. Specifically, the teachers answered this question: "Using the MTSK model, explain which topics covered during the course, which tasks and activities contributed, in your opinion, to the development of your specialist knowledge". The teachers knew that answers would not have been assessed. Data relating to 52 questionnaires administered to the pre-service teachers a have been collected and analyzed. The gathered data were analyzed by an inductive content analysis (Patton, 2002); by using the MTSK theoretical lens, a top-down were performed.

INVALSI tasks analysed by pre-service teachers

In this section, we describe an example which is part of a broad prospective primary teacher academic course, in which different contents were involved and macro-phenomena and teaching practices were analyzed and framed with different constructs of mathematics education. The tasks selected, according to cross-research allowed by GESTINV according to categories described above, belong to INVALSI standardized tests administered to all Italian grade 5 students. Figure 1 shows the texts of the INVALSI tasks and the national percentages of correct, wrong and invalid answers.

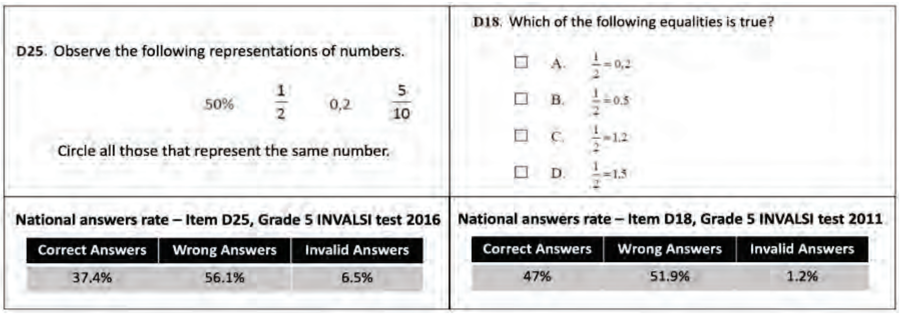

Figure 1: INVALSI items and national rates (www.gestinv.it)

As we can see in the Figure 1, in both tasks less than half of the students nationwide gave the correct answer. INVALSI provides percentages for each option chosen by the students and these data are available in the GESTINV database. These tasks were identified by teachers through the GESTINV database, using the "Guided Search" function by searching for tasks from the grade 5 INVALSI tests concerning rational numbers and with correct response rates below 50%. Among the items returned by the database, the items D25 and D18 were selected because they clearly show some possible errors related to the representations of rational numbers. By means of the qualitative analysis of the tasks and the quantitative results, researchers/TE and pre-service teachers can share ideas and reflections. Starting from the analysis of these data researchers/teacher educators and pre-service teachers discuss about students' difficulties in conceptualizing and making sense of decimal and fractional notations (some of the main findings of research in the field were deepened, e.g. Iuculano & Butterworth, 2011, Ni & Zhou, 2005). As a matter of fact, they notice that quantitative results show that many Italian students gave the wrong answers, in particular in D18 we can notice that 33.5% of the students chose option C. The teacher educators/researchers address the mathematical content selected for the task from an epistemological and educational point of view. Furthermore, they discuss with pre-service teachers the main research findings of the research that can help frame the macro-phenomena that emerged (Ball, 1993; Empson & Levi, 2011). As highlighted in literature, often, many difficulties are related to the management of the different representations of rational numbers, both in terms of the comparison and ordering of fractions and their comparison with decimals. They agreed that, in order to answer both tasks correctly, it is necessary to properly perform treatments between different semiotic representations (Duval, 2006).

Pre-service teachers' reflections

In this paragraph we show some excerpts from per-service teachers' answers to the questionnaire administered at the end of the teacher educational program. Pre-service teachers state that the analysis of the INVALSI tasks was useful in strengthening their knowledge about the process of teaching and learning rational numbers. They stress the importance of discussions about students' learning processes, possible students' difficulties and effective/ineffective mathematics teaching practices. By using the interpretative lenses given by MTSK model, they declare an increase in their Mathematics Teacher Specialized Knowledge, in particular in their Pedagogical Content Knowledge (PCK) declined into three subdomains: Knowledge of Mathematics Teaching (KMT), Knowledge of Features of Learning Mathematics (KFLM) and Knowledge of Mathematics Learning Standards (KMLS).

For reasons of brevity, we will only provide a few examples of statements for each PCK sub-domain.

As far as KMT is concerned, some pre-service teachers declared:

PT_17: As far as fractions are concerned, […] I have become aware that they need to be taught from the beginning to represent the same concept in different semiotic representations.

PT_18: Knowing the different representations of a mathematical concept means recognizing its connections and underlying structure. In this case, we can see how each number is represented differently by a percentage, a fraction or a decimal number. Through the analysis of this item we can see the strong connection between percentages, fractions and decimal numbers, which every teacher needs to know very well in order to foster the most effective teaching-learning process possible from a mathematical point of view.

PT_21: I have therefore understood that the teacher's task will be to offer children different representations of the same mathematical object and will have to make them aware of this knowledge. […]

Below we provide excerpts referring to KFLM:

PT_17: Thanks to this activity, I became aware that for students one representation is not the same as another.

PT_39: I have seen that students have difficulties in both processing and converting, leading to misconceptions about fractions.

Finally, here are some pre-service excerpts referring to their KMLS:

PT_21: As stated in the National Guidelines, children at the end of primary school will need to be able to handle all the different representations and so it is up to the teacher to structure pathways and activities to help students achieve this understanding.

PT_23: With this topic, I got to know the standards of knowledge and skills possessed by the pupils, as well as what learning objectives are required at the end of primary and secondary school. This activity has also underlined that it is necessary to respect the design of the objectives as much as possible, defined in such a way that does to create inconsistencies in later grades.

As we can see in these excerpts, pre-service teachers reflect on their PCK, in terms of KMT, KFLM and KMLS, and recognize aspects of their knowledge that have emerged and developed.

Conclusions and further directions

In this paper we presented an example of a teachers' professional development program for primary pre-service teachers in which meta-didactic praxeologies, linked to the analysis of selected items from the national standardized assessment INVALSI test, were shared. We have shown how the use of GESTINV database, as a boundary object in professional development paths, allows an improvement of pre-service mathematics teacher specialized knowledge. As a concluding activity of the program the pre-service teachers were asked, using the MTSK model, to identify what specialized knowledge they think/believe they had developed during the professional development program. The MTSK model was used by pre-service teachers to reflect on teaching and learning processes. MTSK model become part of logos component of meta-didactical praxeology and it could also be considered a theoretical boundary object between the two communities of researchers/educators and pre-service teachers. This aspect as well as the analysis of the pre-service teachers' declarations concerning the MK domain will be objects of our next studies. As literature highlights (i.e. Doig, 2006), standardised assessments, designed with the aim of assessing mathematical learning at the system level, are increasingly having implications from an educational, didactic, cultural-historical and political perspective at both global and local levels. Using data from standardized assessments in pre-service teachers program fits into this line of research and it increases the potential of the educational implications of linking standardized assessments to mathematics education.

Exploring Indonesian prospective teachers’ teaching belief and teaching practice

Linda Devi Fitriana

University of Debrecen and MTA-ELKH-ELTE Research Group in Mathematics Education, Hungary; linda.fitriana@science.unideb.hu

This study aims to report preliminary findings on prospective teachers’ teaching beliefs and teaching styles when implementing their proposed problems. Three second-year Indonesian prospective teachers who were accustomed to the teacher-centered teaching tradition were involved in a brief collaborative workshop. In the workshop, they get an advantageous opportunity to broaden their perspective about mathematics teaching through sequential activities, such as formulating problems collaboratively, teaching practice, reflecting on their teaching practice, and providing suggestions to each other. After the workshop, they expressed their belief in the ideal problem-solving teaching style and implemented their proposed problem.

Keywords: Teaching belief, teaching practice, prospective teacher.

Introduction

In the early 1990s, the usual mathematics teaching technique in Indonesia was to directly explain the solution of mathematical problems (Kuipers, 2011). Subsequently, the most recent curriculum has been introduced as an attempt to upgrade educational traditions with the cornerstone: place problem-solving as a challenging skill to master and position students at the center of learning to collaborate and share ideas. Nevertheless, some challenges remain in practice, such as the persistence of conventional teaching traditions along with belief that an effective teaching style is to manage the class completely. Thus, when students from this environment become prospective teachers, it is not surprising that this belief naturally exists in their minds.

To support the new curriculum and address the existing belief for better teaching quality, a collaborative workshop was held with two principal activities: problem-posing which cannot be considered part of the conventional teaching tradition and implementing the posed problems in the classroom, which is directed towards a problem-oriented approach. Involving prospective teachers in problem-posing activities and asking them to implement their problems, accompanied by discussions, can be fruitful endeavors to enrich their perspective to mathematics teaching. Implementing their own problems appertains to the classroom activity in which prospective teachers will face in the future. Providing opportunities for prospective teachers to practice teaching from the early years of the training while most teacher preparation programs put it off towards the final year of the program constitutes a complementary point of this study.

This study focuses on the second principal activity and reports preliminary findings through the research questions: (1) What is the prospective teachers’ belief about the ideal problem-solving teaching after the workshop? (2) What is the teaching style of prospective teachers when implementing their proposed problem before and after the workshop? As supported by Ellerton

(2013), disclosing how prospective teachers implement their problems after experiencing problem-posing activities will contribute to the literature.

Theoretical background

When it comes to teaching problem-solving, the diversity of beliefs emerges as an influential constituent of teaching styles. Some believe that teaching should be straightforward, focusing on clear explanations to pupils (Richardson, 1996). This belief seems to have developed due to familiarity with traditional teaching practices that favor teacher-centered learning. On the other hand, some believe that teaching should actively involve students to spur their thinking skills in which can be considered as student-centered learning (Kofa, 2018).

Nowadays, there has been increasing awareness in applying student-centered learning due to its prosperous benefits. One approach to student-centered learning is problem-oriented instruction. According to Kovács and Kónya (2019), problem-oriented instruction has three characteristics: (1) students analyze the situation of a mathematical problem, (2) students critically adapt to their own and their classmates' thinking, and (3) students learn to explain and justify their thinking. Considering one feature of problem-oriented instruction that the classroom activity evolves into a critical discussion of the problem being addressed, the implementation of problem-oriented instruction can be recognized by studying talk formats. Critical discussions are triggered by specific forms of talk that support a deep understanding of concepts and robust reasoning. Sohmer et al. (2009) characterized the talk format into four as shown in Table 1.

Table 1: Talk format

Talk format	Description
Recitation	The teacher completely controls the content and direction of the conversation by presuming special right to ask the questions and evaluate students' answers. Students are positioned as seekers for the correct answers that the teacher is looking for.
Stop-and-talk (Partner talk)	The teacher gives a pointed question to the students and asks them to discuss it with one or more partners. Students are positioned as active reflectors and contributors. During small group discussions, the teacher selects key voices among students to be heard by the entire community.
Student presentation and group critique	The teacher asks the student to present his/her work in front of the class accompanied by follow-up questions proposed by the other students or teacher. The presenter student is positioned as the expert of their work.
Whole-group 'position-driven' discussion	The teacher leads a discussion on a single problem or question which has more than one answer, so that reasonable arguments appear from the students. This kind of discussion promotes active participation of the students by proposing an idea and listening to each other even before being fully competent in the discussed domain.

Supportive talk formats for problem-oriented instruction, such as partner talk, student presentation and group critique, and whole-group position-driven discussion, require appropriate teachers' behavior. Rott (2019) classified teachers' behavior when implementing problem-solving into three. In more detail, he stipulated the behavior at each problem-solving step by Polya (1945), as shown in Table 2. The classification refers to the differentiation between teachers as controllers or facilitators. The indicators show that the closely managed style represents a teacher-centered learning in which the teacher acts as a controller, while the other two styles are closer to the teachers' role as a facilitator which aims to generate mathematically rich and meaningful discussions in the classroom.

Table 2: Teachers' behavior in each problem-solving step

	Closely managed	Neutral	Emphasizing strategies
Understanding the problem	The teacher explains the problem formulation.	The teacher does not comment on the problems and does not answer students' questions.	The teacher gives hints but does not explain the problem.
Devising a plan	The teacher tells the students which approach is correct to use.	The teacher does not give any guidelines and strategic support.	The teacher hints at (ideally) different approaches and encourages the students to follow their ideas.
Carrying out the plan	The teacher gives the students concrete content-related support (often early in the process).	The teacher gives (almost) no (strategic) help and does not answer students' questions related to the problem.	The teacher gives staggered aids (motivational/feedback/general strategic/task-specific strategic/content-related).
Looking back	The teacher fixates on results; perhaps, one (arithmetic) approach is presented.	Different approaches are presented; however, strategic ideas or the differences between approaches are not highlighted explicitly.	The teacher highlights approaches and strategies; results might also be presented, but it is of secondary importance.

By studying talk formats and teaching styles, we will find the connection between those two. For instance, recitation goes hand in hand with a closely managed style, while the other talk formats assist neutral or emphasizing strategies styles. In other words, the teaching style could be detected from the tendency to use a particular talk format, whether it leads to a productive talk or not.

Both talk formats and teaching styles during the lesson might indicate tendencies in beliefs about teaching. As Rott (2019) emphasized, teachers' belief is a component of professional teacher competence that influences their teaching behavior. Moreover, analyzing talk format and teaching style will cue whether the lesson appertains as problem-oriented instruction or not. Figure 1 illustrates the relation between talk formats, teaching styles, and problem-oriented instruction.

Another effort to improve mathematics teaching is to examine teaching practices as has been done in Japan. Through lesson study, Japanese teachers discuss lessons they have planned and observed together which then direct them to look for ways to improve it and broaden their knowledge of the teaching profession (Fernandez & Yoshida, 2004). Thus, it is precious to adapt.

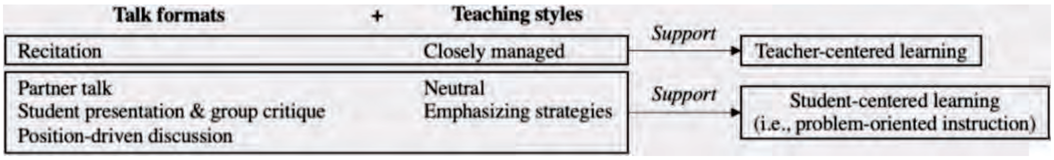

Figure 1: The relation between talk formats, teaching styles, and problem-oriented instruction

Method

The participants of this study were three second-year Indonesian prospective teachers (Vey, Ann, Kay – pseudonym) who enrolled in a 4-year mathematics teacher training program for grades 7-12 in a private university. To select the participants, 22 prospective teachers were offered to participate in the workshop and implement their proposed problem voluntarily. Prospective teachers who had a chance to implement their proposed problems with real pupils, such as those who handled a private course, a non-formal additional class outside of school which aims to strengthen the lesson provided at school, occupied the priority positions to be selected. The number of participants was limited based on several considerations: to get them more actively involved in the workshop and to make the activity during the workshop better observed since the workshop was held online due to the ongoing COVID-19 pandemic. The cornerstone of the workshop is adapting Japanese lesson study by involving prospective teachers. Figure 2 shows the problem-posing backgrounds and the implemented problems by Ann as one of the participants.

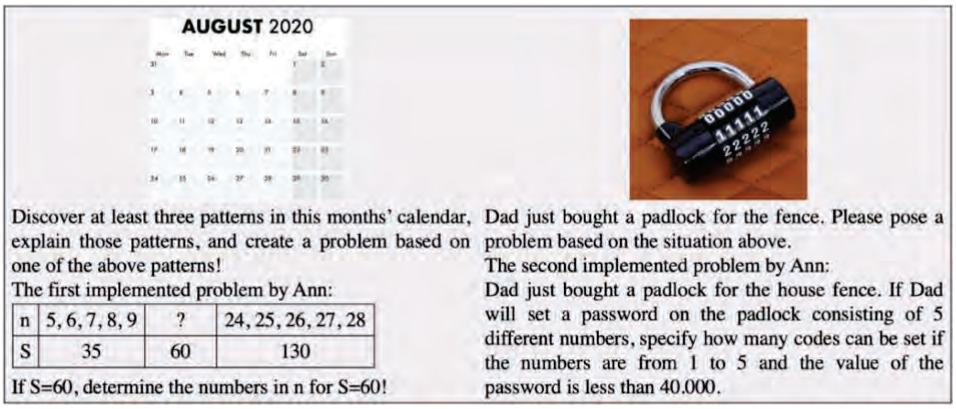

Figure 2: The problem-posing backgrounds and the example of implemented problems

Table 3: Research activities

Pre-test	Posing problem autonomously related to patterns on calendar and implementing the proposed problem to pupils.
1st meeting (50 minutes)	Teaching reflection, giving feedback to each other, and discussing how the situation in mathematics classes should be.
2nd meeting (100 minutes)	Discussing several paradigms of problem-posing: free, semi-structured, and structured problem-posing.

3rd meeting (100 minutes)	Analyzing a less feasible problem, fixing it collaboratively, and posing problem collaboratively by modifying the initial situation.
4th meeting (100 minutes)	Posing problem collaboratively by using a what-if-not strategy.
5th meeting (100 minutes)	Posing problem autonomously based on the given situation and fixing the proposed problems collaboratively.
Post-test	Posing problem autonomously related to the padlock and implementing the proposed problem to pupils.
After post-test	Filling out a questionnaire and teaching reflection.

The questionnaire was directed to capture the prospective teachers' viewpoint on ideal problem-solving teaching implementation. Among three styles, they were asked to choose which one is their ideal teaching style. Since this study is part of a larger research project, only two data are presented: data from the questionnaire after the workshop and data from the videos of teaching implementation at the beginning and at the end of the workshop. The teaching implementation data consists of 24 sections, 8 sections for each prospective teacher for the first and the second implementations. It was analyzed in terms of behavior by Rott (2019) and talk format by Sohmer et al. (2009). All teaching practice data were coded independently by two raters which resulted in 23 of the 24 cases (96%) being agreed. While the divergent code was recoded consensually thereafter.

Research findings and discussion

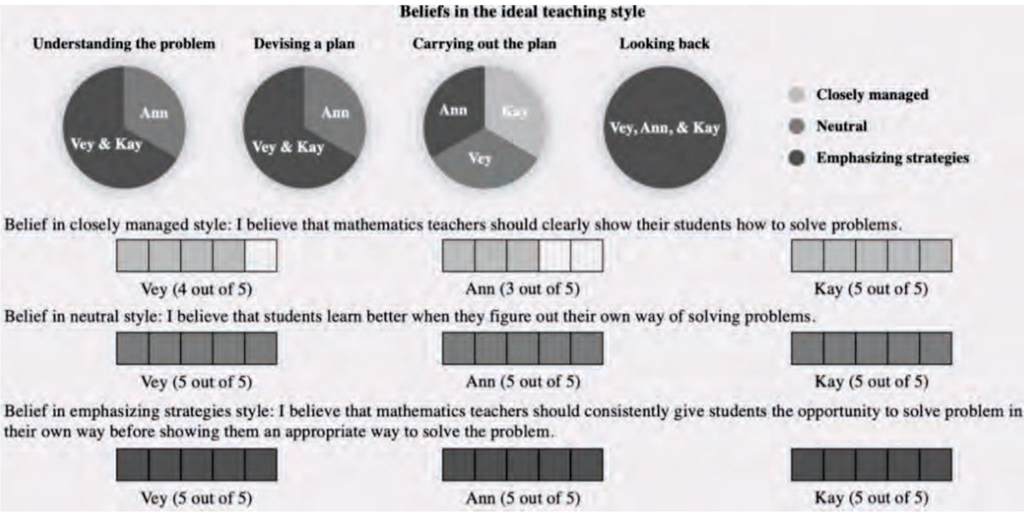

Figure 3: The results of the questionnaire

Based on pie charts in Figure 3 that show prospective teachers' beliefs about the ideal problem-solving teaching, a closely managed style was not the primary choice. It only appeared in Kay who believed in the necessity to control the class when carrying out the plan. Those findings were reinforced by the result of the second part of the questionnaire. All prospective teachers gave the maximum point to neutral and emphasizing strategies styles that signify student-centered learning.

The closely managed style became a secondary preference for them except for Kay, who did not indicate her teaching belief tendency (see Figure 3).

Figure 4 presents the prospective teachers' teaching styles and beliefs about problem-solving teaching. Considering the research of Ellerton (2013), which revealed the impact of problem-posing activities on prospective teachers while they were taking courses in teacher preparation programs and the impossibility to follow those prospective teachers into their classrooms once they became teachers, data in this study regarding the prospective teacher's teaching practice in implementing the problem they posed might be an alternative response to the condition.

In the first teaching implementation, Vey skipped the looking back step that appeared to be deemed unnecessary. As she recognized this step was consistently carried out in the lesson throughout the workshop, she stated, "Usually, if we arrive at the solution, that's all. We don't think if it's reasonable or not. Now that I think about is there should be follow-up activity like we did in this lesson". Realizing the importance of looking back step, she undertook the step in her second teaching implementation. Her teaching styles in the first and the second implementations were neutral and closely managed over the classwork activities. Particularly, in the second teaching implementation she thought that the fundamental counting rule, which is the mathematical background of the implemented problem, had been taught in school but evidently it was an unfamiliar topic for her pupils. There was a school lesson delay due to the covid-19 pandemic. This emerged as her consideration for performing the closely managed style. The only noticeable difference between the first and second implementations was the use of the talk format. In the first teaching implementation, recitation was applied in all problem-solving steps, while in the second teaching implementation, she applied position-driven discussion in the looking back step among recitations in the other steps.

Ann had been involving her pupils since the first teaching implementation. She received positive reinforcement for her behavior from her peers during a reflection and discussion meeting. They said, "I like how she communicates with her students" and "The class is active". In the second implementation, she maintained her behavior and even improved it. She obviously encouraged her pupils to express their idea by asking them to tell the strategy they used and explain their reasons. The closely managed style had been sidelined in favor of being neutral and emphasizing strategies. The combination of position-driven discussion and recitation remained her preferred talk format. She also organized student activities in which students worked on the task individually, rather than just implementing classroom work activities.

In the first teaching implementation, Kay controlled the class completely. She explained how to solve the problem without allowing her pupils to speak and only asked if they understood or not which led them to say they understood but probably not. The closely managed style with full recitation dominated her demeanor aside from trying to be neutral in the step of understanding the problem. At the discussion and reflection meeting, she received feedback from her peers. They said, "It looks like your implementation must be in accordance with your plan. You seem unfree and constrained while teaching" and "You must be confident. We are learning how to teach together. Keep your spirit up". The feedback seemed to spur her on to make improvements. Although the closely managed style continued to dominate in the second teaching implementation, she tried to be neutral in understanding the problem and emphasized strategies in the looking back step. By involving pupils, she attempted to highlight several strategies to solve the problem that did not appear in the pre-test. Both the strategy and the result proposed by her pupils were considered. She let them choose their own preferred approaches. The entire lesson was classwork activity in both implementations, but she combined position-driven discussion and recitation in the second implementation.

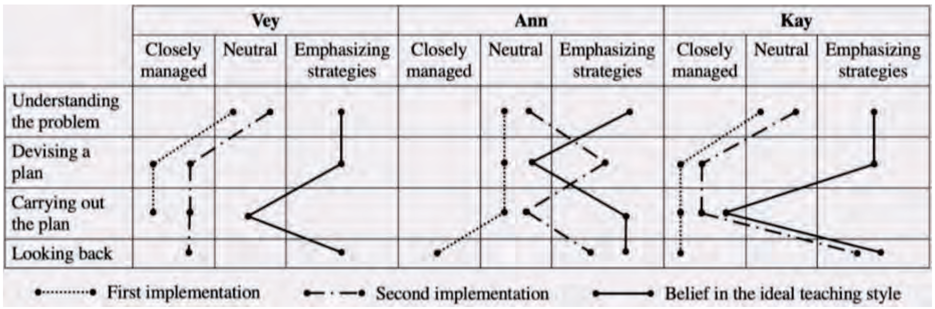

Figure 4: Teaching style and belief

The finding contributes to the literature on whether there is a link between belief and practice or not. This contradictory insight appears in Safrudiannur and Rott (2019). In this study, prospective teachers' beliefs and practices are not always in line. Among those three prospective teachers, only Ann holds a closer attachment between her belief and practice, either neutral or emphasizing strategies that belong to the student-centered paradigm. Meanwhile, belief in student-centered learning accompanied by teacher-centered implementation was found in other prospective teachers. The discrepancy between belief and practice brings out consideration of another aspect, i.e., their pedagogical knowledge since it directs them to a firm understanding on classroom management, lesson planning, and student assessment (Koehler et al., 2009).

The finding also reveals how adapted Japanese lesson study goes among prospective teachers. Discussions, sharing ideas, and giving suggestions to each other during the workshop provide them empirical experience about student-centered paradigm, as they were positioned not as receptive but active members in the class. They can reflect on the activity, make it as a shoot for their teaching belief, which then direct them to increasingly involve their pupils in the second implementation. As stated by Ambrose (2004), beliefs may lead to behavior in ways that could be depicted as habits. Moreover, their beliefs and the second teaching implementation which are more towards student-centered paradigm might be the impact of reflection and feedback activities, since reflection leads to finding new solutions and paths in teaching to improve learning (Šarić & Šteh, 2017) and helps teachers to become more successful (Lee, 2005). Thus, the whole activity during the workshop appears to be a fruitful endeavor.

Limitation, further research, and acknowledgement

This study only involves three prospective teachers in a short action. The contribution is part of ongoing research involving prospective teachers on the role of problem-posing and problem-oriented teaching in active mathematics learning. The workshop is conducted as an attempt to broaden their perspective about mathematics teaching. The author is a member of MTA-ELKH-ELTE Research Group in Mathematics Education, and this study is funded by the Hungarian Academy of Sciences through its Scientific Foundations of Education Research Program.

Developing Preservice Teachers’ TPACK Through a Virtual Number Talks Field Experience: A Case Study

Nicole Fletcher[1] and Audrey Meador[2]

[1]Fairfield University, Fairfield, Connecticut, USA; nfletcher@fairfield.edu

[2]West Texas A&M University, Canyon, Texas, USA; ameador@wtamu.edu

Field experiences are an important part of preservice teacher education. However, interruptions caused by the COVID-19 pandemic and the sudden shift to virtual and hybrid learning presented challenges for implementing classroom-based field experience opportunities. In response to this challenge, the authors developed and implemented a virtual field experience based on the Number Talks routine in our elementary mathematics methods courses. We utilize case studies to explore the ***t****echnological,* ***p****edagogical, and* ***c****ontent* ***k****nowledge (TPACK) development of two preservice teachers as they engaged in the Virtual Number Talks field experience.*

Keywords: TPACK, field experience, virtual education, preservice teacher education, elementary mathematics education.

Introduction and Focus

In Fall 2020, schools across the United States were in a time of great instability due to the COVID-19 pandemic, with schools shifting between remote, hybrid, and in-person instruction. Mathematics teacher education was also at a time of great instability as in-person, school-based field experiences were no longer available to preservice teachers. In response to this challenge, the authors collaborated with other teacher educators to develop a Virtual Number Talks Teacher Learning Cycle (Joswick et al., 2020). The authors implemented this virtual mathematics field experience in their preservice mathematics methods courses in Fall 2020. For this study, we explore the following question: How does a virtual field experience based on the Number Talks routine develop preservice elementary teachers’ technological, pedagogical, and content knowledge (TPACK)? The authors utilize case studies to illustrate examples of TPACK development as two preservice teachers engaged in the Virtual Number Talks field experience.

Background and Relevant Literature

Field experiences provide preservice teachers with opportunities to “observe and work with real students, teachers, and curriculum in natural settings (i.e., PK-12 schools)” (Huling, 1998). Due to the COVID-19 pandemic, teacher educators had to develop flexible field experiences that could be implemented in virtual or hybrid classrooms. For example, Zolfaghari et al. (2020) employed the use of multi-perspective 360 videos to provide a virtual preservice teacher field experience. Evagorou et al. (2020) shifted a conventional science, technology, engineering, and mathematics fair to a virtual delivery using technology to provide preservice teachers with this field experience while schools were shuttered. Number Talks were selected as the focus of our virtual field experience due to the structure, content, and length of the routine. A Number Talk is a short activity—usually 5 to 15 minutes long—during which a teacher facilitates a discussion with a whole class or a small group of students about a carefully designed sequence of problems (Parrish, 2010). Students solve problems mentally and the teacher facilitates dialogue about students' strategies with open ended questions. The teacher records student thinking on the board using equations and visual models to help students consider others' ideas and make connections between strategies and representations (Parrish, 2010; Sun et al., 2018).

Number Talks are implemented in classrooms to achieve several important goals: to help students develop number sense and understanding of numerical relationships (Sun et al., 2018) and to shift focus towards making sense of strategies and away from a singular focus on solutions (Parrish, 2010). By centering students' thinking, Number Talks contribute to the development of a community of mathematics thinkers, doers, and learners in which "mathematical authority" is no longer held solely by the teacher and is instead shared among students (Lambert et al., 2017).

The US National Council of Teachers of Mathematics (2014) has identified a framework of essential teaching practices that stimulate meaningful mathematics learning: "establish mathematics goals to focus learning, implement tasks that promote reasoning and problem solving, use and connect mathematical representations, facilitate meaningful mathematical discourse, pose purposeful questions, support productive struggle in learning mathematics, build procedural fluency from conceptual understanding and elicit and use evidence of student thinking" (p. 10). Number Talks were chosen as the focus of our virtual field experience due to the potential for preservice teachers to engage in these essential mathematics teaching practices while facilitating virtual instruction.

Theoretical Framework: Technological, Pedagogical, and Content Knowledge

Built on Shulman's (1987) conceptualization of pedagogical content knowledge, Mishra and Koehler (2006, 2009) introduced the TPACK framework to account for the knowledge that must be developed for effective teaching practice given considerable technological change. The framework identifies the complex relationships that exist from the interactions between content, pedagogical, and technological knowledge for effective teaching practice (see Figure 1). Utilization of the framework, in a theoretical sense, provides a method of communicating the presence or absence of connections between content, pedagogy, and technological knowledge (Mishra & Koehler, 2006).

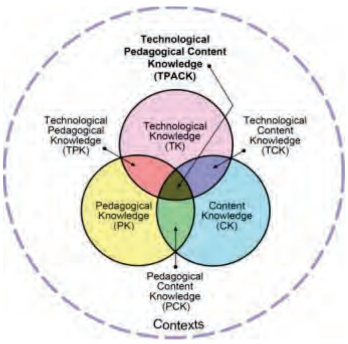

Figure 1: TPACK framework, reproduced by permission of the publisher, © 2012 by tpack.org

Pedagogical and content knowledge components of TPACK used in Number Talks can be categorized into the subdomains of mathematical knowledge for teaching (MKT, Ball et al., 2008). Common content knowledge (Hill & Ball, 2009) of school mathematics serves as the knowledge base needed to facilitate a Number Talk. Teachers need specialized mathematical knowledge (Hill & Ball, 2009) to record number relationships and operations using various visual models during Number Talks.

Knowledge of content and students is needed to anticipate and interpret students' strategies, to be aware of common developing (mis)conceptions or points of confusion, and to make sense of nonstandard strategies (Ball et al., 2008). Knowledge of content and teaching (Ball et al., 2008) is needed in Number Talks to select appropriate tasks and to choose in the moment which representations to use, which strategies to explore deeply or save for later, and which probing questions to ask to best support students' sense making. When facilitating Number Talks virtually, teachers must use their pedagogical and content knowledge and the subdomains of MKT to purposefully select and use technological tools to meet the mathematical goals of the Number Talk.

Methodology

Scientific and Cultural Context

Number Talks have become increasingly common in classrooms in the US as teachers have begun to incorporate the US Standards of Mathematical Practice, such as "make sense of problems and persevere in solving them, reason abstractly and quantitatively, and construct viable arguments and critique the reasoning of others" (NGACBP CCSSO 2010), into daily instruction. However, due to the COVID-19 pandemic and the switch to emergency remote instruction, much of the progress made in shifting mathematics teaching towards conceptual understanding and sense making came to a halt. Schools were forced to put together emergency remote instructional materials in a matter of weeks or even days, and many did so with packets of rote exercise worksheets and videos of direct instruction. As mathematics teacher educators, we sought to offer a field experience that translated best practices in mathematics teaching and learning into the digital environment.

Development of a Teacher Learning Cycle for the Virtual Number Talks Field Experience

The Association of Mathematics Teacher Educators' (2017) Standards for Preparing Teachers of Mathematics calls for teacher preparation programs to incorporate practice-based experiences that "develop core pedagogical practices and pedagogical content knowledge for teaching mathematics" (Indicator P.3.4.). To provide such a field experience while many schools were operating remotely, we created a Teacher Learning Cycle (TLC) in which preservice teachers learned about and engaged in Virtual Number Talks (Joswick et al., 2020). The TLC was developed using Teacher Education by Design's (University of Washington, 2014) learning cycle and includes four phases: learn, plan, implement, and reflect (see Figure 2).

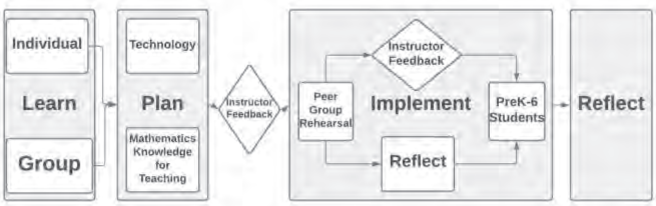

Figure 2: Teacher learning cycle for the Virtual Number Talks Field Experience

Setting and Participant Selection

The Virtual Number Talks Teacher Learning Cycle field experience was implemented in two sections of an elementary mathematics course taught at a university in the northeastern United States in Fall

2020. The course was a requirement for a master's degree in Elementary Education. 29 students, most of whom were preservice teachers, were enrolled between the two sections of the course. Of the 29 students enrolled, 21 students gave permission for their course assignments to be analyzed for research purposes. Most students took the course in the semester prior to their student teaching semester. The course was taught as a fully online course. Many students were working as school-based interns while enrolled in the course. Internship modalities ranged from fully online to hybrid and shifted during the semester due to changes in local COVID situations. Purposeful sampling was utilized to select "information-rich cases" (Patton, 1990, p. 169) to learn about the potential for TPACK development through the Virtual Number Talks field experience. In this paper, we chose to focus on two students, Tatum and Skyler, as illustrative cases (Yin, 2009) because they represented a range of prior teaching experience and prior technological knowledge and because they each demonstrated change over time in their knowledge of various elements of the TPACK framework.

Demographic Data: Tatum and Skyler

Tatum was a preservice teacher who worked for three semesters as an intern in a suburban public school for grades K-4 at the time of the project. Tatum completed the mathematics methods course and Virtual Number Talks Teacher Learning Cycle in their second year of an elementary education Master of Arts program during the fall semester before student teaching. Tatum had no prior teaching experience outside of their internship placement. Tatum's school was implementing a hybrid model at the time of the project; they completed their Virtual Number Talks Teacher Learning Cycle with three third grade students outside of their internship placement due to videotaping not being permitted at the school. Tatum demonstrated basic general technology knowledge at the start of the course.

Skyler was a preservice teacher who was working as an intern in a suburban public school for grades 3-5 at the time of this project. Skyler was in their fifth year of a five-year integrated Bachelor of Arts/Master of Arts program in elementary education, and they completed their mathematics methods course and the Virtual Number Talks Teacher Learning Cycle in the fall semester prior to student teaching. She previously worked as a paraprofessional in a summer school program for grades 9-12. Skyler completed their Virtual Number Talks Teacher Learning Cycle with three third grade students from their internship. Their school was implementing a hybrid cohort model at the time of the project. Skyler was adept at using newer technological tools and demonstrated more advanced technology knowledge at the start of the course.

Analysis

In a deductive approach and prior to analysis, *a priori* codes were developed from the three foundational areas of the TPACK framework. A code book containing these *a priori* codes along with their respective definitions from the existent literature was created to assist the analysis, create a consensus among coding members of the research team, and "maximize coherence among codes" (Creswell & Creswell, 2018, p. 199). Data sources for analysis existed in the form of nine assignments related to Number Talk learning, planning, implementation, and reflection completed by student participants throughout the semester. Each data source was then read and coded by members of the research team to the corresponding *a priori* codes. As a peer-debrief (Creswell & Creswell, 2018), members of the research team discussed themes emerging within the data for consistency, verification, and discrepancies. Validity in qualitative research is identified as one of its methodological strengths and was achieved through the triangulation of themes among the multiple data sources (Creswell & Creswell, 2018), discussion of discrepant codes, and peer-debriefing.

Results

Tatum: Developing Technological Knowledge and TPACK

Tatum demonstrated growth in their technological knowledge as they moved through the components of the teacher learning cycle from planning to rehearsing to implementing their Virtual Number Talk. Though Tatum practiced their use of technology tools during the rehearsal of their Virtual Number Talk with peers, he experienced technical difficulties when working with children. In their reflection on their first Number Talk, Tatum discussed their technical difficulties and the need to practice the use of technology tools simultaneously.

> In the beginning, I think that it was working well, but there was a time where I wasn't sure how to move from slide to slide from my screen in Zoom. I think that I should troubleshoot my number talk with all of my technology instead of both separately. It worked well during my rehearsal, but not as smoothly with my actual number talk. (Assignment 6, Reflection on first Virtual Number Talk)

In their final reflection after conducting two Virtual Number Talks, Tatum reflected on the growth of their technological knowledge through the peer rehearsal assignment and the benefit of teaching with technological tools.

> After our rehearsal and hearing back from my peers, I was able to use controls in the Zoom toolbar to use as ways the students can show me what they're thinking. I also was able to fine tune how to use PowerPoint as a constructive tool to make the virtual lesson feel more like an in-class lesson. (Assignment 9, Final Reflection after conducting two Virtual Number Talks)

Beyond simply learning how to use technological tools, Tatum's knowledge of using technological tools for specific pedagogical purposes in mathematics teaching showed significant development. For both Number Talks, Tatum showed images of dots, asking students to share how many dots they saw and to describe their strategies (see Figure 3). In their first Virtual Number Talk, Tatum showed dot images by screen sharing a PowerPoint but otherwise focused the activity on a verbal discussion.

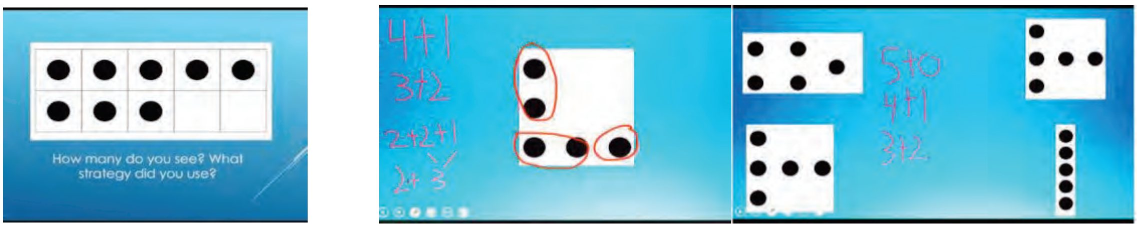

Figure 3: Images from Tatum's first (left) and second (middle and right) Virtual Number Talks

In their second Virtual Number Talk, Tatum once again showed dot images by screen sharing a PowerPoint, but this time used the pen tool to record on the screen throughout the conversation. By circling dots and writing equations to record student thinking, they made children's mathematical ideas visible to one another (see Figure 3). They closed the conversation by showing a slide with all of the dot images from the Virtual Number Talk, using the pen tool as they facilitated a conversation about connections across the dot configurations showing different ways to decompose the number 5, demonstrating the knowledge of content and teaching subdomain of MKT (Ball et al., 2008).

Skyler: Developing Pedagogical Content Knowledge and TPACK

As Skyler engaged in the Virtual Number Talk Teacher Learning Cycle, they demonstrated growth in their both pedagogical content knowledge and TPACK. Skyler focused their first Number Talk on dot patterns, facilitating an exploration of composition and decomposition of small numbers with their students. For their second Number Talk, they focused again on number composition and decomposition, but this time through a series of double-digit addition problems, a significantly more challenging task to facilitate. Skyler's recording of student thinking at the start of their second Number Talk was disconnected from place value. She honored students' thinking by typing what children said verbatim, but they did not ask any follow up questions about the value of the digits being added in the tens place. In a discussion board post early in the teacher learning cycle, Skyler stated the following, "I know in my experiences as a child and adult I have always had a harder time with auditory/nonvisual problems. Once the teacher wrote the problem and strategy on the board it was easier to follow along" (Assignment 2, learning about Number Talks and discussing with peers). Though Skyler recognized the importance of making mathematical ideas visible for children, their use of technological tools did not allow them to achieve the mathematical goal or support student sense making.

Midway through their second Number Talk, Skyler stopped typing students' explanations on virtual sticky notes and started recording using the pen tool. In doing so, Skyler began to "mathematize" the children's thinking by connecting their verbal explanations to mathematical equations, demonstrating specialized mathematics knowledge, knowledge of content and students, and knowledge of content and teaching subdomains of MKT (Ball et al., 2008). Through their recorded equations, Skyler highlighted the place value understanding inherent in the student's partial sums strategy. Skyler's in-the-moment shift in their use of technology tools, shown in Figure 4, made one student's mathematical thinking accessible to the other children and helped them to focus the discussion on important place value concepts, demonstrating a significant development in their TPACK skills.

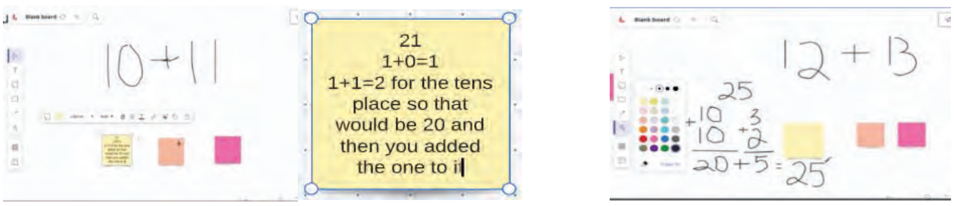

Figure 4: Images from the start of Skyler's second Virtual Number Talk (left and middle) versus the end of the Number Talk (right)

Benefits and Challenges of Virtual Number Talks as a Virtual Field Experience

There were several benefits to using Number Talks as a virtual field experience for preservice teachers. Virtual Number Talks allowed for maximum flexibility of implementation in terms of group size, content, and student location, creating access to teaching experiences for preservice teachers who were not able to enter schools due to COVID-19. While many classrooms shifted to videos of direct instruction and worksheets of practice problems at the start of the pandemic, Virtual Number Talks provided preservice teachers the opportunity to facilitate a mathematical conversation with students, creating windows into student thinking that many of our students had not experienced previously. Planning for and facilitating Virtual Number Talks also aided preservice teachers in developing and practicing their technological pedagogical content knowledge (Koehler, & Mishra, 2009) as they learned to utilize technological tools to create and display visual models, record equations and strategies, and facilitate students' thinking, discussions, and learning in the virtual classroom.

There were also challenges in implementing the Virtual Number Talks field experience for preservice teachers. New privacy concerns have arisen from K-12 virtual instruction, which prevented some preservice teachers from being permitted to facilitate or video record instruction within school-based placements. Virtual classroom management, including using conferencing software and tech tools for displaying and recording models and equations while engaging students online, was challenging for many preservice teachers. Writing on a digital whiteboard space also proved to be difficult for preservice teachers who did not have access to a stylus or touch screen device and had to write with a track pad or mouse, impacting the amount and quality of recording of students' strategies done by preservice teachers during their Virtual Number Talks.

Conclusion

Number Talks contribute to the creation of a mathematics community in which all students' contributions are valued. Number Talks also allow for the development of teachers' MKT (Ball et al., 2008) through selecting tasks, anticipating strategies, facilitating discussions, and recording strategies with equations and visual models. Bringing Number Talks to online classrooms helps teachers to maximize limited synchronous class time with a short but effective instructional routine. Through Virtual Number Talks, teachers can leverage technology to provide high-quality learning opportunities that empower students, center students' thinking, and position students as creators of mathematics. To do so effectively, teachers must start with their mathematical goal in mind and use pedagogical and content knowledge, MKT subdomains, *and* technological knowledge to purposefully choose technological tools best suited for the mathematical goal. As a virtual field experience, Virtual Number Talks can allow preservice teachers to develop their technological, pedagogical, and content knowledge (TPACK) as they learn to engage in essential teaching practices, use technology to achieve mathematical and pedagogical goals, and foster a virtual mathematics classroom community.

Acknowledgment

We thank the Service, Teaching, & Research in Mathematics Education Fellows Program and Jennifer M. Suh and Matthew Felton-Koestler for their support of our research collaboration. We thank Kimberly Conner, Candace Joswick, and Brandon McMillian for their contributions to the development of the VNT TLC course assignments.

Prospective teachers' specialized knowledge on periodic number: mathematics knowledge and beliefs

Galleguillos Jeannette[1] and Miguel Ribeiro[2]

[1]Universidad de Valparaíso, Mathematics Institute, Valparaíso, Chile; jeannette.galleguillos@uv.cl

[2]UNICAMP, Education Faculty, Campinas, Brazil; cmribas78@gmail.com

In this work we analyze the specialized knowledge about periodic numbers of a group of prospective mathematics teachers by means of a task for teacher development. The results revealed that a KoT and the KPM knowledges were displayed in the transformation of a periodic number to a fraction. In the discussion there appeared a resistance to accept the equality $0,\overline{9}=1$. *The prospective teachers (PTs) based their initial discussion on their beliefs rather than on mathematical arguments.*

Keywords: Periodic and semi-periodic number, mathematical knowledge, beliefs.

Introduction.

One of the causes of difficulties in rational number is the mechanistic style with which fractions (and decimals) are approached, focusing on the application of nonsense rules and due to the underestimation of the difficulty of this subject (Streefland, 1991). Thus, it is necessary to implement strategies from the initial teacher development that include a comprehensive point of view of this issue. In this work we focus on determining this knowledge from a development task focused on periodic (and semiperiodic) decimal numbers from the MTSK perspective (Carrillo et al., 2018).

Theoretical framework.

One issue that can cause confusion within periodic decimal numbers is the two different representations of the number $0,\overline{9}$ and 1, which corresponds to the equality $0,\overline{9}=1$. Rittaud and Vivier (2013) reported the difficulties of university students to establish that $0,\overline{9}=1$, since most of them answered that these numbers were different. We used the Mathematics Specialized Teachers' Knowledge (MTSK) model (Carrillo et al., 2018) particularly in *Mathematics Knowledge* (MK), *Knowledge of Practices in Mathematics* (KPM) and *Beliefs* of and about mathematics and its teaching.

Analysis and Results.

PTs solved a task on periodic number. From question 1 (Figure 1-image 1) they reveal that they know the procedure to transform a periodic number into a fraction, which corresponds to the knowledge of the topics (KoT) and of the procedure category (KoT-p1: Know the method to transform a periodic number into a fraction by applying the usual algorithm). From question 2 (Figure 1-image 1) it is shown that PTs know the method to transform a semi-periodic number to a fraction (KoT-p2: Know the method to transform a semi-periodic number to a fraction applying the usual algorithm).

From question: How would you explain the procedure to solve $0,\overline{16}$? From the resolution (Figure 1-image 2), we observe that the fraction transformation procedure was applied using operations on periodic numbers in an equation - method 1 (KoT-p3: Know a procedure to transform a periodic number into a fraction by performing operations in an equation).

The Figure 1-image 3 shows the use of an example and a mathematical work in which he uses method 1 to mathematically justify the case of a semiperiodic number. Both issues imply that knowledge associated with the KPM was mobilized. From the analysis emerges the label mathematical justification (“j”) that is not yet a category since it requires broader discussions (KPM- “j1”: Know how to mathematically justify the transformation of a semiperiodic number to a fraction from one more case simple). After, despite their knowledge, PTs did not identify than $8,\overline{9} < 9$. They stated that they believe that $0,\overline{9}$<1, which shows a *resistance* to accept that mathematical equality (Bel-1: Belief that different representation records cannot be associated with the same quantity ($0,\overline{9} < 1$)).

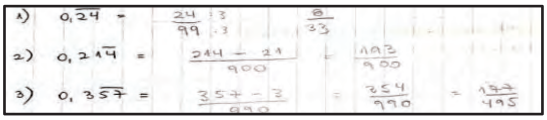

Image 1

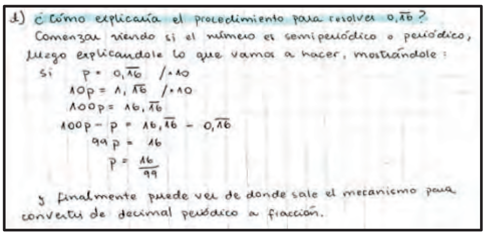

Image 2

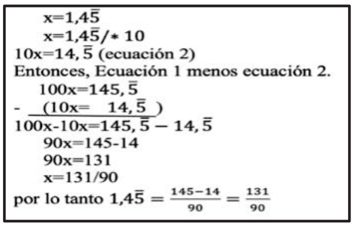

x=1,4$\overline{5}$
x=1,4$\overline{5}$/* 10
10x=14,$\overline{5}$ (ecuación 2)
Entonces, Ecuación 1 menos ecuación 2.
100x=145,$\overline{5}$
- (10x= 14,$\overline{5}$)
100x-10x=145,$\overline{5}$ − 14,$\overline{5}$
90x=145-14
90x=131
x=131/90
por lo tanto 1,4$\overline{5}$ = $\frac{145-14}{90} = \frac{131}{90}$

Image 3

Figure 1: Answer on (image 1) periodic numbers; (image 2) semiperiodic numbers; (image 3) transform a periodic number to a fraction.

Conclusion.

Here, mathematical knowledge associated with KoT and KPM was found. In addition, there was a resistance from PTs to accept the equality $0,\overline{9}$=1 and can be explained because there are two numerical representations of the numbers $0,\overline{9}$ and 1 for the same value (Rittaud & Vivier, 2013).

Introduction

The amount of research on division of fractions has increased largely since 1970s, however it is still a challenging topic both for teachers and students (e.g., Newton, 2008). Among the operations involving fractions, the division has been considered the most mechanical and less understanding by teachers (Lo & Luo, 2012), which reveal to know how to find the solution, but lack understanding on the how’s and whys grounding the division involving fractions. For students to develop such an understanding, we, has teachers are required to be in possession of a specialized knowledge which we consider in the perspective of the M*athematics Teachers' Specialized Knowledge* – MTSK (Carrillo et.al, 2018). Also, due to the central role of tasks in teachers’ practices, its essential do develop research focusing on the role of such tasks in teacher education. Aiming at enriching our understanding of such a knowledge here we focus on the following research question: What knowledge is revealed by teachers who teach Mathematics in the context of fraction division when solving a task in their continuing education?

Some theoretical dimensions

Students reveal difficulties in understanding fractions and the operation involving them, in particular, division. The same can be said for teachers and such difficulties might be grounded in the lack of understanding multiplicative conceptual field in mathematics curriculum and in previous school experiences teachers have encountered (Lamon, 2007). When considering teachers’ knowledge, we assume its specificities bit in terms of mathematical and pedagogical knowledge and we assume the MTSK conceptualization and aligned with our research focus here we address the Knowledge of Topics subdomain and, in particular: procedures, definition and representation.

Context and method

Here we report on data gathered in a six hours workshop which occurred in two days in a row (3 hours each day) with the participation of six mathematics primary teachers (teaching students aged 7 to 14). Data concern questionnaires, teachers written productions to a task for teacher education and video recordings of the sessions – through google meet. Here we focus on one of the questions of the task: Why when dividing by a fraction do, we invert the divisor and multiply to get the result in the operation 12/15: 3/5= 12/15 x 5/3 = 4/3.? The analysis has been made using the MTSK categories related to KoT.

Data analyses

Preliminary results enhance teachers' knowledge grounding the inability of justifying the IM method –the teachers knew how to use the procedure, but they do not understand and cannot explain why it works. Only one teacher provided a production trying to give meaning to the arithmetic expression. The teacher's representation does not justify the IM and shows that the teacher confuses the concept of partitive with measure.

T1: We do representations to represent fractions, but not their operations.

T5: My students ask me why it is needed to multiply to divide, and I was always sad that it was the rule, but I didn't know how to explain and why. When I learnt it, I learnt it through the rule.

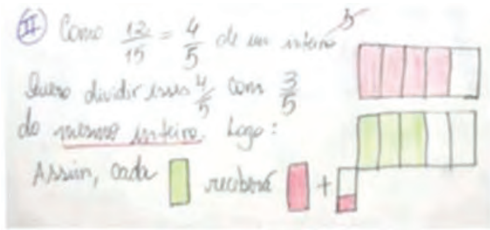

Figure 1: teacher production

The analysis revealed teachers' knowledge related to sense of division (measure/ partitive); different kinds of representation that cope with the sense of each mathematics constructions (beyond the unit fractions) and the relationship between division and other topics, for example, measure (Fazi & Siegler, 2011).

T6: Now, I understand why the algorithm works, because I have always used the IM and I have never thought about its meaning.

T3: I didn't know the division as a measure and now it makes sense to think of rations and in the resolution of problems, in a whole.

Conclusion

With the task, it was possible to know and develop the knowledge of the mathematical content necessary for the teacher in teaching fraction division. The investigation suggests an improvement in training courses *to* develop the teacher's mathematical knowledge in these topics for an improvement in teaching.

Teachers' Knowledge of Topic revealed via lessons plans for linear function introduction

Zuzana Gönciová and Veronika Hubeňáková

Pavol Jozef Šafárik University in Košice, Faculty of Science, Slovakia;
zuzana.gonciova@student.upjs.sk; veronika.hubenakova@upjs.sk

In this paper, we present preliminary results of the study where teachers' lesson plans were analysed to inquire about their content knowledge. Our theoretical background stands on the model Mathematics Teacher Specialised Knowledge (MTSK), particularly we focus on the element Knowledge of Topic. In the paper, an analysis of two lesson plans is provided to answer the research question: "What Knowledge of Topic (as described in the MTSK model) and what gaps in it are evident in the teacher lesson plans concerning the topic of a linear function?" The analyses revealed that indicators of all four components of Knowledge of Topic can be observed in the teachers' lesson plans whereas gaps in the particular components could be diagnosed as well.

Keywords: Teacher content knowledge, MTSK, lesson plan, linear function.

Introduction

A list of scholars starting with Shulman (1987) has tried to provide a model describing knowledge specific for (mathematics) teachers. Many others tried to "measure" or "describe" teacher knowledge using different methodologies. The broader objective of the research group is to use the collected knowledge in their practice as mathematics teachers' educators. Particularly, to develop a tool to track the progress of pre-service and in-service mathematics teachers achieved in their practice or during a specialised course. Hopefully, such a tool can support the reflection of mathematics teachers' educators and subsequently enhance the quality of provided courses or informal professional development meetings. This paper refers to the first step of the process.

Our approach was motivated by the work of Zakaryan and Ribeiro (2019) who used the model Mathematics Teacher Specialised Knowledge (MTSK) to classify knowledge about the content of the topic of rational numbers. The other resource of inspiration is the paper by Corey et al. (2021) who used written instructional products of teachers to "understand what knowledge (of student mathematical thinking) is evident in them and how that knowledge is used to justify instructional decisions" (p. 635). This idea encouraged us to use the lesson plans of teachers as a resource to learn about their knowledge. As pinpointed by Carlson and Daehler (2019) teacher knowledge can be enacted in planning, teaching, and reflecting. Therefore, to inquire about planning is as valid as inquiring about teaching practice or teachers' reflections. Naturally, it is not enough to inquire only about lesson plans, when it comes to the knowledge of an individual teacher. However, in terms of having a tool, which should be both – practical and as authentic as possible – we consider a lesson plan (possibly supported by an interview or a group discussion) as a good choice. For the beginning of the tool development, in the paper, we try to answer the research question: "What Knowledge of Topic (as described in the MTSK model) enactments are evident in the teacher lesson plans concerning the topic of a linear function?" Further, we will use LP instead of the full "lesson plan".

Theoretical framework

As already proposed above, we will frame mathematics teachers' knowledge with a focus on the Knowledge of Topic. From many possible ways, we opted for the model Mathematics Teacher Specialised Knowledge (MTSK) introduced by Carrillo et al. (2018). The section Knowledge of Topic, which is part of the model mainly interesting for this paper, consists of four components: (1) The first component (KoTp) is the knowledge of definitions, mathematical properties, and their foundations. (2) The second element (KoTph) is knowledge of phenomenology and applications for related problems in the topic. (3) The third sub-part (KoTmp) is knowledge of the procedures applicable to a specific topic. It includes situations such as "How to do something? When to do something? Why is something done this way? Characteristics of the resulting object." (4) The last sub-area (KoTrp) covers the knowledge of the different registers of representation and representational change. In general, KoT "combines the knowledge that the students are expected to learn with a deeper, and maybe more formal and rigorous understanding" (Carrillo et al, 2018). *The knowledge that the students are expected to learn* is dependent on the country's curriculum. This cultural aspect is not of a small importance as underscored at previous CERME (Ribeiro et al., 2019). Therefore, to describe KoT, it is possible to look at the national textbooks. The following table describes KoT specific for teaching the topic of linear function as introduced in the appropriate Slovak and Czech mathematics textbooks (Šedivý et al. 2004; Šedivý et al., 2006; Šedivý et al., 2011; Molnár et al., 2001; Binterová et al., 2010; Kolbaská, 2014; Berová and Bero, 2015, 2013; Kohanová et al., 2016; Hecht et al., 2001; Odvárko et al., 1985; Odvárko, 1993). The process of analysis and its deeper levels, which are beyond the scope of this paper, is part of the thesis which is being elaborated by the first author.

Table 1: KoT in the topic Linear function

KoTp:	
def	the linear function definition (any of the correct approaches, e.g. function which graph is the straight line, the same change in the "x" causes a constant increment in the "y", or the function which equation is $y=kx+q$)
nF	ability to formulate the examples of the relationship which is not functional (e.g. $x=2$)
q	knowledge of the q (y-intercept) interpretation, both cases acknowledged $q=0$ and $q\neq 0$
k	knowledge of the k (slope) interpretation, acknowledgment of differences between $k<0$, $k=0$ and $k>0$
Df	knowledge of the domain of the linear functions and its restriction due to the real context of the task
KoTmp:	
belong	to determine whether the point is (not) the point of the function
x	to determine the intersection with the x-axis (graph, notation)
y	to determine the intersection with the y-axis (graph, calculation from the equation)

coor	to determine the missing coordinate of the point (not in the context of filling the table)
inters	to determine the intersection of two linear functions
Rf	to determine the range of the function in correspondence with the context
mon	to determine whether the function is increasing/decreasing/constant (not using the interpretation of *k*)
KoTph:	
dts	the context of the task is focused on distance, time, and velocity
eur	the context of the task is money
t	the context of the task is time (but not velocity)
V	the context of the task is a volume of some substance
n	the context of the task is the number of something
m	the context of the task is the weight of something
KoTrp:	
verbal	change of representation from equation / table / graph into verbal description
equation	change of representation from verbal description / table / graph into equation
tab	change of representation from equation / verbal description / graph into table
graph	change of representation from equation / table / verbal description into graph

One might object that such a list of KoT represents also students' knowledge and thus, it is not specialised for teachers. We argue, that firstly (and sadly), it is not granted that teachers have valid “students' knowledge”. Secondly, the context in which we will inquire about it is directly connected to teaching. Thirdly, the planning of teaching in Slovakia is somehow specific, as our curriculum is not well developed and teachers often combine many resources (not always with externally guaranteed mathematical quality) in order to prepare a lesson plan, or they build on their ideas.

Methods and context

In our study, we analysed ten lesson plans (LP) created by lower-secondary mathematics teachers. Only two of them will be presented in the paper. The teachers were from different schools in the East Slovakia region. The LPs consisted of the commented materials (e.g. goals formulations, solved tasks, instructions for the teacher, comments on expected problems, …) and the student worksheet. They were collected during the professional development course provided as part of the National Project IT Academy. Before the course module about functions and functional thinking started, some teachers were asked to submit the LP about linear function using the inquiry method. All LPs were focused on the topic linear function. Some of the teachers elaborated the introduction of a linear function (n=5), the others worked on the examination of its properties (n=5). In this paper, we focus on the first type of LPs.

The main tool of the analysis was the codebook which is presented in the theoretical framework (Table 1). In the case, any other KoT indicator would be presented in the LP, we would inductively add it into the codebook. The LPs were analysed by both authors and the results of the analyses (for the sake of this paper) were summarized in a so-called “KoT map”, where each of the codes is presented and coloured in green/red/yellow (see e.g. Figure 2). The analyses were conducted to find:

(1) the evidence (e.g. correctly solved task, correct mathematical statement, assigned task with the specific context, …) that the KoT indicator is actively used by a teacher. In the KoT map, these codes are highlighted in green.

(2) the indication, that the piece of KoT is not valid (e.g. incorrect solution of the task, tasks which are not in the line with the mathematical goal of the lesson, …). In the KoT map, these codes have a red colour.

Certainly, one LP from the whole topic is not enough to be analysed to see the teacher’s KoT. If our research was aimed at assessing teacher’s level of KoT, it would be true. However, we could use only part of the topic because we aimed to inquire about LP as a resource to “measure” teachers' KoT.

Results

In this paper, we will provide an analysis of two LPs, which were chosen to pinpoint different strengths and difficulties in KoT. The first one, submitted by Jana (names changed), is stated to show the following situation: within many different contexts, only a few correct indicators of KoT are presented. Moreover, some invalidities were found as well. In the other one, proposed by Kristína we want to pinpoint the diversity of correct indicators of KoT revealed within one task for students.

Jana

Jana proposed 5 tasks in her LP. All of them were similar to the one presented in Figure 1.

The brick weighs 6 kg. What is the weight of 2, 3, 4, 5, 6 bricks? Build a table of dependencies between the number of bricks and their weight. Write the equation between the number of bricks and their weight. Plot a graph of the number of bricks with their weight.

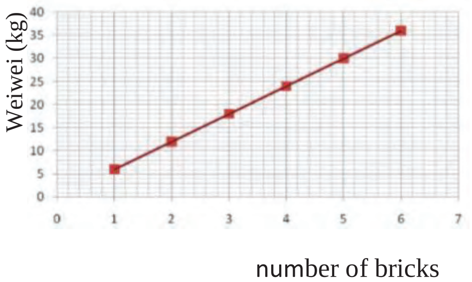

Figure 1: Task to introduce Linear function (Jana)

KoT map (Figure 2) pinpoints, that Jana used many different contexts for her tasks and she was focused on the representational change. Nevertheless, she did not reveal deep KoT in the other two components and what is more, some incorrectness was observed as well.

KoTp	def	nF	q	k	Df		
KoTmp	belong	x	y	coor	inters	Rf	mon
KoTph	dts	eur	t	V	n	m	
KoTrp	verbal	equation	tab	graph			

Figure 2: KoT map (LP by Jana)

KoTp:

- q (red) – The teacher used exclusively tasks where the *y*-intercept, *q*=0, in other words, to introduce the topic of the linear function, she used only direct proportionality, which is in the contrast to the goals she set in her LP and which directly mentioned *linear function*. She specified direct proportionality as the prior knowledge.

KoTph:

- dts, eur, t, n, m (green) – Jana used all marked contexts in her LP.

KoTrp:

- equation (green) – Students were required to write the equation which describes the relationship between the variables – to change the verbal description/table into an equation, and she had the correct solution of this task presented in the LP.
- tab (green) – Students were asked to fill the table which describes the relationship between the variables – to change the verbal description into the table.
- graph (red) – The teacher asked students to create a graph, however, the graph depicted in Figure 4 (which is proposed by her) is not correct in the context of the given task. The graph should start at (0,0) and its continuity is at least disputable. Moreover, it should not end at (6,36).

Kristína

Kristína planned one task to be solved in small groups of students. Each group worked on the same situation; however, they were asked to answer different questions as shown below (Figure 3):

> The mobile provider offers two different tariffs. When choosing tariff A, we will pay € 0.10 for a minute. When choosing tariff B, we will pay 4 € at the beginning of the month and € 0.05 for each minute. 50 text messages and 1.5 GB of data are offered on both tariffs for no extra payment.
>
> Group 1: Which tariff do you think is more advantageous?
>
> Group 2: Which tariff do you think is more advantageous if you estimate that you will call about 0.5 hours a month?
>
> Group 3: Which tariff do you think is more advantageous if you estimate that you will call in about an hour in a month?
>
> Group 4: Which tariff do you think is more advantageous if you estimate that you will call in about 1 hour and 20 minutes per month?

Group 5: Which tariff do you think is more advantageous if you estimate that you will call in about 2 hours a month?

Figure 3: Task to introduce Linear function (Kristína)

Kristína's KoT map (Figure 4) is visualised, and the codes are explained below. We can see that within the narrow context of only one task she revealed many different indicators of correct KoT and did not show any incorrectness.

KoTp	def	nF	q	k	Df		
KoTmp	belong	x	y	coor	inters	Rf	mon
KoTph	dts	eur	t	V	n	m	
KoTrp	verbal	equation	tab	graph			

Figure 4: KoT map (LP by Kristína)

KoTp:

- q (green) – We can see the interpretation of the *y*-intercept $q = 4$ in her task – Tariff B initial payment.
- k (green) – She offered the interpretation of the slope *k* by visualization $k_1 = 0{,}1$ and $k_2 = 0{,}05$, which are different minute prices for the tariffs A and B.
- Df (green) – She worked with the domain of the function concerning the real context of the problem. In her solution, she restricted the graph to the positive *x*-axis.

KoTmp:

- coor (green) – In the subtasks for groups 2-5, she wanted students to determine which tariff is better for the particular number of minutes. She had a correct solution for each of the groups in her LP and therefore she displayed the knowledge of determining the missing coordinate of the point.
- inters (green) – From the LP, it was visible, she prompted pupils to calculate the time in which are both tariffs the same cost and she had solved this task as well.

KoTph:

- eur, t (green) – The variables in the task are money and time.

KoTrp

- tab (green) – Pupils are asked to fill the table to solve the task, in other words, to change the verbal description into the table. The teacher displayed the correct knowledge as well.
- graph (green) – Pupils are prompted to draw a graph to solve the task, in other words, to change the table into the graph. She had the correct solution for this task as well.

Discussion

Coming back to the research question: "What Knowledge of Topic (as described in the MTSK model) enactments are evident in the teacher lesson plans concerning the topic of a linear function?" we can say the following: Firstly, the LPs are a good resource to find the indicators on teachers' knowledge on the application of the topic (KoTph). It was clear, which context of application teachers was familiar with (Kristína – used time and money contexts, Jana – distance-time-speed, money, time, number of something and weight). Comparably, LPs reveal teachers' knowledge on representations and representational change (KoTrp). In this case, we were able to observe not only the indicators of correct KoT but also signs of the invalid KoT, for example (in the case of Jana) in the graph representation, where it was necessary to restrict the line into discrete points (or possibly a ray).

Moreover, concerning teachers' Knowledge of definitions, mathematical properties, and their foundations (KoTp) and the component Knowledge of mathematical procedures (KoTmp), we could observe differences between the LPs, especially in the terms of "being" or "not being" presented. These two components were much more elaborated in the LP of Kristína (we observed determining the intersection and finding the missing coordinate of the point), however, barely presented in the LP of Jana (where we did not observe any indicators and her tasks were focused only on the direct proportionality, therefore she did not cover the topic of linear function).

Based on these two LPs we could exactly name the differences between the two teachers. Therefore, we can see that LPs could serve us as a good tool to discern all four components of a teacher's KoT, of course, if analysed in whole (not only one LP for a topic). In the sense of the broader goal (development of a tool to track the progress), we also see the potential of such analysis. If two presented KoT maps did not describe two different teachers' LPs, but LPs of one teacher at the beginning and the end of the course (or at the beginning of the career and after five years), we could be able to reveal how his/her knowledge was developed. This approach is to be applied in future research.

Furthermore, the other issue, which we would like to discuss, are parts of the LPs, which were not coded, because none of our codes was applicable. For instance, one of the teachers proposed the task focused on reading the statistical information from the bar chart (e.g. to count arithmetic mean) as the activity to revise important knowledge before the linear function is introduced. Possibly, this could be understood as some gap in the Knowledge of the Structure of Mathematics – another element from MTSK. This observation prompts us to the next analysis of the LPs to find out, what – except for KoT – we can learn about the teachers from their written instructional plans.

Acknowledgment

Collaborative knowledge creation of teacher subject knowledge using concept maps

Rachael Horsman

University of Nottingham & Cambridge Mathematics, United Kingdom;
Rachael.horsman@nottingham.ac.uk

This paper sets out the theoretical foundations and design of a future study planned for early 2022. The study focuses on the use of concept maps as the object of collaborative knowledge creation. The aim of the research is to explore the potential role concept maps have in supporting in-service primary teachers in developing their subject knowledge for teaching through collaboratively constructing a concept map mediated by an online tool developed by Cambridge Mathematics.

Keywords: Teacher knowledge, concept mapping, collaboration.

Introduction

In the pursuit of supporting teachers to develop richer more connected conceptualisations of mathematics this study will explore an example of a technology-mediated knowledge creation activity. The activity will involve multiple steps. Initially, I will invite teachers to explicitly describe their own image of an area of mathematics, detailing the structure and content of their subject knowledge. During the second stage participants will develop a representation of this by sketching and refining a concept map in an online environment. Third, an online community will be created in which teachers will have the opportunity to reflect on their own and others' concept maps through sharing, analysing and questioning each other. Finally, the participants will collaborate to build a single concept map using the online tool. It is hypothesised that the outcome of this collaboration will not only be an accumulation of knowledge, which for participants will include the accommodation of new or alternative perspectives and connections, but also enable new knowledge to be created. This paper discusses the theoretical background to the study and details the phases in the current design.

What do we mean by teachers' subject knowledge?

What teachers need to know to be successful has received a significant amount of attention (Remillard & Kim, 2017). International comparative studies persistently search for reasons for and methods to avoid poor outcomes for learners of mathematics. Policy makers and mathematics educators have placed their focus on the identification, development and improvement of teacher mathematical content knowledge. Understanding what is to be learned enables teaching to commence and in this role a teacher "must understand the structures of subject matter, the principles of conceptual organization" (Shulman, 1987, p. 9).

In considering teacher knowledge, Shulman (1986) identifies (amongst other types) *content knowledge* that extends beyond recognition of assumptions, facts and concepts and necessitates familiarity with the structure of the subject, including how truth is established, why knowledge is worth knowing and the relationships within and beyond the subject. *Pedagogical content knowledge* is described as the range and power of representations, analogies, illustrations, examples, explanations and demonstrations. Also included is understanding pupils' preconceptions, many of which may be misconceptions, and their effect on future learning. Within *curricular knowledge* Shulman highlights the importance of teachers' *lateral* curriculum knowledge, in other words how the content being taught in mathematics relates to that being taught in other subjects. V*ertical* curriculum knowledge, being familiar with the mathematics being taught in preceding and future years, is identified as essential. Throughout Shulman's work, the organisation of mathematical content is identified as an important feature of teaching.

In the study of teachers in China and the United States Ma (1999) describes how successful teachers exhibited profound understanding of fundamental mathematics; connected, curricula-structured, longitudinal knowledge of core mathematical ideas. Such teachers had a breadth and depth of connected knowledge that enabled flexibility in their approaches and an awareness of the implications of what and how things are taught on later learning.

The mental organisation of a teacher's knowledge plays an important role in developing a positive relationship between content knowledge and classroom instruction (Fenneman & Franke, 1992), implying that the deeper, more connected knowledge a teacher holds the more successful they will be in developing learning with understanding. What is deemed to be a valuable measure of a teacher's potential, in these studies and others (Loewenberg Ball et al., 2008; Mason & Spence, 1999), is not just their declarative knowledge but what they understand this knowledge to mean, its place in school mathematics, the representations used, and misconceptions held.

A flexible connected schema of mathematical content knowledge offers a structure into which pedagogical content knowledge can be embedded, explored, connected and also developed. This may be knowledge of content and students (KCS): typical misconceptions, areas of confusion and challenges, learners' interests and motivations, knowledge of content and teaching (KCT): how to teach, worthy examples, representations, or knowledge of content and curriculum (Lowenberg Ball et al., 2008). In turn this knowledge enriches the original schema and supports teachers' understanding of why specific tasks, manipulatives, representations, misconceptions, and learning sequences arise and relate. What representation can be used productively to enable the development, of this schema? What professional activities enable teachers to construct and work flexibly with these schemas, allowing them to represent and develop their subject knowledge for teaching?

Why are concept maps a suitable vehicle to represent mathematical ideas?

Each individual holds their own visualisation or personal mapping of their mathematical knowledge – the schema by which they organise their mathematical ideas (Asiala et al., 1997, Skemp, 1978). This structure is not stable, but dynamic, reflecting the developing knowledge and experiences of each of us. An individual's schema is not possible to study, compare or discuss directly. An instance of it must be elicited into some explicit form that can then be interpreted. A variety of artefacts could support this through being the focus of a discussion, including schemes of work, resources, worked solutions or questions. Alternatively, teachers could be interviewed about or observed in their classroom practice. Such verbal discussions, written solutions and texts tend to represent ideas in a linear manner, offering little insight into the conceptual structure someone holds (Grevholm, 2008).

Graphic organisers show relationships between concepts and processes, employing spatial position, connecting lines and overlapping structures (Nesbit & Adesope, 2006), and therefore offer a tool through which a non-linear structure can be represented. Concept maps are a type of graphic organiser, "a diagram representing the conceptual structure of a subject discipline as a graph in which modes represent concepts and connections represent cognitive links between them" (McGowen & Tall, 1999, p. 2). These links that may be directed or undirected, labelled or unlabelled (Nesbit & Adesope, 2006). Crosslinks identify relationships between concepts in different segments or domains of the map, showing relations between domains (Novak & Cañas, 2008).

An individual's concept map is a visual representation of their concepts (Novak & Gowin, 1984) and a tool for analysing expression of current concept structure (Grevholm, 2008). Any map will be constructed from a personal mental representation of knowledge although, how accurate the representation is, is impossible to know (Williams, 1998). A concept map's structure depends on the context in which knowledge is being applied or considered (Novak & Cañas, 2008). Not only will this adapt and change as the context varies; it will also be altered, refined and elaborated as the creator's own maths develops. Concept maps are not "inert and finished, but interactive and expandable" (Eppler, 2004, p. 200).

The software chosen for this study to represent concept maps is based on an off-the-shelf network graphing tool; Neo4J (n.d.). This has a bespoke visual interface designed by Cambridge Mathematics (n.d.) a curriculum research and design project based at the University of Cambridge. The interface consists of nodes and edges. Nodes can include a title, free text description, images and be tagged to implement colour coding. Edges can be directed or undirected, include free text and be tagged to implement colour coding. As a member of the Cambridge Mathematics writing team, the author was instrumental in the design of this software.

What is collaborative knowledge creation?

In their discussion of socio-cultural perspectives on collaborative learning, Hakkarainen et al. (2013) describe three significant metaphors of learning: knowledge-acquisition, participation and knowledge-creation.

In the knowledge acquisition metaphor for learning knowledge is viewed as a personal characteristic that is developed by individuals. Interactions that occur may provoke cognitive conflict enabling learning but not as a product of any collaboration but because of an internal dialogue (monological). From the perspective of the participation metaphor knowledge is viewed as the objects and practices (including rules and beliefs) of communities. It has been influenced by the history and culture of the community. Learning is seen as gradually becoming aware of this knowledge, joining the community through learning how to function according to its rules. Through participating in collaborative activities learners become aware of their own and others knowledge (dialogical) and develop shared meaning.

In describing their third metaphor, collaborative knowledge creation, Hakkarainen et al. (2013) reference ideas of knowledge building (Bereiter, 2002), expansive learning (Engeström, 1987) and organisational knowledge creation (Nonaka & Takeuchi, 1995). Rather than acquainting themselves with a community, as in the participation metaphor, collaborative knowledge creation focuses on the deliberate pursuit of advancing shared objects for future development and use (Hakkarainen et al., 2013). These knowledge artefacts are to be created and mediate activity (Paavola et al., 2012). Often with the help of technology, learners take collective responsibility to design, construct, modify and manage versions of knowledge artefacts that partly pre-existed. and have the "capacity to unfold indefinitely" (Cetina, 2001, p. 181 as cited in Paavola et al., 2012, p. 2).

A concept map: A flexible representation that can be created collaboratively

The knowledge-creation metaphor offers the study a theoretical background which accepts and capitalises on teachers' varied experiences, expertise, beliefs and theories whilst they collaborate to develop a deeper understanding of their subject, thus impacting on their teaching. Each participant holds their own image of any area in mathematics, including the different types of teacher knowledge described above. With the correct mediating object this can be shared, modified and extended through collaboration. A concept map provides an example of an epistemic object, its boundaries non-existent, as multiple connections link ideas across domains and into related subjects. In fact, a map could expand across multiple subject domains. The concept map is being defined as it is being designed, decisions are being made about how far to go in any direction and set its limits. It has no boundaries, whereas a curriculum, learning resource or learning trajectory tends to be a finite linear progression a concept map can expand indefinitely. It is proposed that both the process of collaboratively creating a shared concept map and the map itself emphasise eliciting, enriching and creating new teacher knowledge.

Theoretical framework

The foundations of the learning theory ascribed to in this study are that; mathematical knowledge is created and agreed to by a community because of a need to explain, interpret, communicate or explore (Hersh, 1979); learning is continuous, evident in every aspect of our lives, there is no one final 'knowledge' in any domain (Vollrath, 1994); and participating in activity, including a social activity or personal reflection, impacts on our knowledge, understanding and interpretation of the world, hence results in learning (Engeström, 1999; Vygotsky, 1978).

Research Questions

The aim of this study is to explore if and how collaborative knowledge creation, concerning teacher subject knowledge, can be mediated using an online concept mapping tool (alongside conferencing software). The goal is to develop a practical model that elicits deliberate enrichment and creation of subject knowledge as well as transform the way in which those teachers perceive and reflect on the subject both abstractly and when carrying out the associated activities of teaching.

The research questions are:

1. What types of teacher knowledge do teachers use to create, populate and justify the content and design of a concept map?
2. Does an online concept mapping tool enable teachers to create, share and elaborate upon a representation of mathematical ideas? How?
3. Does an online concept mapping tool enable knowledge creation? How?

Study Design

The study design is detailed in table1. It reflects the aim of collaboratively creating a shared structural representation of mathematics, viewing knowledge as socially created yet considering individual perspectives, experiences, and reflections. An analytical framework has also been designed, details of which can be found in an extended version of this paper, available from the author.

Participants will be purposefully selected, the criteria for participation being that the teachers are in their first five years of teaching, have experience of holding online discussions about teaching mathematics and do not have existing professional relationships (such as being in the same school, co-teaching, training together). The choice of early career teachers was made so that each teacher has a similar number of years of classroom experience on which to draw. Participants with no existing relationships are being chosen in order to encourage them to be clear in their explanations, as no assumptions can be made about each other's experiences, including approaches during their training, specific teaching resources or activities or pupils. In order to promote some heterogeneity, the aim is for those selected to have experience of working with different age groups, to have entered the teaching professional from a variety of routes and have experiences of a variety of institutions (promoting cross-fertilisation). Another aim is for all participants to have had experience of online professional development and therefore, have familiarity with online meeting software and in participating in collaborative discussions with their peers.

Table 1: Study design

Phase	Part	Activity, participants, and format	Aim(s)
1	a	Online demographic questionnaire	To collect demographic information about each participant
	b	Administration and answering questions Online discussion (not recorded) between individual participants and researcher	To familiarise the participants with the research intentions and processes To answer any outstanding questions from the participants To explore and clarify answers given to the demographic questionnaire
		Eliciting initial concept image	To elicit a representation of the participants' concept images for the chosen area of mathematics and

		Individual participants observed by researcher online completing a think aloud activity	To give participants the opportunity to consider the area of mathematics in advance of using a concept map
	c	Introducing concept maps and software Online presentation by researcher and discussion with individual participants	To ensure participants have as much of a shared understanding of concept maps as possible To introduce the Cambridge Mathematics Framework software and develop familiarity in using it
		Eliciting initial individual concept map Individual participants observed by researcher online completing a think aloud activity	To elicit an initial concept map for the chosen area of mathematics To give participants the opportunity to consider the area of mathematics in advance of group discussions using a concept map.
2	a	Paired then group discussions concerning individual concept maps Pairs then group of participants observed by researcher online	To give participants the opportunity to describe, explore and critique their own and other's concept maps
	b	Group collaborative construction of a concept map Group of participants observed by researcher online	To give participants the opportunity to negotiate and collaborate in constructing a shared concept map.
3		Reflection Semi-structured stimulated recall interview between individual participants and researcher	To give participants the opportunity to reflect on the impact taking part in the study has had on their conceptualisation of the chosen area of mathematics To give participants the opportunity to reflect on the impact taking part in the study has had on their own mathematical beliefs; and To give the researcher a chance to explore any observed identified changes in the way that participants discuss mathematics.

Next steps

The data from a pilot study (to the main study detailed above) is currently under analysis. The pilot's aims are to:

- ascertain reasonable expectations for the number and length of interactions;
- assess the clarity and usefulness of the questionnaire, prompts, and other documentation;
- allow the researcher to develop their interview skills;
- verify that the data collection procedures – recording, scanning, transcribing and saving – are appropriate and useful; and
- examine the planned analysis design and process, on a more compact data set.

The pilot provides the opportunity to revisit elements such as specific questions, prompts and planned use of technology, and use these to make adjustments. This iterative process may yet also result in changes to the design of the phases of the full study itself. Whereas there will be four participants in the main study, the pilot study involved two. Initial findings from the pilot are promising with significant commentary from participants on ideas that they had not considered before, ways in which the activity made them re-evaluate existing learning trajectories and their own subject knowledge as well as a request to use the mapping tool outside the study.

Acknowledgment

It is my ethical obligation to report that I am employed by Cambridge Mathematics whose software design is being used for this study and who are funding my PhD studies.

A methodological approach to the development of prospective teachers' interpretative knowledge

Arne Jakobsen[1], Maria Mellon[2] and Miguel Ribeiro[3]

[1]University of Stavanger, Norway; arne.jakobsen@uis.no

[3]State University of Campinas – UNICAMP, Brazil; cmribas78@gmail.com

In this paper, we propose a methodological approach—the SCS cycle— suitable to develop prospective teachers Interpretative Knowledge (IK). In particular, this study focus on a group of 19 prospective secondary teachers attending a mathematics education course in Italy who were given an interpretative task involving measurement of the surface area of a rectangle. Their work on the task followed the SCS cycle and was video recorded and later transcribed. The analysis showed that the SCS cycle supported the development of the prospective teachers' IK, but further work is needed to evaluate the effectiveness of the cycle as a way for developing prospective teachers' IK.

Keywords: Interpretative knowledge, SCS cycle, measurement, surface area.

Introduction

Measurement (e.g., of length, area, volume, mass) is an integral part of the school mathematics curriculum (e.g., NCTM, 2000). However, how measurement should be taught for relational understanding (e.g., Skemp, 1976) is often neglected by teachers, as this topic is typically approached as a problem of "finding the correct number" by using a mathematical procedure, indicating that the main goal is finding the final result instead of developing relational understanding.

In order to enrich the understanding of a mathematical topic and use such understanding in the development of fruitful mathematical discussions with students, teachers need to possess a mathematical knowledge which is considered specialized to the practice of teaching mathematics. One of the teaching tasks entailed in the work of teaching is grounded in proposing and discussing tasks with students (Ball et al., 2008). We assume that developing students' relational understanding should be one of the goals of all mathematics teaching, and thus, it is critical to consider the starting point for a mathematical discussion on what the students know and how they know it. This requires that teachers can "listen to the students' thinking" and possess what we have termed as Interpretative Knowledge (IK), which is a specialized kind of knowledge that is not necessarily developed in teaching practice, and is thus an essential focus of teacher education (Mellone et al., 2020).

In our previous work, we discussed the nature and content of (prospective) teachers' IK on the topic of area measurement (e.g., Ribeiro et al., 2018) posed in a context aimed at giving meaning to the area formula for the rectangle. For that purpose, we developed an ad hoc interpretative task. In such a task, prospective teachers (PTs) are situated in a practice-based context where they have to mediate and give meaning to different students' reasonings and justifications for the formula for calculating the surface area of a rectangle. In particular, by proposing this task, we challenged PTs to give a mathematically meaningful justification for the area formula of the rectangle as a direct reading of multiplying the measurement of the length by the measurement of the width. In pursuing the goal of developing PTs' IK, an ad hoc way of implementing the task was developed. We call this method the Small group−Collective−Small group (SCS) cycle, as it is a modification of the Individual−Collective−Individual cycle proposed by Pacelli et al. (2020). In this paper, we focus on the following research questions: What kind of knowledge development can be recognized in PTs when experiencing an SCS cycle involving an interpretative task? In particular, can we recognize any development of IK in these PTs?

Literature review and theory

Understanding a mathematical topic goes beyond knowing the mathematical procedures associated with the topic. This also applies to measurement, considering that it is one of the core mathematical topics in the school curriculum since kindergarten (e.g., NCTM, 2000). For this reason, it is of fundamental importance to develop PTs' and students' understanding of the measurement process in general, and in particular in the context of surface area. Such an understanding can be described by the six principles defined by Clements and Stephan (2004) for the length measurement, which can also be adapted for other magnitudes.

In traditional school practice, the teaching of surface area measurement tends to focus on formulas without meaning, sometimes preceded or followed by teaching of the measurement process where only standardized measurement units are used (Policastro et al., 2017). Moreover, no opportunities are provided for exploring with students the differences and similarities concerning the measurement processes based on different magnitudes. For example, looking at similarities among the measurement processes, it is possible to recognize a common planned action of choosing a convenient unit of measurement to be compared to the quantity being measured, ensuring that both have the same magnitude, and counting how many times the unit of measure fits in the quantity to be measured (e.g., Clements & Stephan, 2004).

The Dynamic Measurement approach is an alternative method of surface area measurement (Parnorkou, 2020). The approach focuses on how space is measured by the lower-dimensional objects that generate it. An inductive approach to visualizing this generation of area (and volume) attributes involves moving objects in space (Parnorkou, 2020). By imagining that a line segment 'a' is swept in a perpendicular direction across a distance 'b', we generate a rectangle with area 'ab'. These two different approaches demonstrate the richness and complexity of a mathematical topic, such as measuring the surface area of an object that is usually considered a trivial task. From this perspective, we argue that teachers should possess a sound and broad mathematical knowledge that contributes to the development of students' mathematical knowledge. Such knowledge will allow them to take the students' own mathematical work, and the differences in the provided representations and argumentations as a starting point—including mathematical work that contains mathematical ambiguities, errors, and non-standard reasoning—assuming that they can be used in practice as learning opportunities (Borasi, 1996). In this sense, the notion of IK (Jakobsen et al., 2014) refers exactly to this deep and wide mathematical knowledge that enables teachers to support students in building their mathematical knowledge by starting from their own reasoning and productions (Di Martino et al., 2019). It includes the ability to expand one's own space of solutions by looking at situations from a wide range of points of view and the capacity for developing specific feedback based on the meaning ascribed to individual students' reasoning (Jakobsen et al., 2014).

Our aim is to develop a methodological approach to support mathematics teachers in the development of IK. Extant research indicates that having in/pre-service teachers working on interpretative tasks can be an effective tool for this purpose (Mellone et al., 2020). By interpretative task we mean a task that in which we ask teachers to solve a mathematical problem and then to interpret students' answers to the same problem (Jakobsen et al., 2014). However, even if PTs' individual work on the interpretative task can contribute to the development of new insights and awareness, it is insufficient for developing a sound IK. As a consequence, referring to the design study methodology (Cobb et al., 2009), we designed an ad hoc methodology for implementing an interpretative task based on the SCS cycle. As implied by the SCS, teachers first work on the interpretative task in small groups of two or three members, after which the task is discussed by all participants in a collective discussion mediated by the teacher educator. Finally, the same small groups of teachers are asked to work on the same interpretative task after one month. This methodology aims at disrupting the vicious cycle of teachers being passive listeners by prompting them to assume an active role in their learning—a strategy we expect they can transpose to their practice.

Moreover, it is widely established that, when teachers work and learn through collaboration, this can have a crucial positive effect on their practices (e.g., Jaworski et al., 2017). Thus, we used the collective mathematical discussion as a collaborative and knowledge-generating activity, in which students' productions are placed at the center of interpretation and feedback construction (e.g., Cobb et al., 2009). Perceiving knowledge as a social elaboration (e.g., Bartolini Bussi, 1996) and recognizing the crucial role of collective discussions in developing awareness about errors and nonstandard strategies (e.g., Levin, 1995) convinced us that we need to allow PTs to be active participants in the learning process and not passive listner, as "when they do talk they ask clarifying questions or acknowledge that they agree or understand" (Spillane, 2005, p. 394). By focusing on the collective discussions about students' productions related to a mathematical problem, our intention is to develop PTs' (teachers') IK from their mathematical social interactions with peers. The task for teacher education (Ribeiro et al., 2021)—an interpretative task in this case—is used both to measure the PTs' IK level and to stimulate subsequent peer discussions. Owing to its nature and structure, the interpretative task aims at prompting PTs to develop novel insights into the mathematical reasoning involved in students' productions. Consequently, IK development is transformed from an individual to a collective activity—a transformation characterized by the evolution of community's norms. This evolution is facilitated by the social setting, where the educator's knowledge is a crucial element for the development of PTs' IK. The collective discussions of PTs' diverse interpretations, reasoning, and reflections upon students' productions is the resource for the educator to orchestrate collective discussions, aimed at identifying mathematical and pedagogical insights and developing the IK. The ultimate goal of this strategy is an evolution from a group of PTs into a professional teaching community (e.g., Cobb et al., 2009), which requires a set of four types of norms pertaining respectively to: (a) general participation; (b) pedagogical reasoning; (c) mathematical reasoning; and (d) institutional reasoning. It is worth noting that the evolution of one type of norms creates conditions within the group for the evolution of norms of another type (Cobb et al., 2009).

Context and method

The context of this study is a Mathematics Education course held in the Autumn of 2020 as a part of a Master's Degree in Mathematics at an Italian University. The requirement for becoming a secondary mathematics teacher in Italy is to have Master's Degree in Mathematics (or Physics) and to successfully pass a public competition organized by Italian government for secondary school teacher recruitment. The students had already completed a Bachelor's Degree in Mathematics or in Physics and are considered to have a strong mathematical knowledge. The Mathematics Education course is a non-compulsory course, but it is typically chosen by students who intend to become secondary teachers, due to which all participants are considered to be PTs. The study participants are the 19 PTs who attended the course which was held online in a synchronous way—through Microsoft Teams—due to the restrictions imposed on mobility and gatherings to prevent the spread of COVID-19. The online teaching was recorded.

Task and activities

The interpretative task we discuss here was proposed to the PTs during the final part of the course. It consisted of three parts. First, the PTs were asked to answer a generic question on how to define the area of a figure in a plane. Then, there they were asked to find the area of a rectangle with sides measuring 3 cm and 4 cm, to provide an argument for their answer, and relate their answer to the first question. Finally, they were asked to interpret four 5th graders' productions to the area of the rectangle problem (Figure 1), focusing on "listening to the students' thinking and reasoning" to make sense of their solutions, and provide a constructive feedback to each one of those reasonings to support students' mathematical understanding (Ribeiro et al., 2018). One of the aims of the task was to discuss the meaning of the area formula for the rectangle and to refine the PTs' understanding and meaning attribution to the product of two lengths.

Consider the following students' productions to the question: Determine, and justify, the area of a rectangle with sides measuring 3 *cm* and 4 *cm*.

Caio: Multiplying the length by the width, we get $4\ cm \times 3\ cm = 12\ cm^2$.

Douglas: The area is a surface measurement and thus it has two dimensions (length and width) so we need to put the 2 in the exponent and we get $3 \times 4 = 12\ cm^2$.

Camila: We just need to count the number of square centimeters needed to cover the square, and thus we get $3\ cm^2 \times 4\ cm^2 = 12\ cm^2$ or, similarly, $4\ cm^2 \times 3\ cm^2 = 12\ cm^2$.

Fernanda: I think the area is $12\ cm^2$ as we have to do $4 \times 3\ cm^2 = 12\ cm^2$ or $3 \times 4\ cm^2 = 12\ cm^2$.

Figure 1: Students' productions included in the interpretative task

Although all students' numerical answers are correct (12 cm^2), their reasoning and argumentation differ and are associated with different interpretations of area, area units, and the meaning associated with the formula (A = length × width).

This interpretative task was implemented in three phases using the SCS cycle methodology. It was implemented in the middle of the master's course and the interpretative activity was proposed to the

PTs during an online class using the “Activity” function of the Microsoft Teams platform. Using the “Breakout rooms” function, the PTs were divided into small groups (of two or three members) for working on the task for one hour. At the end of this period, they had to deliver to the educator a shared written interpretation using the “Activity” function. Upon completion of this phase, the educator orchestrated a 90-minute collective discussion of the task for all the PTs using Microsoft Teams (phase two). In the final phase, the PTs were given Parnorkou’s (2020) paper as a reflection on the Dynamic Measurement approach for measurement of surface area. The PTs had one month to read the paper, reflect upon the task and co-write, using the same small working group as in phase one, a reflection on the lived experience and to hand it in to the educator. This phase was also part of our goal as educators to constitute a professional teaching community (Cobb et al., 2009).

When conducting the analysis of the PTs’ productions in the three phases of the SCS cycle, we focused on identifying the knowledge mobilized. In what follows, we present our analysis of one group’s work during the first and third phase, while attempting to trace the knowledge and awareness developed during the collective discussion (phase two).

Interpretative knowledge revealed and developed – some discussions

Danilo, Pietro, and Caterina, as a group, wrote in the first phase of task implementation (before the collective discussion) the following:

> Caio gave the standard definition and therefore it is not clear to us if he actually understood the meaning of the operation or if he simply applied a definition he had memorized. We would recommend a graphic approach in which the sides are divided into respectively 3 and 4 equal parts and from there we can see that each of these forms a square with a unitary area.

In some sense, we can see that these students are mature in giving feedback. In particular, in their suggestion to divide each side in equal segments—hence linking up to the idea of making a regular grid of squares with unit area—we can recognize their effort to help Caio to link his calculations with the meaning of covering the surface of the rectangle with unit squares.

The idea of making regular grid also emerged in the collective discussion:

Marco:	In my opinion, if we talk about units of measurement and therefore the symbolic expression, only Caio wrote well. The others have all made a mistake, either because they didn't write the unit of measure or because they added too many of them.
Rino:	In Fernanda’s case, I don't see formal errors.
Marco:	In my opinion, Fernanda is wrong because you can't write like this for units of measurement.
Rino:	The area is expressed in square centimeters, and she took four of them.
Pietro:	It is as if she had taken four strips three high, or three strips four long and covered the rectangle. It could be interpreted like this, obviously I don't know if that's what she thought.

We can see that there is a collective effort to give meaning to Fernando’s answer, and to create a link between Caio’s and Fernanda’s answers by making a regular grid covering the rectangle. After this, the educator prompted the PTs to choose between Caio and Fernanda:

Educator: If you have to write on the blackboard which formula would you write?

Caterina: If I had to explain the area, I would always use the covering technique. I would try to highlight this concept every time because it seems to me the central one in the measurement theory. But obviously I also like a unit of measurement written each time and, therefore, a dimensional analysis like Caio's works.

Danilo: But in some way also Caio is a covering if you mean a covering of thin strips, as many strips that would be the height for how long the base is.

Caterina: But in fact he did not make any mistake, he wrote well, if one really has to go to the bottom and ask what the area is, then I would like a child to understand that it is a covering with small cells at will.

Danilo: But you must also go and explain what the elementary area with which he covers is.

Educator: I believe that what Danilo tried to do by reading Caio's formula is to define this elementary square with a side of 1 cm and see it as generated by a segment of one cm which is repeated continuously a certain number of times. This is strange to say sometimes because it is a continuous movement, then cover it with very small strips in this case 1 high, which is precisely the fundamental theorem of integral calculus.

Danilo: Yes, it was how I imagined it when I was as a child.

Educator: So you already had a vision of the fundamental theorem of integral calculus and you didn't know it.

The educator's provocation was overcome by Caterina proposing to look at the area first as a covering process (referring to Fernanda's answer), but also expressing appreciation for the dimensional analysis present in Caio's answer. Caterina's comment created the opportunity to Danilo to present his crucial observation that gave new insight into Caio's answer. He proposed interpreting Caio's answer also as a covering process, but performed by using a "thin" linear segment to repeat for "how long the base is." We can recognize a link between this interpretation provided by Danilo and the Dynamic Measurement approach mentioned earlier that relies on visualizing the generation of a rectangular area by mentally sweeping a segment corresponding to one side of the rectangle along its perpendicular direction, in other words along the other side, for a distance corresponding of the length of the side (Parnorkou, 2020). It is important to underline that this interpretation of Caio's answer was not presented by Danilo in the previous phase in which the group comprising of Danilo, Pietro, and Caterina just expressed the grid covering perspective, and this represents an evolution of the mathematical reasoning norms (Cobb et al., 2009). It is also noteworthy that the evolution of one type of norms created conditions within the group for the evolution of norms of another type. In particular, the evolution in this mathematical reasoning norm also created an evolution in the pedagogical reasoning norms in the sense that the PTs were also expanding their space of solutions by looking at the situation from a wide range of different points of view, consistent with the IK approach.

Caterina's emphasis of the importance of considering the covering process as the underlying meaning of the area measurement shows that she has in fact failed to grasp Danilo's point of view. Still, the fact that Caterina does not understand gives Danilo a new opportunity to advocate for his point of view, challenging Caterina's suggestion for how to define the area of the square, used as unit of measure. The educator tried to respond to Danilo's challenge by proposing that PTs visualize generation of the area of the square (used as a unit of measure) using Danilo's dynamic way of looking at it, and by making an explicit reference to the Fundamental Theorem of integral calculus behind this vision.

One month after Parnorkou's (2020) paper was provided to all the PTs, Danilo, Pietro, and Caterina wrote a new interpretation, part of which is replicated below:

> Beyond some errors concerning the units of measurement, two different approaches emerge from the words of the students, already known in literature: that of covering and that of dynamic measurement. […] In any case, it is important to underline how the teacher must be able to recognize these two different approaches, consider them equally valid, but choose a starting one to present to the class, and then show equivalence with the alternative approach (perhaps following a discussion in the classroom from which this dichotomy may emerge).

In this excerpt, we appreciate the careful and effective summary made by this group of PTs of their new knowledge, which emerged from their participation in the SCS cycle and by working on this interpretative task. We stress that this final writing represents an important part of the cycle. By completing this written reflection, the PTs were able to organize their new IK. In particular, in the text provided by Danilo, Caterina, and Pietro, we see how their initial IK has been developed and enriched by the two approaches to surface measurement, and they are now able to present it in organized manner. The awareness of the possibility of approaching the measurement of the surface in two ways represents an evolution of the PTs' mathematical reasoning norms. This also prompted an evolution of their pedagogical reasoning norms (Cobb et al., 2009), as evident from this quote from one of the PTs: "the teacher must be able to recognize these two different approaches, consider them equally valid."

Some final comments

In this study, we have found that the adoption of the SCS cycle methodology has supported the IK development among the PTs. This is an initial study, and we propose that further research into the effect of the SCS cycle on developing the IK among PTs be conducted.

Foundation and justification of mathematics teaching decisions

Jimmy Karlsson

Karlstad University, Department of Mathematics and Computers Science, Sweden; jimmy.karlsson@kau.se

Keywords: Decision-making, teacher knowledge, mathematics education, research design.

Poster summary

Already in the seventies Alan Bishop considered decision-making at the "heart of the teaching process" (Bishop, 1976, p. 42) and together with other scholars of that time, such as Lee Shulman and Richard Shavelson, thought that if we better understand these decisions, we can better understand teaching (Borko et al., 2008). In more recent years, decision-making has gained a renewed interest as a situation-specific skill, especially within research pertaining mathematics teacher noticing (Dindyal et al., 202, Stahnke et al., 2016). In a review by Stahnke et al. (2016) regarding mathematics teaching situation-specific skills; perception, interpretation and decision-making, the latter was the construct least commonly addressed in the included studies. They also found that especially decision-making was difficult for pre-service teachers.

Within research on pedagogical content knowledge (Depaepe et al., 2013) and situation-specific skills (Stahnke et al., 2016) in mathematics education two perspectives are identified: a cognitive and a situated. The cognitive perspective focuses more on knowledge as a disposition. The situated perspective on the other hand pays more attention to the context where the knowledge is used (Depaepe et al., 2013). Common designs for the first mentioned includes larger samples with less contextual focus and the latter often utilizes smaller case studies in classroom settings.

Both perspectives have their merits and pitfalls (see Depaepe et al., 2013, p.23) that will have consequences for methodological design and study results. Hence, Stahnke et al. (2016) calls for designs that integrates perspectives and further notes that approaches that links mathematics teaching competence, skills and performance are rare. This is also in line with Mason (2016) who underlines the need for both studies with sufficient samples sizes for multivariate analyses and studies that acknowledge teacher actions and their justifications that could be beneficial for teaching development. As Depaepe et al., (2013) points out, teachers' justification of decisions in teaching is a core component of their knowledge base, these decisions and their justifications could provide grounds to further understand mathematics teachers' knowledge base.

In summary, this calls for further attention to mathematics teachers decision-making, its relation to other aspects of teaching competence, and how theory and design could address both disposition and skills, with attention to context and eliciting justification as means for understanding mathematics teaching. This is of importance both to the mathematics education research community but also to teacher education.

The aim of this poster is to contribute to the ongoing discussion regarding mathematics teaching competence by focusing on decision-making in mathematics teaching, its foundation and justifications. This is done by presenting an ongoing project that combines aspects from different perspectives with the purpose of gaining further understanding of mathematics teaching. The project draws from Schoenfeld's (2010) theory of goal-oriented decision-making together with the view of competence as a continuum from Blömeke et al. (2015), where decision-making is seen as a mediator between disposition and observable behavior. The project utilizes a mixed methodology to be able to explore the foundation and justification of teaching decisions and also connecting this to student learning and affective outcomes, which has been rare in previous research.

Engaging community colleges faculty in developing items for assessing mathematical knowledge for teaching

In this paper we investigate how experienced community college mathematics faculty, taking part in an item-writing camp designed to generate items to assess mathematical knowledge for teaching college algebra, thought about student thinking and the work of teaching in this context. We conceived of the participants' knowledge as practice-based professional learning. By analyzing video records of item development sessions, drafts of items produced, feedback sessions on the items, and self-reports of their learning during the camp, we identified four major themes related to participants' work highlighting the possible advantages of engaging faculty in item-writing: understanding mathematical knowledge for teaching, understand the item writing process, drawing on their teaching experience in the item-writing process, and noticing the complexity of writing MKT items. These themes make salient the advantages of engaging classroom-based faculty in item-writing.

Keywords: Mathematical knowledge for teaching, tasks of teaching, choosing problems, understanding student's work, student thinking.

Introduction

Over the last two decades, researchers have attempted to identify and describe the relationship between teacher mathematical knowledge for teaching and student achievement (Hill, Rowan, & Ball, 2005). Several research groups have developed instruments for measuring this special type of knowledge targeting specific grade bands (e.g., Hill, Schilling, & Ball, 2004). To develop items that reliably assess this type of teacher knowledge researchers have collaborated with mathematicians and practitioners (teachers, teacher educators, and professional developers), so that both the mathematics at stake and the ways in which it manifests in the classroom are authentically represented in the items. Relevant grade-level teachers have taken part in cognitive interviews, instrument piloting, or assessment item-writing camps (Phelps et al., 2014). Selling and colleagues (2016) have argued that

[1] In addition to the authors the AI@CC 2.0 VMQI Research group includes: Megan Breit-Goodwin, Anoka-Ramsey Community College; Nicole Lang, North Hennepin Community College; Mary Beisiegel, Oregon State University; Judy Sutor, Scottsdale Community College; Claire Boeck, University of Michigan; Bismarck Akoto, and Dexter Lim, University of Minnesota. Colleges are listed alphabetically.

item developers need support to make sense of the nuances of the knowledge construct and the best ways to assess it, yet there is little documentation about how classroom-based faculty work in collaboration with mathematical knowledge for teaching (MKT, Hill, Schilling, & Ball, 2004) researchers to create items for MKT instruments, or about their thinking process as they generate ideas and contribute to the item-writing process. This paper presents an exploration of how a group of 13 practitioners (community college mathematics faculty who teach college algebra), chosen from different regions of the United States, thought about their students' thinking, in the context of a two-week item-writing camp in which they were asked to produce 10 different multiple choice or testlet MKT items each. Involving teaching faculty in writing MKT items is not typically done by other MKT-assessment instrument developers—those groups limit practitioner input to feedback through cognitive interviews and pilot studies. We set out to answer this research question: In what ways does leveraging hypothetical examples of student work facilitate the development of MKT items designed to measure instructors' knowledge of students' mathematical reasoning?

The participants were invited as part of a large project that seeks to develop an assessment for mathematical knowledge for teaching college algebra at U.S. community colleges. College algebra is a credit-bearing course taught in postsecondary institutions in the United States, and typically covers content related to linear, rational, and exponential functions, as well as other relevant algebraic concepts in preparation for calculus. The number of students taking this course at U.S community colleges has steadily increased from about 190,000 in 2000 to about 300,000 in 2015 (Conference Board of the Mathematical Sciences, 2015). This course is considered a gateway to degrees in science, technology, engineering, and mathematics (STEM), being a prerequisite for a STEM calculus sequence. The immense number of students who take this course at U.S. community colleges, and consequently the large number of teachers needed to fill this need, creates an opportunity for developing an instrument that assesses the MKT of community college faculty teaching college algebra, (MKT-CCA), in these institutions; such instrument can serve as a tool for understanding the quality of instruction of this key course and its impact on student learning.

Sustained prior work to corroborate that MKT is composed of the various dimensions identified in the literature (e.g., subject matter knowledge, pedagogical content knowledge, Shulman, 1986) has proven very difficult. We chose follow Ko and Herbst (2020) who successfully distinguished knowledge needed when geometry teachers perform two different tasks of teaching, understanding student work and choosing problems. Tasks of teaching are the "recurrent practices that make up the work of teaching [school] subjects" (Phelps, et al., 2014, p. 3). Since these tasks of teaching are indeed foundational for teachers' work and given that there is evidence that it is possible to identify two distinct types of knowledge, we chose this conceptualization to develop our instrument. We used a tasks of teaching framework and adopted a two-dimensional hypothesis for the construct: (1) choosing problems and (2) understanding student work. We hypothesize that the knowledge that community college instructors use to choose problems for teaching college algebra can be distinguished from the knowledge that they use to understand students' work in college algebra. We (four university researchers, four community college faculty-researchers, three graduate students) developed a pool of items after training in instrument development. After developing a set of principles for writing items we invited practitioners to develop items along these two dimensions.

Methods

We recruited 13 community college faculty to participate in a two-week item-writing camp. These practitioners came from different geographical regions, taught at different types of colleges (urban, suburban, large, small), had varied demographic characteristics (e.g., race, gender), and had some experience writing cognitive tests and working collaboratively in small groups. These criteria generated a diverse group and shortened the time needed for training and team building. During the virtual item-writing camp we provided training for the participants that included: (1) an introduction to MKT literature, (2) definitions of the two tasks of teaching, (3) examples of items from our item pool, and (4) ways of checking that items fit the definition of the task of teaching they were targeting. We also provided a set of algebra topics we selected as representative of core mathematical ideas in college algebra, and that relate to linear, rational, and exponential functions. The faculty worked in self-selected teams of 2 to 3 participants; they were asked to draft items with feedback being provided by other participants and members of the research team in several cycles of feedback and revision.

Data and analysis

We collected two types of data (1) audio and video recorded work sessions in which the faculty worked collaboratively in teams to draft items, reviewed draft items from other teams, and used other teams' review comments to change and improve their drafts, and (2) reflection memos from the 13 instructors written at the end of each week, and that sought personal insights on the work of writing items. We used both ongoing and retrospective analyses of the data. Ongoing analysis occurred during the item-writing camp and involved reviewing the reflection memos after Week 1 to identify common themes using an open coding and a constant comparative method (Corbin & Strauss 2008).

Theme: Complexity of Writing MKT Items	
Objective Choices for Multiple Choice Items	It is challenging to create tasks with objectively correct options and objectively incorrect options (Mark, Memo #1, June 2, 2021)
Evidence for Student Understanding	A big reminder from the past week or so has been the idea of "what does it mean to understand __?" For example, to demonstrate understanding if a student computes the annual growth factor based upon 10-year percentage growth, that doesn't guarantee that they understand. (Steph, Memo #1, June 4 2021)
Metacognition	It feels very meta to write not just what student thinking might be but to take it to the level of what a teacher might be thinking about student thinking and how student thinking can be elicited. (Maggie, Memo #1, June 4, 2021)

Figure 1: Sample theme, subthemes, and sample quotes

These themes informed prompts for the reflection memo delivered after Week 2. Figure 1 shows one of the themes, its subthemes, and sample quotes that emerged. During retrospective analysis, we examined all available data (recordings and memo responses) using the coding system used to analyze the reflection memos from Week 1 while adding new themes and sub themes as needed. Four researchers independently coded these records; then met to compare, discuss, and agree on a final list of themes identified across the data set. This paper presents preliminary findings focusing on the data found in participants' memos.

Preliminary Findings

Four themes emerged from our data related to the participants': (a) attempts to understand MKT, (b) attempts to understand the MKT-item writing process, (c) attempts to draw on their teaching experience in the item-writing process, and (d) realizations of the complexity of writing MKT items. The first two themes were not entirely surprising, as they represent issues that anyone doing the work of MKT instrument development has to grapple with. Due to space limitations, we present findings about the last two themes to highlight insights into experiences of MKT writers who were encountering MKT research for the first time. These themes represent ways in which participants wrestled with writing items to assess community college instructors' thinking about student thinking.

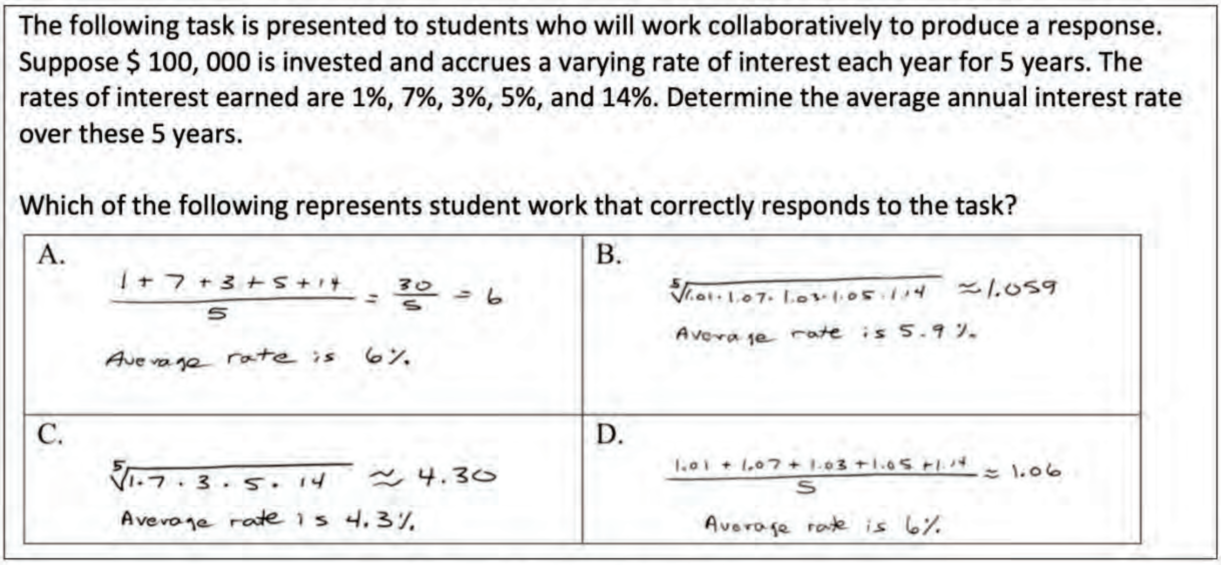
Drawing on Teaching Experience

Participants leveraged their teaching experience in the item-writing process in two different ways: (a) They used common student errors that they have observed in their own teaching of college algebra and (b) negotiating the goals of the college algebra course impacted their decisions in item writing.

Using Common Student Errors. Of the 13 instructors, ten reflected on how they sought to use common student errors they have encountered in their experience teaching college algebra to write items that would assess community college instructors' thinking about student thinking. They wrote that they began with common "mistakes," "errors," or "misconceptions" that they see in their own teaching. For example, Steph (pseudonym) wrote:

> I thought about problematic areas… common (from my experience) struggles [students] face or challenges they have in making sense of the ideas… like percent, geometric mean, ... then I created a couple of items to assess an instructor's ability to connect their math content knowledge with these hypothetical student responses. (Steph, Memo# 2, June 10, 2021).

Steph gave Figure 2 as an example of an item he created by reflecting on his knowledge of students' thinking. His ability to reflect on a common student struggle informed his decision to draft a realistic problem for college algebra at community colleges. Participant's knowledge of students' struggles with mathematical ideas was valuable for the item development process.



The following task is presented to students who will work collaboratively to produce a response. Suppose $ 100, 000 is invested and accrues a varying rate of interest each year for 5 years. The rates of interest earned are 1%, 7%, 3%, 5%, and 14%. Determine the average annual interest rate over these 5 years.

Which of the following represents student work that correctly responds to the task?

A. $\frac{1+7+3+5+14}{5} = \frac{30}{5} = 6$ Average rate is 6%.	B. $\sqrt[5]{1.01 \cdot 1.07 \cdot 1.03 \cdot 1.05 \cdot 1.14} \approx 1.059$ Average rate is 5.9%.
C. $\sqrt[5]{1 \cdot 7 \cdot 3 \cdot 5 \cdot 14} \approx 4.30$ Average rate is 4.3%.	D. $\frac{1.01+1.07+1.03+1.05+1.14}{5} \approx 1.06$ Average rate is 6%.

Figure 2: Draft MKT-CCA Item Created by Steph

Negotiating Goals for College Algebra. Our analysis revealed that participants leveraged their teaching experience as they wrote items to assess instructors' ability to interpret students' work relative to the instructional goals for the course. For example, Taylor wrote about the importance of writing items that focus on community college instructors' ability to understand their students' conceptual and procedural understanding:

> I tried to think about common errors or misconceptions I observe students making consistently... I also try to go back and forth between procedural and conceptual knowledge. Having procedural knowledge doesn't guarantee having conceptual understanding but it was difficult sometimes to pull and separate the two… I think that some of my items were focused on procedural knowledge more so than conceptual knowledge although having conceptual knowledge is key. (Taylor, Memo #2, June 10, 2021).

Taylor's understanding about the goals for college algebra enabled her to be mindful of the different types of understanding that the course seeks to develop, and to then think about the types of items needed to assess instructors' thinking about these types of student understandings. Trent also seemed to be thinking about the goals for this course when he wrote:

> There is still a large divide between what different [other participants] think is most important in college algebra. My team is very much focused on conceptual understanding and big ideas and others appear to still hang on to what I personally think are outdated aspects of the course. (Trent, Memo #2, June 10, 2021).

Trent's comment highlights a challenge related to intended outcomes for college algebra as there is variation in course outcomes for college algebra across institutions and states. Trent's statement seemed to go a step further than Taylor's by thinking about how other participants in the item camp were thinking about teachers' thinking about student thinking. Professional teacher organizations in the U.S. encourage mathematics teachers at all levels to strike a balance between developing their students' conceptual understanding and procedural fluency (e.g., American Mathematical

Association of Two-Year Colleges 2018). The challenge of making sense of a students' depth of understanding using a snapshot of a student's work presented on an MKT-CCA item in the absence of a dialogue with the student complicated the ability of item camp participants to write items that would assess an instructors' ability to think about and make judgements about student thinking. The participants' insights about the varying goals of college algebra contributed to the item-writing process in terms of the development of MKT-CCA items that assess test takers' ability to think about students' understanding in both procedural and conceptual terms.

Realizations of the Complexity of Writing MKT Items

Our data showed participants negotiating the complexity of writing MKT assessment items in three ways: (a) creating multiple-choice options that could be evaluated objectively, (b) evaluating evidence of students' understanding, and (c) the challenge of metacognition.

Creating multiple-choice options. Not only did the participants have to contend with crafting an item stem about an identified common student error but they also had to create either multiple-choice options or binary options for testlets that would be realistic for the stem and for college algebra. Eight participants wrote about their struggles with writing multiple-choice options. They gave varying reasons for why they struggled including: writing options that could be evaluated without subjectivity, writing realistic incorrect student responses, and using snapshots of students' incorrect work produces some unpredictability since students' work cannot be easily explained or packaged into a multiple-choice item. For example, Steph said:

> Multiple choice questions are VERY hard to write. Do the MC choices have to be right or wrong? Or can they all be viable and the response will tell us something about the respondent? In my first case, correct student work is shown and the respondent is asked which question they might ask to follow up on student thinking. It might be argued that all 4 questions (MC options) are possible (that is... not really "wrong" or "right"...) (Steph, Memo #1, June 4, 2021)

Like Steph, most participants struggled to decide on how to orient multiple-choice options to best assess a test taker's understanding of students' work or the test taker's perceptions of the best way a teacher would respond to help a student struggling with a math concept. The latter was further exacerbated by test takers' perceptions of the goals of college algebra and how it should be taught—two instructors could select diverging paths of intervention (e.g., two different follow up tasks) they believe would be appropriate intervention depending on their believes about teaching mathematics.

Evidence of student thinking. Ten participants wrote about the challenge of using students' written work and how that made writing items assessing community college instructors' ability to understand students' work difficult. Of the ten, five wrote about the difficulty of moving from a common student error to an MKT-CCA item, as illustrated in the following excerpt from Star's reflection memo:

> Nearly all of my items were drawn from actual work that my students have done in the past. I found that more often than not, the mistakes that students make cannot easily be explained/do not follow a predictable pattern. While it made it very difficult to write options for those stems, I think those will be the most valuable for testing MKT! Writing the "Understanding" items was an interesting experience because it highlighted the assumptions we make about student work. What

evidence do we base those assumptions on? Or is it all experience? (Star, Memo #2, June 10, 2021).

Star's pondering about the challenge of writing items about students' work, that different test takers who bring different teaching experiences, can interpret in a way that leads them to choose the same correct choice without the option of asking the student follow-up questions was shared by other participants. The jump from identifying common student errors to crafting an item that would meaningfully assess a community college instructor's thinking about the student's thinking posed challenges that Star and other participants had never wrestled with.

The Challenge of Metacognition. The reflection questions prompted participants to make explicit not only their thinking about their knowledge for teaching college algebra but to also think about the test takers' thinking about students' thinking and how that thinking would elicit knowledge needed in the particular task of teaching. The difficulty item writers had in thinking about student thinking suggests that the activity is not standard practice among community college instructors, that is, thinking about other faculty's knowledge is not in the scope of community college instructors' role as teachers, and we hypothesize that it is therefore rare. Star said:

> The line between knowledge of college algebra and knowledge for teaching college algebra is much finer than I thought. My first pass at a lot of the items I wrote ended up testing the participant's [mathematical] knowledge, rather than their knowledge for teaching. I think a lot of my knowledge for teaching college algebra is subconscious, and I still haven't quite figured out what the difference is, in explicit terms. (Star, Memo #2, June 10, 2021).

Star's reflection suggests that the work of writing MKT items is different from the work of writing assessment items for students that focus on college algebra content. MKT items, especially those focused on understanding students' work are inherently different in the sense that they target to assess a test taker's mathematical thinking about students' thinking. Maggie touched on this in her memo:

> The writing of the items is also new for me. It feels very meta to write not just what student thinking might be but to take it to the level of what a teacher might be thinking about student thinking and how student thinking can be elicited. Putting that into parallel foils is hard. Heck, writing the stem is hard! (Maggie, Memo #1, June 4, 2021)

Discussion

Involving practitioners in item writing meant adding a layer of training—as this was a group not intimately engaged in researching MKT—but also brought valuable perspectives to our item-writing process. Practitioners' experiences teaching college algebra at community colleges and their understanding of linear, rational, and exponential functions helped to enrich our database of items. Further, their ability to draw on their experiences to highlight common student errors for students in the targeted college algebra topics and their reflections on the goals for the course impacted the types of MKT-CCA items they drafted, which we believe will add to the diversity of items in the instrument. Finally, we found that the process of writing MKT-CCA items to assess instructors' thinking about student thinking provided the instructors who attended the item camp valuable insights into their own practice. Analysis of the data offered clues about how participants wrestled with issues such as what it means for a student to understand an idea and the kind of evidence needed to show understanding. The discussions held among partners in the item writing or reviewing process were rich and allowed the writers to think about issues around instruction that they do not ordinarily think about outside the context of thinking about a colleagues' thinking about student thinking.

Functional thinking development in Slovakia

Monika Krišáková and Matej Slabý

Pavol Jozef Šafárik University, Faculty of Science, Košice, Slovensko;
monika.krisakova@strudent.upjs.sk, matej.slaby@student.upjs.sk

Keywords: Function, aspects of functional thinking, mathematics teachers.

Introduction

This research deals with the teaching of functions and students' functional thinking development in Slovakia. According to Doorman et al. (2012) and Pittalis et al. (2020), there are four main aspects of the functional concept and functional thinking:

1. The function as an input-output assignment: This view on function as an input-output machine stresses the operational and computational character of the function concept. It also comes into play when patterns and structures are investigated (recursive patterning).
2. The function as a dynamic process of co-variation: This aspect concerns the notion that "two quantities varying simultaneously such that there is an invariant relationship between their values that has the property that, in the person's conception, every value of one quantity determines exactly one value of the other." (Thompson & Carlson, 2017, p. 444)
3. The function as a correspondence relation: A correspondence relation includes identifying a correlation between variables, using the function rule to predict far-function values, and finding the value of one variable given the value of the other. (Confrey & Smith, 1995)
4. The function as a mathematical object: "A function is a mathematical object which can be represented in different ways, such as arrow chains, tables, graphs, formulas, and phrases, each providing a different view on the same object." (Doorman et al., 2012, p. 1246)

This set of four views has some taxonomy characteristics, in the sense that it shows an increasing level of sophistication and may also suggest an order in which to acquire functional thinking. Therefore, the main aim of this research is to describe how is the functional thinking perceived by Slovak teachers and how the Slovak textbooks cover this topic.

Method

This study is part of the European project Erasmus+ FunThink that tries to improve functional thinking in a transnational perspective drawing on the partners' specific and complementary expertise. To describe the situation in Slovakia, we conducted six semi-structured interviews with Slovak teachers from primary to tertiary schools and analysis of the Slovak mathematics textbooks. Subsequently, we analyzed the data collected in the terms of the mentioned aspects.

The interviews were focused on the person's understanding of functional thinking, ways to address functional thinking in the class, and the implementation of some design principles. Due to the current situation, the interviews took place online, all of them were recorded. The Slovak mathematics textbooks, by Kubáček (2010-2012), cover all four years of secondary education in Slovakia and are the only mathematics textbooks approved by the Ministry of Education. In the tasks, we monitored which aspect occurs in them and which aspect is used most often in the tasks.

Results and conclusions

All six interviewees mentioned the search for connections and relationships between values or variables when describing functional thinking. They also agreed on what is the main problem in developing functional thinking in Slovakia. That is, as one teacher said: “Mathematics tools - variables, algebraic expressions, equations were reduced in the secondary school curriculum. Therefore, high school students have a big problem with the perception of variables. That in turn hinders the development and inquiry of a mathematical model of a function. The student intuitively perceives the dependence between variables, but the problem pops out when it is necessary to work with a mathematical apparatus.” Teachers emphasized that as many tasks as possible with a real context should be included in the teaching, thus linking knowledge to practice.

Given the four aspects of teachers' way of teaching, we have come to the following conclusion: When teaching some unit e.g., a linear function, they begin with aspect 1. Then their teaching methods differ. They either solve problems with the real-world context or everyday situations (aspect 2) by which they gradually generalize new knowledge (aspect 3) until they are completed with the definition of a linear function (aspect 4), or first they define the concept of a linear function (aspect 4) and then address tasks involving aspects 3 and 2. We can also add that in Slovak textbooks by Kubáček, the first three aspects occur in approximately the same number, tasks for the fourth aspect are rare, in some cases absent. In conclusion, we can add that there is a certain discrepancy between interviews and textbooks, which is influenced by the tradition of teaching functions.

Didactic suitability criteria related to the reflection on the implementation of mathematical modelling in a virtual context

Carlos Ledezma[1], Adriana Breda[1], Alicia Sánchez[1] and Gemma Sala-Sebastià[1]

[1]University of Barcelona, Faculty of Education, Barcelona, Spain;
cledezar25@alumnes.ub.edu, adriana.breda@ub.edu, asanchezb@ub.edu, gsala@ub.edu

We report the results of a research focused on studying what aspects of the instructional process prospective mathematics teachers relate to their reflections on the implementation of mathematical modelling in their didactic proposals. To do this, we used the construct Didactic Suitability Criteria proposed by the Onto-Semiotic Approach, which is the tool used by prospective teachers in their Master's Degree Final Projects to reflect on their own practice. In methodological terms, we carried out a content analysis of 122 Projects written during the 2019-2020 academic year, and whose implementation was performed in a virtual context due to the COVID-19 pandemic. Among the results, we stress that the prospective teachers related their comments on mathematical modelling mainly to the epistemic, affective, and ecological criteria of the implemented instructional process.

Keywords: Didactic suitability criteria, mathematical modelling, teacher reflection.

Introduction

There is a worldwide consensus on the development of competencies that involve the use of mathematics to solve real-world problems, among which mathematical modelling stands out (Kaiser, 2020). This competence is considered as: a) a central aspect of PISA for problem solving (Organisation for Economic Co-operation and Development, 2019); b) a beneficial process for the learning of mathematics (Blum, 2011); c) essential to train individuals capable of linking their mathematical knowledge to contemporary needs (Doerr & Lesh, 2011). Some studies have been reported on the role of modelling in teacher training (e.g., Tekin, 2019; among others), which are in line with the Maaß's (2007) idea that it is not enough just to train teachers in modelling, but they must also experience it. Unlike such studies, the one here reported focuses on the reflection of prospective teachers on the implementation of modelling in their Master's Degree Final Projects (MFP).

In the Spanish context, prospective teachers must obtain a master's degree in order to teach mathematics at secondary and baccalaureate education, for which they must prepare an MFP. This is an original, autonomous, and individual work, which allows the student to show the training content received and the general competencies acquired during the master's program in an integrated way. Furthermore, it must contribute to reflect on and deepen the analysis of their own practice, making it possible to propose elements for its improvement. Thus, due to the importance of both modelling and teacher reflection within teacher training, this study raises the question: What aspects of the instructional process do prospective mathematics teachers relate to mathematical modelling when they reflect on its implementation? In order to answer it, we analysed the reflection that prospective teachers made in their MFPs on the design and implementation of their didactic proposals, in which they included the work with modelling. We analysed this reflection using the Didactic Suitability Criteria (DSC) proposed by the Onto-Semiotic Approach (OSA) (Godino et al., 2007), which was the same tool used by the prospective teachers to reflect on their own practice.

Theoretical framework

Mathematical modelling

In general terms, the modelling process is understood as a transition between the «real world» and «mathematics» for solving a problem-situation taken from reality. At a theoretical level, different cycles have been designed to explain this process (Borromeo, 2006), as well as different perspectives on its implementation in classroom have emerged (Abassian et al., 2020). Since in this study we did not adopt any particular modelling cycle or perspective, we considered some consensual attributes that characterise both the work with this process in classroom and a modelling problem.

The work with modelling in classroom is usually carried out in small groups of students, to whom a real-world problem-situation is posed that they must mathematise (Doerr & English, 2003). Modelling activities involve a cyclical process, with different ways to obtain a plausible and coherent solution with the context of the situation posed (English, 2003). This problem must be *open* (not limited to specific answers or procedures), *complex* (useful information must be distinguished from the rest of the wording of the task), *realistic* (adding elements taken from reality), and *authentic* (a situation consistent with a fact from reality) (Borromeo, 2018).

Didactic suitability criteria

In the OSA (Breda, 2020), the *didactic suitability* of a teaching-learning process is understood as the degree to which it (or a part of it) meets certain characteristics that allow it to be qualified as suitable (optimal or adequate) in order to achieve an adaptation between the *personal meanings* achieved by the students (learning) and the *institutional meanings* intended or implemented (teaching), taking into account the circumstances and available resources (environment). This multidimensional construct consists of six *suitability criteria*: *epistemic criterion*, to assess whether the mathematics that is taught is 'good mathematics'; *cognitive criterion*, to assess, before starting the instructional process, whether what is intended to be taught is at a reasonable distance from what the students know; *interactional criterion*, to assess whether the interaction solves students' doubts and difficulties; *mediational criterion*, to assess the adequacy of resources and time used in the instructional process; *affective* (or *emotional*) *criterion*, to assess the students' involvement (interest, motivation) in the instructional process; *ecological criterion*, to assess the adaptation of the instructional process to the educational project of the school, the curricular guidelines, the conditions of the social and professional environment, etc. Each of these criteria has its respective components, and its utility requires defining a set of observable indicators, which allow assessing the degree of suitability of each of the facets of the instructional process. The list below shows the components of each DSC with the codes used in this research to label them, based on the Breda and collaborators' (2017) guideline.

Epistemic: Errors (ES1); Ambiguities (ES2); Richness of processes (ES3); Representativeness of the complexity of the mathematical object (ES4).
Cognitive: Prior knowledge (CS1); Curricular adaptation (CS2); Learning (CS3); High cognitive demand (CS4).
Interactional: Teacher-student interaction (IS1); Students' interaction (IS2); Autonomy (IS3); Formative assessment (IS4).
Mediational: Material resources (MS1); Number of students, class schedule, and conditions (MS2); Time (MS3).
Affective: Interests and needs (AS1); Attitudes (AS2); Emotions (AS3).

Ecological: Curriculum adaptation (EcS1); Intra and interdisciplinary connections (EcS2); Social and labour usefulness (EcS3); Didactic innovation (EcS4).

In the OSA, mathematical modelling is considered as a *hyper* or *mega process* (Godino et al., 2007), since it involves other more elementary *processes* (representation, argumentation, idealisation, etc.). Furthermore, within this framework, enhancing modelling is an aspect that improves the suitability of the instructional process (Ledezma et al., 2021).

Methodology

In this study we followed a qualitative research methodology from an interpretative paradigm (Cohen et al., 2018), which mainly consists of a content analysis (Schreier, 2012).

Research context

This research was carried out in the context of the Master's Program in Teacher Training for Secondary and Baccalaureate Education (mathematics speciality), taught by the public universities of Catalonia (Spain), during the 2019-2020 academic year. The master's program prescribes (within the Internships module) to carry out educational internships in collaboration with the institutions established through agreements with the universities. In these internships, the prospective teachers must design a didactic unit that they must implement, which is determined by the educational institution, the students' level, and the time of the school year in which they carry out their intervention. Because of this situation, the margin that a prospective teacher has to work exclusively on modelling in his/her didactic unit is subject to certain restrictions, but not in the redesign proposed in his/her MFP. Due to the lockdown because of the COVID-19 pandemic, the prospective teachers of this course had to implement their didactic units, either partially or totally, in a virtual context.

For the elaboration of a MFP, the DSC are presented to the prospective teachers, along with the Breda and collaborators' (2017) guideline that allows their application. With these tools, the prospective teachers are suggested to assess in their MFP the didactic unit that they implemented, so that they propose changes that can help improve the suitability of the instructional process. The structure of an MFP consists of five chapters: *Introduction* (institutional and curricular context of implementation), *Implementation analysis* (assessment of the didactic suitability of the didactic unit, using the DSC), *Redesign proposal* (reformulation of the didactic unit), *Competence self-assessment* (according to the knowledge and competencies acquired in the master's program), and *Annexes*.

Content analysis

For this study we considered 122 MFPs, corresponding to the 2019-2020 academic year. For their qualitative analysis, we followed steps similar to those used by Sánchez and collaborators (2021). In a *first step*, according to the literature review and our knowledge on the topic, we drawn up a list of keywords related to mathematical modelling (context*, model*, problem*, real*), in order to identify the references about this process in the evaluative comments of the MFPs. In a *second step*, we recorded the data of each document (author, title, educational level, mathematical content), in order to have an ordered database to consult the MFPs and, in this way, keep a first record of which MFP mentioned the keywords from the *first step*. In a *third step*, we classified the MFPs according to four levels of reference to modelling that we could identify in their proposals, as detailed below:

Level 0 (L_0): No modelling problems are proposed/implemented; the inclusion of modelling is not considered in the redesign proposal.

Level 1 (L_1): No modelling problems are proposed/implemented; the inclusion of modelling is considered in the redesign proposal.

Level 2 (L_2): Modelling problems are proposed and there is a reflection on their implementation; no improvements are proposed to enhance modelling in the redesign.

Level 3 (L_3): Modelling problems are proposed and there is a reflection on their implementation; improvements are proposed to enhance modelling in the redesign.

In a *fourth step*, we categorised the comments with references to modelling using the DSC. Various studies have addressed the teacher reflection in mathematics teaching training processes (see Breda, 2020, for didactic analysis; Hidalgo-Moncada et al., 2021, for self-regulation practices; Sánchez et al., 2019, for the development of creativity, among others), using a content analysis methodology to make evident the use of the DSC components. In this research, these components are considered as a priori categories (Schreier, 2012), in order to identify the aspects of the instructional process that the prospective teachers related to the work with modelling. More specifically, we considered the evaluative comments from the *Implementation analysis* and *Redesign proposal* chapters, since they include all the prospective teachers' reflections on their own practice, from the MFPs classified in the levels of reference L_2 and L_3. As an example of the content analysis described above, we use the MFP #24. We found several references to the keywords: «model», «modelling», and «problem» in this MFP, which consists of a proposal for the teaching of functions in the third grade of secondary education (students aged 14-15). Among many others, we found this comment in the assessment of the CS4 component: "We tried to have activities and sessions that were more competent to work on cognitive and mathematical processes such as […] modelling and problem solving" (p. 12). However, this MFP did not include improvements to modelling in its redesign proposal, so we classified it in the level L_2 (a more detailed analysis can be found in Ledezma et al., 2021).

Results

Classification of the MFPs according to the levels of reference to modelling

From the search for keywords in the MFPs (*first step* of content analysis), we identified that 86 of the 122 documents referred to the terms related to modelling. After recording each MFP (*second step* of content analysis), we classified them according to the levels of reference to modelling (*third step* of content analysis), thus we obtained the following results: 33 MFPs in L_0, 41 MFPs in L_1, 21 MFPs in L_2, and 24 MFPs in L_3. The *first* and *third step* of content analysis also allowed us to refine the number of MFPs to analyse: a) during the *first step* we identified three MFPs presented under the research project format, so we did not consider them for this study; b) during the *third step* we identified three MFPs which did not explicitly refer to modelling in the *Implementation analysis* chapter, but they referred to implemented modelling activities in the *Annexes* chapter, including comments related to this process but not being attached to any specific DSC. Although we classified these last three MFPs in L_3, we did not consider them in the *fourth step* of content analysis. Taking into account these considerations, the following results show the analysis of 45 MFPs classified in levels L_2 and L_3.

Classification of the comments according to the DSC components

From the previous classification (*third step* of content analysis), we categorised the evaluative comments related to modelling according to the DSC components. To do this, we focused on the

Implementation analysis chapter of the 45 MFPs classified in levels L_2 and L_3, and then we identified in which DSC component the prospective teachers –explicitly or implicitly– made their reflections on the role of modelling in their didactic units (*fourth step* of content analysis). In this way, the results presented in Table 1 show the number of comments that we identified in the assessment of each DSC component, using the codes mentioned in the theoretical section.

Table 1: Number of comments referring to modelling in each DSC component

Components	No. of comments	Components	No. of comments	Components	No. of comments	Components	No. of comments	Components	No. of comments	Components	No. of comments
ES1	1	CS1	5	IS1	3	MS1	4	AS1	32	EcS1	2
ES2	2	CS2	1	IS2	4	MS2	0	AS2	3	EcS2	14
ES3	40	CS3	1	IS3	1	MS3	4	AS3	5	EcS3	20
ES4	11	CS4	12	IS4	0					EcS4	4
Total	54	Total	19	Total	8	Total	8	Total	40	Total	40

Discussion and conclusions

The *first step* of content analysis made us evident that around two thirds of the 122 prospective teachers referred in some way to modelling in their MFPs, through the keywords related to this process. The *second step* of content analysis allowed us to identify the mathematical contents of the MFPs in which the presence of such terms was stressed (in descending order): Functions, Trigonometry, and (linear and quadratic) Equations. This tendency to use modelling to teach functions, on the part of the prospective teachers, is in line with Michelsen's (2006) position, who highlights the role of this mathematical object as a tool to develop the modelling process in classroom. The *third step* of content analysis refined the results of the *first step*, as it allowed us to narrow the number of MFPs to analyse (from 122 to 119), and also showed us that around a quarter of the 122 prospective teachers implemented modelling in their didactic units. A relevant aspect is that, although the master's program includes a submodule on modelling (within the Specific Training module) in which the cycle proposed by Blum and Leiß (2007) is presented, none of the MFPs referred to this cycle (or any other) and neither used it to describe the proposed problems or to analyse their implementation. This suggests, on one hand, that there is insufficient clarity on how to use a modelling cycle to analyse this kind of problems and, on the other hand, that carrying out this kind of analyses in the reflection on their own practice is not considered as a relevant aspect. However, since this is an autonomous work, the prospective teachers are not asked to specifically reflect on modelling from the theoretical perspective in their MFPs, but rather it is an open decision, taking into account the pages number and time constrictions for its elaboration.

The *fourth step* of content analysis made us evident that most of the comments on the implementation of modelling focused on the assessment of the *epistemic*, *affective*, and *ecological criteria*, although also –to a lesser extent– on the *cognitive criterion*. Regarding the *epistemic criterion*, the assessment of the ES3 component (on the realisation of relevant processes in mathematical activity) was the one that gathered the largest number of comments on modelling, because here the processes worked in the didactic unit were defined. A relevant aspect is the tenuous differentiation established in some MFPs to define the processes: «problem solving», «modelling», and «contextualisation», in which, for instance, if a statement was posed within the mathematical world, then they did «problem solving», but if it was posed in the real world, then they did «modelling»; or also, if a problem developed «contextualisation», then it was a «modelling» problem. This situation could indicate that there is insufficient clarity about the theorising around mathematical modelling and the characteristics of this kind of problems (as described in Borromeo, 2018). Derived from above, the comments in the ES4 component (on the meanings and representation modes for the treatment of mathematical objects) mainly refer that modelling problems allowed working the mathematical objects using different semiotic representations. Regarding the *affective criterion*, the assessment of the AS1 component (on the interest and utility of the tasks) was the second with the largest number of comments on modelling. These comments pointed out that this kind of problems, being 'contextualised' and 'realistic', caught (or intended to catch) the students' attention, due to many of them took advantage of the context of COVID-19 and lockdown as a topic in their wordings. Regarding the *ecological criterion*, the assessments of the EcS2 (on the relation between mathematical contents with other disciplines) and EcS3 (on the utility of contents for social and labour insertion) components included comments referring to modelling as a tool to relate mathematics, both to other curricular contents and to the students' context. We make a special mention regarding the *cognitive criterion*, since the assessment of the CS4 component (on the activation of relevant cognitive processes in mathematical activity) stressed that modelling problems made it possible to work on other relevant processes of mathematical activity (in line with Godino et al., 2007). Regarding the *interactional* and *mediational criteria*, it is evident that their assessments included very few comments on modelling. Due to the virtual teaching context, the prospective teachers commented that they had many difficulties in developing a collaborative work between their students (affecting the *interactional criterion*), as suggested for the work with modelling (Doerr & English, 2003). For this reason, in both *criteria* they made comments on the components that would potentially be addressed by the solving of this kind of problems in their redesign proposals.

Resuming the research question, the main conclusion is that the prospective teachers mainly related the *epistemic*, *affective*, and *ecological* (and to a lesser extent, the *cognitive*) aspects when they reflected on the work with modelling in their didactic units implemented in a virtual context (similar result to that found in Breda, 2020). The study reported in this paper is part of a broader research project, which aims to contribute to research on teacher reflection in teacher training, specifically, on the implementation of modelling. Since this part was carried out during the 2019-2020 academic year, the next step is to compare these results with the prospective teachers' reflections in the MFPs from the 2020-2021 academic year, implemented in a face-to-face context. As a final purpose, we intend to design a guideline of specific DSCs for the work with mathematical modelling in the instructional processes implemented both in a face-to-face and in a virtual context.

The emotions of a mathematics teacher educator in an online context

Mónica Marbán[1] and Miguel Montes[2]

[1]Universidad Rey Juan Carlos, Madrid, Spain; monica.marban@urjc.es

[2]Universidad de Huelva, Spain; miguel.montes@ddcc.uhu.es

The global health emergency caused by COVID-19 has had profound repercussions in education around the globe. In response, many educational institutions, including universities, have shifted teaching to online formats. This sudden and abrupt change has had a significant impact on teachers' emotions. In this study, we use an instrumental case study to explore the effect this unexpected context has had on the emotions of a primary teacher educator. Drawing on the theory of the cognitive structure of emotions, we analyse the educator's emotions, as evidenced and as reported, over a series of teaching sessions. The results show the occurrence of both positive and negative emotions deriving from the situation, which should give pause for thought in the university context.

Keywords: Emotions, online teaching, affective domain, mathematics teacher educator.

Introduction

There is an increasing amount of research focussed on investigating the affective domain and its importance in the teaching and learning of mathematics. Interest in the topic has developed over the last few decades, and this has been reflected in different theoretical and methodological approaches (Hannula, 2011). One of the constructs constituting this domain which has received increasing interest is that of the emotions. It has been demonstrated within the fields of cognition and neuroscience that emotions are fundamental to people's learning and development. The importance of affect and the emotions is now also beginning to be recognised within the area of educational research (Pekrun & Linnenbrink-Garcia, 2012). Furthermore, teacher educators have centered the attention of the field as key professionals in the management of (prospective) teachers professional development (Goos & Beswick, 2021).

As the emotions are profoundly intertwined with thought (Immordino-Yang & Damasio, 2007), it is natural that they should play a role in the relationships and situations that the teacher manages in the classroom. This is because the emotions reflect not only an individual's external relationships with other people, society and the situation, but also their internal relationships with their own reflections and memories (Mayer et al., 2011). Bearing this in mind, and consistent with Zembylas (2007), in order to teach effectively, educators should be able to marshal their emotional knowledge to establish or strengthen links with the topic and with the students, to develop the syllabus, and to make decisions on how to act. Further, it makes sense to assume that an appropriate environment for learning is fostered when the experience is pleasant for educator and learner alike. In this respect, various studies have set out to describe and analyse students' emotions and their influence on learning (e.g., Fernández-Berrocal et al., 2017; Pekrun et al., 2002). Within a supportive environment, the student will be willing to make an effort to learn and to reconfigure their existing knowledge, which is the main purpose of learning.

On the other hand, the pandemic (COVID-19) has triggered significant changes at all levels of education, obliging institutions and teachers to rely on technology to conduct lectures and other teaching-learning activities (Engelbrecht et al., 2020). With so much uncertainty, it is unsurprising that teachers have experienced a range of emotions more intense and keenly felt than usual.

In response to this issue, the research question for this paper is the following: What impact has the imposed online context had on the emotions felt by a primary level teacher educator while teaching the course "Mathematics and its Didactics I"? To answer this question, we carried out an instrumental case study. This involved video recording an educator's classes, and conducting follow-up interviews with her to clarify and explore the emotions she had felt.

Theoretical framework

In our study of emotions, we draw on the Ortony, Clore, and Collins (OCC) Theory (Ortony et al., 1996), based on the cognitive structure of emotions. We assume, following Ortony et al. (1996), that prior to any emotion there is a system of analysis and information processing, that is to say, the subject's cognitive construal of a specific external situation. We use the definition provided by these authors, for whom "emotions are valenced reactions to events, agents, or objects, with their particular nature being determined by the way in which the eliciting situation is construed" (Ortony et al., 1996, p.13). Emotions arise from specific situations and the perception the subject has of them. The subject cognitively construes the situation in a manner which can be more or less conscious, and this construal produces a valenced reaction on the basis of the subject's own internal system of goals, rules and attitudes. The valency refers to the positive or negative charge of the emotion, according to whether the event taking place fulfils or not the subjects goals, rules and attitudes.

When a teacher is giving a class, consciously or unconsciously, they are constantly construing the different interactions and situations which arise, eliciting different emotional responses: some of greater intensity, some longer lasting, and some with a larger cognitive load. One of the functions of an emotion is prime the subject for action (Ortony et al., 1996). In this way, emotions can provide us with information about both the eliciting situation and the reaction this produces, as we might not always react in exactly the same way when faced with similar situations. The explicit analysis of these processes can reveal information that the teacher might not have been consciously aware of, and can thus help them to understand why they acted as they did, and to decide whether such responses would be effective in similar situations.

According to the OCC model, emotions can be classified into three large groups, corresponding to the three major aspects of the world which can trigger them: events, agents and objects (Ortony et al., 1996). Prior to the emotion, the subject appraises the situation and focuses on one of these three aspects, that is to say, either the consequences of the event, or the responsibility of the person (or other agency) involved in bringing about the event, or on the simple pleasure or displeasure that the event has caused. For this reason it is important to describe the situation which has triggered the emotion, and to study emotions in the context in which the event takes place. According to Ortony et al. (1996), each individual has a structure of goals, interests and beliefs underlying their behaviour; in other words, the construals preceding an emotion vary from person to person on the basis of this structure. Naturally, this structure is directly related to the three major aspects of the world mentioned above. Hence, consistent with the OCC theory, the appraisals determining whether or not an event is desirable are underpinned by an internal structure of goals; likewise, whether the action of an agent is praiseworthy aligns with the subject's system of norms; and whether or not an object is considered attractive is based on their system of attitudes. The OCC theory proposes a classification of emotions according to the context that elicits them (Table 1). Hence, it identifies emotions as reactions to events, agents, and objects, or a simultaneous combination of event and agent.

Table 1: Classification based on information from the OCC theory (Ortony et al., 1996)

Reactions to events	
Well-being	*Joy*: pleased about a desirable event
	Distress: displeased about an undesirable event
Fortunes-of-others	*Happy-for*: pleased about an event desirable for someone else
	Sorry-for: displeased about an event undesirable for someone else
	Resentment: displeased about an event desirable for someone else
	Gloating: pleased about an event undesirable for someone else
Prospect-based	*Hope*: pleased about the prospect of a desirable event
	Fear: displeased about the prospect of an undesirable event
	Satisfaction: pleased about the confirmation of the prospect of a desirable event
	Fears-confirmed: displeased about the confirmation of the prospect of an undesirable event
	Relief: pleased about the disconfirmation of the prospect of an undesirable event
	Disappointment: displeased about the disconfirmation of the prospect of a desirable event
Reactions to agents	
Pride: approving of one's own praiseworthy action	
Shame: disapproving of one's own blameworthy action	
Admiration: approving of someone else's praiseworthy action	
Reproach: disapproving of someone else's blameworthy action	
Reactions to objects	
Love: liking an appealing object	
Hate: disliking an unappealing object	
Combined reactions to event and agent	
Gratitude: pleased about a desirable event and someone else's praiseworthy action	
Anger: displeased about an undesirable event and someone else's blameworthy action	
Gratification: pleased about a desirable event and one's own praiseworthy action	
Remorse: displeased about an undesirable event and one's own blameworthy action	

In addition to identifying emotions and interpreting the corresponding situations which elicited them, we will also analyse whether the unexpected online context had an influence on the educator's emotions, or indeed actually acted as a trigger for them. It should be borne in mind that the majority of Universities in Spain opted to switch to online classes during the pandemic. This situation saw teachers having to modify not only their material but also their manner of running classes just to keep students' attention. Although the health crisis has been seen by some as an opportunity for change, there has also been a degree of uncertainty in the sudden shift to online teaching (Engelbrecht et al., 2020). These anxieties are likely to be reflected in the educator's emotions on finding themself in an unfamiliar environment, without the kind of control they are accustomed to having in the physical lecture hall.

At the same time, teachers are aware that if they are to be effective in the new environment, they need to adapt their teaching style (Hollebrands & Lee, 2020), and equally importantly, they need to do so within the confines of the limited resources and facilities their institutions are able to provide. In the best case scenario, they can count on the support of colleagues who generously share their material, time and ideas, or even agree to work as a team. Even so, every teacher has found themselves investing considerable time in learning how to use new applications which might be of use, and in creating or adapting their teaching material so as to fulfil the requirements of the online medium. These new challenges facing teachers can make them feel isolated and uncomfortable (Collazos et al., 2021; Hollebrands & Lee, 2020).

It should be remembered that for most teachers and students the circumstances we find ourselves in are completely new. Due to the lack of feedback, one of the main challenges for teachers in online teaching is how to get the information they need from learners to check that the desired knowledge has been acquired (Collazos et al., 2021). This will be the guiding principle when educators plan their classes and elicit responses during the sessions, as in the new context, the traditional channels – monitoring students for reactions or still less circulating around the lecture hall or classroom – are no longer available.

Methodology

This study follows an instrumental case study design, taking an interpretative perspective with an exploratory intention. The informant for the research, who will be identified as Nora, is a primary teacher educator in Mathematics. At the time of the study, she had been a university teacher for 27 years, the last 7 of which completely focused in teacher education at primary level and in Mathematics teaching. She was also an active participant in research projects into Mathematics education. We chose Nora because of her great communication skills and her willingness to discuss her own emotions, and because of her experience teaching teachers to teach mathematics (more than 10 years).

The teaching observation took place during the delivery of Mathematics and its Didactics I, a course in the second year of the Degree in Primary Education, which focused on teaching arithmetic. Nora had taught the course previously, but this was her first time via online/ mixed modality classes, with students following the class remotely by computer. Data collection was carried out by means of video-recording ten sessions of approximately one and half hours each. After five of these sessions, one of the researchers – who had observed the sessions in a non-participatory capacity– asked Nora to answer a set of questions (formalised as a report) about situations that had arisen; this was followed up by four semi-structured interviews aimed at amplifying and confirming Nora’s responses.

According to Ortony et al. (1996), there are four kinds of evidence which can help us to understand emotions: language, personal reports, the type of behaviour elicited, and physiological cues. In our case, we were principally interested in the first two of these – language and personal reports – as they provide information about the subject’s prior cognitive appraisal leading to the elicitation of the emotion. For the purposes of this study, a content analysis was carried out (Krippendorff, 2018), taking the emotions proposed by the OCC theory (Table 1) as the categories of analysis. This model allows us to work with the cognitive part of the emotion. The analysis will show the triggering situation of the emotion and information about Nora's appraisal and how it makes her feel.

Analysis of the results

This section shows the first emotions identified and classified in the research process, and the influence on them of the online context. Interlaced with the analysis, and marked by italic, we include some of Nora's commentaries providing further evidence of the emotion.

Reactions to events

This category, we remind ourselves, concerns emotions bound up with Nora's system of goals, and focuses on events, adjudged desirable or undesirable, depending on whether or not they enable her to achieve her goals.

At various points, Nora mentions how important it is for her that the students participate and talk to each other; they should be at the centre of things, and it is they who should set the pace of the class. On occasions she finds it difficult to get any kind of response, while the students claim they are having problems activating the camera and even the microphone – when they do respond, they tend to write in the chat window. Typical among Nora's comments is this: *It does cause me a bit of frustration, I would like there to be more interaction through the microphone or with the camera because that makes the session more dynamic*.

Related to this is her sense that sometimes the classes are not going as she would like, according to her own conceptions, in direct contrast to the in-person format: *I think that the activity with the multiplication tables, if they could come up to the blackboard to do it, interact and so on, it would be better. I mean, I feel bad for doing it in such a traditional way*. In addition, at certain times, she would like to be able to deal with her students differently, to be more accessible and elicit the kind of answers and interaction mentioned above: *Those interactions when you get closer: "Come on, what have you seen here?" That leaves me with a sense of disappointment ... in that I don't have a more direct relationship with them*.

This is a new challenge for Nora, and when she achieves the dialogue she wants with the students, as might be expected, she shows her pleasure: *When I began giving the classes online I thought the level of interaction would be higher. When I saw that wasn't the case, each time it happens, I feel pleased*.

When Nora puts herself in her students' place, she evokes the category 'fortunes-of-others' (Table 1) with her empathetic response, appraising events as desirable or undesirable for her students. It seems clear that she perceives an enforced distance, which it is difficult to avoid in the online context. On the one hand, not being able to attend to and manage the emotions of her students is disappointing for her: *I can't be with them, the supportive role of saying "Come on everyone, you can do it"*. On the other hand, she is sympathetic of her students' situation. She recognises that the online context is also proving a challenge for them, particularly with regard to working in groups and to communicating with her when they are not in the classroom: *They may be right that this year, until they get up to speed with deadlines and so on, they need a little more time*.

The final group of reactions to events are prospect-based, that is to say, based on events which the educator hopes or suspects might happen. Here we see how the online context causes her unease: *I've already lost 10 minutes before the class even starts, what with the computer won't boot up, the camera, and whatever ... I don't have any leeway, I'm much more dependent on the time*.

Nora modified the activities so as to be more manageable in the online context, but she worried that in the end something might not work, or the students might get distracted and it might be difficult to gain their attention again: *Fear of starting something and taking a long time to get going, or that the platform crashes; and then it's that idea/emotion that stays with the students about the class (those problems and not the content)*.

To this can be added the background worry that although the class seems to be progressing, nobody is asking any questions: *In class they are more willing to ask questions, even if they are not following you. Online, though, to interrupt, to put their hand up, that is harder for them to do*. When the students are in the classroom, if Nora spots a look of doubt on their faces, she encourages them to ask for clarification. Online, there is no way of seeing whether they understand, there is no visual feedback loop.

In contrast to the above, however, there are also moments of satisfaction, when Nora manages to create a dynamic in which the students do intervene: *Each time they get more involved, even though it is through the chat window, it gives me a certain degree of satisfaction*. The same sense of achievement is felt after she manages to readjust the classes and still meet the stated objectives: *I've covered what I wanted and I felt good. And I think they liked the slides*.

Reactions to agents

This category of emotions concerns the attribution of responsibility for the triggering situation to a person (in our case usually the students or the teacher educator) on the basis of Nora's norms, codes of conduct, rules and so on.

When talking about the process of evaluating her students, Nora expresses a degree of discomfort (a process she feels is very demanding of her integrity), putting the focus on herself: *I'm worried about not being fair in the evaluation ... discriminating who is well trained at that moment and who needs more time*. It is an emotion which could appear in any context, but the fact that the exam is likely to be online, and therefore devoid of the usual measures to prevent cheating, increases her unease and mistrust.

At other times, the focus is on the students, such as when in a group none of them is able intervene to discuss the activities because no-one has a microphone: *I'm not happy about it, I get the impression they're not being honest with me*. Such as things are, the students can, if they wish, blame the tech and disappear, a ruse to avoid participating which is unavailable to them in the face to face classroom.

Combined reactions to events and agents

This category of emotions concerns appraisals involving both goals in relation to events and norms in relation to agents. An example is Nora's sense of gratification for having successfully completed the large amount of extra work involved in adapting the course to an online context, and her feeling that the results have been good: *I've done it, I've worked hard and have reaped the rewards ... Their faces have an expression of 'Oh, that's interesting!'* This particular comment arose when some students, following a mixed online/in-person methodology, had returned to the classroom with Nora and hence she could see their faces. Previously, when all the students were online, she had missed this kind of feedback.

Finally, there is specific moment when Nora feels indignant at the something a student says. The student switches on their microphone to complain about the latency affecting the online students, something she had been at pains to warn them would happen: *I had gone over it a lot to make sure it was clear: I made sure the slides were large, and didn't use the blackboard too much ... It seemed extremely unfair to me and I <u>felt bad</u>.* In this instance, in addition to being, in the terminology used in OCC theory, an undesirable situation for Nora, she also found the action of the student blameworthy, as he had not listened to her or appreciated her efforts.

Final reflections

The analysis foregrounds how the educator's emotions respond to the changes she perceives in her interactions with her students and the teaching-learning environment (Mayer et al., 2011), and how influential the online context is in triggering these emotions. According to Engelbrecht et al. (2020), teachers have to face new problems and may feel uncomfortable and isolated in this online context. From the beginning, we verified how for Nora it was a concern and trigger for many of the emotions we have analysed. It also makes sense of the fact that eleven of the emotions analysed have a negative valence and only four have a positive valence.

The majority of the emotions which Nora affirms to have experienced are based on her dynamic structure of goals, which demonstrates her commitment to planning session with clear objectives that she wants to achieve. When this happens, the resultant emotions are happiness, feeling good and satisfaction, because the session has worked according to these approaches. If the focus is also on the agent (herself), the resulting emotions are of gratification and pride for having achieved them. The online context challenges teachers to adapt the way they teach (Hollebrands & Lee, 2020) and to take stock of their own capabilities, something worth noting.

With respect to the events which Nora deems undesirable, we can see that the online context causes her anxiety and suspicion, as it does not allow her to carry out the class in the way that she is familiar with and that she considers appropriate for facilitating the students' learning. She highlights this when she states that she misses being able to get close to the students to encourage them, guide them in what they are doing, and encourage them to share things with the group and enrich the contributions. In addition, she lacks feedback from the looks on the students' faces when she is in the classroom: what they are understanding and what not, what they want to ask or reply to, what they like, and so on. This forms part of the isolation of the online teacher and the lack of feedback and interactions with the students in the online context (Collazos et al., 2021). Based on these emotions, questions arise not only regarding the need for support in adapting to the online context, but also for emotional support. According to Fernández-Berrocal et al. (2017), training in emotional competences can provide benefits at both a personal and group level.

Acknowledgment

This study has been developed within the framework of the COIDESO research group at the University of Huelva, project RTI2018-096547-B-I00 of the Ministry of Science, Innovation and Universities of the government of Spain, and the research group DESYM (HUM-168).

It has also been funded from a contract of "Predoctoral Research in Training by the URJC call 2020".

Teachers' professional development: a cultural matter. How to describe cultural contexts?

Riccardo Minisola[1] and Carola Manolino[1]

[1]University of Turin, Italy; riccardo.minisola@unito.it, carola.manolino@unito.it

Teachers' professional development in collaborative contexts is a growing trend in Mathematics Education research. Particularly, Japanese Lesson Study has seen a great focus on its dissemination around the world. Research shows that Japanese culture is one of the main reasons that makes Lesson Study effective: understanding Lesson Study means understanding the cultural context in which it originated. We attempt to describe the Japanese and the Italian cultural contexts. Since there exists no consensus on what is essential to analyse in order to understand a cultural context, we present two approaches to this description, and consider some advantages and shortcomings. We hope to sprout discussion on the possibility to create guidelines for describing cultural contexts, shared by the community of researchers in Mathematics Education: awareness of beliefs, identity and practice is a sensitive element for successful mathematics teacher professional development.

Keywords: Cultural context, culture, Japan, Lesson Study, Italy.

Introduction

Over the last 20 years, teachers' professional development (TPD) in collaborative contexts has received ever-growing attention from the community of researchers in Mathematics Education (Robutti *et al.*, 2016), and a recent survey by Bakker and colleagues (2021) confirmed the trend. Among the many different collaborative methodologies for TPD in Mathematics and Mathematics Education, Lesson Study has seen a great deal of research focused on its dissemination (i.e.: Huang *et al.*, 2019; Huang & Shimizu, 2016; Quaresma *et al.*, 2018). Lesson Study (LS) is a collaborative TPD methodology, part of the Japanese paradidactic infrastructure (Winsløw, 2011) since the 1880s, focused on the co-responsibility in the lesson-planning process of the involved teachers and knowledgeable others (Huang *et al.*, 2019).

LS is also the focus of the authors' doctoral dissertations (in progress), which also aim at introducing LS in the context of Italian TPD. During YESS11, TWG1 dedicated to *teacher education and professional development* saw four out of eleven papers focused on LS in different contexts (Italy, Mozambique, Portugal, and Switzerland). In the discussions around the four papers, one question resulted relevant: what is the *cultural context* in which the research takes place? Indeed, being aware of their cultural context is one of the essential competences of mathematics teachers (and researchers) to gain awareness of their beliefs, their identity and their professional practice and to develop their teaching knowledge: a sensitive element for successful mathematics teacher professional development, and a demand evermore necessary and therefore not negligible (Andrews, 2010). Yet, issues arise when we try to address such demand: in the following, we will attempt to describe the Japanese and Italian cultural and institutional context and discuss such issues.

Literature review

Unsuccessful attempts at translating LS outside of its cultural context (Demir *et al.*, 2012; Fernandez *et al.*, 2003) suggest that, if LS is not introduced in a cultural context with proper consideration to the differences with the Japanese cultural context, it might be rejected by the institutions. Ebaeguin & Stephens (2014) suggest to address the cultural compatibility of LS. A number of scholars proposed different theoretical lenses to analyse why LS is so widespread in Japan (i.e.: Krainer, 2011; Lewis, 2016). We can suppose that LS exists because of the Japanese culture, and Japanese culture is one of the main reasons why LS is effective: LS is a cultural activity (Stigler & Hiebert, 2016). The question arises if maintaining the efficacy of LS across different cultural contexts is feasible.

Despite the rising awareness on the importance of studying cultural contexts and identities to contextualize global trends in Mathematics Education (Bakker *et al.*, 2021), the majority of reports on LS around the world seems to depict LS as an isolated practice in the Japanese panorama of TPD practices (Miyakawa & Winsløw, 2019) and seemingly ignores that the Japanese definition of LS is not as clear cut as the American one (Miyakawa & Winsløw, 2013). This suggests that "to develop a deeper understanding of Lesson Study in a post-modern global world, there is a need to seek views beyond those presented from an American perspective" (White & Lim, 2008, p. 915).

Understanding LS means understanding the context in which it originated. At the same time, to introduce LS in a new context, it is essential to know the TPD practices already in existence (Miyakawa & Winsløw, 2013). Yet, there exist no consensus on what is essential to analyse in order to understand a cultural context. What is *culture*? This paper has two aims: to provide arguments to the importance of understanding the cultural contexts involved in the research, and to provide a currently-missing description of the Italian TPD context in the English language. We provide a tentative analysis of the Japanese and the Italian cultural and institutional contexts to guide future studies on LS in Italy, and we also hope to sprout discussion on the possibility to create guidelines for describing cultural contexts that might be shared by the community of researchers in Mathematics Education.

Theoretical Framework

Culture may be described as "any aspect of the ideas, communications, or behaviours of a group of people which give them a distinctive identity and which is used to organise their internal sense of cohesion and membership" (Scollon & Scollon, 1995, p. 127) or as "[t]he system of shared beliefs, values, customs, behaviours, and artefacts that the members of society use to cope with their world and with one another, and that are transmitted […] through learning" (Bates & Plog, in Freimuth, 2006, p. 2). Anthropologists have not reached a shared definition (Spencer-Oatey, 2012), and proposing one would be outside of our expertise. In fact, our aim is not to propose our own definition but to observe how existing approaches and definitions may interact with learning and teaching processes in Mathematics, particularly in TPD. It is a facet of our doctoral research, especially within a semiotic context (Manolino, 2021). Here we rely on a *popular* understanding of what *culture* is, as the definition is not central to this paper. In the following, we propose two different approaches to the definition and description of *culture* and *cultural contexts*: the first one is synthetic, the second one is descriptive. We hope to show some advantages and shortcomings of each of them, which should provide a mean to engage in this discussion.

Hofstede's Dimensions of Culture

Hofstede defines culture as "the collective mental programming of the people in an environment. Culture is not a characteristic of individuals; it encompasses a number of people who were conditioned by the same education and life experience" (in de Mooij, 2010, p. 48). Hofstede identifies basic value orientations of a certain national culture. These values "are broad preferences for a certain state of affairs (e.g., preferring equality over hierarchy) […] transmitted by the environment […] shaped by the time we hit 10-12 years of age" (https://news.hofstede-insights.com/news/what-do-we-mean-by-culture described in five dimensions, scored over 100 points, and represent:

- *Power Distance* Index: “the extent to which less powerful members of a society accept and expect that power is distributed unequally” (de Mooij, 2010, p. 75). The higher the score, the more hierarchical a society is.
- *Individualism* vs Collectivism: “[…] people looking after themselves and their immediate family only, versus people belonging to in-groups that look after them in exchange for loyalty” (de Mooij, 2010, p. 77). Higher scores indicate individualistic values.
- *Masculinity* vs Femininity: “The dominant values in a masculine society are achievement and success; the dominant values in a feminine society are caring for others and quality of life” (de Mooij, 2010, p. 79). Lower score indicates a feminine society. Please note that this label is problematic as it reinforces harmful gender stereotypes, and in the following we will use the alternative “*Tough* vs Tender”.
- *Uncertainty Avoidance* Index: “[…] the extent to which people feel threatened by uncertainty and ambiguity and try to avoid these situations” (de Mooij, 2010, p. 82). The higher the score, the less open to changes is a society.
- *Long-Term* vs Short-Term Orientation: “[…] the extent to which a society exhibits pragmatic future-oriented perspective rather than a conventional historic or short-term point of view” (de Mooij, 2010, p. 85). Lower scores point to a society that prefers short-term planning.

One peculiarity of Hofstede’s dimensions is that “[t]he country scores on the dimensions are relative, in that we are all human and simultaneously we are all unique. In other words, culture can only be used meaningfully by comparison” (https://hi.hofstede-insights.com/national-culture).

Levels of Co-Determination

We start from “the notion of [teaching] “practice” as a link between culture […] and the larger cultural contexts” (Hatano & Inagaki, 1998, p. 80). In the Anthropological Theory of the Didactic, practices are described in terms of praxeologies: the know-how (*praxis*) and the know-why (*logos* - the discourses that justify the know-how) related to a task. Chevallard (1985) suggests that teachers’ praxeologies are shaped by a plurality of agents (politicians, scholars…) and historical or institutional conditions that defines the boundaries of what teachers can or cannot do, their *noosphere* (the sphere of those who thinks). Chevallard (2002) pictures the complex relations of the factors influencing teachers’ praxeologies, which are influenced not only by the teachers’ decision, but at a higher level by the society in which the teachers and students are immersed, as shown in Figure 1.

Upper levels	*Lower levels*
Humanity	↓↑
↓↑	Discipline
Civilisation	↓↑
↓↑	Domain
Society	↓↑
↓↑	Sector
School	↓↑
↓↑	Theme
Pedagogy	↓↑
↓↑	Question

Figure 1: Scale of levels of co-determination (Florensa *et al.*, 2018, p. 5)

Similarly, we suggest that professional development practices are influences by the context in which teachers and their educators are immersed. It is important to notice that Chevallard's framework does not use the term *culture*.

Context Analysis

Hofstede's Cultural Dimensions

Ebaeguin and Stephens (2014) suggest that comparing Hofstede's scores might be a starting point for studying the introduction of LS in Australia, as they connect the efficacy of LS in Japan to the Japanese scores. The scores for Japan and Italy according to Hofstede's cultural dimensions can be freely collected from the website https://www.hofstede-insights.com/product/compare-countries/ and are shown in Table 1. The labels are simplified because of space constraints.

Table 1: Hofstede's score for cultural dimension for Italy and Japan

	Power Distance	**Individualism**	**Tough**	**Uncertainty Avoidance**	**Long-Term**
Italy	50	76	70	75	61
Japan	54	46	95	92	88

Within Hofstede's description, the two cultures appear different in almost all categories: according to these descriptors, Japanese culture appear less individualistic, more prone to success (and therefore more competitive), less open to "thinking outside of the box", and keener to long-term planning. There are some similarities, as Japanese and Italian cultures seem to have a shared approach to hierarchy.

Levels of Co-Determination

Using Chevallard's didactic transposition lens and moving within the co-determination levels, we attempt to provide a description of the Japanese and Italian institutional contexts. Since many sources are available on the Japanese context, the description will be briefer. The description of the Italian context, on the contrary, will be as detailed as the format allows, inspired to that proposed for Japan by Miyakawa and Winsløw (2019).

Japan is an East-Asian country, influenced by countries of "Confucian Heritage Culture" (Mason, 2014) such as China and Korea. These countries generally share some cultural values that are reflected in the school system, and can be considered part of the Japanese system of school-related beliefs:

> a high regard for education […]; […] the cultivation of the self; a strong work ethic […]; a belief […] that success depends more on effort than on innate capacity […]; respect for teachers […] (Mason, 2014, p. 2).

In Japan, the national curriculum is detailed and rigid. Textbooks are essential for lesson planning. Long-term planning is centralized at the prefectural or school level, so teachers' attention is focused on learning units and lessons. Classes are homogeneous by level: strict entrance tests are usually required for accessing high schools, while students with disabilities attend special schools. Japanese teachers spend the working day at school, where they have their personal workspace in a room shared with the whole teaching staff: in this space, they prepare lessons and discuss with their colleagues. In-service professional development is compulsory and takes place during working hours (Bartolini Bussi & Ramploud, 2018). LS is only part of Japanese TPD activities, which have many common features: in particular, the practice of open classes with observers is common (Miyakawa & Winsløw, 2013). Participating in optional TPD activities increases teachers' chances of career advancement (Miyakawa & Winsløw, 2019).

The Italian school system is centralized. Recent reforms (2010 and 2012 respectively for secondary and primary school) stressed the importance of inclusiveness (law 133 and 169/2008). Italian school is structured around the concept of equity, and special schools do not exist: all students are given the same opportunities to reach the same goal, plus aids if needed. The Ministry of Education provides the *Indicazioni Nazionali* (National guidelines), which contain contents and aims for each subject, and its number of hours in a year. These contents are not prescriptive, but at the end of the 8th and 13th grades there are two national exams. Each teacher has the responsibility of the didactical plan for their classes, also according to the *Piano Triennale dell'Offerta Formativa* (Three-year Educational Plan – describing the cultural-pedagogical inspiration and the curricular, extracurricular, didactic and organisational design of the proposed activities). The contents of this document are specific of each school and decided by the collegiality of teachers and school staff.

Freedom of teaching, understood as professional autonomy in carrying out teaching activities and free cultural expression of the teacher, is guaranteed as a constitutional right: Article 33 of the Constitution states "Art and science are free and free is their teaching". Institutionally, the duration of the lesson is 60 minutes. The teacher can have up to three consecutive lessons in the same class, without interruptions. During the lesson, the teacher is usually the only adult figure in the class. The Italian teacher works at school from one to six hours a day, dedicated to classroom lessons. The planning of individual lessons is not part of the working hours, nor there are places in the school dedicated to this activity: the teacher's paradidactic activity takes place in personal and private time and space. There are no compulsory contents or practices for TPD, they are chosen by teachers according to their own needs. In-service TPD is compulsory (law 107/2015), there is no minimum number of hours per year, and must be carried out outside working hours. Teachers' career advancement is based exclusively on seniority, although some economic incentives are given to those that take relevant roles in the school organization (Blandino, 2008; Capperucci, 2008).

On paper, teachers have numerous occasions for improving their professionalism. The Ministry[1] attests more than 500 agencies offering TPD opportunities. Universities, academic associations, teachers' associations, and educational companies which fulfil quality standards defined by the Ministry, are registered in a national database and can publish their TPD proposals on a digital platform (S.O.F.I.A.). The in-service professional development "system" is conceived as a "lifelong learning environment" for teachers and is intended as a "network of opportunities for professional growth and development for teachers" (law 107/2015). At national level, proposals come from the national education centre, academic associations, teachers' associations, educational companies. At regional level, regional school offices intervene by supporting, managing, and publicising the proposals. At local level, experienced teachers also offer courses in their school, sometime opens to teachers in the surrounding area. No official account is given on how many teachers participate in TPD. Yet, the impression is that this vastity of opportunities does not correspond to a high-quality offer: the Ministry states that the quality of TPD programmes is compromised by the general "low quality of models and methodologies" (law 107/2015) suggesting that teachers might be easily lost

[1] https://www.miur.gov.it/accreditamento-enti-e-qualificazione-associazioni

and caught in low quality programmes. The Ministry does not provide guidance to orientate in this labyrinth.

Some Reflections

At the end of this section, we can ask ourselves: is this description complete? Did we miss any essential point? Did we provide too much information, and made our description useless? Is this description reliable? Hofstede's synthetic data, for example, provides a quick overlook on the differences between two cultures and invite to carefully consider LS introduction in Italy. Yet, this description is problematic as it eliminates complexity, and the risk of overgeneralizing is high. Furthermore, these scores are open to interpretation. The similar scores for PDI might suggest that Italy and Japan have a shared view on hierarchy, but we propose a different interpretation: while Japanese invites consciousness of one's hierarchical position in any social setting and act accordingly (Ebaeguin & Stephens, 2014), Italian culture dislike control and formal supervision. An analysis based on Hofstede's cultural dimensions, in support of our assertions, can be found in Giordanengo's Master Degree dissertation (2020)[2].

Discussion

It emerges that the Japanese and the Italian cultural and institutional contexts share some similarities and come with a number of differences. Hofstede's cultural dimensions show divergent basic values. However, to consider Hofstede's analysis *complete enough* to understand the similarities and differences between Japan and Italy would be preposterous, and similar numbers can still be interpreted with very different founding values. A detailed look suggests similarities between the two educational contexts, yet striking differences in the institutional and paradidactic organization. We believe this is sufficient to justify the importance of a cultural approach when practices from a cultural context are brought in different contexts. A tentative description of the Italian institutional (school) context was provided as a reference for future studies. Italian researchers are invited to amend this description, which is certainly lacking details.

This paper answers no research questions but considering our attempt to respond to the need to provide a description of the Italian institutional context in which students, teachers, and researchers work every day, leaves us with some questions. Are we satisfied with the result? No, we are not: the description misses many details, and we are not sure that what we provided is enough to really understand the context. How is Mathematics as a school subject considered at a cultural level? How is the teacher role considered in each society? Many questions are left unanswered, yet we often hear from reviewers that we should focus on describing just some aspects. How detailed can these descriptions be? Too little or too many information will lead to the same result: little understanding of the cultural context. Can we really achieve this *correct* kind of detail? Again, the answer, in our opinion, is no. The gap is embedded in the notion of cultural context and in any possible analysis of it. A number of scholars (e.g., Lotman, 1990) have declared the impossibility of a full knowledge of culture, as we are embodied in it and in what François Jullien - sinologist - calls the *unthoughts* (for a broader understanding, see Mellone *et al*., 2019). To be aware of these unthoughts may not be

[2]https://sia.unito.it/studenti/intesi/Ricerca_tesi_libera/ricerca_tesi_dettaglio.asp?id_upload=192959&cdl_tesi=&cdl=&matricola=781420

enough anymore. What is incumbent on us is to frame our research accordingly, as to provide careful attention to their influence on teaching and learning processes in mathematics.

Math for All (MFA) is an intensive professional development (PD) program for in-service teachers. It consists of five one-day workshops and classroom-based assignments, providing a total of 40 hours of PD. MFA engages teams of general and special education teachers in adapting math lessons collaboratively to help all students, including those with disabilities, achieve high-quality learning outcomes in mathematics. A cluster randomized controlled trial (RCT) was used to test the efficacy of MFA; it included 32 schools, 98 4th and 5th grade teachers, and approximately 1,500 4th and 5th grade students. MFA had statistically significant, positive effects on teachers' self-reports of their preparedness and comfort with teaching mathematics to students with disabilities. A school-level analysis found a moderate MFA effect on student achievement. Quasi-experimental analyses of a subgroup of teachers showed initial evidence of MFA impacts on their classroom practices.

Keywords: Mathematics teacher professional development, mathematics teacher beliefs, mathematics teacher self-efficacy, mathematics teaching practice, mathematics achievement.

Introduction

This paper presents the results of a randomized controlled trial (RCT) that tested the efficacy of a professional development (PD) program called Math for All (MFA). MFA is an intensive PD program designed to help general and special education teachers in Grades K–5 to personalize rigorous mathematics instruction for a wide range of learners, including students who are low performing, and students with disabilities. MFA consists of five full-day PD sessions and related assignments (a total of 40 hours of PD) carried out at regular intervals throughout the school year. The program is designed to have a direct impact on teachers' knowledge, beliefs, and classroom practice. The PD introduces teachers to a neurodevelopmental framework[1] (Barringer et al., 2010) as a lens for better

[1] This framework describes eight constructs related to learning processes (i.e., attention, temporal-sequential ordering, spatial-ordering, memory, language, neuromotor function, social cognition, and higher order cognition). Those who use the framework are encouraged to think through how these constructs interact when student learn, and to adapt mathematics lessons based on individual students' neurodevelopmental learning profiles.

understanding individual students' strengths and challenges and the demands of mathematical activities. The PD also engages teachers in in-depth analyses of mathematics lessons, including examination of their mathematical goals, and different instructional strategies and teaching practices that support the attainment of these goals while attuning to individual students' strengths and needs. MFA was developed by Bank Street College and EDC with funding from the National Science Foundation and is published by Corwin Press (Moeller et al., 2012; 2013). MFA incorporates several components that RCTs or quasi-experimental studies (QEDs) have shown to be effective for supporting elementary school teachers' professional learning and for improving achievement of struggling students, such as teacher collaboration for instructional planning and peer coaching (e.g., Stevens & Slavin, 1995), formative assessment and progress monitoring of students (Gersten et al., 2009), and lesson study (Lewis & Perry, 2017).

MFA is not tied to any specific K–5 mathematics curriculum. Rather, it helps teachers to use and adapt their existing mathematics curriculum to make it more accessible to a wide range of learners. With funding from the Institute of Education Sciences at the U.S. Department of Education researchers carried out an RCT in collaboration with a large urban school district in a midwestern state in the U.S. In this paper is we report findings relating to three main research questions, which probed for the impact of MFA on (a) teachers' comfort and preparedness to teach mathematics to students with disabilities, (b) teachers' classroom practice, and (c) student performance on a standardized mathematics achievement test.

Theoretical framework and related literature

A number of factors influence student achievement (as measured by performance on standardized achievement tests), with teacher quality being the most powerful (e.g., Nye et al., 2004; O'Dwyer et al., 2010). Various teacher characteristics such as experience, education background, dispositions (beliefs and motivations), as well as their knowledge (content knowledge, pedagogical content knowledge, general pedagogical knowledge), have been shown to impact student outcomes to varying degrees (e.g., Clark et al., 2014). Classroom practice is another factor that has been linked to student achievement (e.g., Clements et al., 2013). Research has helped to identify key features and principles of instructional practices that are associated with higher student achievement in mathematics, such as strategies for teaching students who struggle in mathematics (Gersten et al., 2009).

However, major questions remain with respect to how PD can play a role in improving teacher quality, practice, and student achievement, given the mixed findings often generated. Recent reviews of research on teacher PD (e.g., Darling-Hammond et al., 2017; Gersten et al., 2014; Yoon et al., 2007) attest to the paucity of rigorous evidence that links PD to improved student outcomes in mathematics and other subject areas. Moreover, little is known about the specific aspects of teacher quality that PD can most effectively target. Although there is general consensus that teachers must have mathematics content and pedagogical content knowledge to effectively teach mathematics, and many PD efforts target these teacher qualities, evidence that attests to the effectiveness of content-focused PD has been difficult to come by. Three recent studies (e.g., Garet et al., 2016; Jayanthi et al., 2017; Jacob et al., 2017) found only limited evidence of the impact of content-focused PD on teachers' mathematical and pedagogical content knowledge and instructional practices, and no effects on student outcomes.

In assessing the efficacy of MFA, we were particularly interested in understanding its impact on teachers' dispositions. Teacher dispositions are related to teachers' professional background and experiences, knowledge, and teaching contexts, and to characteristics of the students they teach (Clark et al., 2014). Research has demonstrated that teachers who have negative self-efficacy about mathematics (math anxiety) can have negative effects on the mathematics achievement of their students (Beilock et al., 2010; Ramirez et al., 2018). Because teachers draw on cognitive and affective resources during instruction (e.g., Anderson et al., 2018), teacher dispositions constitute an important outcome to measure when assessing the impact of professional development.

To assess teacher dispositions, we constructed two eleven-item scales that measure teacher comfort and preparedness with various practices that have been associated with differentiated mathematics teaching practices (see Table 1). These scales have been used in multiple studies of MFA (Duncan, et al., 2022) and have demonstrated high internal consistency with Cronbach alphas ranging from .85 to .95.

Table 1: Comfort and preparedness scales

Question stem: How prepared/comfortable do you feel about the following?
a. Teaching standards-based math to students with disabilities.
b. Identifying the math strengths of students with disabilities.
c. Identifying the math needs of students with disabilities.
d. Understanding the mathematics of the lessons I teach.
e. Analyzing the demands of mathematical tasks on students.
f. Determining the goals of the math lessons I teach.
g. Understanding learning trajectories in mathematics (how the math I teach relates to what students learned before and what they will learn later).
h. Selecting specific strategies to address the strengths of students with disabilities in math.
i. Selecting specific strategies to address the needs of students with disabilities in math.
j. Adapting math lessons for students with disabilities to help them meet standards-based goals.
k. Collaborating with my colleagues when planning math lessons.

Note. Items are rated on 1-5 Likert scales, anchored by 1=not at all prepared to 5=very prepared, or 1=not at all comfortable to 5=very comfortable

We hypothesized that improved comfort with and preparedness for teaching mathematics to students with disabilities will result in high-quality classroom practices, which are differentiated based on individual students' strengths and needs without undermining the rigor of the mathematics to be taught. This in turn would lead to improved student mathematics achievement (as measured by performance on standardized achievement tests), so we expected coordinated improvements in teachers' dispositions, classroom practices, and student achievement.

Methods

An RCT of MFA was conducted from 2015 to 2017 to help build the evidence base around the impact of PD interventions. Schools were randomized by a statistician blinded to study condition into either the MFA PD treatment group or business-as-usual (BAU) control group. The sample included 32 schools from a large, midwestern urban school district in the U.S., 98 4th and 5th grade general and special education teachers, and approximately 1,500 4th and 5th grade students. This study focused on estimating MFA impacts on teacher outcomes after one year of PD because this was the point when the maximum MFA-BAU contrast was expected. For student-level outcomes, a two-year study was originally planned but findings presented here describe outcomes after Year 1 because there were challenges in maintaining the sample across both years, largely because of student mobility and difficulties with collecting parent consent to use achievement data collected by the school district. Key Year 1 findings are supported by a strong design and allow for solid causal inference.

Research Questions and Outcome Measures

The study's first research question was: *Does participation in MFA PD, compared to business-as-usual (BAU) experiences of a control group, improve teachers' comfort and preparedness to teach mathematics to diverse students (including those with disabilities) after the completion of the PD?* Separate measures of teachers' self-reported comfort-level and preparedness were used as dependent variables to address this research question. Two researcher-developed 11-item scales were used (see Table 1), and corresponding Cronbach alphas were .886 and.950. The scales were included in a larger teacher survey that was administered at the beginning and end of the school year.

Research Question #2. Does participation in MFA PD, compared to the BAU experiences of a control group, result in improved mathematics classroom practice after the completion of the PD? A subsample of 40 classrooms were observed at the beginning and end of the school year using the Classroom Assessment Scoring System (CLASS). The CLASS, a widely used and psychometrically sound observation approach (Pianta et al., 2012), was used to generate dependent variable data for this question. Unfortunately, only 40 teachers agreed to be observed and this undermines the benefit of randomization. Therefore, related analyses were conducted using a quasi-experimental design wherein the strength of causal inference is predicated on showing that teachers across the two study conditions were similar on baseline assessments of their classroom teaching practice.

Research Question #3. Does the use of an MFA approach in the classroom result in improved student achievement in mathematics after one year of intervention exposure? The NWEA MAP assessment, used by the school district in which the study was carried out, was the measure used to assess student mathematics achievement. Coefficient alphas for this measure's related subtests range from .92 to .96 and test-retest reliabilities range from .77 to .94; there is also strong evidence of the measure's construct and concurrent validity (see Malone al., 2020 for details).

Data Analyses

Impact analyses for Research Questions 1 and 2 entailed using a two-level hierarchical linear model with teachers clustered by schools, and a term for assessing the treatment impact at level two (i.e., schools, the unit of randomization). Impact analyses for Research Question 3 were conducted using three strategies: (1) a school-level analysis; (2) a student-level hierarchical analysis that accounted for student clustering within schools; and (3) a hierarchical student-level analysis that included grade level as a moderator. The first strategy was used because of the difficulties with attrition. This school-level impact model entailed using each school's mean achievement at post-test as a dependent variable to assess MFA's impact on student achievement at grades 4 and 5. This analysis included all 32 study schools and does not have cluster-level missing data. The second two strategies both accounted for student clustering in schools and included a term for assessing the treatment impact at the school level. All mean contrasts presented here adjusted for baseline differences. These baseline differences were observed using the same measures that produced dependent variable data. Missing data (and by extension Year 1 attrition) were addressed by using multiple imputation procedures, which we consider to be our primary analyses. We did however re-run impact models using listwise procedures (i.e., no imputed data) to perform sensitivity checks (see Enders, 2010). For Resarch Question 3, school-level impact analyses did not formally have missing data; furthermore, Grade 4 subsample analysis yielded inconsistent results across imputed and listwise analyses, so we present related findings from both approaches. All required assumptions for impact modeling were met.

Key findings

Research Question #1

The pattern of results was the same for both scales: the MFA group reported lower levels of preparedness and comfort at the pretest, compared to BAU teachers, but there was a steep increase from fall to spring. The opposite pattern was observed for the BAU group. Results were statistically significant. Effect sizes using the Hedges' g statistic were $g = .54$ ($p < .05$; $M_{diff} = .803$; $SD_{pooled} = 1.48$) for preparedness and $g = .67$ for comfort ($p < .05$; $M_{diff} = 1.08$; $SD_{pooled} = 1.621$). To summarize, MFA teachers increased their senses of preparedness and comfort in teaching students with disabilities, as compared to BAU teachers.

Research Question #2

Unfortunately, there was a large baseline difference favoring the MFA group, which undermined causal inference, and Bonferroni corrections for multiple comparisons rendered results from this small sample not statistically significant. Analyses showed that at the posttest (and after adjusting for pretest levels), MFA teachers scored higher in the domains of Emotional Support ($g = .98$; $p > .05$; $M_{diff} = 1.115$; $SD_{pooled} = 1.118$), Instructional Support ($g = .69$; $p > .05$; $M_{diff} = .526$; $SD_{pooled} = .765$), Classroom Organization (.78; $p > .05$; $M_{diff} = .733$; $SD_{pooled} = .94$), and Student Engagement (.54; $p > .05$; $M_{diff} = .435$; $SD_{pooled} = .8$). These contrasts should be interpreted with caution, but they do suggest MFA had a positive impact on teachers' classroom practices.

Research Question #3

The resulting g from the first school-level analytic strategy was .33 ($p > .05$; $M_{diff} = 1.82$; $SD_{pooled} = 5.45$), favoring MFA schools. This finding was however not statistically significant, which likely stems from the analysis being underpowered given there were only 32 school-level means. The student-level analyses mirror the pattern shown in the cluster-level analysis; that is, while the results favor the treatment group ($g = .11$; $p > .05$; $M_{diff} = 1.54$; $SD_{pooled} = 14.46$), the differences were, again, not statistically significant. When grade level was examined as a moderator, different patterns between grade 4 and grade 5 students were found. In grade 4, students whose teachers participated in the MFA PD had higher posttest scores than students whose teachers were in the BAU group and results based on analyses with imputed datasets were statistically significant (g = .26; $p < .05$; M_{diff} = 3.62; SD_{pooled} = 13.9). However, impact analyses that did not entail use of imputed data did not allow for rejecting a null hypothesis (g = .20; $p > .05$; M_{diff} = 2.77; SD_{pooled} = 13.6). In grade 5, there were small mean differences between the MFA and BAU groups. The overall pattern of findings suggests MFA PD might have had a positive impact on student achievement, but student attrition prevent conclusive findings.

Discussion

This study yielded evidence that MFA had a positive impact on teacher's self-reported sense of comfort and preparedness with respect to teaching students with diverse learning needs. While the evidence that MFA impacted teacher classroom practice and student achievement is less strong, it is still compelling. As we seek to better understand the impacts of PD on teacher and student outcomes, it is important to "open the black box" and flesh out the mechanisms by which PD can affect teacher practice, which in turn, affects student achievement (cf., Clarke & Hollingsworth, 2002; Goldsmith et al., 2014). The data presented here converges with other recent studies that have demonstrated that teacher dispositions may be key mediators to consider in our models of teacher PD (e.g., Miele, et al., 2019; Schoen & LaVenia, 2019).

Developing an identity as a mathematics teacher through group work

Reidun Persdatter Ødegaard[1] and Marit Buset Langfeldt [1]

[1]Norwegian University of Science and Technology, Norway; reidunp@ntnu.no, marit.b.langfeldt@ntnu.no

A concern in teacher education is to tighten the connection between coursework and practice through work with core practices. In this study, we investigated student teachers' learning processes when working in groups in mathematics teacher education, where the tasks the student teachers worked with were centered around core practices. Taking a social view of learning, we describe student teachers' learning to teach mathematics through developing an identity as a mathematics teacher. Group discussions were audiotaped, transcribed, and analyzed using a grounded approach. Our findings suggest that group work centered around core practices gives student teachers good opportunity to negotiate meaning of core practices and develop an identity as mathematics teachers.

Keywords: Mathematics education, communities of practice, elementary school teachers, group activities, educational practices.

Background

The development of a mathematics teacher identity is critical for learning to teach (Goodnough, 2010). da Ponte and Chapman (2008) suggest that investigation and reflection on practice play important roles in developing a mathematics teacher identity, and several researchers have investigated opportunities for developing identity during teacher education (Lutovac & Kaasila, 2018). Essien (2014) found that during instruction in teacher education, student teachers develop an identity as mathematics learners, not as mathematics teachers. Learning mathematics and learning to teach mathematics is different in that the latter draws upon a broad range of experiences and knowledge, and teacher education programs should provide student teachers with coherent experiences to support their learning to teach mathematics. Hence, the contexts in which the student teachers develop their mathematics teacher identity through the teacher education program need to be tightly interwoven (Van Zoest & Bohl, 2005).

A concern in teacher education internationally and in Norway is that there is a gap between the teacher education coursework and school practice (Hammerness, 2013). The gap is due to a lack of coherence between activities in teacher education coursework and school practice, and teacher education programs need to build bridges between the different contexts. To bridge coursework and practice, Grossman et al. (2009) suggest that teacher education programs should be organized around the central practices of teaching, called core practices. Core practices are something a teacher often does, which enhance the students' opportunities to learn and preserve the complexity of teaching at the same time as novices can begin to master them (Grossman et al., 2009). Examples of core practices are eliciting and responding to students' ideas, leading a whole-class discussion towards a mathematical goal, or attending to students' understanding and helping them progress. Teacher education programs centered around core practices will help student teachers develop knowledge, skills, and identity, which can narrow the gap between coursework and school practice.

A typical learning activity in mathematics teacher education is group work. The goal is often that the student teachers get the opportunity to discuss and develop their mathematical thinking and their knowledge of students' mathematical thinking (Crespo, 2006). Tasks in group work can be organized around core practices, such as asking students teachers to make sense of their students' work (Crespo, 2006; Kazemi & Franke, 2004) or planning and co-teaching together (Haniak-Cockerham, 2019). More research on implementing work with core practices in teacher education coursework is needed (McDonald et al., 2013). In this study, we investigate the learning processes when student teachers participate in group work organized around core practices.

Taking a social view on learning, we consider identity to be learning as becoming (Wenger, 1998). Our research question is: *how does some student teachers' identity develop as they work with tasks centered around core practices of mathematics teaching?*

Theoretical framework

Wenger (1998) stated that learning is participation in communities of practice. A community of practice is defined by mutual engagement, joint enterprise, and shared repertoire. Student teachers learn to teach in several communities of practice during their education, for example, the coursework in mathematics teacher education, the school in which they have school placement, and the classroom in which they have school placement. When student teachers participate in each of these communities, they become more central members of the communities, and their learning to teach mathematics is a nexus of their learning trajectories in all these communities. Van Zoest and Bohl (2005) argue that a theoretical framework that considers the broad range of student teachers' experiences and contexts is necessary when studying learning to teach.

In studying student teachers' learning to teach, *identity* is a useful theoretical construct (Van Zoest & Bohl, 2005). Wenger (1998) introduced identity to shift the focus to the individual, but from a social perspective. Following Wenger (1998), identity is more than the everyday use of identity as a sense of self. The construct includes knowledge, beliefs, our perceptions of others, and others' perception of us as we participate in communities of practice (Van Zoest & Bohl, 2005). As student teachers engage in practices related to mathematics teaching, their identity is developed through their modes of belonging in these practices, and we can study student teachers' learning beyond the scope of only one community.

Identity is developed through participation and non-participation in three modes of belonging: engagement, imagination, and alignment (Wenger, 1998). First, participation in engagement means to contribute to negotiation of meaning and adopt others' contributions. In engagement, members gain ownership over meaning through how they make use of, control, and adopt the meanings they negotiate (Wenger, 1998, p. 200). Non-participation is to not contribute to negotiations or to have one's ideas ignored. Second, participation in imagination is to imagine oneself across time and space, experiencing the meanings of other communities as one's own. Non-participation in imagination is to have limited access to other communities' practices, making negotiation impossible. Third, participation in alignment is to coordinate actions and efforts with the practices and meanings of another community, while non-participation is when directions are strict, leading to inflexible and vulnerable coordination. The modes of belonging strongly influence both one's identity and the community one participates in (Goodnough, 2010). To operationalize mathematics teacher identity, we will draw on the practices of mathematics teaching.

Wenger's (1998) framework describes learning in general, so we draw on core practices of mathematics teaching (Grossman et al., 2009) to describe mathematics teacher learning as modes of belonging. We operationalize the development of mathematics teacher identity as modes of belonging in the core practices learning about students' (mathematical) understanding and orchestrating (mathematical) discussions. *Engagement* in these core practices is to mutually participate in understanding and fine-tuning how one can learn about students' understanding through attending to their work, responding to their work, asking questions, and eliciting their understanding. *Imagination* in core practices is to understand students' work and plan questions through imagining oneself as a teacher in the classroom. In coursework, the core practices student teachers participate in belong to an imagined classroom community. *Alignment* in the core practices is to align efforts with the valued enterprise. In our mathematics teacher education, reform-oriented mathematics education is communicated by the teacher educators. Student teachers participate in alignment through questioning and responding in line with the reform-oriented view of mathematics. Through modes of belonging, student teachers develop a shared understanding of the core practices, and since practice and identity influence each other (Lutovac & Kaasila, 2018), participation in core practices influences student teachers' identity development.

Method

We collected data from two groups of participants: in-service teachers (ISTs) participating in a one-year teacher development program and pre-service teachers (PSTs) in their third year of teacher education. The ISTs were primary school teachers working in the 1st to 7th grades. From 2019 to 2021, group discussions in four lessons were audio-recorded and later transcribed and coded. The group discussions centered around different activities that involve working with core practices.

The tasks in the group work were centered around four core practices: attending to student work, eliciting students' ideas, responding to student work, and asking questions for whole-class discussions. First, the student teachers (ten ISTs and sixteen PSTs) practiced attending through making sense of students' written work with a multiplication task, a fraction task, and through making sense of students' utterings in a transcription of a dialogue about area measurement. Further, the student teachers practiced eliciting students' ideas and responding when they were planning questions to get insight into their thinking and support further thinking in the fraction and measurement tasks. Last, they practiced planning questions for a whole-class discussion in which connecting students' ideas was the goal in the multiplication task. The group discussions on the multiplication, fraction, and measurement tasks lasted approximately 50, 20, and 30 minutes, respectively.

We took a grounded theory approach to the analysis (Charmaz, 2006), meaning that questions arose from the codes, minimizing the risk of any pre-existing assumptions affecting our analyses. The two researchers first coded the discussions statement by statement, led by the question "what are they saying?". Comparing and grouping led to an initial set of codes, and in the next cycle, we coded the discussions based on actions, leading to a set of codes of actions student teachers do when they work with core practices in groups. We noticed that what the student teachers said and did depended on the context they were discussing. Further, we chose to analyze our data through Wenger's (1998) notion of identity, taking the multiple contexts into account. The data was coded again through participation and non-participation in the different modes of belonging. The researchers coded one of the transcriptions together before coding the rest of the data material separately. Dialogue between the researchers was maintained throughout the coding process to secure similar coding and increase reliability.

Results

We organize our results in two sections, participation and non-participation. We found participation to be more prominent than non-participation, and through excerpts of our data, we will show how the different modes of belonging contributed to the student teachers' identity as *mathematics* teachers.

Participation

Throughout our data, we observed participation in a combination of engagement and imagination. The following discussion between ISTs where they discuss students' strategies for solving the multiplication task 13·27 is an example of this.

Tiril:	Sort of, added them.
Kaia:	Yes, eight and four.
Tiril:	Eight and four is this one.
Oda:	But I don't understand. Why did she multiply 27 by two first?
Lisa:	In order to be able to double it.
Tiril:	Because now she has, in a way, she is supposed to have 27 thirteen times. Now she has 27 two times, which is 54, and that is, if she takes 54 twice, then she will have 108.
Oda:	Yes, four times.
Tiril:	And this is eight times.
Oda:	And then she has five left.
Tiril:	Yes, and then she has, she has taken it eight times, right? Plus four times.
Oda:	Ok, like that
Tiril:	So, she has taken not two, but one
Oda:	Thank you, now I understand.

In the first part of the excerpt, the ISTs participate in engagement, working with the core practice of attending to students' work by discussing every step of a student strategy in detail, building on each other's statements, and listening to each other. Meaning about students' multiplication strategies and their ideas is constructed. Further, in the last half of the excerpt, when they discuss the strategy, they actively refer to the student and her work and talk about her as if she was a real student. Through work with the representation of the student's work, they imagine how the student has been thinking and participate in negotiation of meaning about attending to students' work through imagination.

Further, we identified participation in a combination of alignment and imagination. In the following excerpt, PSTs discuss how they can continue to help students develop their ideas about equivalent fractions based on some students' written work.

Anna:	(…) "How can you continue the discussion if a student answers the following?" Maybe to get them to explain what they have been thinking. How did you get this? What did you do?
Nina:	Yes, I would follow up with "how have you been thinking to reach this answer?"
Anna:	Yes, and put into words what they have done.

Nina: Yes.

Anna: (…) "What can you, as a teacher, ask the students in order to build understanding for equivalence and common denominator?" That's what we have to help Martin with, who does not have [common denominator in] his numerical expression.

Nina: We can ask Jenna, what is, or in another way, but something about her answer, which is 1 and 8/16. She must have understood that 8/16 is equal to 1/2. (…) We could, for example, use a number line, mark 1/2, and then divide it into 16 pieces, and check that 8/16 is at the same place as 1/2. Then they can maybe realize that 1/2 is the same as 8/16. That they are equivalent, isn't that what it means to be equivalent?

In the first four statements, Anna and Nina are planning questions they can ask the student to emphasize their thinking process, aligning with the view of reform-oriented mathematics teaching that has been communicated in the teacher education program. However, the questions they are planning are quite general and could be asked in almost any kind of mathematics teaching. In contrast, in the last two statements, Anna brings in one of the students and her interpretation of his understanding, which Nina builds upon by bringing in the other student and using her answer as a starting point for showing equivalence using a number line. When imagining the students and how they can elicit and respond to students' thinking, the PSTs are also negotiating meaning through imagination, and their questions are directly connected to the teaching situation in question.

Further, several discussions were guided by the use of a framework or instructions in the task. Below, the ISTs are discussing a dialogue between students measuring the area of a blackboard using sheets of paper.

Hedda: (…) Are we using all these points? Or… the eight, those from Lehrer?

Oda: Yes, that's what we'll do.

Hedda: The first, they found out with some help from the teacher that they couldn't write letters. Isn't that the first point? To realize that unit of measure has the same property as the object.

Oda: No, isn't this two? Where are you?

Hedda: He got some help from the teacher to figure out that it would be difficult to measure using the letters.

Else: Yes, but that is the same as number four?

Oda: Tiling… No identical units.

Here, the ISTs are engaging in the core practice of attending to students' understanding, trying to label student actions in the dialogue using Lehrer's (2003) framework. In the third utterance, Hedda points to what the students do and tries to understand what aspect of measurement they are working with by connecting the student actions to the framework. Their attempt to apply the framework to the dialogue leads them into a discussion about the meaning of the different aspects and the students' understanding, and together they figure out which of Lehrer's (2003) aspects is the relevant one. When they are engaging in attending to students' understanding, the framework is supporting their work.

Non-participation

As mentioned, participation was most prominent in our data, but there were also occurrences of non-participation in different modes of belonging. In the excerpt below, the ISTs work with students' written solutions to 13·27 and plan questions for the following classroom discussion, where connecting students' ideas is the goal.

Else: Why is it 90 plus 50 here? (…) 140. Nothing about why she picked those numbers. Maybe it is to figure out 295 plus 54? Then it is just 90 plus 50, and then maybe she added 200.

Anne: And then 9.

Else: And the ones. I don't have the slightest clue what I would say, I would call in sick that day.

Bettina: I find this really hard.

Else: I don't understand what…

Anne: I think it looks like her strategy is quite good. Per Christian, on the other hand, can't continue to add forever. He can't start in the seventh grade and add, for example, 13 times 69.

Bettina: That is a very non-effective strategy. (…) What we want is for him to learn a more effective strategy.

Anne: Yes, maybe through the use of the area model, and later learn this strategy. (…) How can we facilitate for the students to share their thoughts? That is easy, they can just come in front of the class and explain. Which talk moves will we use? Well, confirm their strategies, and maybe let someone else repeat.

Bettina: Yes, that is what we have talked about today regarding conversations.

Anne: Yes. I think these questions are easy. But this planning sheet, I don't think I will use it. It is not useful for me.

They are building on their engagement in making sense of the student strategies they have chosen to emphasize in the discussion when they try to formulate questions for the whole-class discussion, but they do not conclude on any questions they can ask. When Else says that she would call in sick that day and the others respond that they find it difficult as well, non-participation in engagement is shaping their identity. Further, they try to formulate some questions through the use of talk moves as a framework, but the questions they are formulating are not helping them connect students' ideas. The ISTs apply the talk moves inflexibly, not taking the teaching situation at hand into consideration, and their identity is shaped through non-participation in alignment. In the last statement, Anne creates a distance between herself and the learning material in the group work, and since she is unwilling to negotiate meaning, her identity is shaped through non-participation in engagement.

Further non-participation in imagination shaped student teachers' identity when they felt that they did not have enough information about a situation, as illustrated below.

Anna: Yes, we might ask those questions, but as I've said, I find it hard when I haven't seen what they have drawn or how they came up with these fractions.

Anna's statement indicate that she would have been able to negotiate meaning if she had been the teacher and had access to the students' work, but here she lacks information and is therefore not able to imagine the students' work and her responses to it.

Discussion

Our analysis of the group discussions provided insight into how participation and non-participation shaped the student teachers' identity as mathematics teachers. Student teachers' identity was developed through engagement in the core practices the tasks were centered around, through imagination of the teaching situation, and alignment with the practices for mathematics teaching communicated in the teacher education programs. The student teachers' participation in engagement could be supported by frameworks for understanding students' ideas, as in the discussion about the measurement task. However, as we can see in the discussion between Anne, Else, and Bettina, teacher educators need to ensure that the student teachers are not adopting frameworks strictly and inflexibly. Further, student teachers' participation in imagination was supported by a representation of the classroom situation, either written work or transcriptions of dialogues. Our results are in contrast to those of Essien (2014), who found that student teachers developed a mathematical, not mathematics teacher, identity in coursework. One explanation for differing results can be that the coursework in Essien's (2014) study was not centered around core practices. From our analysis, it is evident that a combination of tasks centered around core practices, representations of the teaching situation, and frameworks for understanding student ideas support student teachers in developing a mathematics teacher identity.

Wenger (1998, p. 183) stated that most of what we do involves a combination of different modes of belonging, which is also evident from our analyses, where the student teachers negotiate meaning through more than one mode of belonging. The different modes of belonging working together promote student teachers' identity development, because they counterbalance each other (Goodnough, 2010). For example, imagination is helping the student teachers in attending to students' ideas when engagement becomes too narrow in the discussion about the multiplication strategy. Van Zoest and Bohl (2005) suggested that the different communities in which student teachers learn to teach should be strongly intertwined to help the student teacher develop a mathematics teacher identity. Work centered around core practices is a way of intertwining the school community and the teacher education community (Grossman et al., 2009), and the student teachers had opportunities to develop their mathematics teacher identity in several modes of belonging.

When we were planning this study, we chose to collect data from both PSTs' and ISTs' coursework, because we were expecting a difference in how they would work with core practices. Despite our expectations, our analyses did not reveal any differences in the two groups of teacher students' participation in core practices. Since identity captures beliefs, experiences, and knowledge (Van Zoest & Bohl, 2005), one could expect that PSTs' and ISTs' identity development would be different. However, the ISTs in our study are participating in a teacher development program for teachers who do not have any prior education from mathematics teacher education. The ISTs' mathematics teacher identity might therefore not include much prior experience or knowledge, making their identity more similar to the PSTs' identity. Further, in our study we are not giving a description of the student teachers' identity before and after group work, because we would need longitudinal data, and possibly interview data, to do so. Rather, we describe the processes in which the student teachers develop their identity, finding that group work around core practices gives both PSTs and ISTs opportunities to participate in different modes of belonging.

Secondary teachers' conceptions of infinity in different context

Nikoletta Palamioti[1] and Theodossios Zachariades[1]

[1]National and Kapodistrian University of Athens, Greece; nikipalam@math.uoa.gr tzaharia@math.uoa.gr

This study investigates how secondary school mathematics teachers think about infinity when they deal with this in different context. The research tool was two tasks based on hypothetical scenarios. The first one concerns the calculation of an infinite sum and the second is a version of the Ping-Pong Ball conundrum. Two math teachers evaluated the hypothetical students' reasoning and expressed their views in writing and during interviews. From the findings emerged that the different context of the tasks, formal and non-formal context, influenced the teacher's approach to infinity. The perspective through which the participants approached the infinite processes of the tasks, as well as the duration of these determined their views.

Keywords: Teachers conceptions, infinite sum, infinity, paradox.

Introduction

The concept of infinity as a learning item has been widely studied by mathematics education researchers (Montes, Carrillo & Ribeiro, 2014). Montes et al. (2014) highlighted that the process of developing the cognition of infinity and the differing conceptions of infinity were the focal point of the research. However, they consider that a study on the conception, knowledge, and practice of secondary teachers, especially in-service, about infinity is needed. Dubinsky, Weller, McDonald & Brown (2005a) noted that "Philosophers, mathematicians, mathematical historians, students, and mathematics education researchers, among others, have struggled to resolve various paradoxes, dichotomies and issues regarding conceptions of infinity" (p.336). Kolar and Čadež (2012) referred that the abstract nature of infinity, the understanding of it as an endless process or as a set of an infinite number of elements as well as the understanding of paradoxes are the difficulties that the individuals have to manage.

The paradoxes can be used as a lens to understanding infinity and as means to identify specific difficulties of the actual infinity (Mamolo, 2014). It is noted that these paradoxes are based on paradoxical assumptions, and they are inspired by the attributes of the mathematical infinity and the overturns of fundamental preconceptions (Mamolo & Zazkis, 2008). Kolar and Čadež (2012) focusing on primary teacher students, pointed out that an individual's understanding of infinity can be influenced by the context and type of the given task.

This paper aims to investigate how the context influences secondary mathematics teachers' conception of infinity through their engagement in two tasks with different context.

Theoretical Background

The conception of infinity is related to the dichotomy between potential and actual infinity. In particular, the potential infinity is considered as an infinite – endless process, and the actual infinity can be perceived as a completed process (Dubinsky et al., 2005a). In this context, Dubinsky, Weller, McDonald & Brown (2005a; 2005b) focused on understanding the aspects of infinity using the APOS

Theory. The potential infinity is seen as a process of infinite repeating steps and the actual infinity is the mental object obtained through the encapsulation of that process. Thus, they highlighted that infinity can be perceived as an infinite process, as a single operation that can be carried out and finished as well as a completed totality (Dubinsky et al., 2005a). According to them, it is important to notice that the potential and actual infinity represent two different cognitive conceptions that are related to mental mechanisms. Dubinsky, Arnon, and Weller (2013) studying the preservice teachers' understanding of the 0,999… =1 introduced an intermediate stage in APOS Theory between Process and Object, which they called Totality (TOT). Thus, the completed idea for the infinity can be constructed by the interiorization moving from action to process, detemporalization to progress from process to totality, and encapsulation to progress from totality to object (Dubinsky et al., 2013).

Moreover, Dubinsky, Weller, Stenger and Vidakovic (2008) and Mamolo and Zazkis (2008) studied the understanding of infinity using paradoxes, in which procedures with infinite steps could be completed in a finite time. As Dubinsky et al. (2008) found, when resolving the Tennis Ball paradox, university students focused on the existence of an incomplete process, or they claimed that infinite balls would be in the two bins at the end of the process. Mamolo and Zazkis (2008) studied high school mathematics teachers who participated in a master program and undergraduate students of liberal arts and social sciences, the perceptions of infinity using the "Hilbert's Hotel" paradox and "Ping-Pong Ball" conundrum. They noted that the students' answers focused on the practical impossibility of paradoxes. Thus, they concluded that "the students who acknowledged the gap between their intuitive and formal understandings of infinity may have taken an important first step toward encapsulating infinity as an object" (Mamolo & Zazkis, 2008, p. 180).

Methodology

In this paper, we present a part of border research focused on secondary education mathematics teachers' conception of infinity. This research is a multiple case study focusing on ten in-service teachers, with various teaching experience. They were informed about the aim of the research and they agreed to participate in this. They had a degree in mathematics and during this research, they were postgraduate students in mathematics education. In this paper, we analyse the data of two of them, Alice and Sergio. These cases were chosen since they approached the infinite processes under different perspectives. Specifically, perspectives based on the actual, potential, a combination of the potential and actual conceptions, and finite reasoning of an infinite process have emerged.

The research data were the teachers' written answers in two tasks and semi-structural interviews. The aim of the interviews was to insight into teachers' thinking. The interviews were recorded with teachers' consent and transcripted. The presented extracts in the results are a translation from Greek, which is the language that interviews were conducted, into English.

The research tool was two tasks regarding the conceptualization of infinity. They are based on hypothetical scenarios grounded on previous research findings and experience concerning learning and teaching of series. The tasks aimed to engage the teachers with students' misconceptions. Thus, we are not focused exclusively on the correctness of the responses but on whether the teachers can identify students' errors and their causes, as well as teachers' reasoning about them (Biza, Nardi & Zachariades, 2007).

1st Task

Two math students were asked to calculate the infinite sum $\frac{1}{9}+\frac{1}{81}+...$ The students thought for a while and continued with the following dialogue:

Stud. A: This is the infinite geometrical series $\sum_1^{\infty}\frac{1}{9^n}$, which converges due to $|\frac{1}{9}| < 1$. Am I right;

Stud. B: Yes. So, the infinite sum is converging to $\frac{1}{8}$.

Stud. A: No, it is equal to $\frac{1}{8}$.

Stud. B: It cannot be equal to $\frac{1}{8}$ since as we add terms the infinite sum is continually increasing. So it will converge on $\frac{1}{8}$.

Stud. A: It is continually increasing, but when the process will be completed, it will be $\frac{1}{8}$.

Stud. B: In an infinite sum the process is infinite and endless. Thus, this cannot be equal to a number. It is continually approaching the number and it tends to this.

a) Do you consider that one of the two answers is correct? Justify your answer. b) If you think all the answers are incorrect, which one do you think is the correct answer? Justify your view. c) For the ones that you think are incorrect, which are the misunderstandings that led to this answer.

The first task provides a context based on the formal mathematical knowledge about series. However, it is inspired by the dilemma of series' (as an infinitely repeating process) equality or convergence to a number. According to Spivak (2008, p.389) the expression "the series $\sum_{n=1}^{\infty} a_n$ does or does not converge" used to refer to infinite series is somewhat peculiar because the symbol $\sum_{n=1}^{\infty} a_n$ denotes at best a number (so it can't converge) and nothing at all unless (a_n) is summable. Thus, the given answers are based on the fact that the used terminology is conflicting since we refer that a series converges despite that it is equal to a number.

2nd Task

Three math students were given the following problem: "Imagine you do the following mental experiment with a duration of just 1 minute. It is assumed that you have an infinite set of numbered balls 1, 2, 3. . . and put them in a box as the following procedure demands. Firstly, you put the first 10 balls into the box, and then remove the number 1 ball in 30 seconds. Then, in half of the remaining time, you put the balls 11 to 20 into the box and remove the number 2 ball. Next, in half the remaining time (and with faster movements), you put the balls 21 to 30 into the box and remove ball number 3, and this process continues. After 60 seconds, at the end of the experiment, how many balls will there be in the box? ". The three students thought the problem and the next dialogue followed:

Stud. A: I think that at the end of the experiment there will be infinity balls in the box since those we insert each time are more than those we remove. In particular, at each step of this process, we put in the box 10 balls and we remove one, so we add 9 balls. Due to the infinite steps of the process after 60 seconds we will have infinity balls in the box.

Stud. B: This is accurate but does not mean that at the end there will be infinity balls in the box. I think that the box will be empty.

Stud. A: I do not think that will be empty. How do you think about it?

Stud. B: I think that firstly we will get the number 1 ball, after the number 2 and finally we will get all the balls.

Stud. C: Is it because the experiment has infinite steps that will not be completed?

a) Do you consider that one of the three answers is correct? Justify your answer. b) If you think all the answers are incorrect, which one do you think is the correct answer? Justify your view. c) For the ones that you think are incorrect, which are the misunderstandings that led to this answer.

The second task is based on a version of the Ping-Pong Ball conundrum (Mamolo & Zazkis, 2008; Mamolo, 2014), promoting a non-formal context focusing on "realistic" processes. The conundrum is referred to an infinitely repeating process and its ending due to the existence of a finite time. For its solution, they are needed the formal mathematical knowledge on series and the coordination of the infinite processes (inserting balls, removing balls, splitting the time). The key point for this coordination is the order of removing balls so there will be a specific time interval in which each of the inserting balls will be removed.

The analysis of data was carried out in two phases. In the first phase, we analysed teachers' written responses identifying keywords in their reasoning in order to design properly the upcoming interviews. In the second phase, we analysed the transcriptions of the interviews, reading them line by line, identifying keywords, and characterising an argument according to the conception that was based on.

Results

In the following, we analyse the data from all the phases of the analysis of Alice and Sergio.

The case of Alice

Alice in her written response to the first task agreed with Student A that the series is equal to the 1/8. She calculated the infinite sum $\sum_{n=1}^{\infty}(\frac{1}{9})^n$ by using the formula of the infinitely decreasing geometric progression and she noted that "the infinity sum indeed is continuously increasing but in the end, it ends". She also mentioned the infinite sums 0.3 + 0.03 + 0.0003 + ... = $\frac{1}{3}$ and 0.9 + 0.09 + 0.009 + ... = 1 as most direct and intuitive examples.

During the interview, she distinguished the process from the outcome of the process saying:

> "The process is different from the result. The process will give a result… If we deal the process as a whole, if we are able to see it as a package, as a whole, the whole process… the whole sum, if we consider it as a whole then it will be 1/8."

The use of terms "package" and "the whole process" indicates that she understands the process as complete. This shows her ability to perceive infinity as actual infinity.

Then, commenting on Student B's view of the infinite sum, she mentioned:

"Student B sees this endless process that is continuously increasing, and he just cannot see it from outside. He cannot come out from it, but he is inside… the result is the one that I see from outside, the infinite sum but from outside."

The teacher used the terms "inside" and "outside" to describe the views from which an infinite process can be approached. She claims that the internal view of the infinite sum results in seeing it as an endless process, while the external view helps you to see the result of the process. She then went back to Student A and mentioned:

"The use of future tense in Student A's argumentation is the point that I focused on…. So he indeed considers that it will be completed sometime… we do not know how "time" will take, but we know that whatever time it takes this [infinite sum] will be 1/8. It is like we don't care about the addition. He sees it from outside."

In the above excerpt, Alice connects the external view of an infinite process with its completion time and argues that in order to have an external view of the infinite sum we have not to care about the time required for it.

Regarding the second task, Alice in her written answer she rejected all students' answers and claimed that there will be a finite number of balls in the box at the end of the experiment.

I disagree with all the students. I consider that the experiment is going to be completed since the time will end. I think that in the box will be a finite number of balls, different than 0 (since the balls are increased continuously so the sum is increasing), and there will not be an infinite number of balls (since the time is going to end despite that the process giving us an increasing number of balls. The time is ending because: $1+\frac{1}{2}+\frac{1}{4}+\ \frac{1}{8}+\cdots=\sum(\frac{1}{2})^n\ =\ \frac{1}{1-\frac{1}{2}}=2.$), so neither infinite balls either zero balls.

In the interview, she first expressed her initial thoughts after reading the task:

"[This task] reminded me the Zenon's paradox, and Hilbert's Hotel paradox. ... And then the time is introduced and confused me."

She recalled two well-known paradoxes as tasks that have similarities with the given one. Nevertheless, she mentioned that the existence of finite time in this task confused her. So, the connection of the infinite process with time seemed to create a conflict to Alice.

Then, Alice reiterated the view she had expressed in her written answer focusing on the realistic aspect of the mental experiment:

"I think that there is a natural number of balls different than 0 in the box. It will not be empty… since we have a sum of positive numbers continuously. Despite that, we remove balls, we add more, so the sum is always positive. And there will not be infinite balls because it is referred [in the task] that the process ends due to time. Just I mentioned I saw it realistic… Sometime the time will run out."

Alice seems to be influenced by the fact that it is explicitly stated in the task that time is fixed and this is a key for her view. This is how she deals task 2 as an outside observer:

"I saw it [the experiment] realistically… So, it says that "time will end" and hence I disagree with all three students… I saw it from the outside, it will end, and the time is changed to zero. I still consider the same about the concept of infinity [as in the first task]. I just decided whether I will be in or outside of the process. I decided to see it outside…. I think that the balls are an infinite set. We have infinite balls, but we are going to use a finite number of them."

She seemed to consider that the process of inserting and removing balls will stop at the end of the time and so finite balls will have been used. Summarizing, it has emerged that Alice demonstrates an actual conception in the first task and a conception based on finite reasoning in the second one.

The case of Sergio

In his written answer regarding the first ask, Sergio disagrees with both students. He calculated the partial sum of the series but he started from k=0. He wrote $\sum_{k=0}^{n} \frac{1}{9^{\kappa}} = \frac{1-\left(\frac{1}{9}\right)^{n+1}}{1-\frac{1}{9}}$ and $\sum_{\kappa=0}^{\infty} \frac{1}{9^{\kappa}} = \lim_{n\to\infty} \left(\sum_{k=0}^{n} \frac{1}{9^{\kappa}}\right) = \frac{9}{8}$. He stated "this is a geometric sequence with α = $\frac{1}{9}$, where | α | <1, and therefore the sequence is convergent". Then, for Student's B answer he wrote "Incorrect calculation, probably due to carelessness or not remembering the formula correctly" and for Student A:

> He considers that the process will be completed and that the infinite sum is equal to 1/8, which shows that he has not understood that the infinite sum is the limit of a sequence of partial sums.

In the interview, it was initially made clear to Sergio that the sum starts from k = 1 thus the result is 1/8. Then, referring to Student A, he said "…it bothered me that on the one hand, he said converge and then he said equal.". When asked if he agrees with Student B, the next dialogue followed:

Sergio: …you have troubled me. I say it converges…in the end sums converge to the value 1/8. It is convergence. It is not equal. This is not another representation.
Researcher: OK. What does the series do?
Sergio: The series, you mean the infinite sum, is the limit of the partial sums.
Researcher: So the series is equal or converges to 1/8?
Sergio: It is equal to the value that converges… OK, it is equal to 1/8 … I don't know, I have mixed feelings, I fall into contradictions...

Then, when asked if he still disagrees with both students, Sergio answered:

"I disagree with both of them regarding the completion of the process … The one said that "when it is completed" but it will never be completed, and the other one that he cannot decide because it [the process] will not be completed. … We can admit that if we had infinite time this would be equal to 1/8…. If you stop somewhere ... then you are close to 1/8, but you did not reach it …However, if you do not stop then is going to be 1/8."

From the above, we see that Sergio is not sure if the series converges or is equal to 1/8. He also puts the dimension of time and considers that the infinite sum will be equal to1/8 in infinite time.

In his written response for the second task, he recalled Zeno's paradox and he wrote "…I "tend" to agree to Student A" but he also writes "...but what happens, in the end, I do not think we can decide.".

In the interview he said:

> “I disagree on whether it [the experiment] will end. Thus, I do not know if we can talk about the end of the experiment…. We have two times. The time experienced by the one who is in the experiment and the one who observes it. He who is in the experiment will always have half of the remaining time. It will not stop… the one who is inside in the experiment will tend to have infinite balls because he is constantly holding more and more in his hands [he means in the box] but I cannot say for sure that when it [the experiment] will end because it will not end.”

In the above extract, Sergio highlighted the fact that the infinite sum of time intervals will not be completed even though the experiment will end in a given time. In addition, he deemed that the process of inserting and removing balls cannot have a result since the process is endless. At the end of the interview, when he asked which student he finally agrees with, he agreed with Student C. In conclusion, it has emerged that Sergio demonstrates a combination of potential and actual conceptions in the first task and potential conception in the second one.

Discussion

From the preceding analysis, the secondary teachers’ conception of infinity has emerged. As the literature stated, the teachers were able to perceive the infinity either as potential or as actual infinity (Dubinsky et al., 2005a). However, it is revealed that an individual’s conception may be at an intermediate level, between potential and actual infinity, as Dubinsky et al. (2013) stated. Both teachers demonstrated different conceptions of infinity in the two tasks. Alice demonstrated an actual conception of infinity in the first task and a conception based on finite reasoning of an infinite process in the second one. On the other hand, Sergio demonstrated a combination of the potential and actual conceptions in the first task and a potential in the second one. In particular, in the first task, Alice seemed to have an actual conception of infinity since she approached the infinite process as a completed set. In addition, even though the task did not provoke it, she distinguished the views that the infinite process can be approached as the participant in it or as the observer of it. Her decision to be an observer led her to the actual conception. However, Sergio’s conception is between potential and actual infinity. He referred to the external and internal view on the infinite process, as Alice did, but he considered himself as a participant. Therefore, the endless conception of infinity has appeared. Even though he faced a conflict on the used terminology about series, his prior formal mathematical knowledge seemed to influence him to consider that an infinite process can have an outcome. Thus, this intermediate conception has emerged. We note that in the first task, the teachers introduced the aspect of time in their reasoning, even though its context does not promote it, and they expressed different views on it. Alice noticed that time could not influence the extraction of an outcome because sometime this will be completed, reinforcing her actual conception. On the contrary, Sergio considered that only in infinite time the series will be completed, presenting a potential conception.

Regarding the second task, the “realistic” and controversial context of the paradox seemed to influence the teachers’ conceptions of infinity. In particular, both teachers could not correctly coordinate the infinite processes, and they approached the experiment time differently. Alice focused on the finite time of the experiment, and she considered that the process of inserting and removing balls is not completed but will stop when the time is up. Therefore, she approached the infinite process under finite reasoning. On the contrary, Sergio focused on the infinite process itself, so he opposed that the experiment ends and the extraction of an outcome (Mamolo & Zazkis, 2008), presenting a potential conception

The above findings illustrate that the context of this task influences secondary mathematics teachers' conceptions of infinity. This type of task seemed to allow teachers' misconceptions to emerge and could be used in mathematics teachers' education to enhance their knowledge.

Nurturing Pre-service Teacher's Awareness About Students' Mathematical Thinking Through Lesson Study

Rüya Savuran[1] and Mine Isıksal-Bostan[1]

[1]Middle East Technical University, Faculty of Education, Ankara;
ruyasay@metu.edu.tr; misiksal@metu.edu.tr

The current study aims to reveal the development of the pre-service teacher's awareness on students' strengths and weaknesses in learning the limit concept through lesson study. We focused on a participant's development within instrumental case study. The findings showed that the two phases of lesson study including planning and enacting contributed to the development of the pre-service teacher's awareness on students' strengths and weakness in learning the concept of limit through different aspects.

Keywords: Pre-service teacher education, specialized knowledge, knowledge of features of learning mathematics, lesson study

Introduction

The common idea of many alternative views - how teachers reveal their knowledge rather than what they know - is one of the reasons that makes mathematics teacher knowledge specialized (Scheiner et al., 2019). This specialized knowledge includes mathematical and pedagogical content knowledge as well as reflecting this knowledge on practice. In this structure, one of the most important and comprehensive knowledge can be considered as understanding the nature of learning mathematics which includes students' mathematical thinking, their interaction with content and their strengths and weaknesses in learning the concept (Carrillo-Yañez et al., 2018). The literature has revealed that mathematics teaching, which is carried out in order for students to make sense of the concept and provide a correct conception, is a very complex process (Cengiz, Kline, & Grant, 2011). Therefore, teachers need to attend students' mathematical thinking and make instructional decisions considering students' thinking (Sherin, Jacobs, & Philips, 2011).

On the other hand, the concept of limit can be considered as a cornerstone and one of the comprehensive concepts in mathematics to conceptualize related mathematical concepts. Besides its central position in mathematics (Cornu, 1991), the concept comprises many topics all of which are based on a common basis, either explicitly or implicitly. One of these topics is indeterminate forms (e.g., $\frac{0}{0}$, $\frac{\infty}{\infty}$, 0^{∞}, 1^{∞}) and accordingly the difference between indeterminate-undefined forms in limit. In addition to the difficulties experienced by the students regarding the limit concept itself, students have difficulties in knowing the distinction between the notions of undefined and indeterminate, and they often tend to use these terms interchangeably (Jaffar & Dinyal, 2011). Moreover, the limited literature about these notions indicated that most of the students calculate limits in the indeterminate forms and use L'hospital rule without questioning the reason behind the forms and related calculations (Hulliet & Mutemba, 2000; Arce, Conejo, & Ortega, 2016). Considering these difficulties, teachers need to be aware of students' mathematical thinking, strengths and weaknesses in teaching the concept and its related notions to provide an effective learning environment. Teachers can gain this awareness through the combination of knowledge of content and students, more teaching experience with different level of students, and interaction with their colleagues. Since these notions are quite complex even for pre-service teachers (Hulliet & Mutemba, 2000), this awareness could be acquired while being a pre-service teacher before performing the teaching profession.

One of the ways to nurture the awareness of pre-service teachers for learning students' strengths and weaknesses (Lee, 2019) is lesson study development model which is a cycling process that a group of teachers/pre-service teachers work collaboratively (Stigler & Hiebert, 1999). It includes four main phases: (1) investigation: setting a learning goal in consideration that students have difficulty in understanding, (2) planning: building a research lesson plan in collaboration, (3) research lesson: conducting the lesson plan in a real classroom where one of the group members teach the concept while others record students' reactions and take notes of their thinking processes, and (4) reflecting and discussing on how effective the lesson was in facilitating student learning (Stigler & Hiebert, 1999). This phase might be followed by discussions on how to improve lesson plan, and the cycle might be applied again to revise missing points. Bearing all these in mind, the current study aimed to develop pre-service teachers' knowledge of students' mathematical thinking for the notions of indeterminate-undefined forms through lesson study.

Theoretical Framework: Mathematics Teachers' Specialized Knowledge

As a part of a longitudinal project, we adopted the model of Mathematics Teachers Specialized Knowledge which includes two main domains as mathematical knowledge and pedagogical content knowledge encircled around the belief towards mathematics and teaching mathematics. There are three sub-domains for each knowledge domain: knowledge of topics (KoT), knowledge of structure of mathematics (KSM) and knowledge of practices in mathematics (KPM), which are under the domain of mathematical knowledge. On the other hand, knowledge of features of learning (KFLM), knowledge of mathematics teaching (KMT) and knowledge of mathematics learning standards (KMLS) are under the domain of pedagogical content knowledge. For an effective mathematics teaching, in addition to mathematical knowledge, having knowledge about the students' interaction with the content and how they learn is actually one of the basic requirements of being a good mathematics teacher. Therefore, we paid attention to KFLM which is concerned with the areas of knowledge about mathematical content, the process of learning the content, and the characteristics of this process, and how students interact with the mathematical content in this learning process (Carrillo-Yañez et al., 2018). It should be indicated that the focus of KFLM is not solely students, rather the focus of KFLM is the interaction between the content and students (Carrillo-Yañez et al., 2018). There are four indicators for KFLM including learning theories related to the content, strengths and weaknesses in students' learning relation with the content, the students' interaction with the content, and the student's motivation, expectations and interests with regard to mathematics. In this paper, we focused on the pre-service teacher's awareness of students' strengths and weaknesses in the context of learning indeterminate-undefined forms.

Bearing the lesson study, theoretical framework and the aim of study in mind, we addressed this research question: (1) What is the nature of pre-service teachers' knowledge of features of learning mathematics in the learning indeterminate-undefined forms in the context of limit concept during the lesson study process? (a) How does lesson study contribute to the nurturing of the pre-service teacher's awareness about students' strengths and weaknesses in learning indeterminate-undefined forms in the context of limit concept?

Method

The study was an instrumental case study (Mills, Durepos, & Wiebe, 2010) in which we used lesson study as an instrument to provide insight into development of the pre-service teacher's awareness on students' strengths and weaknesses. To deepen the analytic stance, we focused on one of the three pre-service teachers, Mila, who was chosen purposefully for several reasons, one of which was the fact that she didn't have any experience on making a lesson plan or teaching the concept of limit in addition to her eagerness to learn the concept and to hear the students' voices in learning mathematics.

The study was carried out in the last semester of the undergraduate mathematics teacher education program, as the pre-service teachers take the fundamental mathematics and mathematics education courses until their last semester in the program. The procedure of lesson study was conducted in a similar way with the description in the introduction section. To nurture the pre-service teacher's awareness about students' mathematical thinking, based on the suggestions of the literature on improving teachers' awareness of students' mathematical thinking (Lee, 2019), the phases of the lesson study were designed with some additional steps such as promoting the group to think about interrelationships among important mathematical ideas and students' mathematical thinking.

Data Collection and Analysis

The data were generated through mainly observation of lesson study process including group discussions in planning and reflecting phases and teaching episodes in research lessons which were conducted in Turkish in two lesson study cycles. In addition, the field notes and lesson plans were used to support the claims generated from the data. The first author was the knowledgeable other in the lesson study process. We obtained the data through audio- and video-recording during the data collection process. After all the data was transcribed, we started the data analysis with partitioning of the snapshots of the pre-service teacher's interthinking and exploratory talk (Littleton & Mercer, 2013), which includes contributions of students' mathematical thinking process considering their strengths and weaknesses within the collaborative process of lesson study.

We used thematic analysis with deductive approach in which we determined the codes and the theme before analyzing the data. We used the indicator of KFLM-awareness about students' strengths and weaknesses- as a theme in analyzing data. The codes were determined as (i) lack of awareness- the general expressions about students' mathematical thinking or without consideration of students' strengths and weaknesses, and (ii) being aware- interpretative comments on students' mathematical thinking and the relationship between students' learning and the content in planning. In a similar vein, the codes for enacting were determined as (i) lack of awareness-acting without consideration with students' strengths and weaknesses, and (ii) being aware- acting with considering students' mathematical thinking, using their strengths to overcome their difficulties. In this way, we dealt with the nurturing process from lack of awareness to being aware in the journey of the pre-service teacher.

Findings

We deal with the nurturing process of lesson study in two parts: *planning* (determining lesson goals and planning of the research lessons), and *enacting* (implementing the research lesson and writing reflections).

Planning

The topic of indeterminate-undefined forms was the subject that Mila herself had difficulty in understanding, and furthermore she developed her mathematical knowledge on this subject during the lesson study process. To put it right from the start, Mila actually developed her knowledge of students' strengths and weaknesses based on her own learning process in the past.

We observed in the pre-interview that Mila, similar to other group members, had some confusions about the difference between indeterminate and undefined forms. Therefore, her awareness about students' confusions between these two notions was gained (or developed) in accordance with the awareness of her own lack of knowledge. The following excerpt showed a starting point of the discussion on these two notions in the planning phase:

Mila: For example, let's imagine that $\frac{0}{0}$ equals x. Multiply the ins and outs. x can take more than one value.
Participant 1: Ah yes.
…
Participant 2: When you spoke of indeterminate, something came to my mind. I realized that it was undefined. I realized it after reading the article: Undefined and indeterminate are two different things.
Mila: Honestly, I didn't know either, I think students might get confused.
...
Researcher: Then what do you say about the number divided by zero?
Participant 2: Undefined.
Participant 1: Professor, I think first of all let's start with the difference between undefined and indeterminate? Let's start, as in the way Mila said.

In the excerpt above, we did not pay attention to the mathematical correctness of the expression. Rather, we focused on how the pre-service teacher considered students' mathematical thinking while constructing the content in planning. The development was observed through development of her mathematical knowledge.

In addition, the observation of other group members' lessons provided her to see beyond her thoughts about students' strengths and weaknesses in learning the concept of limit. The observation of the Participant 2's research lesson which was just before Mila and then watching it on video enabled her to make more mathematical contributions to students' learning about mathematics during the planning phase.

Researcher: You can also explain it in that way when you are explaining. You will start with indeterminate forms. There was a question the students asked Participant 2 as "why infinity divided by infinity does not equal to 1". Participant 2 will ask you if it's a sufficient explanation.
Participant 2: I said that if there is only one number, there is infinity divided by infinity which equals to the number of a, then infinity equals to 'a times infinity'. Well, do I know this a, but it may be 1, it may be 2, it may be 1000, I asked whether I could say something definite for a, they said no, so I said there would be indeterminate.

Mila: This is not the answer of the student's question "why not 1", instead it looks like the answer to the question of "why does this indicate indeterminate"!

Participant 1: Let’s say, here is already undefined! Again, infinity divided by infinity must be one for the inside and outside product.

[*Researcher intervened here*]

Participant 2: I should have said infinity can be described as an increase; it is not an infinite number.

Mila: We need to be particularly careful about the infinity; a bit as an adjective! So, we can start from there and talk about indeterminates.

Researcher: So, you can start here!

Participant 2: For example, they asked why 1 to the power of infinity and zero times infinity indicated indeterminate.

Mila: They are right about the 1 to the power of infinity, we should definitely mention it!

It can be understood that Mila's ability to express more mathematically what aspects of students can be strengthened and which weaknesses can be eliminated shows the change that occurred during the planning phase.

Enacting

In implementing the third lesson plan aiming to grasp the concept of continuity by establishing mathematical relations and to use it together with limit in mathematical applications, Mila started her lesson based on her experiences. In other words, she knew that it would happen because she got to know the students from the narrations of her previous friend and told them about their learning only out of curiosity.

Mila: Now I guess you guys were pretty curious about indeterminate.

Student 1: Yeah!

Mila: Yes, I've already had such a feeling, so I want to examine these indeterminates together with you. First, let's talk about the $\frac{0}{0}$ and $\frac{\infty}{\infty}$ uncertainty. What do you think might be the reason for this indeterminate?

Students: [Grumbling sounds of what they don't know]

Mila: So, I'm going to write you two functions and ask you to find the limit at the point I gave you.

In the excerpt given above, Mila tried to make them notice the different results of the same limit forms which caused the indeterminateness. By wanting them to calculate the limits of the given points of the functions, it can be understood that Mila considered students’ strengths about the concept of limit. Moreover, it should be indicated here that this is an example about Mila’s awareness about students’ expectations about mathematics.

The example given above is an example from a planned situation in implementing the lesson plan. However, our main expectation was to observe the pre-service teacher’s awareness and actions in unplanned and unexpected situations. It would show how the pre-service teacher use her awareness in her teaching. In the enacting phase of the first cycle, there were two situations she faced with in this way. In the continuation of the indeterminate form of $\frac{0}{0}$ and $\frac{\infty}{\infty}$, she observed that students tended to make mistakes while exemplifying or demonstrating indeterminates based on the question frequently asked by students in the implementation of the second lesson plan.

Mila: If I ask you a question now (She turned to her presentation but realized that the question she wanted was not there). Yes, I didn't write it here... (Closing the presentation screen) Forget about it then. I will write the question myself. Let's say

I take $f(x)$ to the $g(x)$ as limit x goes to infinity ($\lim_{x\to\infty} f(x)^{g(x)}$) What if $f(x)$ was 1 for me as the limit goes to x. If limit x goes to infinity and $g(x)$ is infinity for me, what will the result be? So, when I think about this $f(x)$ to the $g(x)$ structure…?

Student 1: 1 to infinity (1^{∞}).

Mila: 1 to infinity becomes infinity. Because I know from the limit rules that I can distribute this limit and the limit $f(x)$ to the $g(x)$ would be 1 to the infinite for me.

Student 2: I think it should be 1 too.

Student 3: I've always wondered about that too.

Mila: You were wondering, right? I heard it. There is actually a reason for this. What we said is that the main reason for the indeterminates is that we get different results in the same form of the limit. In fact, nothing different from the ones here (she showed what she wrote about $\frac{\infty}{\infty}$) appears for 1^{∞}. Now I will write you two examples.

Up to now, the excerpt showed that she tried to use students' strong sides to teach them the logic of indeterminate forms. In addition, it can be said for this introduction that she considered the students' interest (emotional aspects of learning the concept) which was their curiosity about why the forms of 1^{∞} is not equal to 1. In the continuation of the excerpt, she wrote the functions: $\lim_{n\to\infty}\left(1+\frac{1}{n}\right)^{n} = e$ and $\lim_{n\to\infty}\left(1+\frac{1}{n}\right)^{n^2} = \infty$. While she aimed to use their strengths, students got confused about why they look for the same results for different functions. The following excerpt showed her awareness about the aspects related to students when she answered students' questions.

Mila: So that's why 1 to the power of infinity is indefinite.

Student 1: But that's not 1 to the power of infinity, right? We said 1 to the infinitely indefinite thing, isn't it something different? e is here.

Mila: Hmm, is it confusing that it's equal to e?

Student 1: No, there is a number called n.

Mila: Yes.

Student 1: 1 is not infinity, I mean, I don't think they are the same thing!

Mila: There is a number called n, is your question related to it?

Student 1: n goes to infinity or exactly 1 to the infinity is not equal to this.

Student 3: He means something (talking about his friend) different in two functions. As if the two functions are different, it's logical that we find different results anyway, isn't it?

Mila: Hmm I got it! But I'm telling you this. So, let's look at the equation I got over here, okay (it shows the resulting limit e)? When I look over there the limit n goes to infinity and that inner side is equal to 1 for me. Therefore, when I overwrite it here, I get the 1 to the infinity form. Here I got 1 to the infinity, and what happens when I get the same form of other functions? Here I am writing the same thing again (showing the second function). Here, my inner side became 1 and my upper side became infinity. In other words, they seem to be different functions, but since we do not perceive infinity as a number, we say that it is increasing gradually, but we do not know how much it increases, so this is the reason why it creates indeterminate.

Student 1: I get it!

Student 2,5,7: Yeah, I understood perfectly!

In the face of this unexpected situation, the pre-service teacher drew an unplanned path for herself by using the strengths of the students and at the same time establishing mathematical connections. It showed that gaining awareness of students' understanding is closely related to her knowledge of practices in mathematics which can be explained as awareness of mathematical reasoning on how to explore mathematics by seeing connections. At the beginning of lesson study process, Mila commonly preferred to reason by means of counterexample not considering students’ learning whenever it was asked how she would show one’s correctness or incorrectness. Developing her awareness of students’ learning mathematics provided her to use students’ strengths for demonstrating the concept in teaching. The fact that the pre-service teacher is aware of the example she gives to create a mathematical knowledge is closely related to the students' awareness of using calculation, which is one of students’ strengths.

As a result, the lesson study process contributed the development of the pre-service teacher’s awareness on students’ strengths and weaknesses in learning the notions through various aspects. The *planning* phase provided her to discuss on students’ learning and develop her awareness through different perspectives in the discussion with her colleagues. The *enacting* phase supported her development by enabling her to see what she had discussed and planned in a real classroom through students’ interaction with mathematical content.

Discussion

The findings showed that the lesson study process promoted the pre-service teacher’s knowledge for gaining awareness of students’ strengths and weaknesses in learning the topics of indeterminate-undefined forms. In planning, at the beginning of the lesson study process, Mila used her own experiences related to learning the concept. However, such views can be considered as limited, in other words, lack of awareness, for effective mathematics teaching, because attentions of both pre-service and in-service teachers to students’ mathematical thinking and learning process in interaction with mathematical content provide them to see beyond what they think about mathematical knowledge and enable them to make instructional decisions (Sherin, Jacobs, & Philips, 2011). As the literature supported (Guner & Akyuz, 2020), working collaboratively on students’ learning in planning might promote to open their eyes to observe students’ strengths and weaknesses in interaction with mathematical content. Accordingly, the development of Mila’s awareness enabled her to make the instructional decision to create her own path by being aware of the strengths of the students rather than applying the lesson plan as it is in the enacting phase. The indicator of KFLM does not only include knowing where students have difficulties or strengths; rather it covers to enact this knowledge combining with content knowledge in making instructional decisions (Carrillo-Yañez et al., 2018). Considering that Mila took instructional decisions to help students overcome difficulties by leveraging their strengths, it can be concluded that the enacting phase of lesson study presented a great opportunity to develop this side of knowledge of students’ learning mathematics.

The study focused on one pre-service teacher within classroom discussion during the lesson study process. In future research, the focus could be given on more participants in classroom discussions. Furthermore, the study contributed to the limited literature about the pre-service teacher’s knowledge of indeterminate-undefined forms in the context of limit concept. In addition, as a part of the nature of the limit concept, there is a powerful relation between the development of mathematical knowledge (KPM, in this study) and increasing awareness of students’ learning mathematics. Therefore, the future studies which examine other notions within the nature of the limit concept considering other indicators of MTSK can shed light on the literature on mathematics teacher knowledge.

Examining assumptions about the need for teachers to transform subject matter into pedagogical forms accessible to students

Thorsten Scheiner

Institute for Learning Sciences and Teacher Education, Australian Catholic University, Australia; thorsten.scheiner@acu.edu.au

This paper explores fundamental assumptions about the notion of transforming subject matter, which is widely regarded as a central practice of teacher work and a crucial feature of teacher knowledge. First, the notion of transforming subject matter and the ways in which it has been taken up in discourses on teacher knowledge are discussed. Second, fundamental but mostly implicit assumptions are explored and challenged, including the individual teacher as the locus of transformation, the possessor of the knowledge in question and the gatekeeper who provides students access to subject matter content. Finally, these widely held assumptions are problematised against the background of French and German traditions of didactics. These traditions see the ability to transform subject matter not as a characteristic of the individual teacher, but of social and cultural systems that are institutionally contextualised and oriented towards normative conceptions of education.

Keywords: Didactic transposition, elementarisation, pedagogical content knowledge, pedagogical transformation, subject matter content.

Introduction

It would be fair to say that Shulman's (1986, 1987) work on teacher knowledge has been a major driving force in promoting teaching as a profession, particularly in the English-speaking educational research community. Shulman (1986, 1987) provided the impetus for the view of teaching as a profession by asserting that teachers have a specialised knowledge base that differs from other professionals. Of particular importance was Shulman's (1986) introduction of the construct of pedagogical content knowledge, which refers to a specialised kind of content knowledge that goes beyond subject matter knowledge per se and encompasses subject matter knowledge for teaching. Pedagogical content knowledge, according to Shulman (1986), includes "the most powerful analogies, illustrations, examples, explanations, and demonstrations – in a word, the ways of representing and formulating the subject that makes it comprehensible to others" (p. 9).

It is these ways of representing and formulating of the subject matter content – the transformation of subject matter in ways comprehensible to students – that Shulman (1987) conceived as the core task of teaching and the defining feature of pedagogical content knowledge. Teachers must transform subject content into pedagogical forms, such as examples, representations, and instructional tasks, which make the content accessible to pupils. Guided by this orientation, Shulman (1987) defined pedagogical content knowledge as "the blending of content and pedagogy into an understanding of how particular topics, problems, or issues are organised, represented, and adapted to diverse interest and abilities of learners, and presented for instruction" (p. 8).

While the construct of pedagogical content knowledge has received wide attention and has been the subject of numerous examinations (e.g. Abell 2008; Bromme 1995; Cochran et al. 1993; Depaepe et al. 2013; Gess-Newsome & Lederman 1999; Hashweh 2013; McEwan & Bull 1991), the underlying notion that teachers necessarily transform subject content into pedagogical forms has, for the most part, been taken-for-granted. Indeed, the notion of transforming subject matter has often been used implicitly instead of explicitly thematised in educational research, and thus, has hardly been the subject of debate and hence remained beyond the scrutiny of critical reflection (see Deng 2007).

This paper examines the notion of transforming subject matter by identifying and questioning theoretical underpinnings that have not been discussed in any substantial way. Such examination is particularly relevant in the field of teacher knowledge, where the vast majority of the literature has reproduced and reinforced the basic assumptions in Shulman's path-defining contributions.

On the notion of transforming subject matter and its context

The notion of transforming subject matter came to light in Shulman and his colleagues' research program *Knowledge Growth in Teaching* (e.g. Grossman et al. 1989; Shulman 1986, 1987; Wilson et al. 1987), which studied the interaction of content knowledge and pedagogical development among novice school teachers of different disciplines. The primary focus of this research program was on how novice schoolteachers adapt their content knowledge of an academic discipline so that it becomes suitable for classroom teaching. The fundamental assumption was that subject matter contents "must be transformed in some manner if they are to be taught" (Shulman 1987, p. 16). It is this transformation of subject matter into pedagogical forms accessible for students that has been taken as the central intellectual task of teaching and that became the defining principle for pedagogical content knowledge. In arguing for a knowledge base of teaching, Shulman (1987) claimed that

> the key to distinguishing the knowledge base of teaching lies at the intersection of content and pedagogy, in the capacity of a teacher to *transform* the content knowledge he or she possesses into forms that are pedagogically powerful and yet adaptive to the variations in ability and background presented by the students. (p. 15, italics added)

The notion of transforming subject matter has sparked wide interest in the English-speaking education research community after Shulman (1986, 1987) introduced it as the defining premise for pedagogical content knowledge. The notion of transforming subject matter content has been described and interpreted in multiple ways. For instance, Gudmundsdottir (1991) described this transformation process as a 'reorganisation' of content knowledge that derives from a disciplinary orientation, and Grossman et al. (1989) defined it as a 'translation' of subject matter knowledge into instructional representations. Marks (1990), on the other hand, portrayed it as a process of 'reinterpretation' that means, "the content is examined for its structure and significance, then transformed as necessary to make it comprehensible and compelling to a particular group of learners" (p. 7).

Common to these considerations is the view that the transformation of content knowledge into a form of knowledge "that is appropriate for students and specific to the task of teaching" (Grossman et al. 1989, p. 32) is seen as a means and an end in itself. However, such considerations can hardly be regarded as new from the point of view of several European traditions of didactics, especially the French and German traditions of didactics. Questions of preparing subject content are described in these traditions yet as part of didactic theories and broader educational considerations, not as characteristics of teacher cognition. For example, in the French tradition of didactics (*didactique*), it has long been known that disciplinary subject content cannot be directly adopted as content for teaching. The notion of didactic transposition (*transposition didactique*) refers to the processes that take place from the moment it is decided that some scholarly body of knowledge should be taught, to the moment this body of knowledge is taught in educational settings such as school classrooms and learned by a group of students (Chevallard 1985). The taught knowledge, however, is not a reproduction of scholarly knowledge, but originates from it and is shaped by various institutional and cultural forces that may vary in time and space. In the German tradition of didactics (*Didaktik*), on the other hand, the preparation of subject matter for teaching was not only about making it accessible to students, but also about expanding its potential for the personal and cultural formation and maturation of students. An important approach in this tradition is the didactic analysis (Klafki 1958), in which subject matter is examined for its exemplary significance and its present and future relevance for students, in addition to its accessibility.

Though different in their suggested practices, these traditions share the idea that disciplinary subject matter needs to be structurally modified in ways teachable by the teacher and learnable by the students.

On the fundamental assumptions about the notion of transforming subject matter

For Shulman (1986, 1987), the bridging from the disciplinary subject matter teachers acquired in college or university to the content they teach in school is the central issue that novice teachers have to face. The key to this bridging is the transformation of the disciplinary subject matter knowledge a teacher possesses into pedagogical forms accessible to students – a transformation assumed to be engineered by the individual teacher. The teacher's own content knowledge of the academic discipline is the matter or substance of transformation, and the teacher's orientation to the structure of the discipline and the structure of students' minds (including their prior knowledge) is the foundation for the restructuring of content knowledge for pedagogical purposes.

On this view, the subject matter content knowledge taught in school is a pedagogical and personal revision of the disciplinary content knowledge of the teacher. How well this pedagogically revised content knowledge fits or connects with students' prior knowledge, then, determines whether students have access to the knowledge at stake. Consider, as a case in point, Shulman and Quinlan's (1996) retrospection on the research program *Knowledge Growth in Teaching*:

> The central feature of this research program was the argument that excellent teachers transform their own content knowledge into pedagogical representations that connect with prior knowledge and dispositions of learners. The effectiveness of these representations depends on their fidelity to the essential feature of the subject matter and to the prior knowledge of the learners. The capacity to teach […] is highly dependent on […] how well one understands ways of transforming the subject matter into pedagogically powerful representations. (p. 409)

On this view, the individual teacher is the locus of transformation. It is the teacher who possesses the content knowledge at stake and who controls the selection, sequencing, and pacing of what knowledge is learned and how it is learned. Such assumptions rely on a teacher-direct view of the teaching-learning process, in which learning is directed and modelled by the teacher. Figure 1 illustrates the simplicity of which this view operates from within the didactic triangle, focusing the attention on the teacher–subject-matter edge of the didactic triangle.

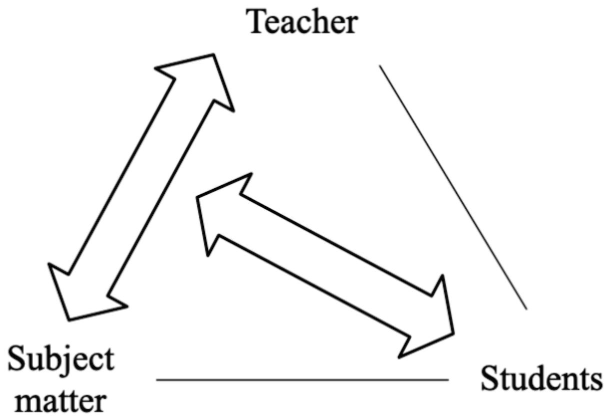

Figure 1: Shulman's view of the transformation of subject matter

For Shulman, it is the individual teacher who *structures* the subject matter content; *represents* it in the form of analogies, demonstrations, examples, metaphors, and so forth; *adapts* these representations to students' general characteristics; and *tailors* the adaptations to those specific individuals or group of students to whom the subject matter will be taught in the classroom (Shulman 1987, pp. 16–17). Through structuring, representing, adapting, and tailoring of subject matter, the teacher identifies and creates ways of representing and reformulating content knowledge that makes it comprehensible for students.

According to this view, the decision of what knowledge (and how knowledge) is acquired is made through the authority of the individual teacher, as the possessor or owner of the knowledge at stake. That is, the teacher controls what is learned and holds the criteria for what forms of knowledge are valued. This view, however, is problematic as the choice of which forms of knowledge are valued becomes a question of whose forms of knowledge are valued, leaving unexamined the *problématique* that any issue of 'what knowledge' is indeed an issue of 'whose knowledge' (see Moore 2009). Knowledge, consequently, is reduced to those who hold it or gain access to it, and those who have it or get it are in power. The teacher is positioned in the locus of power – as the knowledgeable who grants students access to the content knowledge in question. What students have access to are the pedagogically and personally revised forms of the content knowledge the teacher possesses. This understanding is problematic as it prevents realisation that the knowledge students have access to might not necessarily be 'powerful knowledge', which is deemed critical for responsible citizenship in a society (Young & Muller 2013). It might instead be 'knowledge of the powerful', which reinforces the interest of those previously educated within a system built on that understanding.

What the French and German traditions of didactics set apart from the notion of transforming subject matter

The notion of transforming subject matter reflects certain premises of the French and German traditions of didactics. One of the commonalities of these approaches and traditions is that they consider the content knowledge of an academic discipline to be an essential point of departure for transformation or transposition. Another commonality is the idea that such content knowledge is to be transformed or transposed in some ways to be accessible for students. These traditions differ fundamentally, however, in regard to their theoretical underpinnings. First, in Shulman view, the individual teacher is the locus of transformation, and transformation is seen as an internal process that takes place in the mind of the teacher. In the French and German traditions, however, didactic transposition is institutionally contextualised and culturally shaped and directed towards normative conceptions of education.

Second, the unit of analysis, in Shulman approach, is the individual teacher and her or his mental processes, and the capacity of transformation is a key characteristic of teacher expertise. How well a teacher transforms her or his personal content knowledge into forms that fit or connect with students' prior knowledge and dispositions defines whether students have access to the knowledge in question. Access for students is, thus, a pedagogical and psychological matter. In the French and German tradition, however, the unit of analysis goes well beyond the individual teacher. It includes how social, cultural, and political contexts shape and frame the work of teachers. Knowledge is institutionally contextualised and actualises in social practices and cultural activities, such as teaching. The issue of student access is as much a social, cultural, and political one as it is an epistemological, cognitive, and didactic one. In the following, the theoretical principles and foundations of the French and German traditions and their implications are discussed in more detail.

Transformation of subject matter content knowledge, in Shulman's view, is something engineered by the individual teacher. Chevallard (1985), the initiator of the French tradition of didactic transposition, however, portrayed transposition as socially and culturally produced. Didactic transposition describes the inevitable processes of change by which scholarly knowledge as it is produced by scholars, for instance, is transformed through various negotiations to knowledge to be taught that is socially considered as important and, as such, officially prescribed by the curriculum. Over different elaborations according to various circumstances, this knowledge is then transformed to knowledge as it is actually taught by teachers in their classrooms, and eventually to knowledge as it is actually learned by students. The theory of didactic transposition accounts for the various constraints the diverse agents in the transposition process are subject to, and it attempts to reveal the 'transparency illusion' of those who think of transformation of subject matter as something deliberately chosen (see Bosch & Gascón 2006).

The activity of transposition does not belong to any individual but involves groups of people who interact with one another, including disciplinary experts, education researchers, curriculum developers, and teachers, among others. These groups of people belong to what is called the *noosphère*, the sphere of those who think about education, an intermediary between the education system and society (Chevallard 1985).

The capacity of transformation is, in this view, a property not of a single teacher, but of social and cultural systems that enable the development of subject matter knowledge in social institutions and the organised and institutionalised preparation of subject matter for students. This tradition acknowledges institutions at the source of knowledge and highlights the fact that what is taught at school originates in other institutions and is a result of complex processes of negotiations among different actors involved in the process of didactic transposition (Chevallard 1992).

The process of didactic transposition, thus, underlines the 'institutional relativity of knowledge' and situates didactic phenomena at an institutional level, beyond individual characteristics of the institutions' subjects (Bosch & Gascón 2006). What is taught at school has to be legitimised by external entities that guarantee the social value and epistemological significance, as well as the cultural relevance of the subject matter content (Chevallard 1992).

Similarly, subject matter content, in the German tradition of didactics, is selected based on normative criteria according to its educational value for promoting and actualising *Bildung* – that is, the personal and cultural formation and maturation of students (von Humboldt 1795/1960). Via didactic analysis, the role, meaning and importance of the subject content in contributing to general educational aims are to be explored and questioned (Klafki 1958). The selection of subject matter content is, thus, a selection of aims, goals, and values of education in a given society. What content knowledge is valued and what is worth teaching are not left to be decided by the individual teacher but are based on formal criteria developed in the interplay of cultural-historical traditions and current societal needs.

For subject matter content to become educative, it needs to be 'elementarised' (*elementarisiert*) that is, concentrated, intensified, or abstracted to what has fundamental relevance for students (Klafki 1954). Elementarising does not simply mean a simplification of subject matter content, but a magnification of educational content (*Bildungsinhalt*) for opening or unlocking the educational substance (*Bildungsgehalt*) of the subject matter content.

Conclusion

The introduction of pedagogical content knowledge in the English-speaking community has re-introduced the centrality of subject matter content into the teaching equation, a centrality well-known and well-established in several European traditions of didactics. This paper in no way undermines Shulman's efforts in bringing the subject matter to the forefront in discourses of teaching, teacher knowledge, and teacher education. Instead, this paper has examined fundamental assumptions underlying the notion of transforming subject matter as introduced by Shulman in light of the French and German traditions of didactics. The fundamental differences between Shulman's lines of thinking and these European traditions of didactics are not in the focus, in the instructional process itself, but in their theoretical principles and foundations.

Transforming subject matter content, for Shulman, has been seen as a central characteristic of an effective teacher, a process that takes place in the teacher's mind. It is the individual teacher that is the locus of transformation, the possessor of the content knowledge at stake, and the gatekeeper for granting students access to the subject matter content. Such an understanding has largely derived from cognitivism and the individualisation of the teacher in engineering the transformation. That is, questions of core practices of teacher work and issues of access have been mostly psychologised, with little or no account of broader social, cultural, and political aspects of education. In the process of individualising the transformation process, any serious sense of social structures and the cultural and political forces that shape and form the transformation of subject matter for educational purposes have generally been disregarded.

The French and German traditions of didactics, on the other hand, are based on social and cultural aspects of education, and on tradition and history. Processes of transposition or elementarisation in these traditions are socially and culturally constructed, institutionally contextualised and directed towards normative conceptions of education. The capacity of transformation of subject matter content, thus, is not a property of an individual teacher, but of social and cultural systems that organise ways of preparing subject matter content for students, in which certain kinds and forms of knowing are valued based on history and tradition, as well as on societal needs and cultural practices. Rather than an end state, the didactic transposition and elementarisation are continuously driven by unrelenting negotiations – balancing different interests and concerns of a given society.

The unit of analysis, thus, goes well beyond the individual teacher and includes the cultural and institutional contexts that shape how transformation unfolds in any given community and institution. Such considerations reveal that ways of transformation always reproduce social arrangements of power and privilege that need to be carefully examined and questioned. This may be of particular importance as the reliance on the individual teacher as the locus of transformation and the possessor of knowledge in Shulman's account perpetuates an educational system that favours the interests and concerns of those who already control intellectual and thus curricular legitimacy.

Introduction

The title of this poster is a name of a Horizon 2020 project with the acronym MaTeK. The project belongs to the Twinning action, which stands for research infrastructure building and institutional networking. The general goal of MaTeK project is to strengthen the research performance and develop the excellence of the Department of Mathematics Education (DME) at the Faculty of Mathematics, Physics and Informatics of Comenius University in Bratislava, Slovakia (UK BA), in the field of mathematics teacher knowledge enhancement. Teacher knowledge is the prerequisite of the education enterprise, and student knowledge development its objective. For researchers, it is essential to understand what kinds of knowledge mathematics teachers develop, and how they use their expertise in teaching in order to help students to develop deep knowledge in mathematics. One of the ways how to address this issue is to work with pre-service mathematics teachers on lesson and learning progression design capacity (Pepin et al., 2017). The specific goal of MaTeK is to provide the DME with opportunities to work with and learn from partners and exchange best practices in the field of mathematics lesson and learning progression design, with focus on the topic of reasoning and proof (R&P). R&P is an important strand of mathematical proficiency (e.g., Kilpatrick et al., 2001), and research has shown that pre-service teachers are often not adequately prepared to cultivate opportunities for students to engage with reasoning and proof (e.g., Stylianides & Stylianides, 2009).

MaTeK is twinning the departments of Mathematics Education of five European universities: 1) Comenius University in Bratislava, Slovakia (UK BA), coordinating/applicant institution; 2) Charles University, Prague, Czech Republic (CU); 3) University of Palermo, Italy (UNIPA); 4) Norwegian University of Science and Technology, Trondheim, Norway (NTNU); and 5) Middle East Technical University, Ankara, Turkey (METU).

Research plan and activities

The general goal of MaTeK will be achieved through a series of twinning schemes, including workshops, seminars, summer schools, staff exchanges, and conference attendance, that will all be closely related to a well-defined common research study, with the following research question: *How can pre-service teachers' design capacity in terms of reasoning and proof be enhanced?*

The project has started in January 2021 and, within its duration (until December 2023), will follow a Design Research approach (McKenney & Reeves 2019), with the following three research phases: 1) Exploratory study (context and needs analysis); 2) Lesson and Learning Progression design & Intervention; and 3) Enactment & re-design. Our main target group in phases 2 and 3 is pre-service mathematics teachers for grades 5-10 at each MaTeK institutions. Their understanding of the mathematical learning progressions and lesson plans design involves important aspects of pedagogical content knowledge (Carlson & Daehler, 2019).

Proposal

The poster will present in more detail the design of the study, including the planned research phases, as well as the theoretical frames used (e.g., design capacity (Pepin et al., 2017); learning progression (Fonger et al., 2018); different modes of reasoning (Stacey & Vincent, 2009) and expected outcomes. In addition, selected preliminary results related to the context and needs analysis will be presented, e.g., a framework for textbook analysis regarding R&P, and a survey on in-service mathematics teachers' use of resources for designing and conducting lesson plans.

Acknowledgment

This poster was supported by the H2020 project no. 951822, MaTeK. https://www.projectmatek.eu/ We would like to express our special thanks to all local and scientific coordinators of the MaTeK project, as well as to all other project consortium members.

The paper presents a study of the development of TPACK of Preservice Mathematics Teachers (PMTs). Two interconnected components of TPACK, the use of digital tools (DT) as instruments for solving problems and for creating digital materials, are dealt with from the perspective of their role in teacher education and mutual relationships. The paper aims to provide examples of how different teaching approaches could develop the knowledge and skills of PMTs in such a way that PMTs will be able to use DT properly in their own teaching.

Keywords: TPACK development, PMTs education, digital technology in PMTs preparation, searching and evaluation of existing materials.

Introduction

The use of DT in mathematics education at all levels has been a broadly studied topic already for several decades (see e.g. Ruthven, 2007). In 2011, Jančařík and Novotná see one of the reasons for a slow integration of DT into (not only) mathematics education in comparison with the robust development of technological tools for education and the low level of teachers' experience with using it. The rate of this integration increases markedly slowly when compared with the speed of development of technology. Jančařík and Novotná (2011) named as one of the reasons for the situation insufficient teachers' preparation for this integration. Successful use of DT in mathematics classrooms requires that the teacher is able to use it efficiently when solving problems. This is only one of the required competencies. Without additional pedagogical knowledge, e.g. designing lesson plans, selecting suitable materials available (e.g. on the internet), modifying and creating materials intended for the taught group of pupils, evaluating their quality and needed improvements, the use of DT in classrooms remains less efficient.

The research presented in this article is based on a long-lasting collaboration of two groups of researchers/teacher educators at two faculties, the Faculty of Mathematics, Physics, and Informatics of Comenius University in Bratislava and the Faculty of Education of Charles University in Prague. The history of both countries, Slovakia and the Czech Republic, is connected in their past histories, even from the Great Moravia period. The educational systems in the current two independent countries develop separately, but they have many similarities and we found it interesting to look at differences and similarities after almost 30 years of separate history. One of the common topics is an integration of DT into (lower and upper) secondary teacher education. Needing to understand if "insufficient teachers' preparation" is one of the reasons why we analyzed the integration of DT in different preservice secondary mathematics teachers' courses. Teacher knowledge should not only concern the ability to work with DT or solve mathematical tasks. The further important teacher' abilities are proper implementation of DT into the educational process, which includes lesson plan preparation, design and re-design of teaching resources, choosing appropriate and available educational materials, and the design of appropriate assessment and evaluation tools. All these abilities are partial domains of model TPACK that are briefly addressed in the next part of the paper. The collaboration of the two research teams opened new perspectives to handling several questions dealt with by both groups individually. The perspectives stemming from this collaboration can be clustered into two major groups.

The first group (represented here by Case 1) is concerned with the use of DT as a scaffolding and "technical" support when learning mathematics, especially when introducing a new concept and solving problems. This group is linked with improving future teachers' skills in using DT. The second group (represented here by Case 2) is concerned with the use of ready-made digital resources available on the internet and their own production for use in classrooms.

Current research also identified issues such as "limitations of trained staff and the need for practitioners to troubleshoot issues" (Buteau et al., 2010, pp. 58–59). The research question is: What components and forms of the implementation of DT into teacher education should be incorporated into PMTs training and what is the recommended order of their implementation?

Theoretical framework

The framework for TPACK was introduced by Mishra and Koehler (2006). This framework clarifies the kinds of knowledge required by a teacher in order to ensure the effective integration of technology into their teaching. It can be seen as an enlargement of Shulman's (1986) PCK model with technology as an additional domain.

There are three main competencies in the TPACK model defined by Mishra and Koehler (2006): Technological knowledge (TK), Content knowledge (CK), and Pedagogical knowledge (PK). Technological, pedagogical, and content knowledge (TPACK) is one of four competencies, Technological-content knowledge (TCK), Technological-pedagogical knowledge (TPK), Pedagogical-content knowledge (PCK), and Technological, pedagogical and content knowledge (TPACK), that address how these three main domains interact (see also Fig. 1). TPACK was proposed as the interconnection and intersection of TK, CK, and PK.

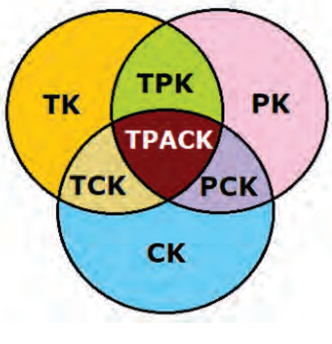

Figure 1: TPACK framework (based on the image at tpack.org)

TPACK, according to Koehler et al. (2014, p. 102), “refers to knowledge about the complex relations among technology, pedagogy, and content that enable teachers to develop appropriate and context-specific teaching strategies”. The development of TPACK could be done in three possible ways as identified by Koehler et al. (2014). The first is from PCK to TPACK, the second from TPK to TPACK, and the third, developing PCK and TPACK simultaneously. In our research, we also used the fourth way from TCK to TPACK, which is not mentioned in Koehler et al. (2014). We used it in our previous studies (a summary of those studies is in Slavíčková, 2021). The layering of theoretical frameworks can help us to better understand the studied phenomenon. We used such an approach in Slavíčková (2021) when layering Mishra and Koehler’s framework (Mishra & Koehler, 2006) with Ball’s “egg” framework (Ball et al., 2002).

In this paper, we focus on two from seven components of teachers’ TPACK: the use of DT in mathematical courses (Case 1) and the development of the ability to critically evaluate and modify materials available on the internet (Case 2).

Methodology

The collaboration of the two teams is ongoing which is why we can present at this point only the results of research anchored in one course at each group level and methodological instruments linked to them. In both cases, a qualitative research design was used.

The Bachelor level mathematics teacher education at both universities focuses on the CK. In Case 1, we focused on PMTs' willingness to use different types of DT in Calculus lessons. The participants were 26 PMTs in the second year of their bachelor study program. We offered them several digital tools like Graphic Calculus, Derive, GeoGebra; they had the freedom to use other devices as well. They were asked to use them not only at home preparation but also in the lessons. The situation in 2020 (and 2021) was more manageable using DT due to the online form of classes.

In the Master’s level mathematics teacher education at both universities, attention is paid to the PMTs’ ability to select and use appropriate digital materials available in a ready-made form and modify them for the conditions of their own teaching. On this level, choosing DT is not guided and it is up to the PMTs judgment to choose the proper one for their lesson preparation. They also learn to design their own original materials. For collecting data about PMTs’ coping with this important activity (Case 2), the course of CLIL (Content and Language Integrated Learning) was selected as representative in our study.

PMT’s worked outside the CLIL course contact lessons. They were asked to choose a material available on the Internet proposed for use in a mathematics CLIL lesson, evaluate it and propose improvements. and justify their proposals. In the research described in Case 2, we worked with 11 students who were in the first year of the Master’s level study. They were used to use DT in the way described in Case 1. Their essays were analyzed and compared. We focused on the selected topics, the nature of criticized issues pointed out and proposed modifications. All analyzed materials were in English. The analyses of essays were accompanied by discussions of the authors of the essays with the researchers.

Case 1: Development of TCK

As an example of TCK development in PMTs preparation, we choose a Calculus course with the integration of DT at Comenius University in Bratislava. The reason is that Calculus is one of the compulsory courses in PMTs preparation. There were two reasons for the implementation of DT into teaching CK. First, we wanted to demonstrate that DT could help PMTs visualize the situation and construct abstract knowledge. Second, we hypothesized that if students experience teaching new concepts by using DT, they will be more open to using it in their future teaching careers.

Research description

PMTs used digital environments for modeling different situations in mathematics or real-life connected tasks. We present two examples of such problems

Problem 1: *An account starts with 1 EUR and pays 100 % interest per year. If the interest is credited once, at the end of the year, the value of the account at year-end will be 2 EUR. What happens if the interest is computed and credited more frequently during the year? How can we make 3 EUR at the end of the year?*

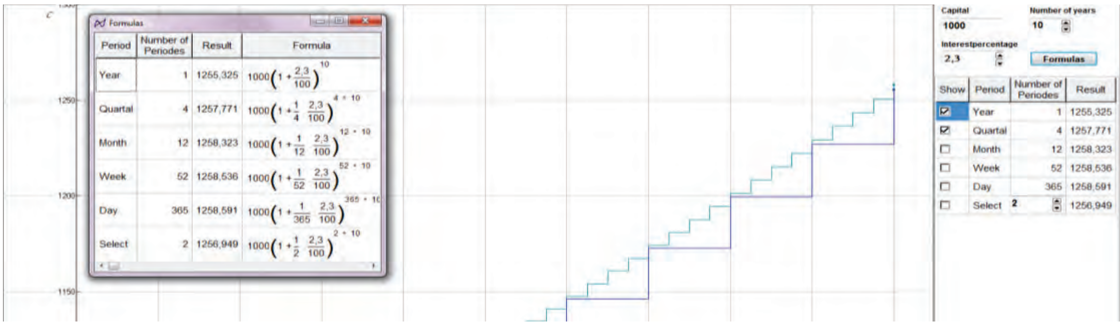

Figure 2: Using Graphic Calculus for modeling the situation

As can be observed in Figure 2, a comparison of compound interest calculated every quarter (bigger steps), and compound interest calculated every month (smaller steps) can bring small differences in the final amount of our money at the end of a year. Making these calculations more often does not change the output a lot, the changes are on the positions of thousands or lower. Not all PMTs noticed this phenomenon and the answer, it will never be 3 EUR, was surprising to them. This activity led to the definition of the Euler number in a limit form.

Problem 2: *Using a preferable DT, find out (a) properties of given sequences, (b) categorize them into several categories so every sequence in that category fulfill the condition characteristic for that category, (c) provide example of at least 2 sequences for each determined category.*

$$\left\{\frac{1}{n}\right\}, \left\{1-\frac{5}{2n}\right\}, \left\{3+\frac{2}{5n}\right\}, \left\{\frac{n+5}{n^2+7}\right\}, \{(-1)^n\}, \{\cos(\pi n)\}, \{7.(-1)^n\}, \left\{(-1)^n\frac{n+5}{n^2+7}\right\}, \{2^n\},$$
$$\{n+5\}, \{9n+7\}, \left\{\frac{n^2+5}{n+7}\right\}, \{7-n^2\}$$

Will your categories work for other sequences as well? Justify your answer.

When working with this problem, we followed the spiral scheme Manipulating–Getting-a-sense-of–Articulating–Manipulating–… described by Mason and De Geest (2010). We merged some types by articulating and further manipulating the original 7 categories of sequences (increasing, decreasing, lower bound, upper bound, bounded, no bounds, periodic). We started activities related to the intuitive understanding of a limit of a sequence. The role of DT was crucial here since the possibility of visualization, zoom, and change the interval for making observation and getting a sense of noticed phenomenon, helped students predict the situation for a "larger *n*".

Introductory problems or tasks were introduced also for the limit of a function, derivatives of a function, the definition of Riemann integral, etc. Different GeoGebra applets and software mentioned above were used during the lessons for the discussions and for home preparation.

Results

There are two main results we observed during the teaching period. Firstly, PMTs who actively used DT were having fruitful discussions during the lessons. We observed that mostly those who have a high level of TK were in that group of PMTs. Additionally, nowadays this group of PMTs in their Master's level (2 years after the intervention) is more open to integrating DT into their lesson plans. Unfortunately, PMTs mostly focused on repeating existing knowledge, and most of the tasks they re-design were strongly procedural.

PMTs proved high flexibility in the 2nd semester. The guidance from the teacher was not as significant as in the 1st semester of Calculus. PMTs started looking for different types of software that would help them to manage the abstract concepts they had to learn.

Discussion of Case 1 results

In the curriculum, PMTs in their 2nd year of study at the university had only one subject focusing on the development of the three main domains identified by Mishra and Koehler (2006): TK, CK, PK. The course of calculus was the first in which TCK started to be developed. From the results, we can conclude that PMTs development of TCK was in general sufficient. Following our previous results (Slavíčková, 2021), PMTs with lover DT skills were less willing to use DT. This phenomenon changed in 2020 when the COVID-19 situation pushed us all to use them in everyday life.

The reason for procedural-oriented outcomes of PMTs could be our colleagues' teaching when they stress procedures or algorithms for solving typical tasks. PMTs could conclude that mathematics aims to manage plenty of procedures. Single intervention is not sufficient here, and more collaborative work is needed. Therefore, cooperation with other colleagues preparing lessons focusing on using DT, in general, is crucial.

Case 2: Further development of TPACK

As an example of a suitable activity in a course, for future mathematics teachers aimed to develop their ability to choose and modify existing materials available on the internet, we choose the course of CLIL (Content and Language Integrated Learning) at the Faculty of Education of Charles University.

Coyle, Hood, and Marsh (2010, p. 3) characterize CLIL as follows: "CLIL is an educational approach in which varies language-supportive methodologies are used which lead to a dual-focused form of instruction where attention is given both to the language and the content." CLIL teaching units have two educational goals of the same importance (language and content). Teaching and materials have to pay attention to both. Both educational goals are interconnected even if the teacher or students focus on one of them. The dual-focused nature of CLIL offers a rich resource of ready-made digital teaching materials. They can focus on the non-linguistic subject, language or, in the ideal case, on both at the same time. An example of such dual-focused material is presented e.g. in (Hofmannová & Novotná, 2007).

Evaluations of materials

Students focused on both, mathematics and language. From the language perspective, they paid attention mostly to the used vocabulary and mathematical terminology, and suitability of the used language level from the perspective of the target group of pupils. They proposed reformulations of parts where they considered the language too complicated (including the length of paragraphs etc.). In one case they evaluated the used language as outdated and recommended to change it to the contemporary forms. They recommended modifications of the problem settings aiming to have the texts more similar to the Czech environment.

They also mentioned the differences in notation (e.g., in writing dates or mathematical notations). In this case, they did not propose to use the Czech way but to practice the English one continuously so that pupils get used to using it.

They underlined the suitability of the use of problems with more than one correct result and solving procedure. As to the tasks, they evaluated dividing complex tasks into simpler ones as more suitable. They also paid attention to the quality and correctness of figures and the level of difficulty of tasks.

They mentioned also the layout of the material, mainly the comprehensibility of the text and aims of the activities, and proposed improvements. In cases where the answers to the tasks were pre-prepared, the students proposed deleting it and letting pupils formulate the answers themselves.

The students asked for complex materials where the teacher can find all information needed as help for the teacher. One student worked with a whole book and recommended it as an inspiration for the teacher's preparation of lesson plans.

Discussion of Case 2 results

The students who participated in the CLIL course did not have the courses of didactics of mathematics completed. Nevertheless, the majority of them were able to choose materials suitable for use in their CLIL classrooms and propose meaningful modifications. They presented their pieces of work in CLIL course lessons and discussed deeply the quality and usefulness of materials. They used their experiences from the courses of Didactics of mathematics. Their experiences from the use of DT in mathematics courses helped them to overcome obstacles based on the implementation of DT.

The participating students were aware of the importance of similar activities. Let us cite from one student's comment: "*Given how much internet is infested by materials of bad quality, it was nearly impossible to find materials meeting my requirements …*"

Conclusion

The two analyses allowed us to estimate the role of PMTs' mastering the use of various DT as instruments for learning mathematics and solving problems themselves on the one hand and working with digital materials during their teaching at schools.

Answering out our research question, *what components and forms of the implementation of DT into teacher education should be incorporated into PMTs training and what is the recommended order of their implementation*, we identified several aspects which should be considered. Firstly, PMTs should start with the development of TCK and TPK sooner than on the Master level. Secondly, using different topic areas and making connections between the main domains of TPACK can help PMTs gain better insight into the issues of implementation of DT into their teaching. Thirdly, closer communication among PMTs' educators is needed, especially those focusing on three main domains of the TPACK model, in other words, educators responsible for mathematics preparation, technology preparation, and pedagogy preparation. All of them should communicate with each other and with a specialist in mathematics education to be concise and help develop TPACK. Fourthly, our observations and analyses of materials produced by PMTs indicate that PMTs' level of TPACK is sufficient for their successful implementation of DT in their classrooms once they enter the practice. They are able to work with ready-made materials and modify them in a creative way. When doing so, they combine competencies gained in the use of DT in their own learning of mathematics and solving problems, as well as general and subject didactics.

Based on our research, recommendations concerning implementing different activities connected to using DT in PMTs preparation can be drawn. It turns out that starting with TCK development is a good starting point (Slavíčková, 2021). Then we could continue with pedagogy-oriented activities (like in Case 2), re-designing the given (or found) materials to create an own material by using DT. When PCK is developed, it can be quite late to start with TPACK. As Mishra and Koehler (2006) identified, once the teachers are familiar with processes and lesson design without using DT, it is difficult to change their mindset.

The number of participating PMTs and courses was small, and the presented results cannot be generalized. Still, they indicate the importance of both components of including DT in (not only) mathematics teacher education. This study opened new questions, e.g., how well-equipped are our PMTs for their real teaching? How can we measure that? What are the indicators of a well-prepared teacher? This will be the focus of our subsequent research.

Cooperation between our universities continues. We are preparing further interventions and comparisons of our PMTs' results e.g. when creating lesson plans or in their flexibility in adapting their teaching to different environments (mainly by using digital tools).

Mathematical identity transformations

Nadia Stoyanova Kennedy

City University of New York, NYC, USA; nkennedy@citytech.cuny.edu

This paper examines the case of Ruby, *a prospective mathematics teacher, and explores the transformation of her mathematical identity as she moved through her studies from grade school through university. I utilize the conceptual framework of multiple "I-positions" from Dialogical Self Theory to reflect on the changes in Ruby's mathematical identity through analyzing her retrospective self-narrative. Based on this case study, I determine that the dynamics of I-positioning, involving emergent coalitions of I-positions or the emergence of a single I-position of greater authority, may play an important role in the formation of a positive or negative mathematical identity. I also find that significant events such as changing circumstances, new reflections, decisions, and actions may act to precipitate the reconfiguration of I-positions, and thereby bring about the transformation of one's self-understanding as an (in)competent student of mathematics.*

Keywords: Mathematical identity, mathematics learners, prospective mathematics teachers, dialogical self theory.

Introduction

Identity has been explored through various theoretical frameworks, (Beauchamp & Thomas, 2009), several of which are featured in mathematics education research on the concept, e.g., Holland et al. (1998), Sfard and Prusak (2005), and Wenger (1998). Inspired by Lev Vygotsky, Mihkail Bakhtin and Pierre Bourdieu, Dorothy Holland et al. (1998) conceive of identities as resulting from processes in which people are both agents and subjects of simultaneously culturally constructed and socially imposed worlds. Following on such conceptualizations, Boaler and Selling (2017) consider mathematical identity to be informed by the "ways in which students think about themselves in relation to mathematics, and the extent to which they have developed a commitment to, are engaged in, and see value in mathematics and in themselves as learners of mathematics" (p. 82).

Similarly, Wenger's sees identity as developing through "negotiated experiences of self" through dialogue in communities of practice (1998, p. 150). He understands identity formation as a *learning trajectory* in which "the past and the future [are] in the very process of negotiating the present" (p. 155)—a theoretical approach that emphasizes identity continuity and malleability. Following on this conception, Rø (2019) characterizes teacher identity development as a result of identification and negotiation in the process of participation in and at the boundaries of various communities of practice. Finally, a substantial number of identity studies in mathematics education have adopted, following on the work of Paul Ricoeur (1992), the conception of identity as based on narrative (e.g., Sfard and Prusak, 2005 (Kaasila, 2007; Lutovac, S., & Kaasila, 2014, 2018).

Earlier studies that analyzed the identity narratives of mathematics learners and pre- and in-service teachers have described identity changes but have not provided sufficient information about the mechanisms that account for them. This study attempts to add this information through analyzing the retrospective self-narrative of one pre-service mathematics teacher. The study does not focus on her current self-narrative as a pre-service teacher, but rather traces shifts in her mathematical identity as she moved through her studies from grade school through university and until she enrolled in a teacher education program. As such, I aim to analyze transformations in one pre-service teacher's mathematical identity and the process of its realization, and to do so in the context of Dialogical Self Theory, which provides us with an epistemic and analytic lens through which to consider those processes.

Theoretical Framework

Dialogical Self Theory

Hubert Herman's and Els Hermans-Jansen's notion of identity formation as a process of telling and retelling one's self- narrative in dialogue with oneself or another person(s) is congruent with the conceptualizations mentioned earlier (1995). Dialogical Self Theory (DST) (Hermans & Hermans-Konopka, 2010) begins with the assumption of selfhood as multi-voiced and intrinsically dialogical, composed of a dynamic multiplicity of varied internal narratives--"I-positions"—representing multiple perspectives of the self. Each I-position has a voice and is in dialogue with other I-positions, all of which reflect different relationships with independent others. The self is comprised of both internal and external I-positions. Internal positions reflect aspects of the individual's identity (e.g. Korean, prospective mathematics teacher, immigrant, daughter, friend, etc.). In addition, any current set of I-positions includes, not only those existing in the present, but may incorporate past positions as well--for example "I- as once a struggling math student"—as well as external I-positions that represent the attitudes and example of people seen as significant in one's life—a parent, teacher, good friend or boss, for example (Hermans & Hermans-Konopka, 2010). Past and present I-positions are likely to speak in voices that are in conflict, and to present ideas that contradict each other, which puts the self in a position of struggling to reconcile the different views in a coherent narrative.

For DST, the self is both stable and dynamic, always undergoing reorganization of positionings, and making meaning of experiences old and new. In fact, in Herman's and Hemans-Jansen's words "the self is an organized process of meaning construction." (1995, p.14). As part of this process, we construct our self-narratives, which we tell and retell. In these narratives, we give special significance to some events over others. Some special events might disrupt or challenge an established self-narrative. These have been described by Carla Cunha et al. (2012) as Innovative Moments (IMs)—which may be, for example, new actions, thoughts, feelings, intentions. The IMs are seen as voices that are potentially disruptive to the dominant self-narrative and represent a possibility for the emergence of new I-positions, and for a self-narrative reconstruction. The transformation of self-narratives involving IMs's emergence and expansion has been used in DST-based psychotherapy (Gonçalves et al., 2009).

According to Cunha et al. (2012), in successful cases of psychotherapy there is a noted emergence of three types of IMs: action(s) through which the person challenges the dominant self-narrative; new reflections that run counter to person's previous ways of thinking, and protest; action or thought that refuses the current self-narrative. They "announce" a potential emergence of new positions, which may bring forth a different dynamic between I-positions, as well as new dominant I-position(s). The appearance of these IMs is followed by emerging “reconceptualized IMs”—new actions, reflections and protests, and chances for reorganization.

Narrative Inquiry

Mathematical identity is here understood in terms of the narratives persons tell in order to situate themselves not only in relationship to mathematics and their mathematical lives (cf. Kaasila, 2007a; Connelly & Clandinin, 2000; Sfard & Prusak, 2005), but also in relation to significant persons, groups, or cultures (Hermans& Hermans-Konopka, 2010). I consider the notion of the “extended self” (Hermans & Hermans-Konopka, 2010), to be a further development of George Herbert Mead’s concept of the “generalized other” and Lev Vygotsky’s (1962) internalization of cultural and individual voices. All three approaches suggest that mathematical identity includes not only one’s view of oneself as a mathematics learner in the context of one’s classroom and the work with one’s peers, but also the internalized voices of one’s peers, teachers, parents, and other significant others. As such, in analyzing the following case study, I use a multi-voiced dialogical conception of mathematical identity, which acknowledges its extension to include real or imagined voices (views) of those others. Mathematical self-identity is plural and made up of multiple I-positions in continual dialogue (Hermans& Hermans-Konopka 2010).

Here I examine the case of Ruby, a young Korean American undergraduate student completing her coursework in mathematics education and explore her shifting mathematical identity. I reflect on the changes in her retrospective self-narrative, tracing her trajectory as a mathematics learner as she moved through her studies from grade school through university. I use DST and the conception of IMs to identify changes in the relations of authority between internal and external I-positions, reflect on the emergence and dynamics of a coalition of positions, and their significance in the realization of the ongoing reconstruction of her mathematical identity.

Methodology

This study adopts a case study methodology in order to explore and report the details (Creswell, 2005; Stake, 1995) of one prospective teacher’s mathematical identity and its changes over a period of roughly six years. The subject, Ruby (pseudonym), was a twenty-one-year-old Korean American full-time undergraduate mathematics education student in her third year of preparation as a prospective mathematics teacher in a public university in the northeast US. She was a student in an introductory mathematics education course that I was teaching at the time. She was an intelligent and diligent student; her assignments were always on time, and she was detailed-oriented and thorough. Ruby had finished 10th grade in Korea, after which she had relocated with her entire family to the US, and she finished the last two grades of high school in a large urban public school.

Data collection occurred over the course of one academic year during Ruby’ completion of the introductory mathematics education course. Three semi-structured interviews were conducted throughout – two of them administered consecutively within a week, and the third roughly four months later. Each interview was introduced by an invitation to talk freely about her experiences as a mathematics learner in middle, high school, and university. The interviewer asked follow up and clarification questions. The interviews were transcribed and comprised the main data source for this study. Additional informal discussions helped me develop an in-depth understanding of issues

(Creswell, 2012) related to the study of the changes in Ruby's mathematical identity. I used open coding (Creswell, 2006; 2012) to identify and explore the themes that emerged from the data.

Adopting methods from narrative analysis (Polkinghorne, 1995), I sought to identify coherent themes running through the interviews. First, I divided the interview transcripts into episodes reflecting four major narrative shifts related to Ruby's middle and high school experiences in Korea, high school and university in the US. Each episode was further divided into segments, each of which was associated with a specific I-position—for example, I as trying hard in mathematics (internal I-position), or I-as always failing math tests (internal I-position), and I as being encouraged and helped by my mother (an external I position representing the internalized voice of Ruby's mother). Based on a comparison of the segments within and across interviews, I developed codes for the I-positions relevant to the episodes in the self-narrative. Furthermore, I reviewed all identified I-positions, selected the ones that involved self-reflection and observing one or more of the other I-positions, and coded them as meta-positions.

The positions in each narrative episode were analyzed in terms of configurations: were there many different I-positions speaking in single "voices" or were they forming a coalition of voices that spoke as a "choir," and how were these configurations related to Ruby's self-narrative and her positive or negative self-identification as a mathematical learner? For each episode, I searched for evidence of relatedness between Ruby's I-positions, and for the existence of power differences as reflected in the relative dominance of some. I also looked for significant events as identified in Ruby's self-narrative, and for changes in her I-positions around the time of these events. Guided by Cunha et al.'s (2012) conception of Innovative Moments (IMs) I noted new reflections and actions on Ruby's part, and examined them in relation to new I-positions that had emerged.

Findings

Ruby's Self Narrative

"I wasn't good at math back then"

When Ruby was in middle school, she liked math. She described herself as "being interested" and as "enjoying the math classes." She liked all subjects and thought that she was good at them. Things changed when she moved to high school. Ruby said that there were lots of tests, and she was not performing well on them. There were always students who had better test scores. "I don't know what I was doing, but I always had errors [on the tests]." Her high school math teacher was "very strict and stern." Ruby thought he believed that she was not putting enough efforts and being "lazy", although she said that she was trying hard. She felt he was "angry and disapproving of her." He had told her that "she didn't have the mathematical mind." To my question whether her parents were helping her, she described her mother as encouraging and supportive and trying to help with homework. Ruby "dreaded" her math classes and was afraid of failure. When I asked her about this period, she started describing it with "I wasn't good at math back then [in Korea]"

"Not loving math, but **OK"**

Things had changed somewhat when she moved to US. Her last two years of high school were not easy—she was trying to catch up with English--but she suddenly found that she was doing much better in her math classes. She "knew lots of the math stuff" they studied, especially during her first year in the US. To my question whether she felt successful, she replied that she was doing much better than before [in Korea], but that she didn't think at the time that she would study math in the future. She had A's at the time, but at the interview she described herself as "not loving math, but OK"

"I had decided that I can do it"

When she finished high school, Ruby applied to a public university close to her hometown and started her first year as an undeclared major. She had to find out what she wanted to study, but at this point she knew "it wouldn't be math." However, Calculus was a mandatory course and she registered to take it, among other courses. She wasn't sure about it and was afraid of failing it. Then she discovered that she liked the course. It seems like it was the instructor at first and the course structure. "The instructor was amazing," Ruby told me, and she "liked everything about this class"—the instructor and students, the group work and the assignments. "I loved it [the course]," she told me with enthusiasm. Ruby felt that she was doing very well, and she began to think that she might continue to study mathematics and look into related programs. In the following semester she decided to take the next Calculus course with the same instructor. She felt successful, and this is when she began thinking that she might want to become a math teacher. Her mother advised her that it would be a good profession for her. "By the end of this second semester," Ruby said, "I had decided that I can do it [could be successful in becoming a math teacher] and applied to the mathematics teacher program."

The interviews with Ruby revealed the various I-positions she took while she was a middle and high school student in Korea, a student in high school in US, after she moved to the US, and as a university student. Table 1 below shows some of these, identified on the basis of the interviews conducted with her.

Table 1. Ruby's I-positions

Periods	Some of Ruby's I-positions as a mathematics student
Middle school	I as … interested in mathematics (internal) enjoying mathematics (internal) good in all subjects (external, my teachers)
High school, in Korea	I as… trying hard in mathematics (internal) always failing math tests (internal) being encouraged and helped (external, my mother) being lazy and not studying mathematics hard enough (external, my math teacher) making my math teacher angry (external) not having the support/approval of my teacher (internal) dreading math (internal)

	not having the mathematical mind (external, my math teacher) not being good at math (internal, metaposition)
High School in US	I as… knowing lots of [math] stuff (metaposition) not loving math, but ok (metaposition) having As in math (internal) doing much better than before [in Korea] (metaposition) not planning to study further math (internal)
University in US	I as… a university student (internal) exploring possible study paths (internal) not sure about taking a Calculus class, and afraid [of failure] (internal) successful Calculus student (metaposition) loving math (metaposition) someone who might be successful in becoming a math teacher (internal) a future math teacher (internal)

These I-positions seem to have informed her mathematical self, and the way she understood herself as a mathematics learner and one (in)capable of learning mathematics. Table 1 shows a dynamic multiplicity of perspectives--I-positions--representing the multiple perspective of the self in the different contexts in which she found herself, e.g. middle school, high school in Korea, high school in the US, and university. These I-positions have informed her changing self-narrative (Hermans & Hermans-Jansen, 1995) and reflect different relationships with independent others or herself.

In middle school, the I-positions identified in the interviews, “I as enjoying math”, “I as interested in mathematics,” and “I as being a good student in all subjects” supported each other in creating a coalition of I-positions, whose unified voices supported a self-narrative of a good and capable mathematics student. However, when Ruby transitioned to her Korean high school, her self-narrative dramatically changed. Her high school math teacher became a powerful voice and a mirror through which she saw herself in the way she perceived her teacher saw her—not making enough effort, “lazy,” “not having a mathematical mind.” This powerful external I-position had become dominant, overpowering the voices of her other I-positions, including the supportive external I-position of her mother. It led to her shifting her self-narrative and repositioning to new I-positions as “failing math,” and “dreading math.” The voice of her math teacher had taken on special significance in the multi-voiced self, and had challenged, overpowered, and overridden her previous self-narrative.

However, yet another change in circumstances forced further repositioning. Ruby moved to the USA with her family. She found herself in a 10th grade math class, where she discovered that she knew quite a lot of the mathematics content under discussion. The situational change had in fact delivered her from the power of her Korean math teacher’s voice. A new coalition of voices—her mother’s supportive one, and her own metapositions--“I knew lots of the stuff they studied,” and ‘I was doing much better than before”-- helped her move away from some of her previous external I-positions, e.g.

"I- as not good at math." Ruby changed her self-narrative again and described herself at this time as someone who was "not loving math, but ok." At this point, she was not seeing herself as someone who would study math further, and perhaps choose it as a career path.

However, another reconfiguration of new and old I-positions seems to have precipitated yet another shift in her self-narrative when she went to the university. She took a Calculus course with an instructor she liked, in a learning environment she found empowering. Both shifts in her self-narrative seem to have been instigated by innovative moments (IMs)— new reflections of herself as a math learner and her proactive step of registering for a Calculus class, which challenged previous self-valuations (Cunha, et al., 2012). These led to her solidifying new I-positions as a successful Calculus student and as loving math. Table 2 below, identifies some IMs that seem to have contributed to shifting Ruby's self-narrative and her mathematical identity. Her decision to explore a possible university study trajectory and her coping with her ambivalence about the Calculus course led to new reflections and new actions on her part. Her metapositions at this point seem to have been a powerful factor in helping her de-position the "I as not planning to study further math." Over the course of fewer than two semesters, Ruby moved to a new I position as "someone who might be successful in becoming a math teacher," which was, in fact a position of rebellion against the depositioned one.

Table 2. Innovative moments (IMs) in Ruby's positioning

Period	Ruby's I-positions	Emerging Innovative Moments (IMs)
High School in US	I as… *knowing lots of [math] stuff (metaposition)* *not loving math, but ok (metaposition)* having As in math (internal) *doing much better than before [in Korea] (metaposition)* not planning to study further math (internal)	IM reflection IM ambivalence IM action IM reflection
University	I as… a university student (internal) exploring possible study paths (internal) not sure about taking a Calculus class, and afraid [of failure] (internal) *successful Calculus student (metaposition)* *loving math (metaposition)* someone who might be successful in becoming a math teacher (internal) a future math teacher (internal)	IM new action IM new action IM ambivalence IM new reflection IM new reflection IM rebellion/protest IM rebellion/protest

Emerging circumstances, new reflections, proactive decisions, and confronting old I-positions led Ruby to challenge her previous self-narrative and, eventually, to re-write it. Ruby decided to become a math teacher. She applied and was accepted into her university's mathematics education program, graduated successfully, and currently works as a math teacher.

Conclusion

This paper has examined the case of Ruby, a young Korean American undergraduate mathematics education student, and explored her mathematical identity-transformation narrative as she moved through her studies from grade school through university. I have drawn on Dialogical Self Theory and the concept of Innovative Moments to reflect on the changes in Ruby's mathematical identity through analyzing her retrospective self-narrative. I have determined that the dynamics of I-positioning—emergent coalitions of I-positions or a single I-position of greater authority -- may play an important role in the formation of a positive or negative mathematical identity. I also found that significant events such as changing circumstances, new reflections, decisions, and actions may act to precipitate the reconfiguration of I-positions and lead to identity transformation. As such, the study raises questions about the role of reflection in the reconstruction of self-narratives, as well as what classroom methodologies might best facilitate such reflection. In order to nurture students' mathematical identities, new approaches need to be explored that help and encourage students to challenge established self-narratives in reference to their mathematical identity. Mathematics has become a forbidding gatekeeper for many economic, educational, and political opportunities for students, many of whom have developed self-narratives that act to prevent them from identifying themselves as capable math learners. As such, disrupting such self-narratives and working proactively to reconstruct negative mathematical identities represents an important educational task.

Creation in mathematics education Teachers' beliefs and traditions in Hungary

Gergely Szmerka[1] and Ödön Vancsó[2]

[1]Veres Péter Secondary School Budapest and Eötvös Loránd University, Hungary; szmerka.gergely@gmail.com

[2]Eötvös Loránd University, Hungary; vancso.odon@ttk.elte.hu

Keywords: Belief, culture, mathematical creation.

Introduction

The concept of creation flows along the history of European culture starting from the biblical Genesis creation ("God said"), through the creator divine Word (Word = God) which is known from the Gospel of John. To the history of the artistic *creation* belongs the myth of Prometheus, or some works of Shakespeare. According to the conceptualisation of Sturm und Drang, in the *Genieperiode*, the creator is a genius, the self-contained artist is legalised to create a whole world with his own artistic power through breaking the rules. The same power appears in János Bolyai's famous line in connection with mathematical creation, which goes like this: "*from nothing I have created a new different world.*" (Prékopa, 2006, 17)

Research

We use the method of cultural context analysis (Lehtonen 2000). In our research we examine the cultural-historical sources of *creation* in mathematics, and the cultural presence of this idea in the mathematics education in Hungary. We use the sentence of Bolyai to show, how developed the idea of creation from the 19th century to a core element of the Hungarian didactical tradition in the 20th century.

We are convinced that this tradition contributed to the history of mathematics education in Hungary on the one hand, to the education of gifted pupils, and on the other hand, to the movement of *complex mathematics education* in the 20th century. T. Varga's complex mathematics education experiment belongs to the guided discovery method in ME and partially also to the inquiry based ME. Creativity, happiness, autonomous thinking, the freedom of doing failure were the key-elements of Varga's method, and *belief*, creation must be the part of mathematics also in the school. Of course, it does not mean the creation of a new mathematical world, but the understanding of it within the environment of school mathematics, mainly among the frames of conceptualisation taking place during games which were based on experience. (Halmos & Varga, 1978, 229).

In Bolyai's sentence – according to the concept of Romanticism – only the chosen ones and geniuses are blessed with the ability of creation who are separated from the public. By the 20th century, the concept of creation was deprived of this romantic genius-cult and one of the key points of Tamás Varga's reform was that he did not think in elite education but he intended to make mathematics and the possibility of experiencing mathematical creation within the frames of public education available for everyone (C. Neményi, 2013).

Conclusions

1) With philological methods we can proof, that Bolyai's sentence was inspired by a Hungarian poem or by a poetical biography.

2) This fact belongs to the history of the connection between creation and mathematics. With all its antecedents and effects it can be proof for the fact that the *need for creation* as a *belief* is a key part of the Hungarian tradition. This *belief* is worth being taken into consideration when a current phenomenon of the teaching of mathematics is to be interpreted. As the need for mathematical creation is not only present in the works of the quoted authors, but it is also present in those collaborations where primary and secondary school teacher training takes place. This way, primary and secondary school teachers encounter the *need for creation* in the context of school mathematics either indirectly or directly, but with high probability.

3) The relation of arts and mathematics has a remarkable tradition in the Hungarian concept of mathematics. (See Rózsa Péter's popular titled *Playing with Infinity* (Péter R., 1961), or István Lénárt's work and the so called *Lénárt Sphere*, which is suitable for visualising and teaching spherical and hyperbolic geometry in the junior section of elementary school (Lénárt, 2003); or the *Experience workshop global steam network* by Kristóf Fenyvesi / https://experienceworkshop.org/?lang=en .)

An exploratory study on the difficulty perceived by primary school teachers on a mathematics INVALSI item

Valentina Vaccaro[1], Álvaro Aguilar-González[2], Giorgio Bolondi[3] and Luis J. Rodríguez-Muñiz[2]

This paper deals with the knowledge that teachers demonstrate when they interpret pupils' difficulties in the teaching and learning of whole numbers and decimals. This is part of a project aimed at investigating the link between standardized assessment in mathematics and the teaching-learning processes at the primary school level, in which data from a large sample of Italian primary school teachers were quantitively analyzed. In the current paper, we consider the first analysis together with a second questionnaire administered to a sample of 46 to enlarge the qualitative information about their perception of the difficulties. The answers from the second questionnaire were analyzed using the Mathematics Teachers' Specialized Knowledge model (MTSK) as a descriptive and interpretative tool. The results highlight the teachers' lack of awareness of the difficulties and reveal the need for specific training.

Keywords: MTSK model, mathematics teacher educator, teaching-learning process, INVALSI national assessment.

Introduction

Our starting point is that standardized assessment data can be considered as a tool that teachers can use not only for the design and implementation of meaningful teaching and learning activities, but also for providing students with detailed information on their learning (Wiliam, 2010). This also applies to the Italian National Standardized Assessment (by the INVALSI Institute), through which teachers can thus build reflective and metacognitive paths, functional to a real teaching by skills. Our goal is to analyze teachers' perception of difficulty and their beliefs about the INVALSI mathematics tests. In particular, in this study, we want to determine what specialized knowledge and beliefs can be inferred from teachers' answers to a questionnaire about the difficulty of a specific INVALSI item.

Theoretical framework

The current research belongs to an interdisciplinary research project, which was initiated in 2017 by the "Gruppo INVALSI", composed of disciplinary experts and pedagogues, within the Observatory of Didactics and Disciplinary Knowledge established by SIRD (Italian Society for Educational Research). These researchers were interested in exploring, on the one hand, the proximity or distance between the functions and contents of the INVALSI items and, on the other hand, the beliefs and statements about teachers' teaching practices. To this end, they shared an interest in constructing a questionnaire for investigating the perceptions of primary school mathematics teachers with respect to the INVALSI tests.

The questionnaire concerned the teaching of mathematics (how teachers interpreted seven INVALSI items of grades 5 and 6, and their results, and how teachers perceived misconceptions, errors and levels of difficulty), aspects of general education (what beliefs and attitudes teachers have and how they pour them into teaching practices) and questions regarding teachers' opinions on the INVALSI assessment program, the didactic usefulness of INVALSI items didactic practices related to INVALSI items, and the attitude towards the ideology of natural gifts (Ciani & Vannini, 2017), together with professional training and personal data. This questionnaire was administered to N_1=526 teachers (Faggiano et al., 2021).

Among the various elements to be analyzed, there were undoubtedly factors related to teachers' perceptions and opinions that can facilitate or inhibit the didactic impact of the INVALSI assessment. Main research data showed that there was a metadidactic conflict (Arzarello & Ferretti, 2021) between what teachers believe and their classroom practices. Figure 1 shows the different research variables framing the main study. This framework has its roots in the INVALSI and OECD-PISA ones (INVALSI, 2018; OECD, 2019).

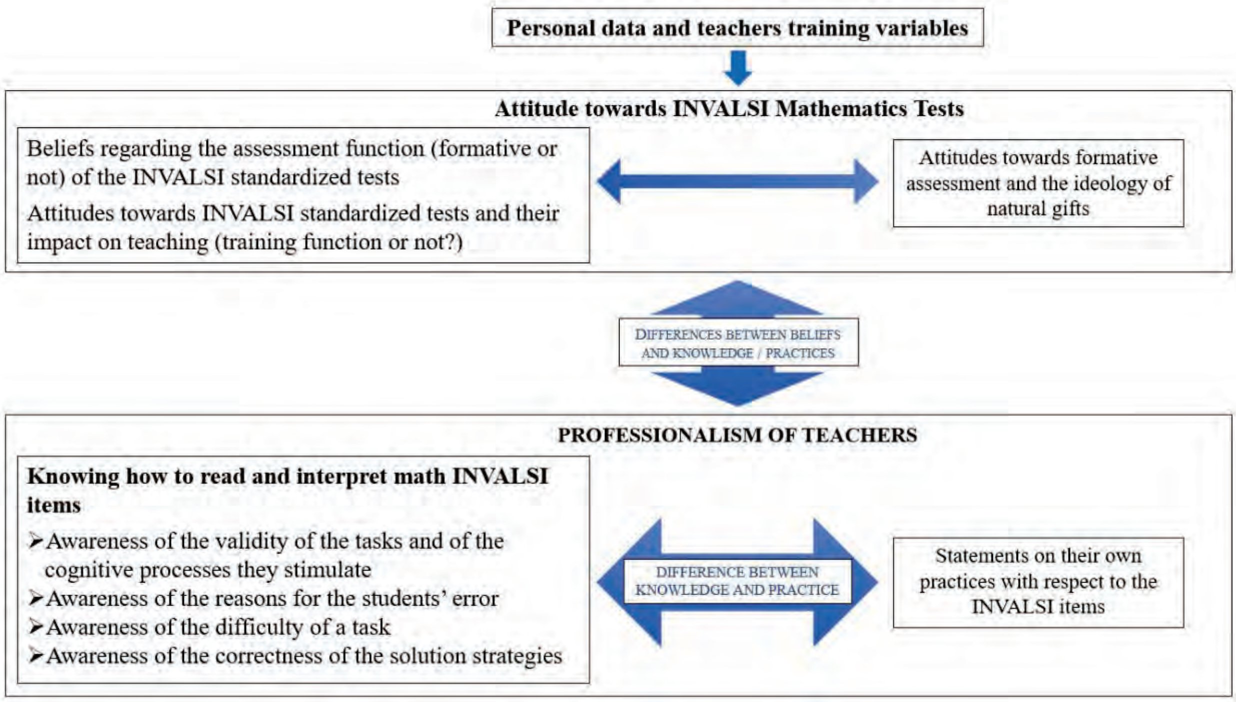

Figure 1: Framework of the study

As a part of this main study, in the current paper our goal is to analyze the knowledge, teaching experiences and beliefs of primary school teachers in reading and interpreting the INVALSI questions and data in the field of mathematics.

Among the different models in the research literature characterizing mathematics teacher's knowledge, we have chosen the MTSK model (Carrillo et al., 2012; Carrillo-Yáñez et al., 2018), due to the intimate relationship it establishes between the specialized knowledge and the beliefs. The MTSK model considers, following the line of Shulman (1986), two major domains of knowledge: Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK). Within the MK domain, the Knowledge of Topics (KoT) refers to knowledge of mathematics as a discipline, and also includes school mathematics. The MK also includes the Knowledge of the Structures of Mathematics (KSM) subdomain, which defines that the teacher can know how the subject matter relates to other mathematical topics or concepts, and, finally, the Knowledge of Practices in Mathematics (KPM), which defines that the teacher knows the mathematical task underlying the mathematical activity, or knows the forms of argumentation, validation, and proof. The PCK includes three subdomains: The Knowledge of Mathematics Teaching (KMT), that contemplates the teacher's knowledge about how to transform the mathematical content to make it understandable to others; the Knowledge of Features of Learning Mathematics (KFLM) is the teacher's knowledge of how the mathematical content is learned, as well as the difficulties or strengths that students may encounter when learning a given content; and, finally, the Knowledge of Mathematics Learning Standards (KMLS), which is defined as the teacher's knowledge of what should be learned at each stage of schooling.

Moreover, the MTSK model includes beliefs on mathematics, and its teaching and learning that are considered as elements that permeate the teacher's knowledge in the different subdomains, with that, we seek to construct increasingly accurate images that allow us to interpret the teacher's knowledge and the aspects that influence it.

Instrument

The analysis of these data from the main study prompted us to plan to carry out qualitative study. Therefore, we identified one of these INVALSI items from main questionnaire to use it as an anchor and we administered it to a small group of primary school teachers (N_2= 46) by adding an open question that allowed teachers to provide a reason for choosing the difficulty items using. The data thus collected were analyzed using the MTSK model (Carrillo-Yáñez et al., 2018). Therefore, the instrument consisted of a first quantitative survey, followed by an open-ended question, and this quantitative-qualitative analysis conforms a sequential explanatory mixed method research design (Creswell & Plano Clark, 2017).

Results

Quantitative study

We show the selected INVALSI item with its nationwide results in 2009 (see Figure 2), obtaining only 33% of correct answers. This means that it turned out to be a very difficult item for Italian students in the last year of primary school.

D10. To which number does “12 tens, 7 tenths, 2 thousandths” correspond?

A.	12.702	44.5%
B.	120.702	33%
C.	12.72	18.6%
D.	120.72	3.3%

Figure 2: Item 10, Grade 5 Mathematics INVALSI test (2009) with percentage of students’ answers (in red those relating to the wrong answers and in green the one relating to the correct answer). The translation of the original item is made by the authors

The purpose of this INVALSI item was to verify the ability to manage the conversion between different representative registers relating to the writing of numbers (Duval, 1993). As it can be seen in Figure 2, 44.5% of Italian 5th graders chose option ‘A’. Those who chose option A did not correctly transform the 12 tens but recognized the correct position of tenths and thousandths. 18.6% of students chose option ‘C’ where both conversion errors are present.

In the main study, without informing the participants about the correct answer rate given by the students, the following question was posed to the teachers: “On a 1 (very easy) to 10 (very difficult) ranking, how difficult do you think the item is for 5th grade students?”

Table 1: “How difficult do you think the question [in Figure 2] is for 5th grade students?” (N_1=526)

	Valid percentage	Cumulative percentage
1 (very easy)	14.5	14.5
2	27.7	42.2
3	16.7	58.9
4	7.6	66.5
5	13.0	79.5
6	5.6	85.1
7	7.2	92.2
8	5.8	98.1
9	1.4	99.4
10 (very difficult)	0.6	100.0

This item was considered by 86.2% of the teachers participating in the main survey as particularly suitable for evaluating students’ learning and, above all, 87.6% said they used similar items regularly in their assessment tests. This result confirmed what was found in an early work on this data (Arzarello & Ferretti, 2021): teachers’ perception of students’ difficulties does not correspond to the INVALSI national data.

Qualitative study

In order to better investigate the phenomenon, we administered the open-ended question about the difficulty of the item to N_2=46 primary school teachers, by asking them to justify their answer on the perceived difficulty of the item. Results for this sample are aligned with the first one. In fact, 71.7% of teachers participating in the qualitative questionnaire considered the question to be easy. To analyze the justifications provided by teachers, we decided to use the classification of the MTSK model, due to the relationship that the model establishes between knowledge and beliefs and conceptions. The teachers' answers were often attributable to different categorizations present in the model; in the following table we try to provide an overview of the choices made and the most significant answers.

Table 2: Example of match between the categories of the model and the answers of the teachers

Teachers' answer (translated by authors)	Categories of the MTSK model
At the end of the 5th grade the pupils are fully capable of composing and breaking down integers and decimals	KMLS + KoT
Because it is in the program and feasible	KMLS + Belief
I think it is quite difficult because, despite being within the reach of a fifth-grade boy or girl, it is necessary to reflect on the INVALSI context which puts pressure and often influences the pupils.	Belief against external assessment

Now let's see what the percentages of the categories were with reference to the perceived difficulty.

Table 3: Number of categories identified in our sample

Perceived difficulty	Categories of the MTSK model	Number of responses that match with the category	Some examples of teachers' answer (translated by authors)
From 1 to 5 (33 out of 46, that is 71.7% of the respondents)	Knowledge of features of learning mathematics (KFLM)	6	Most pupils don't make mistakes
	Knowledge of mathematics learning standards (KMLS)	15	At the end of the 5th grade, they should have a clear understanding of the concept of digit place value, so it should be easy to identify the correct answer.
	Knowledge of topics (KoT)	15	If you work on decomposition, it is not difficult
	Knowledge of practices in mathematics (KPM)	1	It is not very difficult some pupils are used to reasoning
	Knowledge of mathematics teaching (KMT)	3	In classroom activities I have always proposed exercises of this type.

	Belief	7	KMT = he/she talks about what he/she does Belief = repeating similar exercises as a learning method
From 6 to 10 (13 out of 46, that is 28.2% of the respondents)	Knowledge of features of learning mathematics (KFLM)	10	12 tens are difficult for some to transform
	Knowledge of topics (KoT)	3	It is a difficult question on at least two points. The first concerns the non-canonical representation of the number 120, precisely 12 tens. Teachers do not always work enough on these aspects. The second point concerns the presence of 0 at the cents position and if the topic has not been acquired with certainty, students can easily fall into error.
	Knowledge of mathematics teaching (KMT)	2	When explained and visualized with structured material it shouldn't be difficult.
	Belief	1	I think it is quite difficult because, despite being within the reach of a fifth-grade boy or girl, it is necessary to reflect on the INVALSI context which puts pressure and often influences the pupils.

It is interesting to note that beliefs were present exclusively among those who perceived the question to be simple. In fact, the only belief present in the answers of those who perceived the question to be difficult was the one reported in Table 3, and we can see how in reality the teacher judges the question to be simple ("being within the reach of a fifth-grade boy or girl") but he/she considered the complexity came from "the INVALSI context which puts pressure and often influences the pupils".

Discussion and conclusions

The analysis of the answers evidenced that most of the teachers mastered the whole and decimal numbers, as well as their composition and decomposition (Table 3). Reading the answers with evidence of KoT, it can be stated that the knowledge of the positional value of the digits was considered by teachers to be essential for the knowledge of the decimal numbering system, since, in the canonical decomposition, the number 120 can be represented as 12 tens.

In the answers evidencing KMLS there were interesting elements to be interpreted. For example, when a teacher stated that this topic must have been learned in the third year, and that, therefore, this topic must already be known well in advance. Another interesting answer about KMLS was given by a teacher who stated that this topic is processed in the fourth year, but is resumed in the fifth year, thus, it is understood that he/she knew that it is a progressive content which requires several academic courses to ensure it. Other teachers said that, being part of the program, students need to know that content: this shows they knew that at the end of the fifth-grade students should be perfectly able of composing and decomposing whole and decimal numbers (this is relative to KoT). These differences may be related with the fact that teachers can handle at the same time different points of view about mathematics and its teaching and learning (Rodríguez-Muñiz et al., 2021). It seems necessary to underline that, in total, there were 24 answers related to KMLS, KoT, or both, among those who considered the question to be simple. We wonder if the way in which the question was asked pushed teachers to focus only on content and learning standards (KoT and KMLS). It seems to us that some teachers focused on content and standards due to a belief: they assumed the curriculum is well designed, and, so, if this is a standard it MUST be easy.

On the other hand, some answers showed evidence of KFLM, that is, the focus on how students think and construct the mathematical knowledge about this content, rather than on the curricular design (where the topic is, what the standard is). Moreover, they knew those features in the process they went through to understand it, as well as some of the learners' strategies when interacting with the content. They also knew some of the difficulties and obstacles associated with this content. It did not seem casual that most of these teachers perceived the question to be difficult.

The results proved to be significant in understanding the effective impact of the INVALSI tests on classroom teaching and the real need for training accompaniment that should be designed to support teachers in their daily management of teaching-learning processes of mathematics in primary school. Therefore, the most significant result is that the questionnaire highlighted a discrepancy between teachers' beliefs about the INVALSI tests and their statements relating to teaching practices. In addition, the use of the MTSK model to deepen our understanding of the mathematics teacher's specific knowledge has allowed us to understand in more detail the characteristics that teachers express when asked about the degree of perceived difficulty.

The analysis of the results is still ongoing and intends to deepen, in particular, the links between how teachers perceive the difficulties of students in INVALSI questions; how teachers interpret students' responses and errors; how much teachers find the INVALSI questions useful and how they use them in teaching practice. We believe that this information can be extremely useful in the design pre-service training for primary school teachers.

Interpreting the Knowledge Mobilised by Prospective Teachers for Addressing in Learning Polyhedra

Lorena Vergara Alvarado[1], Myriam Codes Valcarce[1], Nuria Climent Rodríguez[1] and Dinazar Isabel Escudero Ávila[1]

[1]University of Huelva, Faculty of Education, Huelva, Spain; lorena.vergara@dci.uhu.es; climent@ddcc.uhu.es; myriam.codes@ddi.uhu.es; eadinazar@hotmail.com

This study provides an interpretation and categorisation of the knowledge mobilised by six preservice primary teachers regarding potential difficulties facing pupils and their modes of reasoning when studying polyhedra. It analyses the collective reflections the prospective teachers make as they carry out a training activity based on the transcription of a recording of a lesson on visualising polyhedra. The extract features a teacher working with six pupils in fifth grade of primary school (10-year-olds) giving their reasoning about how to count the number of edges on a cube. The results show that the prospective teachers are aware of various characteristics of learning about polyhedra, which are underpinned by personal theories (beliefs and conceptions), which are consistent with formal theories in the research community. Nevertheless, there is evidence that some of the preservice teachers need to reinforce their knowledge of the mathematics of polyhedra.

Keywords: Preservice teacher education, visualization, solid geometry, teacher knowledge, primary school.

Introduction

Researchers into Mathematics Education recognise teaching geometric concepts such as polyhedra as an effective way to promote visualisation ability and spatial thinking (Idris, 2005). Various authors consider knowledge of the topic indispensable for prospective teachers (Gutiérrez, 1996; Mulligan, et al., 2020; Sinclair, et al., 2011; Kinach & Coulson, 2014), given that they need to be appropriately trained in order to incorporate aspects of visual space into their mathematics lessons and so develop the ability in their students. There is a tendency to believe that visualisation of geometric figures falls within the scope of people's intuition. However, research shows that visualisation is a complex process, is not purely innate, and can be learnt and developed over time (Nagy-Kondor, 2014).

In this respect, it is appropriate for teacher educators to develop tasks aimed at helping future primary teachers to construct their knowledge of polyhedra and improve their skills of visualisation. Such tasks should deepen prospective teachers' mathematical knowledge of polyhedra, and at the same time develop their awareness of the kinds of difficulties their students might face in learning about the topic, and how they are likely to interact with the topic (Montes, et al., 2019; Policastro, et al., 2019). Drawing on the work of Coles (2019), we designed a training task involving the analysis of transcriptions from actual classroom episodes. The aim was to give the pre-service teachers (henceforth PSTs) some insight into the actual practice of teaching, and in some respects require them to put themselves in the shoes of the learner. This paper reports on the results of one part of the overall task with the PSTs. It aims to answer to the research question: What knowledge is mobilised by the PSTs in carrying out a task based on extracts from a lesson on polyhedra?

Theoretical framework

Below we give an account of the two sources for the theoretical underpinnings of this study.

Mathematical Teachers' Specialized Knowledge

Our framework for situating the PSTs' knowledge is the model of Specialized Knowledge of Mathematical Teachers - MTSK, (Carrillo et al., 2018). This model is concerned with the knowledge that is the basis of a teacher's actions. It is made up of two domains: mathematical knowledge (MK) and pedagogical content knowledge (PCK). The authors of the model divide the two previous domains into six subdomains: Knowledge of Topics (KOT), Knowledge of the Structure of Mathematics (KSM), Knowledge of Practices in Mathematics (KPM), Knowledge of Mathematics Teaching (KMT), Knowledge of Features of Learning Mathematics (KFLM) and Knowledge of Mathematics Learning Standards (KMLS).

In the training task shown in this article we will only focus on two subdomains of MTSK, which are KOT and KFLM. We chose these categories and their indicators to select the transcript of video, pose interesting questions for the training of the future teacher and to be able to categorize the answers of the PST. This decision is based on the interest that the university's training plan had, the methodology worked to date and the style of the teacher trainer. The MTSK is the glasses that helps us to be clear about the aspects that we want our future teachers to learn. Although we recognize that it is necessary to delve into literature that details such knowledge, i.e., literature that details the difficulties of learning polyhedrons and the development of visualization skills.

Knowledge of visualisation abilities and difficulties in learning about polyhedra

Our review identified some of the most common difficulties students face when they learn about solid shapes, including: the complexity of identifying the defining characteristics of polyhedra, understanding the planar representations of three-dimensional objects, determining the hidden elements of a planar representation, and developing and manipulating mental images of 3D objects (Bishop, 1989; Del Grande, 1990; Gutiérrez, 1996; Presmeg, 1986).

Research by Widder et al (2019) and Fujita et al. (2020) confirm that visualization difficulties are still latent in classroom reality. Furthermore, they convince us that whenever there is a planar representation of three-dimensional objects there will be visualization difficulties. We share with these authors the curiosity to understand the problem from the same 3d shape, the cube, an apparently simple geometric body, but one that is not free from visualization difficulties.

We identify with the perspective of Widder et al (2019), who describe a 2-D sketch in spatial geometry as "a cluttered scene comprising geometrical features that consist mostly of points and edges with no clear outer distinction between helpful and misleading attributes that could guide the learner to focus on helpful visual aspects and disregard misleading ones" (p.500). On the other hand, Fujita (2020) in a similar scenario affirms that this visualization difficulty not only needs "visualization skills" and comments on the need to harmonize visualization skills with a high knowledge of the domain, specifically the properties of mathematical content. These are two of the visualization skills proposed by Gutiérrez (1996) that we want to highlight, which are important to learning polyhedra:

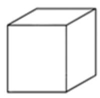
Mental rotation: The ability to produce dynamic mental images and to visualize a configuration in movement.

Perceptual constancy: The ability to recognize that some properties of an object (real or in a mental image) are independent of size, colour, texture, or position, and to remain unconfused when an object or picture is perceived in different orientations. (p.10).

Methodological design

The framework of the study is research-based design (Wake, 2018). The aim is design of training tasks which facilitate the mobilisation of PSTs' specialised knowledge in terms of the MTSK model. The designed task here requires PSTs to read the transcript of a recording of a real lesson (Sherin et al. 2011), which shows the interaction of a primary school teacher with 6 children in the 5th grade of primary education (10 years) who do an activity about how many edges a cube has. The video of this teacher was chosen from a repository of the research group of the University of Huelva, because she is characterized by her good practices, but above all because she empowers her students to verbalize their reasoning, ways of thinking and difficulties when learning polyhedra.

Juan:	How many edges are there? I've counted four from where the vertices meet.
José:	I've counted twelve. Two on the right, plus two on the left, plus two underneath and two on top.
Maestra:	But what you've said doesn't give you twelve.
Álvaro:	I counted twelve counting one by one.
Rocío:	I counted four on top, four underneath, two on the left and two on the right.
Pedro:	José made a mistake because he didn't include two on the top and two on the bottom.
María	Me, I only counted the ones at the top and on the bottom…so that's eight. I forgot the sides.
Maestra:	So, we can say four on top, four underneath, and four on the sides, which is three times four, so, three times four equals twelve.



a. What is the reason for Juan's answer? Draw an illustration.
b. What is the reason for José's answer? Draw an illustration.
c. What is the difficulty for José? What does Pedro note in order to correct him?
d. What is the importance of María's answer?
e. What is the difference between the way Rocío counts the edges and the teacher?

Figure 1. Training Task

It is more common to implement training tasks that use videos of real teachers' classes. However, in this context we decided to use the transcript (a text) because we wanted to ensure that future teachers would focus only on issues related to mathematical knowledge, the way the subjects reasoned and the difficulties that arose in each situation. With a video you can also, but there is more possibility of being distracted and paying attention to questions of general pedagogy.

The questions of the task were aimed at mobilizing the specialized knowledge of the future teacher. For example, in question c the intention is to mobilize the KFLM (the difficulties primary pupils encounter in the topic of polyhedra) is directly sought. Although in question a and b they also have the opportunity to do so. In questions a and b, the main intention is to mobilize the KFLM (the ways they interact with the content, theories of learning about geometric shapes, and knowledge of the interests and expectations of the pupils regarding this topic).The mathematical knowledge that a future teacher would need is implicit in all the questions, however, we decided to establish question d, to raise the importance of the knowledge of the definitions, properties, registers of representation, procedures and phenomenology associated with the topic of polyhedra. And how mathematical knowledge helps future teachers to understand the difficulties of their students. The question e has the same intention as a and b, but adds an extra, which is the interaction of two subjects to the same content (teacher and student). Show the future teacher the possibility of two paths and how they differ or have similarity.

The results reported here derive from the implementation of task with prospective teachers, who are in the final year of the degree in Primary Education at the University of Huelva. To carry out an organized analysis, we consider it appropriate to record the information in a table with the following structure (Table 1).

Table 1. Structure to organize information analysis

Nº	PSTs	Unit	Interpretation	Knowledge, MTSK

The analysis was carried out under a qualitative methodology with an interpretive approach, specifically content analysis was used and the use of the MTSK model as an analytical tool (Krippendorf, 2018; Yin, 2015; Carrillo et al., 2018).

Results

First, we present the results of the knowledge mobilised by the PSTs in response to the difficulties associated with learning about polyhedra which corresponds to the KFLM sub-domain. We then consider their mathematical knowledge of cubes associated with KoT. Finally, we analyse PSTs' knowledge of the ways pupils might interact with content (cubes), also associated with KFLM.

Knowledge of the difficulties associated with learning about polyhedra

Difficulties in interpreting planar representations of 3D objects

All of the PSTs recognised that there were difficulties in interpreting the plane representations of solids. For example, they identified that some pupils have considered just one of the faces of the cube, in other words, a square. This is seen in detail when PST1, PST2 and PST5 explain the reason for Juan's answer, as seen in Figure 2, which is the PSTs' illustration of Juan's reasoning.

PST1: He's thinking of a square with four vertices four sides. He's treating the sides as if they were edges.

PST2: He's only counted the edges of the front face, which is the one he can see.

PST5: Juan's answer tells us that he can't perceive or understand the three dimensions. He only counts the edges of the front face.

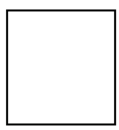


Figure 2. The PSTs' model of visual representation of Juan's difficulty

Another difficulty concerning the representation of a 3D object on a plane is to identify hidden elements. We can see that the PSTs know this difficulty, for example, when PST5 said “how José has counted the edges, we can see that he has not taken into account the hidden edges”. If we follow PST5’s reasoning and look at Figure 3, there are in fact nine edges visible and not 8 as José affirms. PST5 does not question the missing edge.

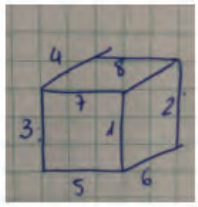

Figure 3. “Failure to count the hidden edges”. PST5 interpretation of José answer

Difficulty in the development of visualization abilities: “Perceptual constancy” and “Mental rotation”

Four out of the six PSTs know the significance of the position and orientation of an object for recognising its properties. PST1, PST3, PST4 and PST6 are of the opinion that José considered only the edges of the front and back faces of the cube when he counted the edges, leaving out the edges running along the sides, which are indispensable for forming the remaining faces; in other words, they think that he excluded the edges which give the cube depth in its visual representation.

PST1: José hasn’t got a clear conception of the definition of an edge, as they are straight segments linking the vertices, as you can see in the drawing, four of the edges that make it a polyhedron are missing.

PST3: He’s missed out the part represented by the dotted lines.

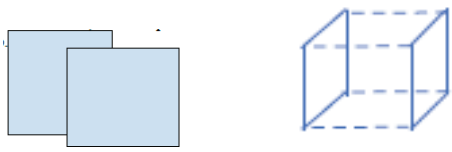

Figure 4. Visual representations by PST1 (left) and PST3 (right)

On the other hand, PST6 knows that José’s answer could be due to a difficulty in mentally manipulating the image, suggesting that: “he hasn’t got the cube fully formed in his mind, it is hard for him to turn it around”.

Difficulty in counting and communicating the processes

The PSTs recognize that pupils have difficulties other than visualization skills such as counting and communicating processes.

PST2 defends José’s answer, suggesting that at first, he gave the right answer, but then subsequently failed in his explanation of his procedure. However, PST2 does not explain a possible cause for the failure in José’s communicative skills. PST5 considers that the pupil might know the answer, but has difficulty in explaining and communicating the procedure by which he got there. PST6 also believes that it might be the consequence of forgetting elements when it came to counting, suggesting: “he forgets to count the edges which give it depth.”

Mathematical knowledge of cubes (definitions, properties, registers of representation, and procedures)

Teachers should undoubtedly have a wide range of knowledge (more extensive than their pupils) so that they can interpret their pupils' interventions, and can understand the origin of their difficulties and the various processes involved in learning. In the results shown up to now it has been possible to see items of mathematical knowledge, some use of formal language, and the identification of elements and ideas associated with how the representation of a cube is constructed, among others. Some excerpts from the PSTs' written answers also provide a direct illustration of their mathematical knowledge regarding the sufficient conditions for constructing and defining a polyhedron. For example, when PST1 and PST4 mention the importance of Maria's contribution in to the lesson, they make it clear that two isolated faces cannot form a polyhedron, while in contrast, the intersection of various polygonal regions (faces) do make a polyhedron.

PST1: The important point is that if they don't count the edges on the sides, it does not make polyhedron.

PST4: The important point is that if they don't count the faces on the sides, they can't construct a polyhedron.

Despite the above, it can equally be seen that the PSTs are not exempt from misunderstandings or being unaware of issues in mathematics topics. An example of this occurs with PST2 when he tries to differentiate the reasoning of María and the teacher (see Figure 5).

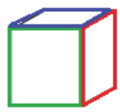

Figure 5. Illustration accompanying PST2's answer

PST2 fails to give the correct interpretation of how the teacher visualises the cube, and how she decomposes the cube into three parts which share the property of having four edges.

By way of contrast, we present the PST4's written answer and accompanying illustration (see Figure 5), who shows knowledge of the representation of a polyhedron, characteristics of a polyhedron and visualisation abilities (KoT) which enables them to arrive at an appropriate explanation of the teacher's and Rocío's reasoning.

PST4: Rocío and the teacher coincide in the way they count the number of edges the top and bottom faces of the cube have, but diverge when it comes to counting the faces on the side. The teacher says that there is a total of four edges, while Rocío divides these four edges into two on the left and two on the right.

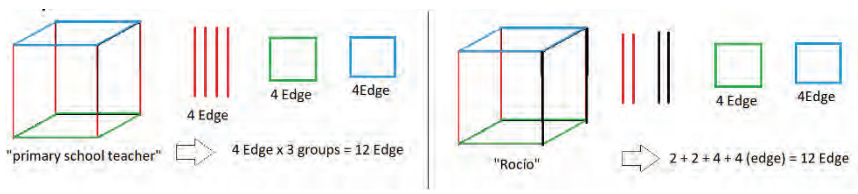

Figure 6. Illustration accompanying PST4's answer

Knowledge of the interaction of the student with the content (cubes)

Based on Figure 6 and the remark made by PST4 in the section above, we can claim there is evidence that the PSTs establish differences in the reasoning of the participants, as in case of the teacher and Rocío, for example. The observations of PST1 and PST3 confirm this, illustrating their knowledge about what strategies the pupils and teacher employ on different occasions for structuring a cube.

PST1: Rocío specifies where each edge is located, that is, on top, underneath, right and left. However, the teacher says straight off that the sides have four edges without specifying the location.

PST3: The way Rocío does it is simpler so that her classmates can understand it, but the teacher groups together the two edges on the left and the two on the right. So, she has three groups with four edges each, which she can multiply together.

PST1 and PST3 show how two participants can interact with a content item in different ways. PST1 notes that Rocío uses previous knowledge of directions (up, down, left and right) to indicate which parts she was talking about. PST3 recognizes that Rocío and the teacher have differences in terms of the way they count the edges of the faces on the sides.

Conclusions

Carrying out this training task has enabled us to identify that the prospective primary teachers know some learning pupils' difficulties, how they reason (KFLM), and their mathematical knowledge (KoT). The performance of the task foregrounds that the PSTs are developing both mathematical and pedagogical content knowledge (Montes et al., 2019).

In the results of PST1, PST2 and PST5 we evidenced the knowledge about the difficulty involved in representing 3d objects in plane (Fujita et al. 2020). Another knowledge that emerges is that the interpretation of the planar representations of 3d objects is linked to the identification of their elements, discriminating the useful elements from the misleading ones (for example, elements that are superimposed or those that are hidden) (Widder et al., 2019).

In the case of PST1, PST3, PST4 and PST6 recognize the elements of a geometric body when it is in a known orientation and position. For example, a cube from a cavalry perspective (Larios, 2003). Finally, PST6 is the one who makes explicit the need to make a mental image and manipulate it (Gutiérrez, 1996). In the planning phase, it was expected that the PSTs would be able express their knowledge in terms of formal theories, because voluntary readings were recommended for the course. It seems that the PSTs base their knowledge of the teaching-learning process on personal theories (beliefs and conceptions), which might be subject to their experience as learners. Despite this, their statements are consistent with the literature (e.g., Gutiérrez, 1996).

Finally, we consider it necessary to review the task and consider the following factors: the importance of drawing, the different types of representations of a cube (other perspectives, decomposition of the cube, in 3D using software, etc) and changes in representation registers.

Place value plays a pivotal role in understanding numbers and arithmetic operations that universally cut across the primary and secondary curriculum. This study investigates the nature of 40 qualified teachers' knowledge in the context of articulating the role of place value in understanding arithmetic operations. The participants have 3-45 years of teaching experience who currently teach grades 1-8 (ages 6-14) in public or private schools in Turkey. The data consists of the videotapes of the semi-structured interviews in which we asked the teachers to analyse five different scenarios consisting of alternative student solutions regarding arithmetic operations. Our initial findings suggest that teachers who operate with (partial) specialised content knowledge or without it analyse the given alternative solutions qualitatively differently. The analysis also reveals that the teachers rely mostly on common content knowledge that has little or no connections to a solid place value understanding.

Keywords: Place value, specialised content knowledge, mathematics teacher knowledge, arithmetic operations

Introduction

Place value plays a pivotal role in understanding number structure and arithmetic operations (Nuerk et al., 2015) that universally cut across the primary and secondary curriculum. Arithmetic and symbolic calculations require a solid understanding of place value. However, numbers and arithmetic operations are mostly treated procedurally in schools and the teaching that fosters rote learning is a common practice among teachers (Pesek & Kirshner, 2000). As a result, we see students treating numbers as a combination of concatenated single digits (Fuson et al., 1997) or having difficulty understanding the meaning of each digit in a number (Kamii, 1986). Furthermore, understanding number requires one to form groups and think about groups (or groups of groups, etc.) as single entities or composite units (Hiebert & Wearne, 1996), which is also problematic among students (Thanheiser, 2015). Such difficulties affect students' understanding of the procedures in making sense of arithmetic operations (Verschaffel et al., 2007) and algorithms (Kamii & Dominic, 1998).

Even teachers struggle to clarify their rationale for algorithms as they primarily operate from procedural aspects (Ma, 1999). They have difficulty articulating number concepts (Thanheiser et al., 2013) and place value (Southwell & Penglase, 2005). Primary school teachers are not even aware of "the impact of place value understanding on the learning of mathematics" (Houdement & Tempier, 2019, p.36). Such a crucial area requires teachers to have the necessary knowledge and understanding to teach conceptually. The research literature piles up in articulating student understandings or misunderstandings (e.g., McClain, Cobb, & Bowers, 1998), whereas it falls short in delineating teacher knowledge and the nature of that knowledge. Several studies focused on the understandings of trainee teachers (e.g., Lo, Grant & Flowers, 2008; McClain, 2003), but our experience suggests that qualified teachers do not have a solid knowledge of concepts, as mentioned earlier. Knowing more about the source of teacher difficulties and the nature of their knowledge specific to teaching would inform educators in developing well-designed professional development programmes and give them opportunities to improve the quality of instruction in schools. As Thames and Ball (2010, p.228) pointed out, identifying the mathematical demands of mathematics teaching "allows us to identify the mathematical knowledge needed for teaching", which will help us improve the quality of instruction in schools. Therefore, the current study investigates the nature of qualified teachers' knowledge specific to teaching place value as it "should be at the core of teachers' education" (Houdement & Tempier, 2019, p.36). We pursue the following specific research question: 'What does it mean to operate with/without specialised content knowledge in the context of place value and arithmetic operations?'

Theoretical Framework

It is hard to argue against the criticality of teacher knowledge for effective teaching. Shulman (1987) characterised teacher knowledge as a combination of two major domains, subject matter knowledge (SMK) and pedagogical content knowledge (PCK). Researchers who followed the footsteps of Shulman (e.g., Grossman, 1990; Fennema & Franke, 1992; Ball, Thames & Phelps, 2008) have refined these domains over the last few decades. Recently, Deborah Ball and her colleagues (2008) defined SMK as a combination of three subcategories: common content knowledge (CCK), specialised content knowledge (SCK) and horizon knowledge. In this framework, they described CCK as "mathematical knowledge and skill used in settings other than teaching" (e.g., simple calculations, solving mathematical problems correctly) (Ball et al., 2008, 399). SCK is "the mathematical knowledge and skill unique to teaching" to respond to everyday tasks of teaching (e.g., mathematical knowledge required to analyse alternative student solutions, sizing up the nature of a nonfamiliar error), and horizon knowledge is "an awareness of how mathematical topics are related over the span of mathematics included in the curriculum" (Ball et al., 2008, p.403). The framework also considers pedagogical content knowledge as a combination of knowledge of content and students (KCS), knowledge of content and curriculum (KCC) and knowledge of content and teaching (KCT). KCS is the "knowledge that combines knowing about students and knowing about mathematics" (e.g., student thinking, common student errors), and KCT is an amalgam of knowing about teaching and knowing about mathematics (e.g., different instructional models of place value and their effective deployment) (Ball et al., 2008, p.401). Finally, KCC is about combining knowledge of content and the curriculum.

To distinguish between these knowledge types, Ball et al. (2008, p.404) gave the following examples for the task of "selecting a numerical example to investigate students' understanding of decimal numbers". In this case, they consider "ordering a list of decimals" as CCK, "generating a list to be ordered that would reveal key mathematical issues" as SCK, "recognizing which decimals would cause students the most difficulty" as KCS, and "deciding what to do about their difficulties" as KCT (Ball et al., 2008, p.404). In this example, knowing what grade level is appropriate for teaching decimal ordering would be labelled as KCC. The development of decimals throughout the mathematics curriculum would be an example of horizon knowledge.

We adopted the Ball et al. (2008) framework to analyse teacher knowledge. We specifically zoomed in on how teachers operate with SCK or in the absence of SCK to pursue the aforementioned research question.

Method

Participants

Participants were 40 teachers, 35 of whom worked as primary school teachers in public or private schools (teaching ages 6-11). Four worked as mathematics teachers in middle schools (teaching age 11-15) by the time this study was conducted. These teachers got their degrees from 20 different institutions from different regions of Turkey. Their teaching experiences range in years: 6 of them 1-5 years, 10 of them 6-10 years, 7 of them 11-15 years, 5 of them 16-20 years, 2 of them 21-25 years, 2 of them 26-30 years, 8 of them more than 30 years.

Data Collection Instrument

The data comes from one-on-one semi-structured interviews. We recruited these teachers using convenience sampling on volunteers by considering their varying teaching experiences. We videotaped the interviews without revealing their identities. We gave the participants previously piloted scenarios consisting of alternative student solutions during the interviews and asked them to analyse these scenarios. Each scenario, applied in separate pages, focused on a single arithmetic operation requiring the teachers to draw on SCK regarding place value. Note that we did not train these teachers about SCK or any other knowledge component. SCK is the mathematical knowledge required to respond to everyday tasks of teaching mathematics. For example, the mathematical knowledge required to analyse students' alternative solutions falls under the umbrella of SCK. Each scenario provided teachers with an alternative student solution requiring them to draw on their mathematical knowledge of place value, and arithmetic operations to some extent. Last two of these scenarios are illustrated in Table 1.

Table 1: Last two scenarios given to teachers during the interviews

	**4.** What would you say about the method used by Nazlı, who did the multiplication as illustrated on the left? If you were the teacher in this situation, how would you respond to this student's work once she made this explanation?
	**5.** Emre, who starts to do the following division (4002÷5), objects using the following reasoning: "When solving such problems, we first ask 'how many 5's are in 4?' Here, there is no 5 within 4. Well, isn't 4 actually 4000? And isn't it the case that there are 800 fives within 4000? Why don't we w rite 800 in the quotient section then?" How would you respond to this student's work as his teacher?

The scenarios allowed us to evaluate the degree of teachers' operating with SCK, the nature of SCK and the teacher knowledge in the context of place value and multidigit arithmetic. This paper will only provide a brief analysis of teacher responses for Scenario 4 and Scenario 5. A mathematical analysis of these scenarios is provided below.

Scenario 4 requires a solid mathematical knowledge of the multiplication algorithm as it is applied in four steps rather than two, making it an alternative solution. In the given solution, 23×15 is calculated using distributive law as follows (also see Figure 1):

$$23\times15 = (20+3)\times(5+10) = (5\times3)+(5\times20)+(10\times3)+(10\times20) = 15+100+30+200 =345$$

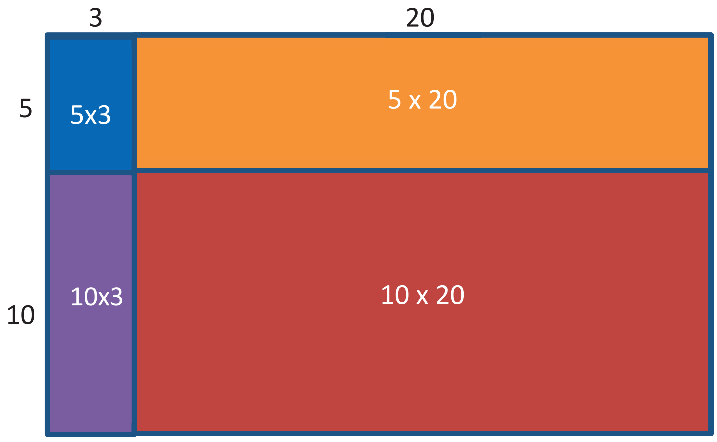

Figure 1: Analysis of 23×15 using distributive law geometrically

The multiplication algorithm includes the calculation of '(5×3)+(5×20)' as a first step yielding 115 and '(10×3)+(10×20)' as a second step resulting in 230 – in fact, procedurally, 230 is written as 23 by aligning 2 with 'Hundreds' column, 3 with 'Tens' column and ignoring 0 in the 'Ones' column. In contrast, the given alternative solution treats these two steps as a combination of four seemingly isolated steps, requiring teachers to analyse the reduction of four steps to two. Therefore, in responding to this alternative solution, teachers need to draw on the following mathematical knowledge: the role of place value in making sense of numbers (e.g., thinking about 23 as a combination of partitions 20 and 3), the connection between distributive law and multiplication algorithm (e.g., thinking about why and how to distribute 5 and 10 onto 20 and 3), and the relationship between four steps described above and two-step algorithm (e.g., how 15+100+30+200 is reduced to 115 and 230 (or reduced to 23, one place shifted to the left)).

Scenario 5 also provides an alternative solution for 4002÷5 by investigating whether the first question to ask in approaching such a problem is 'how many 5s are in 4' (quotative division) as usually taught in schools. Here, "4" within "4002" can mean its face value (4) and place value (4000). To respond to such an alternative solution, teachers need to know that "4 thousand" is to be shared among five parties (partitive division) as thousands, and since this is not possible, it needs to be converted to "40 Hundreds" to be shared as hundreds among five parties. This distribution results in "8 Hundreds", giving the result of the division as 800 with a remainder of 2, or '800R2'. Because of these reasons, the question of 'how many 5's are in 4?' is not mathematically appropriate, and the long division algorithm is to be interpreted by teachers with partitive division meaning (an amount being equally shared among several groups and determining group size).

Data Analysis Procedure

Data analysis is carried out in the form of content analysis and is still ongoing. In analysing the data, we mainly focus on the kind of knowledge the teachers draw on (e.g., SCK, CCK) and its nature. First, we go through all the videotapes and identify instances in which teachers do (not) refer to SCK and the rationale behind their analyses. As we go through the data and as we gain more insight into how teachers operate, we begin to provide a fine-grained description of the nature of SCK for arithmetic operations and place value. After the initial run of the data, we check whether there are similarities among teacher interpretations and how they refer to different knowledge types. We will finally develop categories that characterise the nature of teacher knowledge regarding the place value concept and arithmetic operations. In this paper, we only share some preliminary findings.

Results

The data has given us certain clues about how weak and detached from the conceptual ties the teachers perceive the place value concept and how they drew on their knowledge. In addition, the data led us to believe that inquiring about the validity of the given alternative solution or even having a suspicion about the validity of the given solution help teachers operate more closely with SCK than other knowledge categories. Because of space limitations, we give two examples of this finding below.

I. Evaluation of multiplication scenario: When working on Scenario #4, the teachers considered the alternative solution as a brand-new way of doing multiplication that they had not seen before and pursued one or more of the following methods or arguments:

1. The teachers initially ignored the core of the given alternative solution and labelled it as "wrong" without a thorough analysis. They compared the alternative solution to the routine/procedural application of the multiplication algorithm they already knew (CCK) and used it in their practice. A typical teacher (out of those 12 teachers) reaction to this scenario was, "*If the student comes to me with something like this, I will tell that it can't be done this way, and then I will delete this method*". In this sense, teachers did not focus on the nature of the given solution as they operated with CCK. They were not even suspicious until they solved the given multiplication problem by referring to CCK and realised that their result matched the given result in the alternative solution.

2. The teachers solved the problems in the given scenarios independently of the given alternative student analysis by operating from CCK in a very procedural way – a typical teacher reaction (out of 14 teachers) was, "*Now, I need to find the result of this calculation first*". For example, in multiplying two two-digit numbers (23×15), their initial reaction was to follow the standard multiplication algorithm: applying the 'Ones' column of the multiplier to both 'Ones' and then 'Tens' column of the multiplicand (5×3 and 5×2 without considering 2 as 20), and then doing the same for 'Tens' column of the multiplier and multiplicand (1×3 and 1×2 without considering 1 as 10 and 2 as 20). This way of operating is about the use of CCK others also use in settings other than teaching (mathematics). This way of operating might be convenient to teachers, and therefore they did not feel the need to start with an analysis of the given alternative solution. Finding the matching results fed a suspicion for teachers about the validity of the given alternative solution. Once they became suspicious, they began to analyse the given solution superficially by analysing each given step, which also led them to pursue the question, "*would it be right*?" rather than sticking to their initial rigid observation, "*it is wrong*". What seemed to help teachers move away from operating with CCK and getting close to the use of SCK was the change of perspective (Ball & Bass, 2009) from the "*it is wrong*" argument to "*would it be right*?" argument.

3. Twenty-one teachers referred to one of the other knowledge types (e.g., KCT, KCC, KCS) as if they wanted to fill the void of SCK with those components. For example, teachers referring to

KCT did it by referring to what they would typically do in their teaching and the procedural aspects of the algorithm they would highlight. (e.g., always starting from 'Ones', moving to 'Tens').

II. Evaluation of division scenario. When it comes to Scenario #5 (about division), all the teachers except very few could not sufficiently articulate the dilemma between "*There is no 5 within 4*" and "*there are 800 fives within 4000*" on a conceptual basis by associating the issue with place value. They all, except three, referred to the long division algorithm and ignored the dilemma mentioned earlier. More specifically, a typical teacher's (from among the 37 teachers) initial analysis was:

Teacher:	I need to explain them that we need to work with the face value, we need to have them accept this. … I can take out 4 Turkish Liras [*referring to 1TL coins*] from my pocket and ask, can you give me 5 Turkish Liras from here, can you give or not?

When further probed about the meaning of leftmost two digits, 40, within the number "4002", these teachers were not able to talk about the place value and its role either. Such an approach focused on the face value instead of place value resulting in dependency on CCK or KCT rather than on SCK.

Only three teachers out of 40, when probed to mentally or physically use base-ten blocks, modelled the given division process with the help of base-ten blocks and explained this issue by mentioning that 4 thousand blocks cannot be shared fairly among 5 parties since there would not be enough thousands for each party. This is illustrated for one of those teachers in the below dialogue.

Interviewer:	When we think about the materials here [*referring to base 10 blocks*], what does it mean to say there are no 5 within 4?
Teacher:	Since these are 'Thousands' as wholes, I cannot divide them into 5 people. I need to convert them to 'Hundreds' to be distributed to everyone as 8 'Hundreds'. The remaining 2 would be mine.
Interviewer:	All right, here we say there are 8 fives within 40. Is there a connection between the division algorithm and the application you made with base-ten blocks?
Teacher:	[…] Since I cannot distribute 'Thousands' as 'Thousands', I distribute them as 'Hundreds' [*circling 40 within 4002 on paper*]. So, in a way, I convert this [*referring to 4 thousand*] into 'Hundreds'.
Interviewer:	What does that 40 represent?
Teacher:	Let that 40 represent 40 'Hundreds'. Then 5 times 8 makes 40 – 40 'Hundreds'. I mean, when we say algorithm, if we sift through it, it is 40 [*groups of]* 'Hundreds'.
[…]	
Interviewer:	What does that 8 represent [*referring to the 8 in quotient*]?
Teacher:	8? It represents 8 'Hundreds' per person.
Interviewer:	What does it mean to put zero [*next to 8*] with base-ten blocks?
Teacher:	I do not have any 'Tens'. [*adds 0 next to 80*] I am distributing 'Tens', but I give you zero 'Tens'. I will also share 2, but since 2 is not enough for 5 people, I give you zero 'Ones'. In other words, we confirm that it is '8 Hundreds'.

In this dialogue, the teacher used several components to analyse the given alternative student solution. We consider these components as part of his SCK. These are:

- Investigation of the conditions for which the given alternative solution is correct,
- Referring to place value and its role in division using base-ten blocks,
- Operating from the sharing meaning of division.

This teacher did make a sufficient analysis of the given alternative solution by using all these components together. However, such reasoning was not apparent in this teacher's explanations until the base-ten blocks were shown. In this sense, manipulatives played a particular role in triggering this participant's thinking to carefully evaluate the act of sharing '4 Thousand' units among 5 parties. Base-ten blocks allowed this teacher to question the validity of the given argument. The other 37 teachers, when probed, could not resolve this conundrum, and they continued to operate with CCK and/or KCT even with base-ten blocks. Therefore, the three SCK components need to be abstracted as a totality to sufficiently analyse a given alternative student solution.

Conclusion

Our initial findings suggest that teachers who operate with (partial) SCK or without SCK analyse the given alternative solutions qualitatively differently. The ones operating without SCK are the ones who are under the complete influence of CCK (e.g., procedural application of multiplication or division algorithms) and who analyse the given alternative solutions by purely comparing them to the algorithms. Teachers who operate with partial SCK try to fill the void by bringing in examples from other teacher knowledge types as excuses such as KCS (e.g., this will be quite difficult for students), KCT (e.g., I normally teach it this way) or KCC (e.g., this is not appropriate for lower grades). The teachers operating with SCK approach the given alternative solutions by thinking about the question, 'what makes this solution valuable/reasonable?' and then refer to the role of place value as the core of the given arithmetic operations of multiplication and division.

Introduction

CERME12 followed the COVID-19 pandemic that hit the world. During this time much of what we did within our classrooms and outside was re-thought to allow for social distancing and remote learning. This of course initiated important changes in the assessment of mathematics. In the CERME event held online in 2021, we drew six areas of interest for our group – some of which reflect the need for remote teaching and learning. These included the use of technology in the assessment of mathematics. For CERME12 we received 20 papers and four posters which covered four themes of the call: The assessment of specific mathematics competencies; Technology – computer aided (formative or summative) assessment; Teacher assessment with focus on teacher education; Teacher assessment in the light of transferring assessment methods to methods with technology.

Thematic clusters

Here we group the papers in the thematic clusters to reflect on their links and findings. We then conclude with some reflections for the coming CERME13.

The assessment of specific mathematics competencies: Ramo et al. investigate university students' preferences when choosing between self-assessment and traditional exams. They found that many students selected self-assessment because of the possibility of self-regulation, for affective reasons and for practical reasons (e.g., time-malmanagement). The authors conclude by indicating this methodology as supporting agency and self-regulation. Ferrara and Pozio investigate routes into algebraic thinking by examining the responses to one item of the Italian national text concerning the area and the perimeter of an isosceles trapezoid. They found four distinct routes that students adopt and relate those to proficiency levels. The levels of proficiency increase as the routes become more advanced, which is consistent to the assessment model. Morselli and Robotti describe a learning sequence inspired by the principles of Universal Design for Learning (Rose & Meyer, 2006) on conjecturing and proving for grade 7 students. Promoting appropriate formative assessment strategies, they found that such a sequence can be effective in terms of proof understanding. Færch investigates the potential of tasks in a dynamic online environment for primary school students to foster symbol competency. Okamoto addresses the theme of creativity, proposing a new approach to evaluate the fluency component in Guilford's (1973) model for creativity by means of Fermi problems. His quantitative study involved 291 Japanese junior high school students. Results show a strong correlation between fluency in general, creativity, and fluency measured by the richness of aspects in solving a Fermi problem. However, further research is needed to examine the validity and reliability of a test to measure creativity using Fermi problems. Rieu et al. investigate prospective teachers' diagnosis of students' misconceptions. More specifically, they investigate the presence of confirmation bias in teachers' detection of misconceptions in decimal fractions. The study identifies normative-accurate and confirmatory-biased judgment processes. A follow-up study, investigating relevant information based on alternative hypotheses to obtain an accurate diagnosis, shows it to be an efficient judgment strategy and as such, it should be incorporated into teacher education. Winnberg studies high-stakes summative tests through the lens of connectivity. The framework of connectivity (Gueudet et al., 2018) was initially developed for the analysis of digital resources such as e-textbooks, and Winnberg proposes to adapt it to the analysis of digital tasks. In the paper, two tasks are analyzed and a final discussion on the viability of the use of the framework is presented. Giberti and Passarella address the issue of real tasks in standardized assessment. They propose a criterion to identify "real" tasks in standardized tests, which they employ to analyze items from the Italian national standardized assessment. Data analysis shows that such tasks are widespread in national assessment. A further analysis suggests that such tasks are not particularly difficult for students, but they are discriminative: students with higher ability pass these tasks easily, while students with lower ability struggle. Saccoletto aims to investigate teachers' assessment in argumentation tasks. To this aim, she plans to propose to teachers a selection of students' answers to be discussed.

Technology – computer aided (formative or summative) assessment: Moons and Vandervieren investigate a semi-automated grading approach of handwritten questions which uses atomic feedback. Assessors using this approach appreciated being able to see the effects of their grading choices on the outcome of the assessment. This ongoing work will also shed light on the possibly added value of this semi-automated grading approach in comparison to traditional grading. Min Chia and Zhang describe secondary mathematics teachers' views on online assessment during the first waves of the COVID-19 pandemic. Based on survey responses of 92 teachers and interviews with three teachers they found that teachers mainly used the same assessment methods during the pandemic, and online teaching, as they had done before the pandemic. Online assessment was for them mainly assessment for and of learning. Brunstrom et al. reported on a pilot study focusing on the (re)design of a digitized task environment in which both a dynamic mathematics software and a computer-aided assessment system are implemented. They discuss their research with 256 first year engineering students in calculus and related the characteristics of the explanations and formulae students provided in their responses to the tasks.

Teacher assessment with focus on teacher education: Kaplan-Can et al. investigate the characteristics of tasks produced by trainee teachers aimed at eliciting cognitive demanding algebra tasks. They found that trainee teachers - after suitable training - can generate such tasks but most of the tasks involved algebraic manipulation and few involved mathematical modelling. Andersson and Erixon present the results of an ongoing study that investigates four mathematics teachers' use of formative assessment. They aim to identify aspects of formative assessment that are important for beginning mathematics teachers (BMTs) and the differences between participants' use of formative assessment in practice. Preliminary findings show that BMTs use different ways to present lesson goals and they refer to written tests to elicit evidence of learning. Moreover, students rarely function as agents in the formative assessment processes. Eichholz et al. present a study concerning the evaluation of the effectiveness and acceptance of the education concepts in the qualification program developed for the project. They aim to compare the implementation of two variations of formative assessment: teachers learn to develop diagnostical questions and support activities and curriculum embedded, or teachers use ready diagnostic and support tasks. They expect a positive effect in favour of the first approach and assume a moderator effect of the association between high pedagogical content knowledge and a positive self-efficacy of the teachers on the second approach. Kjensli et al. report on a project in a course for prospective teachers, where the teacher educator modelled feedback based on formative assessment principles. The study analyses prospective teachers' responses when they are challenged to reflect from a teacher's perspective on how to use different models to compare fractions in a primary classroom. The findings indicate that prospective teachers tend to use feedback to move forwards in their teacher perspective. Barana et al. aim to understand the evolution of participants' knowledge and perception of automatic formative assessment throughout a STEM teacher education course. Analysing responses to a questionnaire they found that teachers became more aware of knowledgeable of this type of assessment, over the course, and that this appears to result in a more student-centered approach to formative assessment. Saksvik-Raanes and Solstad investigate digital items that were designed to measure arithmetic competence as a component of the foundational number sense framework for five- and six-year-old children. Using Rasch analysis of the performance of 302 Norwegian children they found that items' difficulty levels were strongly influenced by the type of problems and the magnitude of the answer in it. Supplemented by a qualitative analysis of students' strategies they conclude that there were more factors at play, but that this work could enable us to study in more detail how children model and use strategies to solve mathematical problems.

Teacher assessment in the light of transferring assessment methods to methods with technology: Klothou et al. investigate how secondary school teachers assess students' written texts in mathematics and the resources they draw on while assessing these texts. Findings show the complexity of the factors that influence the outcomes of assessment in mathematics. Teachers grade students' written texts differently. Teachers' beliefs about the nature of the subject and the nature of mathematics matter, either alone or in combination with expectations about 'communicating', emerged as the prevailing resources teachers draw on while assessing students' written texts. Holm Gundersen and Kohanová present the results of a qualitative study focusing on characterisations of enactment of formative assessment during mathematical conversations by Norwegian primary school teachers. Two second-grade teachers were observed during mathematical conversations with their students in a teaching session regarding various strategies for addition. The paper suggests a model that characterises the formative assessment enacted during a mathematical conversation from a teacher's perspective. Faggiano et al. present initial findings from a survey, administered to 421 Italian in-service primary teachers, on the beliefs regarding the knowledge and skills investigated by the national standardized assessment tests, their proximity to didactic practices in mathematics and the role they assume within the school context. The paper discusses the way teachers interpret data coming from standardized assessment and if/how they use them in their teaching practice. Findings show a meta-didactic conflict generated by teachers' difficulties in interpreting the standardised tests and in using them coherently with the framework on which the tests were designed. Kiss et al. analyse Hungarian students' oral explanations based on their written work, looking for additional information about students' thinking processes. Additionally, the study examines the quality of verbal communication. Findings indicate that the teacher obtains a more detailed picture of students' current level of development via oral explanations. Grapin and Sayac describe a comparison between two forms of assessment at the end of primary school: paper pencil and tablet-based assessment. They considered different approaches to digitalizing assessment, either using the opportunities a digital environment provides, or migrating the paper pencil assessment onto a screen. They opted for the former. Students appeared to perform better on the paper-pencil based assessment than on the tablet-based assessment, although more of the possibilities the tablet provides could be used in further studies. Geszler describes the outlines of her PhD study, in which she investigates the opportunities for digitalization of the final examinations of mathematics in Hungary. To this aim she investigated at the practice in four other countries - Finland, Germany, Georgia, and Denmark - and compared them on several aspects. She concludes that in Hungary there is a will to work towards computer-based adaptive testing, allowing for creativity, analyzing, and mathematical modelling can exist, which could have an active impact on education itself.

Conclusions

Our group again represented work engaging with a variety of methodologies and research questions – confirming that assessment is a big umbrella theme that encompasses a great number of approaches and foci such as the assessment of mathematical competencies and specific topics. However, from the summaries presented, there are two main issues that emerge clearly: the increased use of technology for assessment (both for formative as for summative purposes) which goes beyond the consequences of the pandemic, and the attention to the education of new teachers with respect to assessment practices. These two themes are not un-related: the way in which we assess mathematics is changing, new technology that was introduced during the pandemic out of necessity is now adopted widely, and teachers (at all levels) may be trained in how to use the technology appropriately and what are the affordances of technologies in assessment. Moreover – a productive use of technology must also be adopted – therefore we saw many studies addressing affordances and drawbacks of technology in assessment. We believe that the use of technology will be again a big theme in our next meeting in CERME13 in 2023 - Hungary.

Formative assessment
– in the hands of beginning mathematics teachers

Catarina Andersson[1] and Eva-Lena Erixon[2]

[1]Umeå University, Department of Science and Mathematics Education, Sweden; catarina.andersson@umu.se

[2]Dalarna University, Department of Mathematics, Science and Technology Education, Sweden; eer@du.se

Formative assessment is a key competence of professional teachers, yet complex and demanding to develop. Thus, beginning mathematics teachers (BMTs) cannot be expected to have fully developed this competence. In an ongoing study we examine and depict similarities and differences between four BMTs' use of formative assessment in practice. We will use data from video-recorded observations to analyze to what extent and in what ways the BMTs use five key strategies in formative assessment practice and the main idea of this practice, that is, to use information about students' learning to adjust teaching and learning to the students' needs. The study will provide insight into crucial aspects of formative assessment that BMTs need to learn about and reflect on during and after teacher education. Implications for teacher education are discussed.

Keywords: Formative assessment, teacher education, mathematics teachers, beginning teachers.

Introduction

In this paper we focus on mathematics teachers' use of formative assessment in their early careers, and in particular on aspects of formative assessment especially important for these teachers to be vigilant about and reflect on during and after their teacher education (TE). Formative assessment (also called "assessment for learning") refers to a classroom practice in which assessment is used to identify students' learning needs so that teaching and learning can be adapted accordingly (Black & Wiliam, 2009). The teacher as well as the students can be agents in the processes involved in this practice. The empirical evidence of increased student learning in all school years and subjects (e.g., Black & William, 1998; Hattie, 2009) – including mathematics (Palm et al., 2017) – has led to great attention to formative assessment in education research, policy, and practice (DeLuca et al., 2016). Additional theoretical argumentations further motivate the use of formative assessment in mathematics education (e.g., Schoenfeld, 2020).

The increased interest of using assessment to increase the learning of the students has broadened the concept of assessment beyond using assessment for marking and grading (DeLuca & Bellara, 2013), and assessment competence has become a key competence of professional teachers (Xu & Brown, 2016). Consequently, teachers need to learn about formative assessment in their teacher education (DeLuca & Johnson, 2017; Shepard et al., 2005). They need to learn about why using formative assessment and how to put it in practice. More specific, a use of high-quality formative assessment requires teachers to: understand the purposes of and principles on which this classroom practice is based; have ability to incorporate this classroom practice into their teaching; and to use a critical reflection on aspects of quality relating to their understanding of that practice (Xu & Brown, 2016; Young & Kim, 2010). Because the implementation of high-quality formative assessment is complex and challenging (Black & Wiliam, 2009) beginning teachers cannot be expected to have reached full competence for such implementation. Rather, their formative assessment competence will develop under the right conditions (De Luca & Johnson, 2017). However, more studies are needed at different levels and with different foci in order gain knowledge about how to design the right conditions and effective support for teachers' development of assessment competence (DeLuca & Johnson, 2017). In this paper we focus on qualitative aspects of formative assessment classroom practice.

More specific, we use the framework by Wiliam and Thompson (2008) to characterize beginning mathematics teachers' (BMTs) formative assessment practices and shed light on aspects that are important for those teachers to be aware of and reflect on during and after TE. With the involvement of the teacher as well as the students in various assessment and learning processes, this framework reflects the complexity of putting formative assessment into practice. The framework consists of the main idea of using information about students' learning to make decisions about how to adjust teaching and learning to meet students' needs, along with five key strategies (KS) guiding the implementation of this assessment in practice:

KS 1. Clarifying, sharing, and understanding learning intentions and the criteria for success

KS 2. Engineering effective classroom discussions, questions, and tasks that elicit evidence of learning

KS 3. Providing feedback that moves learners forward

KS 4. Activating students as instructional resources for one another

KS 5. Activating students as the owners of their own learning

A clear learning goal with specification of what is counted as criteria of success is crucial in all assessment. In formative assessment the sharing of learning goals and success criteria (KS1) is essential for the feedback processes between the agents (teacher and students) involved in the formative assessment processes. A clear learning goal facilitates eliciting the relevant information about students' learning needs (KS2) and providing adapted instruction, that include teacher feedback (KS3), that move students' learning forward. In addition, a clear learning goal and success criteria are decisive for peer assessment and peer feedback (KS4), and for self-assessment with subsequent adjustments (i.e. self-regulated learning, KS5). Thus, this framework can be used to analyze and characterize qualitative aspects for each KS, as well as the integrated use of them to fulfil the main idea of formative assessment.

In a previous case study, we used the above-mentioned framework to characterize one mathematics teacher's development of formative assessment competency during and after TE. We recognized that the teacher during this time made incremental changes, however crucial for the formative assessment processes in the classroom. That is, the changes enhanced the possibilities for the teacher to gain insight into students' thinking, which is crucial for decisions-making about what feedback to provide the students and/or about adaptions of other learning conditions to meet the needs of the students. This insight about how a seemly small change makes a big difference in formative assessment processes made us interested in comparing BMTs' formative assessment practices. An assumption is that comparing the way the BMTs use formative assessment will gain insight into aspects that are important for BMTs to learn about concerning the purpose and complexity of the use of formative assessment. Such aspects will be significant for early career mathematics teachers to evaluate their understanding and need of development. The insights will also be useful in teacher education when preparing BMTs for the development of formative assessment competence. Moreover, researchers may be inspired to study what variables that affect putting these aspects into practice, circumstances that help mathematics teachers implement those formative assessment aspects, and obstacles the teachers need to overcome to be able to use high quality formative assessment.

Aim and research questions

In the study we examine and depict the similarities and differences in four BMTs' use of formative assessment in their classrooms. The aim of the study is to identify aspects of formative assessment that are important for mathematics teachers to become aware of and reflect on. The study is guided by the following questions: To what extent and in what ways are the five key strategies used in the BMTs' classroom practice?; What are the similarities and differences between the four classroom practices?; and What do those similarities and differences mean from the view of the purposes and principles of formative assessment?

Method

Informants and data

The data used in the study comes from a project called TRACE[1] in which student teachers in their last year of mathematics teacher education at two Swedish universities were asked to volunteer as participants. The informants received information about the study and ethical aspects, and written consent was obtained before data collection began. Due to the 2020 Covid19 pandemic restrictions the data collection was interrupted. In this study we use data (video-recorded classroom observations) from the four informants that were possible to trace more than one year after their graduation. These informants participated in the same teacher program at the same university in Sweden. They graduated with a teaching degree, grades 7-9, with mathematics as specialization. The teaching being observed is also from mathematics lessons in grades 7-9. Three lessons per informant are observed. Gry and Elvin (fictive names) graduated in January 2017. They were observed in October 2018. Tina and Anton (fictive names) graduated in February 2018. They were observed in September 2019.

Analysis

In the analysis we use the framework by Wiliam and Thompson (2008, see above), and draw on previous research experiences of developing and using an analytical tool based on this framework (Andersson et al., 2017; Andersson & Erixon, in press). This means that we use a previously developed tool at start, yet prepared to adapt or complement the coding manual whenever needed. The main codes are: transparency of the learning goals and success criteria (KS1); elicitation of information about student learning (KS2); teacher feedback (KS3); feedback between students (KS4); and students' regulation of their own learning (KS5). For each main code a number of initial subcodes

[1] TRACE project founded by The Swedish Research Council, project/grant number [017-03614]

are set. During initial coding these subcodes are customized to the data so that all lesson activities related to formative assessment are identified and coded. A selection of subcodes is presented in Table 1. These are exemplified in the preliminary findings. We limited the presentation of the process of categorization due to the limited space in this paper. Our analysis is qualitative, but we count some frequencies in our data. This is not because we will try to generalize our result, rather the reason for examining the frequencies is to understand qualitative differences. For example, we compare the extent the informants use different feedback types, by counting numbers and calculating their use as if the lessons were equally long.

Table 1: Subcodes for each main code

Main Code	Subcodes	Main Code	Subcodes
KS1	Explicit formulated learning goal	KS3	Confirming the answer as correct or acceptable
	Goal of doing		Repeating or reformulating what the student said
KS2	Questions about how and why		Explaining (often by simplifying or deepening)
	Questions that require a short answer, yes/no		Initiating mathematical reflection on the solution process
	Assessment material		
KS4	Nothing has been found so far	KS5	Nothing has been found so far

As a last step of the analysis, we will examine the similarities and differences from the view of the purposes and principles of formative assessment. In this step we will consider both the purpose and principles for each KS and their integrated use. This step has not yet started systematically, but we provide one example in the preliminary findings below. Both authors are engaged in data analysis to ensure reliability.

Preliminary findings

Below we present some preliminary findings, with a focus on the similarities and differences in the BMTs' use of the five key strategies. The findings will later be complemented with narratives to contextualize the formative assessment activities each teacher uses. Moreover, an overview of similarities and differences will be presented along with concrete examples. Finally, the findings from analyzing the similarities and differences from the purposes and principles of formative assessment will be presented (one example regarding teacher questions is now included below).

The transparency of the learning goal (KS1)

We have identified three ways of presenting the goal of the lesson: As a learning goal, what students are going to work with, and what pages or tasks to finish. Gry referred about twice as often to the learning goal as the other teachers. For example, she presented the goal as follows:

Gry: Do you know what a polynomial is? We are going to talk about what a polynomial is.

Gry also referred to the mathematical content when she presented the goal of the lesson as something the students are going to work with:

Gry: There are polynomials of degree one, and we have worked with first degree polynomials recently. We are soon going to work with second degree polynomials.

Elvin, however, in most cases presents the goal of the lesson in terms of what tasks to complete, as a goal of doing:

Elvin: Solve the tasks in chapter 1.6.

Elicitation of evidence of learning (KS2)

We were not able to confirm that the evidence of learning that the teachers elicit actually was used to adjust the teaching and/or learning in the classroom. Thus, we treat the KS2-activities as potentially being formative assessment activities. As example, all teachers referred to written tests. A difference was found regarding their use of questions, in terms of what types of questions they used.

Anton and Tina asked a lot of questions that only required short answers. In comparison with Elvin they asked such questions about seven times as often as he did. Gry asked questions about the mathematical content about twice as often as Elvin. About 62% of questions Gry asked could be answered with a yes or a no:

Gry: This became very theoretical, right?

For Gry, the remaining questions (38%) were about what and how, and the students needed to explain to answer them:

Gry: Why is this a polynomial of degree one?

In addition to these activities we could identify that Elvin and Tina used "exit-tickets" to assess what the students have learned during the lesson. Tina introduced the exit-ticket to her students as follows:

Tina: Before you go just so I can see what I have done and what you have learned […] the question is What have you learned? What do you need to develop based on this lesson?

Teacher feedback (KS3)

Also regarding feedback there were differences between the teachers. Elvin used feedback much more often than Gry and Tina did. Four types of feedback dominated. Two of them regard the correctness of student response: feedback confirming the answer as correct or acceptable, and feedback repeating or reformulating what the students said. The other two were: feedback to explain, and feedback to initiate mathematical reflection on the solution process. Elvin and Tina used the last two types of feedback when elaborating on tasks and/or examples that the students found hard to understand. Gry stood out, she did not use the last type of feedback at all. Below quotes will exemplify the different types of feedback:

Example of feedback to confirm the answer as correct:

Student: Well, the square root of 2600.
Elvin: Yes.

Example of feedback to repeat or reformulate:

Student: Can you round to 51?
Elvin: A question from [the name of the student], can you round to 51?

Example of feedback to explain:

Elvin: She converts to centimeters and then she divided by the growth per month, the number of centimeters divided by how much it grows per month.

Example of feedback to initiate mathematical reflection on the solution process:

Elvin: Then we have factorized, can you factorize further?

Moreover, Elvin stood out in another respect. He used a fifth type of feedback, that is, answering questions from the students. He used such feedback about six times as often as the other BMTs:

Student: Can you show another one, so that you have to think a little differently. Like this 327, or any number that you cannot factorize prime numbers?

Erik: Yes, some numbers cannot be factorized in prime numbers, for example 11.

Feedback between students (KS4)

Both Tina and Elvin encouraged the students to work in smaller groups or in pairs so that they could discuss and help each other with the tasks. Nevertheless, there were no examples of how the teachers actually supported their students to be able to assess and provide feedback to each other.

Students' regulation of their own learning (KS5)

Nothing has been found so far.

From the view of the purposes and principles of formative assessment – one example

The questions the BMTs used during the lessons show qualitative difference from the perspective of providing the teacher with useful information to adjust learning activities and providing feedback. The questions that can be answered with a yes or a no are less useful than questions were the students need to explain their thinking. The BMTs used such question to different extent.

Discussion

In this study we aim at identifying aspects of formative assessment that are important for mathematics teachers to be vigilant of and reflect on during and after their TE. Compared to the previous study – where we focused on the development of formative assessment competence of mathematics teachers in early career – this study has a stronger focus on what it means and what it takes to implement high quality formative assessment (see Xu & Brown, 2016; Young & Kim, 2010). When all findings are in place, we will be able to make conclusions about what aspects of formative assessment that were identified as crucial for beginning mathematics teachers. We will then discuss how formative assessment was used by the BMTs; the similarities and differences; what those findings means from the perspective of the purposes and principles of formative assessment; and implications for teacher education. The discussion below is restricted to the preliminary findings.

In all classrooms, the students rarely function as agents in formative assessment processes. This is true for their function as resources for each other (KS4), as well as, for regulating their own learning (KS5). This crucial aspect is also connected to clarifying and sharing learning intentions and criteria of success (KS1). For students to be involved in formative assessment processes, they need an idea of the learning goal and what constitutes progress in that learning. Moreover, the goal of a lesson is often communicated in terms of what pages or tasks to finish. Thus, another crucial aspect is to not take for granted the students' understanding of learning intentions and success-criteria, and maybe even to examine the students' perception of those intentions and criteria.

The differences between the informants reveal other crucial aspects. The teachers' different ways of using questions have different potential for the teacher to receive sufficient information about student learning needs to adjust their teaching and their feedback. Elvin and Tina also stood out by using exit-tickets at the end of their lesson. Regarding feedback, the use of feedback to inform whether the student's thinking is right or wrong can be relevant, but the other types of feedback that were used have higher potential for helping the students to move forward in their learning. The informants' use of feedback to initiate reflection on the solution process and Elvin's feedback answering students' questions, both reveal a crucial aspect about how to get the students involved in feedback interactions. This aspect also includes that the students can be involved in a high-quality way – exemplified by Elvin's student, who asks a specified question that both reveals his learning needs and gives the teacher the opportunity to give effective feedback.

All together, we identified six crucial aspects: Do the students function as resources for each other (i) and themselves (ii)? Does the learning goal surpass the goal of doing and how do the students perceive the learning goal and criteria of success (iii)? Is the information about student learning sufficient (iv), what feedback did actually support students' learning (v); and in what ways are the students involved in feedback interactions (vi)?. We expect to find additional crucial aspects, including aspects that concern the integrated use of the key strategies.

Implications

Implications for TE regard aspects are related to requirements to high-quality formative assessment practice. First, BMTs need to be aware of the importance of having information about students' learning needs and consequences of not having such information, as well as what potential is inherent (or not) in different feedback types (i.e. understand the purposes of and principles on which this classroom practice is based). Second, they need to know what to do when they experience not having enough information and how to decide whether their feedback was helpful and what to do if their feedback was unsuccessful in helping the student (i.e. have ability to incorporate this classroom practice into their teaching). Furthermore, the BMTs need to use a critical reflection on these aspects of quality relating to their understanding of formative assessment practice.

Limitation

In this study the informants participated in the same program at the same university. Possibly, the differences in classroom practice would have been even larger if the informants came from different programs and universities. Another concern is that we will not be able to identify all kind of activities related to formative assessment when only using video-recordings of lessons. We will only be able to identify direct observable activities and phenomena. Regarding both limitations, we believe that – building on the findings from the present study – future studies can find complementing crucial aspects that BMTs need to learn about and reflect on concerning their understanding and need of development. We argue that studying the classroom practice using "in practice data" is a good start.

Formative assessment is a practice that provides ongoing feedback that instructors can adopt to improve their teaching and students can benefit from to improve their learning. Teachers and instructors need training, otherwise formative assessment and immediate feedback could also produce negative results. This paper aims at understanding the evolution of participants’ knowledge and perception of Automatic Formative Assessment throughout a teacher training course. The course was open to STEM teachers of all grades. The analysis considers teachers’ responses to questionnaires with both close-ended and open-ended questions. Results show the empowerment and more awareness of teachers’ application of Automatic Formative Assessment; in particular, teachers developed a more student-centered approach to formative assessment. This experience helped us list a set of recommendations and advice for those who approach Automatic Formative Assessment.

Keywords: Automatic assessment, formative assessment, mathematics teaching, teacher training.

Introduction

Several studies show that formative assessment (FA), when used following proper learning models, is correlated to higher students’ achievements (Black & Wiliam, 1998). Surprisingly, it has been shown that FA and feedback practice could also produce negative results, especially when they are not used appropriately (Kluger & DeNisi, 1996). Many studies point out that a high number of Mathematics teachers lack pedagogical and content knowledge about FA, so they have difficulties in implementing it successfully (Herman et al., 2015; McGatha et al., 2009). Therefore, teacher training is a key element for an effective use of FA in teachers’ daily practice, even more when integrating technologies into assessment. The recent health emergency has required a digitalization of the assessment practices, and this has been one of the most critical aspects of distance education (OECD, 2020). The urgency of re-skilling has been felt by many teachers in the last two years.

This paper deals with an in-service teacher training course on Automatic Formative Assessment (AFA) for STEM teachers, which was held online in Spring 2021. The course was aimed at developing competences in the use of an Automatic Assessment System (AAS) particularly suitable for STEM, and in the design of questions for the FA according to a particular pedagogical model. The goal of this paper is to understand how the teachers’ knowledge and perception of AFA evolved throughout the course. We investigate this issue through a qualitative and quantitative analysis of teachers’ answers to two questionnaires. In the following paragraphs, we will discuss the theoretical framework on AFA and teacher training in Mathematics; then, we will illustrate the structure of the course and the analysis methodology; afterwards, we will present and discuss the results gained and interpret them in light of the theoretical framework; in conclusion, we will provide some hints for the creation and management of activities with AFA, collected through the teachers' experiences.

Theoretical framework

Automatic Formative Assessment in Mathematics

For this study, we accept Black and Wiliam's definition and conceptualization of FA:

> Practice in a classroom is formative to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited. (Black & Wiliam, 2009, p.5)

This definition entails the collection of data about students' understanding, and the use of such data to change the learning path. Their conceptual framework includes five key strategies through which formative practices can be enacted by three agents (students, peers and teachers):

> (S1) clarifying and sharing learning intentions and criteria for success; (S2) engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; (S3) providing feedback that moves learners forward; (S4) activating students as instructional resources; (S5) activating students as the owners of their own learning. (Black & Wiliam, 2009, p.4).

In previous work, we have defined AFA as the use of FA in a Digital Learning Environment through the automatic elaboration of students' answers and provision of feedback, where FA is intended as in the Black and Wiliam's definition (Barana et al., 2021). We have developed and experimented a model for the design of activities with AFA (Barana & Marchisio, 2019), relying on an AAS such as Möbius Assessment, whose engine is empowered by advanced mathematical capabilities. By exploiting programming languages or mathematical packages, similar AASs allow to build interactive tasks based on algorithms where answers, feedback and values are calculated over random parameters and can be shown with different representations. Thus, new solutions for computer-based items can be conceived, including dynamic explorations, animations, and symbolic manipulations, which offer students experiences of mathematical construction and conceptual understanding (Sangwin, 2015). According to our model, AFA activities should: (a) be always available in a Digital Learning Environment, without limitations in data, time and number of attempts; (b) be algorithm-based, so that random values, parameters, formulas and graphs make questions, and their answers change at every attempt; (c) be open-ended; the AAS's mathematical engine assures that open mathematical answers are graded independently of the form in which they are provided; (d) provide students with immediate feedback while they are still focused on the task; (e) provide students with interactive feedback just after giving an incorrect answer. It has the form of a step-by-step guided resolution that interactively shows a possible solving process; (f) be contextualized in real-life, thus contributing to the creation of meanings through the association of abstract concepts to concrete experience.

Teacher Training on Automatic Formative Assessment

In the literature, there are not many studies on teacher training on AFA. Roschelle et al. (2016) showed that combining the use of an AAS and teacher training on how to use assessment information to shape teaching helped improve learning results. The teacher training was mainly based on workshops and coaching. Haj-Yahya and Olsher (2020), in a study involving pre-service teachers, showed that training on FA and on the use of an AAS helped them improve their skills in observing, interpreting and responding to students' work. According to Schütze and colleagues (2017), it is often hard for teachers to put into practice the knowledge gained in teacher development programs. When dealing with teacher training on the use of new technologies, it is common to refer to the TPACK model (Voogt & McKenney, 2017), which aims at integrating technology, pedagogy, and content knowledge for improving teaching skills. Several studies have pointed out that including active learning and job-embedded practices is more effective for improving teaching (McGatha et al., 2009). Moreover, embedding the course in a practice community where teachers can share knowledge and experiences helps them not to feel like isolated learners, empowers their active participation, and boosts the results (Lave, 1991). This aspect is particularly relevant in online courses, especially during pandemic times. Establishing solid AFA practices in the daily teaching is not easy; often, it implies a revolution of one's habits. Supporting teachers in the application of what they have learnt during the course becomes crucial. We based the development of our training course on the following principles:

- providing teachers with technological knowledge and skills about the use and management of an AAS for Science and Mathematics;
- providing teachers with pedagogical knowledge and skills on formative assessment and on the design of tasks for AFA according to our previously cited model;
- embedding the training course in a virtual practice community, where teachers could share materials, experiences, idea, difficulties and find support in their colleagues;
- supporting teachers in the creation of their AFA activities and in their experimentation in the classroom, so that they can feel sustained in their first impact with the change of practices and encouraged to go on in the revolution of their teaching style;
- including teachers, after the training course, in a continuous training program and in a practice community with other expert teachers, so that they can be supported in their future activities.

Methods

Our research about AFA is mainly focused on the training course "Automatic formative assessment in STEM disciplines", delivered 15 hours in synchronous mode and 7 hours in asynchronous mode, where 15 school teachers, 11 of whom teaches Mathematics, learned how to use the AAS Möbius Assessment. Teachers also received methodological training for designing AFA activities according to the model we presented in the Theoretical Framework. In this course, participants had to carry out e-tivities to become confident with the digital environment and to actively enter the community, such as creating items and sharing them in a common database. At the beginning of the course, each teacher had to choose a topic on which to create activities and define learning objectives, and then they identified questions that made the achievement of the objectives stand out. Moreover, they designed feedback that allowed students to bridge the gap between current performance and desired performance and began implementing it with interactive feedback. The last and most important step of the course was to administer the activities they prepared all over the course to their students. The teachers received training and support from tutors, who presented examples of questions and activities and described how to monitor student progress in order to guide, review and modify teaching activities. Tutors actively helped teachers in the delivery of the experimental activities with their students, too. During the course, teachers were encouraged to share their experiences and difficulties through a forum monitored by the tutors, and to share their materials in a common database. After the course, teachers had the chance to enter the wider community of practice of the national “Problem Posing and Solving” Project, which has been adopting similar methodologies since 2012 (Fissore et al., 2020). The course was open to STEM teachers of all grades, from primary to upper secondary education. Also some teachers of humanistic subjects enrolled and followed the course. In total, 24 teachers enrolled in the course. However, we restricted the analyses only to the STEM teachers who reached completion in all the e-tivities and participated in at least 70% of the synchronous meetings.

Teachers had to respond to an initial and a final questionnaire, which represent the main source of data for our analysis. The initial questionnaire asked teachers their previous idea, perception, and usage of AFA, the application of certain methodologies with their classes and their adoption of digital tools. All teachers who attended the first meeting submitted the initial questionnaire. On the other hand, only the teachers who completed the course submitted the final questionnaire. From the final questionnaire we could gather their perception of AFA after the first implementation in the classroom and cast a glance at their future proposal to adopt what they had learned during the course with their students. The questionnaires consist in a mix of close-ended questions (mainly Likert scales) and open-ended questions, thus data collected are both qualitative and quantitative. Concerning quantitative data, we considered the main descriptive statistics, while for qualitative responses we classified the wide range of responses into a smaller number of categories, identified on the basis of the theoretical framework, in order to analyze them: this categorization depends on the researcher's interpretation of the respondents’ responses, thus we compared two independent evaluations.

Results

In the initial questionnaire we asked teachers to give their own definition of FA. We granted them the possibility to answer in an open format, which resulted in a lot of different answers regarding various aspects. The reference to the five key strategies of (Black & Wiliam, 2009) triggered our classification of teachers’ answers in this framework, since we were able to refer them to one or more strategies. All the strategies but one were referenced. S1 was referred in two answers, here we provide an example: “an essential and necessary tool, for both teachers and students, to learn and to communicate”, which highlighted the sharing capabilities of the methodology, and its learning-centered purpose, being communication central for making clear intentions and criteria. S2 was implied in 9 answers out of 15; here we report the most exemplifying: “to understand the learning of the students”, shedding light on the search for evidence of student understanding. S3 is related to two answers, one of them is: “the act of communicating to the student if, and how much, they have acquired the important competences in the context of the course, and how they can improve in the future”; this communication can be regarded by all means as feedback, which allows the learner to move forward. Finally, S5 is mentioned in only one answer: “it has to allow students, in case of errors, to understand and remediate them”: they are invited to master their learning. No answer referenced S4, probably because to be an instructional resource for one another is a process between peers, and therefore probably not the first one a teacher thinks about, albeit the importance of peer instruction and evaluation mediated by teachers is undisputed. Note that some of the answers cannot be properly considered as definitions, regardless of being in accordance with the literature or not: for example, the answer we put in relation with S5 is indeed a feature rather than a true description of the methodology. In three very short answers we could not find any reference to the 5 strategies. The strategy that had been referred to more frequently was, with a large gap, S2: this outcome highlighted how most of the teachers before our course saw FA as a tool centered on themselves, rather than on the students. We also compared the teachers’ answers with the definition of FA (from Black and William, 2009), which considers data collection and their use to improve teaching and learning. Data collection was referred to 10 times, their use to improve teaching and learning 5 times. Teachers also considered the fact that assessment should occur during the course, 6 times explicitly, plus some other answers where it is implied (for example, where FA is described as “a method for detecting students’ knowledge and competences”). We also looked for references to the agents included in the teachers’ definitions (teachers, students, or peers). No answer referred to peers, consistently with the absence of S4; while two answers referenced both teachers and students, the former ones appeared 10 times, while the latter ones only 4. Note that teachers largely included considerations about students’ learning, but mostly without giving them an active role. This is in line with the absence of S4 and confirms a teacher-centric approach to FA before attending the course.

Let us now consider the evolution of the answers relative to the actual use of FA by teachers. Before our course, several of them already made use of it, at least in some of its traits, but it was only after our course that most of them really became aware of its potential. Indeed, before the course, only 2 teachers declared using automatic assessment for FA regularly (most of them, only seldom), while 7 used it for summative purposes with regularity. For example, a teacher stated that she had used formative assessment by assigning students various activities, such as questionnaires, tests, exercises, with a successive discussion on aspects like the difficulties they had faced, the errors they committed, the solving processes. After the course, she recognized that she had acquired more cognizance relatively to the importance of FA, by specifically referring to real time interactive feedback as a tool for giving key support. Another teacher used grids with indicators. However, letting students become aware of how the assessment works or giving them parallels between the evaluation and the formative goals (essentially, S1), is only a first step towards a true obtainment of the strategies’ outcomes. Indeed, answering after our course, she specifically referred to the creation of interactive feedback, with hints also aimed at helping disadvantaged students, in order to let each of them focus on understanding the solving process, rather than on the mere result of the problem. In this context, the use of variable data, thanks to the algorithmic capabilities of the AAS, was recognized as further enhancing the formative scope of a question. A teacher proficiently used automatic means with gamification features, which could be useful to engage students and to foster their interest in using more specific tools for formative assessment, as he noted. Finally, it is noteworthy to take into account one answer before the course, which considered tests, homework checks, actively involving students during lessons, and classroom simulations, in which they were allowed to help one another. The latter feature is important because it references S4, which had been excluded from the answers relative to the direct question about how to define formative assessment. Unfortunately, the teacher giving this answer followed our course only partially, and she did not respond to the final questionnaire, so we are not able to track possible progresses in that direction. These qualitative considerations can be integrated with some quantitative data. In the two questionnaires, we asked teachers some specific questions involving the strategies, in terms of attention devoted, perceived importance, and application capabilities with formative assessment. Specifically, before the course, we asked them how much, in their didactic activity, they paid attention to reaching the goals explicated by the strategies; note that the teachers were generally unaware, at the time, of the relation between the concept of FA and the strategies, as shown by several definitions they proposed. In a Likert scale from 1 to 5, where 1 means "nothing at all" and 5 means "very much", the averages are depicted in row (b1) of Table 1.

Table 1: Average scores of questions relative to strategies, before and after the course

Before (b1, b2) and after (a1)	S1	S2	S3	S4	S5
(b1) Attention paid to strategies and goals	3.5	3.7	3.7	2.9	3.5
(b2) Perceived importance of strategies	3.9	4.1	4.3	3.9	4.5
(a1) Help in applying strategies from AFA	3.5	3.9	4.2	3.1	4.1

It emerges again how, while the other strategies were generally present in the teachers' practices, with an average considerably higher than the midpoint 3, S4 underwent a weaker trend. A similar question regarded again the strategies, but in terms of how much teachers perceived them as important for learning. Two aspects emerged from the row (b2) of Table 1: the first one is the higher marks, likely because it is easier to think about a strategy than actually apply it; the second one is how S4 is still the weak link, although the differences between the other ones are less marked. Finally, after the course, we asked teachers how much they thought AFA would be able to help them in applying the strategies. It can be noted that the averages of row (a1) in Table 1, in comparison with those relative to the attention paid before the course, namely row (b1), increased in the score for all strategies except S1 ranging from +0.2 to +0.6. It can mean, as a general remark from the scores, that teachers recognized the importance of these strategies and of their goals and outcomes throughout the course.

We now give an example, in Figure 1, of a question designed by a teacher towards the end of our course. It has been proposed as an algorithmic question, which means that random parameters allow the exercise to be repeated with different values, and with interactive feedback in case of a wrong answer. The coefficients are random integers in a proper range, generated every time the question is accessed. If the correct answer to the first section is given at the first or at the second attempt, the exercise ends, and the student obtains a full score. If none of the two attempts results in the correct answer, as in Figure 1, subsequent sections open, guiding the student towards the solution by asking questions relative to intermediate steps, with the partial score that can be seen as an indicator of the student still needing help and refinement of their preparation (see the strategies). Note that in formative assessment scores are not as central as in summative assessment, but they can be of some help anyway along the other feedback, for example in moving students forward and letting them aware of their own learning, that are S3 and S5.

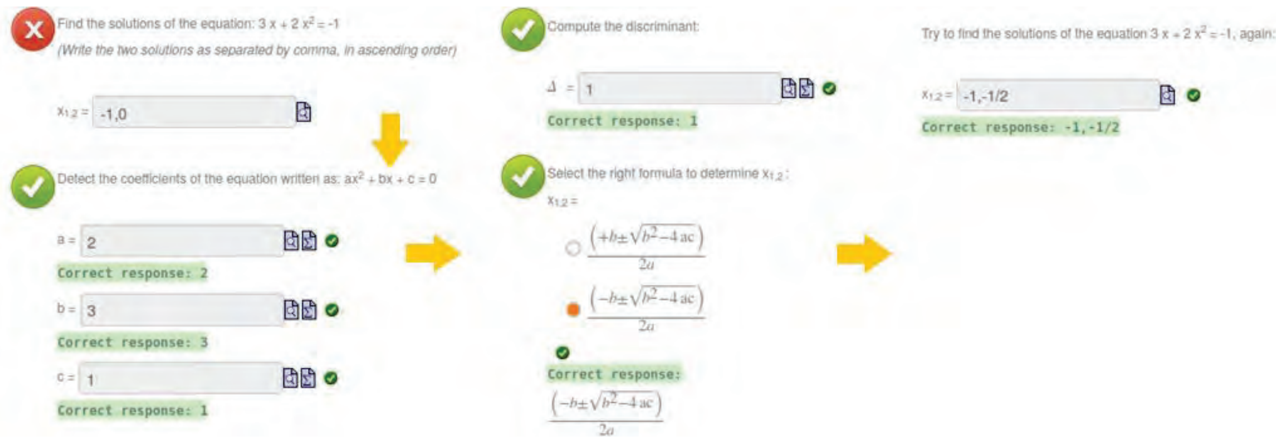

Figure 1: A question designed by a teacher (*sections up to down, then left to right*)

Discussion and conclusions

AFA is a relatively new area of research and there is a need for teacher professional development on the use of it, as well as of research about the impact of training on teachers' practices with AFA. This study presents some limitations; first of all, the low number of teachers involved, which hinders generalization of the results. However, thanks to this study, we were able to observe the evolution of the teachers' knowledge and perception of AFA during a training course. If at the beginning of the course teachers tended to use automatic assessment as distinct from FA, throughout the course they learned to integrate the two methodologies, taking advantage of the potential of the digital technologies to empower the formative practices. We also observed that teachers mostly had a teacher-centered perspective of FA at the beginning of the course. They were used to paying more attention to proposing task in order to collect evidence of students' understanding rather than activating students in covering the gap between actual and desired performance. Their answers could suggest that the course may have given them the necessary tools to give students ownership of their learning during assessment. This resulted both from their answers to the final questionnaire, and from the increase in the scores given to the item relative to S5 after the course, which is not extremely strong (+0.6), but is the highest one. According to the teachers, the provision of feedback to move the learner forward is particularly enhanced by AFA, when implemented according to our model. The training modalities helped teachers to gain experience in the use of AFA, encouraging them to carry on this path. They perceived the usefulness of the course especially in a context of hybrid or face-to-face teaching. Thus, they participated actively and enthusiastically, despite the online training modality, also because the trainers tried to stimulate confrontation and discussion during the synchronous meetings.

Designing for a combined use of a dynamic mathematics software environment and a computer-aided assessment system

Mats Brunström, Maria Fahlgren, Mirela Vinerean and Yosief Wondmagegne

Karlstad University, Department of Mathematics and Computer Science, Sweden; mats.brunstrom@kau.se, maria.fahlgren@kau.se, mirela.vinerean@kau.se, yosief.wondmagegne@kau.se

This paper reports on a pilot study with the focus on (re)design of a digitized task environment utilizing two types of technology – a dynamic mathematics software and a computer-aided assessment system. The data consist of responses from 256 first year engineering students, taking their first Calculus course, on two different types of task. The results are discussed in relation to (re)design of tasks as well as possible feedback design options to enable a formative assessment approach.

Keywords: Asymptotes, dynamic mathematics software, computer-aided assessment, task design, feedback.

Introduction

Central in introductory Calculus courses – a critical course for first year engineering students – is the concept of functions. For example, Oehrtman et al. (2008) highlight a weak function understanding as one of the reasons why many students fail in their first undergraduate mathematics courses. Oehrtman et al. (2008), in discussing important features of students' function understanding, advocate a focus on promoting "…rich conceptions and powerful reasoning abilities…" (p. 27), and not merely "…symbolic manipulations and procedural techniques…" (p.28).

As one way to foster students' conceptual understanding in mathematics, the literature suggest utilizing dynamic mathematics software (DMS) environments for student collaboration on inquiry-based tasks, particularly in relation to functions (e.g. Brunström & Fahlgren, 2015; Jaworski & Matthews, 2011). Today many mathematics courses in higher education utilize computer-aided assessment (CAA) systems (e.g. Rønning, 2017), in which it is possible to embed DMS environments (Sangwin, 2013). However, there are few studies that have investigated the integration of these two types of technology (Luz & Yerushalmy, 2019). Indeed, designing tasks that utilize the affordances provided by a DMS environment and that also can be automatically assessed by a CAA system adds to the already established complexity of designing tasks for interactive learning environments that promote mathematical understanding (Joubert, 2017).

This paper reports some results from a pilot study conducted during autumn 2020 with the aim of trialling different types of task designed for a combined use of DMS and CAA, and to get a deeper understanding of student strategies when performing these tasks. Findings from the pilot study will inform the (re)design of tasks as well as the development of possible types of automated feedback to increase first year engineering students' engagement and conceptual understanding of functions.

Theoretical framing

Besides topic-specific theories, related to mathematical functions, the task design was guided by theories associated with student generated examples and theories on feedback.

Functions and graphs

It is well established that for students to comprehend the concept of functions it is essential to be able to move flexibly between different representations, such as formula and graph (Leinhardt et al., 1990). Moreover, according to Duval (1999), representation and visualization are at the core of mathematical understanding. He distinguishes between two cognitive operations; processing and conversion, where the former concerns mathematical processes made within the same representation, such as algebraic manipulations, and the latter means changing between different representations. While many students can learn processing, it is the conversion, e.g. to translate a formula into a graph or vice versa, that many students find challenging (Duval, 1999). In particular, it is the translation from graph to formula that is the most challenging (Leinhardt et al., 1990). Furthermore, this kind of task, referred to as ‘translation task’ in this paper, is suitable for a CAA system since it can recognize any correct form of the function formula.

Student generated examples (SGEs)

Prompting students to generate examples that fulfil certain conditions has been proposed as a way to engage students actively in their development of conceptual mathematical understanding (e.g. Watson & Mason, 2002). This idea has been adapted to CAA systems since it allows for automatic assessment of higher-order mathematical skills (Sangwin, 2003). In this paper we use the notion ‘SGE task’ when referring to tasks using this idea. To further challenge students’ thinking Yerushalmy et al. (2017) suggest asking students for several examples, which differ as much as possible. Moreover, Yerushalmy et al. emphasize the importance of designing feedback on students’ responses on such tasks to support their mathematical reasoning processes (2017).

Feedback

So far, CAA systems have mainly been used for assessing basic mathematical procedural skills. It is a challenge to design tasks for a CAA system that address higher-order skills in mathematics, and to design feedback that goes beyond categorizing a final answer as being right or wrong (Rønning, 2017). In the wider literature, this type of feedback is referred to as ‘elaborated feedback’ (e.g. Shute, 2008). In a meta study investigating the effects of computer-based feedback on students’ learning outcomes, van der Kleij et al. (2015) found that elaborated feedback was more effective than verificative types of feedback, especially for higher-order skills. In particular, the eight studies related to mathematics pointed in this direction.

When interacting with a DMS environment, the other type of technology reported in this paper, students are provided instant feedback on their action. It is this feedback that makes it possible to use a DMS environment as an arena for exploration, conjecturing, verification, and reflection. However, this feedback does not provide explicit suggestions on how to proceed, and thus the benefit of the feedback depends on students themselves being able to interpret the results of their actions in the DMS environment (Olsson, 2018). By embedding DMS tasks in a CAA system and utilizing the affordances provided by the two types of technology, we endeavor to enhance the provision of feedback – the goal of our upcoming project.

Method

Research context

The pilot study took place at a Swedish university, involving 256 first year engineering students taking a first course in Calculus. The course assignment included small group activities, in the form of task sequences focusing on function understanding, designed for a combined use of a DMS environment (*GeoGebra*) and a CAA system (*Möbius*). However, there were also tasks with individual elements for each group member requiring an individual answer, to ensure active involvement by all students.

This paper will examine patterns of student response to two related tasks concerning rational functions, and specifically the relationship between asymptotes and function formula. In the light of these patterns, we will offer thoughts on the types of elaborated feedback that could be beneficial, and also provided by an automated assessment system.

The tasks

Task 5 (see Figure 1) is an example of a 'translation task' intended to be solved in groups. Students are expected to realize that it must be a rational function with one horizontal and two vertical asymptotes. Then, they are supposed to utilize the vertical asymptotes to construct the (factorized) denominator, and the horizontal asymptote to conclude that the numerator should be of degree two with the coefficient 2 in front of the x^2 term. However, there is a need for further information to arrive at a final formula, i.e. two points on the graph. The reason behind asking for an explanation (Task 5b) was twofold; both to promote student reasoning, and to provide insight into student strategies when solving the task.

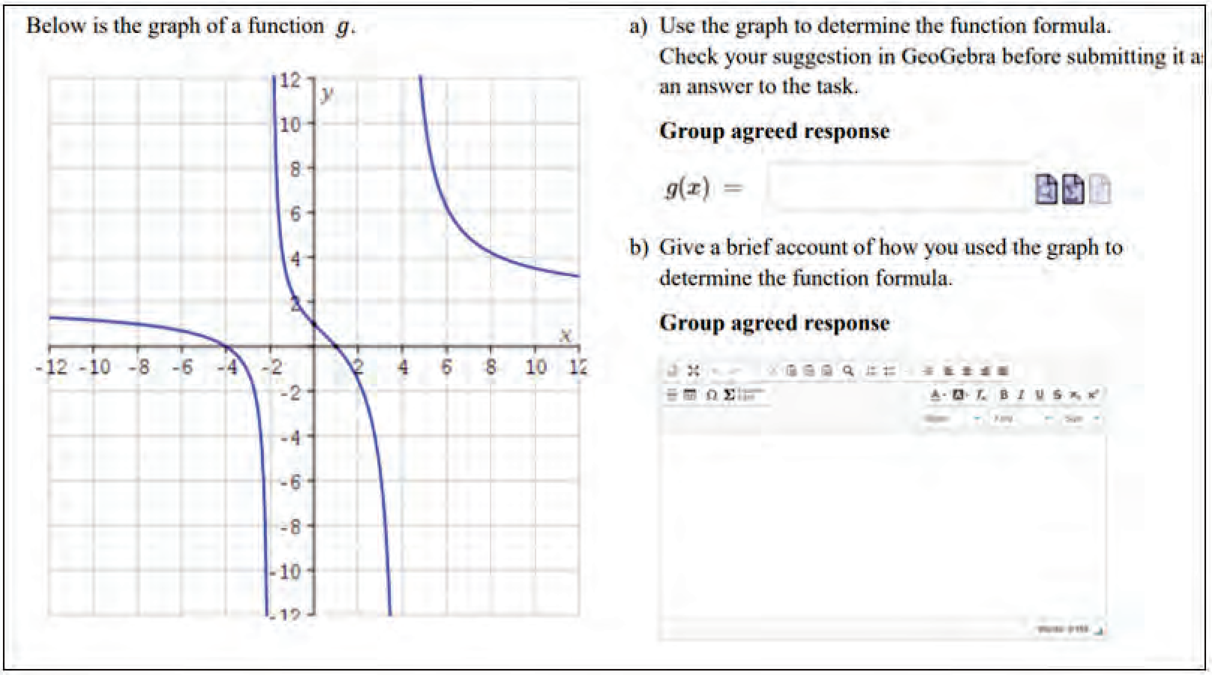

Figure 1: Task 5 as it is presented in Möbius

Task 7 (see Figure 2) is an example of a 'SGE task' in which students received different values of the asymptotes, and were supposed to provide individual answers. This task closely relates to Task 5 in that it involves two vertical asymptotes and one horizontal asymptote. In performing this task, students are supposed to consolidate the key ideas addressed in these tasks.

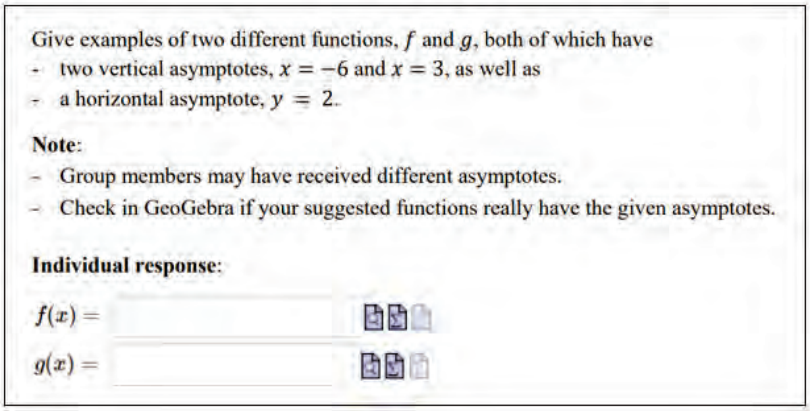

Figure 2: Task 7 as it is presented in Möbius

Data collection and analysis

The data used to analyse student responses to these tasks consists of their answers submitted to the CAA system. The data analysis process involved several stages. To provide an overview of the data material, we made a preliminary analysis based on about a quarter of the submitted responses. This overview of students' various responses to the tasks gave insights into interesting instances. For example, when students provided unexpected responses, i.e. not in line with the expected solution strategy, or when it was a wide range of student responses. In addition, this preliminary analysis generated initial codes to be further developed and used in the next stage of the analysis process. At this stage, all responses to the tasks were analysed and coded. Next, the initial codes were organized into categories to discern general patterns in the data material (Saldaña, 2013). The categories obtained for these tasks are introduced in the tables in the Result Section.

Results

Table 1 provides an overview of the group responses, in terms of function formulas, to Task 5a.

Table 1: Overview of the responses provided in Task 5a[1]

Code	Description	Function formula	Frequence
Formula 1	Single quotient	$g(x) = \frac{2(x+4)(x-1)}{(x+2)(x-4)}$	47 (46,5%)
Formula 2	Partial fraction, reduced quotients, and the constant term 2 (i.e. the horizontal asymptote)	$g(x) = \frac{2}{x+2} + \frac{8}{x-4} + 2$	17 (16,8%)
Formula 3	Reduced quotient, and the constant term 2 (i.e. the horizontal asymptote)	$g(x) = \frac{10x+8}{(x+2)(x-4)} + 2$	22 (21,8%)
Other	Not categorized		9 (8,9%)
No answer			6 (5,9%)
Total			101 (100%)

[1] In some responses, the numerator and/or the denominator is/are not factorised.

Mainly three types of formula were observed. Almost half (47/101) of the groups used Formula 1. Notable is that as many as 39 of the groups gave a Formula 2 (17) or a Formula 3 (22) response. These types of formula have not been present either in the textbook or in lectures when treating asymptotes in the course. Examples presented at lectures concerning horizontal asymptotes has been in the form $\frac{p(x)}{q(x)}$, where $p(x)$ and $q(x)$ are polynomial functions of the same degree (except when the horizontal asymptote is $y = 0$). Among the 9 responses not categorized, there are 4 incorrect answers.

The group responses to Task 5b provide some information about students' thinking behind their answer in Task 5a, since they were encouraged to explain how they arrived at a particular function formula. Group responses were inspected and compared to identify a set of elements of explanation which could be used to summarise the content of any response. This made it possible to code the responses in terms of explanation elements, i.e. descriptions of what students referred to.

In Table 2, an overview of the explanation elements provided by the student groups is given. The rightmost column shows the total number of each explanation element among the group responses. Almost all groups (82/86) explicitly refer to the vertical asymptotes in their explanation. However, all the categorized formulas (1 to 3) indicate that all 86 groups, that provided a function formula, utilized the vertical asymptotes. Similarly, the constant term in Formula 2 ($g(x) = \frac{2}{x+2} + \frac{8}{x-4} + 2$) and Formula 3 ($g(x) = \frac{10x+8}{(x+2)(x-4)} + 2$) indicate that these groups have utilized the horizontal asymptote, even though eight of these (39) groups did not mention this in their explanation.

Table 2: Overview of the explanation elements referred to in Task 5b

Type of formula / Explanation elements	Formula 1	Formula 2	Formula 3	Total
Vertical asymptotes	46 (97,9%)	16 (94,1%)	20 (90,9%)	82 (95,3%)
Horizontal asymptote	16 (34,0%)	16 (94,1%)	15 (68,2%)	47 (54,7%)
Zeros	44 (93,6%)	0	0	44 (51,2%)
One further point	22 (46,8%)	3 (17,6%)	0	25 (44,6%)
GeoGebra	5 (10,6%)	3 (17,6%)	6 (27,3%)	14 (16,3%)
Equation system	1 (2,1%)	7 (41,2%)	10 (45,5%)	18 (20,9%)
Total	47	17	22	

A closer look at the Formula 1 responses reveals that the predominant (46/47) characteristic of the associated explanations was to refer to the vertical asymptotes (to form the denominator of a single quotient expression as the product of the corresponding linear factors). The predominant (44/47) approach was then to refer to the zeros of the function (to form a numerator for the quotient expression as the product of the corresponding linear factors). One further step is needed to complete the quotient expression. Only 16 groups (out of 47) used the approach that the task design hoped to elicit, i.e. to use the horizontal asymptote to establish a limiting value for the quotient expression as $x \to \infty$. Thus, the remaining 31 groups did not refer to the horizontal asymptote as an explanation (see Table 2) for the factor 2 (of the numerator). Among these 31 groups, 22 refer to one further point, 5 to GeoGebra, and one group to a system of equations. Hence, we can conclude that at least 28 groups (out of 47) did not utilize the horizontal asymptote.

In Task 7, each student response consists of two examples of function formulas. However, since few students (6/256) provided a different type of formula in their second example, only the first example is reported in this paper. Table 3 provides an overview of the types of formula discerned (based on the numerical values in the example in Figure 2) as well as the total number of responses belonging to each category (the rightmost column). Moreover, Table 3 shows the correspondence between these answers and the group answer on Task 5a.

Table 3: Overview of each individual response to Task 7 in relation to their group answer in Task 5a[2]

Formula Task 5a / Formula Task 7	Formula 1	Formula 2	Formula 3	Not categorized	No answer	Total
$f(x) = \frac{2x^2 + ax + b}{(x+6)(x-3)}$	26 (20,8%)	2 (4,3%)	3 (5,4%)	1 (5,6%)	5 (50,0%)	37 (14,5%)
$f(x) = \frac{a}{x+6} + \frac{b}{x-3} + 2$	16 (13,1%)	30 (63,8%)	8 (14,3%)	1 (5,6%)	2 (20,0%)	57 (22,3%)
$f(x) = \frac{ax+b}{(x+6)(x-3)} + 2$	75 (61,5%)	14 (29,8%)	43 (76,8%)	15 (83,3%)	2 (20,0%)	149 (58,2%)
$f(x) = \frac{x^2 + ax + b}{(x+6)(x-3)} + 1$	4 (3,3%)	1 (2,1%)	0	0	0	5 (2,0%)
No answer	4 (3,3%)	0	2 (3,6%)	1 (5,6%)	1 (10,0%)	8 (3,1%)
Total	125	47	56	18	10	256 (100%)

The predominant (149/256) type of formula used was a reduced quotient and the horizontal asymptote as a constant term ($f(x) = \frac{ax+b}{(x+6)(x-3)} + 2$). Notably, quite a few students (37/256) expressed the formula as a single quotient, i.e. in the form $\frac{p(x)}{q(x)}$.

As there were no zeros given in Task 7, it is primarily the group answers Formula 2 and Formula 3 in Task 5a that closely relate to the answers in Task 7; Formula 2 ($f(x) = \frac{2}{x+2} + \frac{8}{x-4} + 2$) corresponds to the second type of formula (in the leftmost column) and Formula 3 ($f(x) = \frac{10x+8}{(x+2)(x-4)} + 2$) corresponds to the third type of formula. Most of these students use the same type of formula in their individual response, 63,8% and 76,8% respectively, as in their group answer. However, Table 3 shows that as many as 29,8% of the students who used Formula 2 in Task 5a switched to the third type of formula ($f(x) = \frac{ax+b}{(x+6)(x-3)} + 2$) in Task 7. Moreover, few students that responded Formula 2 (4,3%) or 3 (5,4%) in Task 5a provided an answer in the form $\frac{p(x)}{q(x)}$ in Task 7. Overall, Task 7 worked

---

[2] In the student responses, different numerical values are used instead of *a* and *b*.

well in that most of the students seemed to realize how they could use all asymptotes to produce a function formula.

Discussion

As stated in the introduction, this pilot study will inform the (re)design of tasks as well as the development of possible types of automated feedback. In this section, we elaborate on this issue in relation to the findings.

Since the intention with the ‘translation task’ (Task 5) was to encourage students to reflect on the relation between a function graph with asymptotes and its formula, the high number of Formula 1 responses (to Task 5a) without reference to the horizontal asymptote in the explanation was unexpected and undesirable. One way to tackle this issue might be to use a graph without evident zeros. However, the possibility to use different approaches based on various graph features may promote instructive student discussions. Another way could be to indicate the asymptotes in the graph. However, since the identification of asymptotic behavior in a graph is central in understanding rational functions, this might simplify the task too much.

Yet another way to tackle this issue is to develop automated and adapted feedback, which in turn require a redesign of Task 5b. Instead of asking for an explanation, ask students to declare the explanation elements used by choosing among various suggested options. Depending on their response, they will receive different elaborated feedback (Shute, 2008). For example, if they not have used the horizontal asymptote, they will be asked to solve a new task in which they are (explicitly) asked to utilize the horizontal asymptote.

Also, when considering that almost 10% of the student groups failed to provide a correct answer to Task 5a, there is a need for developing formative instant feedback for these students. One suggestion is to offer the students a second chance to solve the task after they have been watching a short video introducing the key ideas addressed in the task.

The ‘SGE task’ (Task 7) worked well, and revealed various student strategies. However, almost all students provided the same type of formula in both their examples. Since we think that it is instructive for students to realize that there are various ways of thinking, which results in different types of formula, it would have been great if the CAA system could recognize the type of formula used by a student. So, for example, if a student uses a formula of the following type: $f(x) = \frac{ax+b}{(x+6)(x-3)} + 2$ (in both examples), the elaborated feedback (Shute, 2008) could be something like: “Great, the answers are correct. However, another correct answer could be: $f(x) = \frac{2x^2}{(x+6)(x-3)}$. How do you think a student who came up with this answer has been reasoning? Now, use this strategy to provide an example of a function with the following asymptotes…”

The study is limited by the lack of information on how students utilized the DMS environment to check their conjectured function formulas before submitting them as answers to the tasks. To be able to further develop the task design, particularly the formative feedback from the CAA system, we need to better understand the reasoning behind students’ various responses. This requires empirical data in terms of screen recordings (including audio) from students ‘ongoing work. Consequently, we suggest this as a natural progression of this pilot study.

Assessment of/for/as online learning: Mathematics teachers' views on online assessment during the COVID-19 pandemic

Hui Min Chia and Qiaoping Zhang

The Education University of Hong Kong, Hong Kong SAR; s1131888@s.eduhk.hk

Assessment is an important aspect of mathematics teaching and learning. This paper aims to explore Hong Kong mathematics teachers' views on online assessment during the COVID-19 pandemic. The data analysed is part of a larger project comprising an online survey and semi-structured interviews. This paper presents data from the survey responses of ninety-two teachers and from interviews of three teachers. Thematic data analysis is conducted, focusing on teachers' views on assessment during online learning. Findings show that the forms of assessment that Hong Kong mathematics teachers conducted during the pandemic were similar to those from before the pandemic. They view online assessment mainly as assessment for and of online learning. This paper also discusses suggestions for online mathematics assessment.

Keywords: Online teaching, assessment, mathematics teachers' views.

Background

Assessment plays a crucial role in supporting teaching and learning at school (Black & Wiliam, 1998, 2011). Harlen (2007) denoted assessment as "the process of gathering, interpreting and using evidence to make judgments about students' achievements in education" (p. 11). The students' achievements include their knowledge, attitudes, or skills. This process may occur inside or outside the classroom. Assessments can be formal (e.g., an examination or test) or informal (e.g., a conversation between teacher and student), external or internal. Moreover, according to their different functions, assessments can be categorised as summative or formative. Summative assessments refer to those that measure what students have already learned. Teachers may design them for several purposes, such as grading and selecting students, or evaluating experiences regarding a teaching unit. In contrast, formative assessment primarily focuses on informing learning and teaching by providing feedback to students and teachers (Curriculum Development Council [CDC], 2017; Hodge & van den Heuvel-Panhuizen, 2014). Regardless of the forms of assessment, teachers play an important role in the process of assessment (Black & Wiliam, 2011). During the COVID-19 pandemic, all the learning activities are conducted by online mode, including the assessments. Teachers' role became even more crucial during the pandemic. How to conduct online assessment may become challenges for many teachers.

Although assessment is an integral part of curriculum planning, pedagogy, and assessment cycles, there often exists "a major gap between the nature of the planned and implemented curriculum" (Morris, 1995, p. 43). For example, in Hong Kong, the formal curriculum stresses the formative role of assessment by teachers; however, when the curriculum is implemented, internal assessments are frequently based on those used in public examinations (Morris, 1995). During the online teaching, it is necessary to know whether such gaps still exist and how they have been changed. Online assessment refers to any form of assessment conducted during or after online learning, for example, online quizzes, online submissions of homework, online question sessions, and other online interactions. Although some teachers have previously used e-learning tools (such as Kahoot!, GeoGebra, and Google Forms) to teach in traditional classrooms, conducting online assessment is a new challenge for most. Teachers' views on assessment can influence their teaching practices, especially in a new context, such as using online assessment during online teaching (Kaiser et al., 2017; Mirian & Zulnaidi, 2020). By using e-learning methods, teachers can give rapid and accurate feedback to students, which contributes positively to students' motivation for learning (Becta, 2003). However, many barriers and challenges also exist for teachers when conducting online teaching (Jones, 2004; Dhawan, 2020). For example, students in online courses may also feel isolated and disconnected from the instructor and other learners (Choy et al., 2002). The lack of student-teacher interaction in online classes is another primary concern (Mayes, 2011).

Because of the COVID-19 pandemic, teaching online has become a new normal approach worldwide. Given the significance of online assessment in mathematics classrooms, there is a need to examine how technology influences the forms of assessment teachers conduct and their experiences during online teaching. Hence, this paper aims to explore mathematics teachers' views on online assessment during the pandemic. Specifically, this paper investigates four research questions:

1. What kinds of assessment did mathematics teachers use during online learning?
2. What did teachers think of conducting online assessment during online learning?
3. What types of constraints did teachers face in conducting assessment during online learning?
4. How did teachers deal with the constraints on online assessment?

Assessment of/for/as learning in mathematics

Assessment in mathematics can be both summative and formative. Summative assessment focuses more on providing a comprehensive and summary description of students' performance and progress in learning. On the other hand, formative assessment focuses more on diagnosing students' strengths and weaknesses in learning, providing feedback, and reviewing learning and teaching strategies (CDC, 2017). In general, assessment can serve the following three purposes: assessment *of* learning, assessment *for* learning, and assessment *as* learning.

Of these three purposes, assessment *of* learning aims to provide learners with results about what they have achieved in their learning within a certain period (Harlen, 2007). Assessment methods for this purpose include testing at the end of a class session, as well as formal examinations in the middle or at the end of the academic year. Assessment can sometimes also take the form of homework, whereby the teacher gives grades to learners. Next, according to Mok (2011) and Harlen (2007), assessment *for* learning uses assessment methods to provide learners with feedback to assist their future learning. Such methods focus on monitoring and providing feedback to learners during mathematics classes. They can take the form of question-and-answer (Q&A) sessions or classwork. Finally, assessment as learning uses assessment methods to develop self-monitoring (Earl, 2013) and self-directed learning (Mok, 2011) among learners. For such assessments, learners assume an active role in their learning process, unlike for the other two purposes, for which the teacher initiates the learning.

In existing literatures, the above concepts mainly apply to how teachers conduct assessment in physical learning contexts (see Black & Wiliam, 2011; Earl, 2013; Harlen, 2007; Mok, 2011). Conceptual frameworks for analysing teachers' views on assessment during online teaching and learning remain limited. Hence, we are proposing assessment of/for/as online learning as a framework to analyse teachers' views on online assessment during the pandemic. In this paper, online assessments are not limited to strictly online forms, such as live Q&A sessions or online quizzes during online learning, but also include forms that involve a physical component, such as answering questions from textbooks or workbooks to be submitted after online learning.

Methodology

This study examines data extracted from a large comparative study between Hong Kong and Italy, designed as an exploratory study to investigate mathematics teachers' views on online teaching and learning. Data presented in this paper is original and not have been published previously. The study comprised an online survey and semi-structured interviews following the survey.

Participants

Participants were recruited by random sampling through emails and social media. A survey link was distributed online through social media. For this study, assessment-related responses from 92 Hong Kong mathematics teachers were selected, as shown in Table 1. Three interview cases in which "assessment" was mentioned were also selected to support the findings from the survey.

Table 1: Background of selected teacher participants

School level	Teaching experience (years)				Total
	<5	5–10	11–15	>15	
Primary	9	7	5	18	39
Secondary	31	10	4	8	53
Total	40	17	9	26	92

Instrument

A team of researchers from Hong Kong and Italy designed the online survey instrument, which comprised 13 items. Four items captured background information, while the other nine open-ended questions related to teachers' views on online teaching and learning. For instance, item 9 read: "During distance teaching, do you think that your way of teaching mathematics somehow changed? Please explain." Teacher participants were required to state whether any changes in their teaching practices occurred during the pandemic and to provide explanations for them. This paper presents the data extracted from the nine open-ended questions, comprising responses related to assessment during the pandemic.

Data analysis

Data were imported into the analytical software NVivo 12 Pro to conduct thematic analyses on both survey and interview data. For both sets of data, the original interview transcripts in Chinese were used to prevent important information from being lost during translation. Translations are only done for data presented in the results.

Themes related to assessment, such as online assignments, classwork, homework, tests, and evaluations, were first identified from the survey data. Then, similar themes were combined and merged into four major assessment methods: classwork or homework, live Q&A, tests or quizzes, and evaluations. Meanwhile, data related to constraints on and unsuccessful implementations of assessment were coded under the node constraints. Thereafter, based on the proposed framework regarding views on assessment, the data was further coded according to the purposes of "assessment *for* online learning", "assessment *of* online learning", and "assessment *as* online learning". The numbers and percentages of teachers in each coding category were then recorded and calculated. For the interview data, themes that expressed positive and negative views were grouped separately to provide more information about teachers' views.

Results

Online survey

There were 92 teachers who mentioned "assessment" during distance learning in online survey. Table 2 shows that teachers used four main types of assessment during distance learning and the constraints related to the forms of assessment used. 42.39% of teachers used classwork or homework to assess student's learning. For example, one teacher mentioned, "[I] gave students assignments through Google Classroom, marked them and returned them to students." About 6.52% of teachers mentioned they posed questions during online teaching sessions to assess students' understanding. For example, another teacher responded that "[I] need to ask questions frequently to know their learning progress." 16.30% of teachers revealed they had conducted online tests or quizzes to assess their students' understanding, using online platforms such as Kahoot! and Quizizz. A third teacher mentioned that they dealt with distance learning by using "some online interactive platforms, for example, Kahoot! and Nearpod are used to get feedback from students." Lastly, 11.96% of teachers mentioned that they used assessment for general evaluation, without specifying in which form, such as "[I] used Google Meet to follow up student's learning progress too."

Table 2: Forms of assessment used and constraints faced by Hong Kong mathematics teachers during the pandemic

	Classwork/homework (%)	Live Q&A (%)	Test/quiz (%)	General evaluation (%)
Forms of assessment	42.39	6.52	16.30	11.96
Constraints	23.91	7.61	10.87	44.57

There was 44.57% of the 92 teachers disclosed their unsuccessfulness or difficulties in conducting assessment during distance learning for general evaluation (Table 2). As one teacher mentioned, "[it was] more difficult to assess student's level of understanding and did not manage to conduct assessment for learning effectively." 23.91% of teachers reported constraints in assigning, monitoring, marking, or collecting classwork or homework. For example, they were unsuccessful in "monitoring students' progress in doing classwork". Meanwhile, 10.87% of teachers said they struggled to conduct a test to assess their students' learning progress. For example, another teacher said that "a test could not be held". Lastly, 7.61% of teachers reported difficulties in conducting assessments during online live teaching; a teacher stated, "[I] did not manage to ask different types of questions to students to assess their learning progress".

There were 61 teachers who provided explicit descriptions about their views on online assessment, as shown in Table 3. Of these 61 respondents, 39.34% viewed assessment as being *for* learning in general. Most of these respondents gave general answers about assessment purposes, such as monitoring students' progress. 37.70% of teachers view assessment as being *for* online learning through classwork or homework. For example, one teacher mentioned, "[I] used Google Forms for homework" to deal with online teaching and learning during the pandemic, reflecting the purpose of assessment *for* online learning. Lastly, 24.59% of teachers viewed assessment as being *of* online learning through tests or quizzes. As reported in their survey responses, they manage to "[conduct] evaluation of learning progress [by using] Quizizz App", reflecting the purpose of assessment *of* online learning.

Table 3: Teachers' views on online assessment during the pandemic

Views on assessment	Classwork/ homework (%)	Live Q&A (%)	Test /quiz (%)	Evaluation (%)
Assessment for online learning	37.70	16.39	9.84	39.34
Assessment of online learning	6.56	0	24.59	4.92
Assessment as online learning	11.48	1.64	1.64	1.64

Online interviews

Data analysis of the online teacher interviews revealed that overall, Hong Kong mathematics teachers had differing views about the conduct and outcome of assessment. This section describes three cases selected from the interview data to represent teachers with negative, positive, and mixed views, respectively. The negative views recorded such as assessment being difficult, problematic, and ineffective, positive views included technology tools have made the assessment easier and mixed views with both positive and negative aspects.

Janet, a secondary mathematics teacher with less than five years of teaching experience, hold a negative view about online assessment. She thought online assessment was difficult to be conducted. She changed from grading students' homework using Google Classroom to assigning homework and conducting live teaching through online platforms such as Zoom and Kahoot! to assess students' learning. She commented:

> It was very difficult to assess [students' learning]. This was because they may not complete their homework alone. [Then], last time in school, a short test could be conducted [during the lesson]. [But] now [the test] cannot be conducted because it [would be] unfair to [other students] if we conducted [the test] with them.

Janet's responses reflected her emphasis on assessment *for* online learning to assess students' learning during live teaching and through assigning homework. However, constraints existed for the effectiveness of online assessment through homework, in the sense that certain students might not complete their homework independently (assessment *as* online learning). Besides, she had concerns about the validity and fairness of conducting tests (assessment *of* online learning).

Conversely, Nick, a secondary mathematics teacher with less than five years of teaching experience, viewed using technology in assessment positively. He used Zoom for live Q&A to help students who had problems with homework and Google Forms to assess students' learning during distance learning (assessment *for* learning).

> In my opinion, since we have to use technology [now], [then] we have to fully utilise it: why use [the technology] just because we have to? … From the online teaching and learning perspective, objective questions are easier [for students to handle] … In my view, students' self-discipline is very important in the online [teaching and learning] mode.

Nick focused on live Q&A to assist students in their learning, whereby students had to take initiative to ask questions during live teaching sessions (assessment *as* online learning). He then used multiple-choice questions instead of written questions to evaluate his students (assessment *of* online learning) during the pandemic. He changed his assessment methods to enable students to answer questions. Furthermore, he emphasised the importance of assessment *as* online learning during online teaching and learning.

Lastly, Marry, a primary mathematics teacher with over 15 years of teaching experience, held mixed views on online assessment. During distance learning, she used the online platform Power Lesson to upload video recordings and assign exercises to students. She also assigned more multiple-choice questions to students online (assessment *of* learning). However, due to requests from parents, she started to incorporate live Q&A via Zoom (assessment *for* learning) into existing assessment methods:

> You will feel like you are talking alone. I do not know whether they learned something or not, whether they completed [their work], I do not know too. So, I feel the difficulty is I have to treat them as [if] they [had] never [learned it] before.

For Marry, her initial approach to assessment reflected her view of assessment *as* online learning, whereby students completed assigned exercises by themselves after watching her video recordings. Her comments on not receiving responses from students during live teaching sessions reflected constraints in assessment *for* learning. During the interview, she further commented that it was problematic that students did not cooperate during group work (assessment *as* learning). Then, she could not request students to write their answer on the whiteboard (board work) and review their work during live teaching (assessment *for* learning).

Discussion

The present study aims to explore Hong Kong mathematics teachers' views on online assessment during the COVID-19 pandemic. Findings show that the online assessments that teachers conducted during online learning were similar to the face-to-face assessments they conducted during in-person learning. These assessments would be conducted during class time, such as through classwork and Q&A sessions. Then, homework or tests were assigned or conducted at the end of class. Mok (2019) reported similar features in the data collected during 2016: normal face-to-face assessments in Hong Kong mathematics classes took the form of individual classwork, with the teacher walking between desks to monitor students' learning progress. The finding shows most Hong Kong mathematics teachers viewed assessment as being *for* online learning and *of* online learning during the pandemic. Teachers paid more attention to what students learned from the class and valued their performance. This may be due to cultural influences, such as the Chinese culture and the culture of examinations (Wong et al., 2012). Teachers also acknowledged the importance of students' autonomy in online assessments, which reflected the purpose of assessment *as* online learning.

The constraints that Hong Kong mathematics teachers reported primarily concerned the effectiveness of online assessment, as well as students' autonomy in completing homework and participation in live teaching sessions. The constraints that were reported, especially regarding students' autonomy were common challenges that teachers worldwide faced during online learning (Dhawan, 2020). To overcome these constraints, most teachers who viewed assessment as being *for* online learning tried to conduct live teaching and ask more questions during teaching. Teachers who viewed assessment as being *of* learning used more multiple-choice questions to assess students online instead of subjective or problem-solving questions. Nevertheless, teachers who viewed assessment *as* learning posted the answers to classwork or homework online for students to check their work by themselves, or hosted live teaching sessions for students to ask questions.

Conclusion

This study examined current mathematics teachers' views on online assessment during the pandemic. It provided insights into how technology influences the forms of assessment that teachers use and their experiences during online teaching. First, the findings revealed that online assessments conducted during the pandemic were similar to in-person assessments conducted before the pandemic. This implies that mathematics teachers' existing conceptions of teaching may be very strong and not easily changed, even when the teaching environment has changed. Second, teachers' views on online assessment and its constraints in various forms revealed that effective strategies to shape students' autonomy in online learning are needed. More teacher training must be given to teachers in terms of how to conduct online assessment. Information technology is no longer a supplement to teaching and learning, but has become the new norm in a post-pandemic era. The teaching modes that schoolteachers use therefore need to be more flexible to meet the changing times. In terms of our study, we acknowledge that our sample size is not large enough to generalise our findings. Future studies on this topic can be conducted by adopting different methods, such as large-scale questionnaires. Data from students could also provide another perspective on the effects of online assessment.

Introduction

Especially with regard to inclusive education, teachers must recognize the potentials and preconditions of students during the learning process to build on these for successful teaching (e.g. Moser Opitz & Nührenbörger, 2015). However, the formative use of diagnostic information to support decisions is an unfamiliar concept for many teachers (e.g. Zeuch et al., 2017). Studies on the implementation of formative assessment (e.g. van Geel et al., 2016) suggest that structured and curriculum-based measures have positive effects. However, meta-analyses show that there is considerable need for research to understand the conditions of successful implementation (e.g. Kingston & Nash, 2011).

"Formative Assessment in Inclusive Early Mathematics Teaching" is a design-oriented research project in Germany. An in-service program was developed with the focus on diagnosis and individual support. The implementation of two variations of formative assessment – planned for interaction (PI) and curriculum embedded (CE) (e.g. Shavelson et al., 2008) – will be compared. In the approach "Födima-PI" the teachers learn to develop diagnostical questions and support activities, in "Födima-CE", they use prepared diagnostic and support tasks.

Research design

The project explores how teachers and multipliers can be effectively qualified for professional support-oriented diagnostics and how successful transfer processes into practice can be supported (e.g. Gräsel, 2010). In 2021/22 134 teachers from 37 schools will participate in the project. The research goals concern the evaluation of the acceptance and professional effectiveness of the training concepts and the qualification program. In the first year, the project focuses the following research questions:

1 How do teachers evaluate the conceptual framework?
2 What are the effects with regard to attitudes, pedagogical content knowledge and performance?
3 How effective are the concepts with regard to the development of basic mathematical skills, motivational variables and the self-concept of students?

A *pre-post-follow-up-test design* includes standardized questionnaires and interviews to gain information about the participants' *self-efficacies*, *pedagogical content knowledge* and their *attitudes* towards formative assessment before and after their participation, to evaluate the effectiveness of the program. Also, the *acceptance* of the developed in-service program will be surveyed.

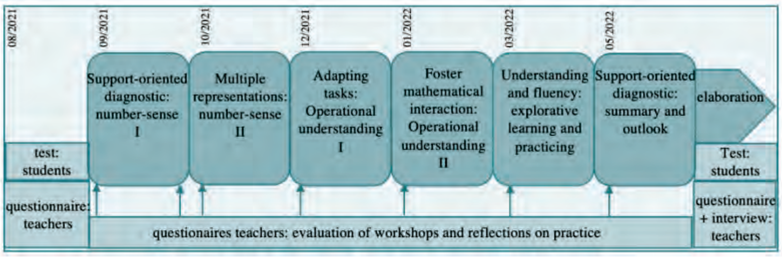

Figure 1: Födima year 1

We expect a positive effect in favor of the Födima-CE approach due to its somewhat tighter structuring and we assume a moderator effect in the form that high pedagogical content knowledge and a positive self-efficacy of the teachers are associated with better effects for the Födima-PI approach.

After evaluation, the two variations will be elaborated into a qualification program for facilitators. There will be further research related to this.

Acknowledgements

The project is funded by the BMBF “Rahmenprogramm empirische Bildungsforschung“ (01NV2102A).

Development and evaluation of primary school students' mathematical competencies via online assignment portals

Julie Vangsøe Færch

Aarhus University/Copenhagen University College, Danish School of Education, Denmark; jvaf@edu.au.dk

Keywords: Formative assessment, mathematics, competency, competency-oriented education.

Mathematical competencies (Niss & Højgaard, 2019) have been developed and implemented in the Danish curriculum through the last two decades. At the same time, online assignment portals have gained considerable ground in the Danish elementary school. Denmark's largest portal alone, matematikfessor.dk, has 75% of the Danish primary and lower secondary schools as regular subscribers, and an average of DKK 1.5 million assignments are answered daily (EduLab, 2021). When Denmark was locked down on March 11, 2020, the number of daily completed tasks rose to approximately 6,000,000. During the lockdown, the number of unique daily logins rose from approximately 45,000 to 130,000 (Elkjær & Jankvist, 2021). Assignments in such portals, however, are mainly used for training students' basic skills. In the Danish context, a report from 2016 concludes that as many as 78% of the tasks that students in Danish primary and lower secondary schools encounter in mathematics teaching can be categorized as training tasks (Bremholm, Hansen & Slot, 2016).

The purpose of this ongoing project is to investigate to what extent it is possible to develop tasks for online assignment portals, so that students in the intermediate stage of primary school have the opportunity to develop mathematical representation competency as defined by Niss and Højgaard (2019). The tasks are to be designed in a way that supports the teachers' formative assessment of their students' mathematical representation competency. As the portal works now, the teachers receive information about the number of correct responses provided by each student. In addition to these information's, the aim is to inform teachers of the level of competency for each of their students.

The methodology of design-based research (Cobb, Jackson & Sharpe 2017) is used for both continuous development and adaptation of the competency-oriented tasks. The tasks are to be designed in clusters in a way that allows for student learning, while the student's answers inform the assessment tool without the student taking an actual test. The assessment tool is formative (Black & William, 2009) as knowledge of the students' representation competency within fractions will both inform the further work in the online assignment portal and support the teacher's formative assessment through a description of the student's competency level in terms of radius of action, degree of coverage and technical level (Niss & Jensen, 2019). A minimum of three design iterations are expected to be completed during the project.

During the first iteration, development of competency-oriented tasks for online assignment portals will be based on findings from a systematic literature review regarding task design with a focus on online assignment portals and mathematical competencies, respectively. Existing knowledge of the interfaces of these areas must result in a framework for how competency-oriented tasks are to be designed for an online portal.

During the second iteration, coding categories for the assessment tool are identified based on three dimensions of possessing and developing a competency: degree of coverage; radius of action; and technical level (Niss & Højgaard, 2019). Degree of coverage regards the extent to which the various aspects are covered. A person who can both interpret and understand relations between different representations and has knowledge about information loss and gain when shifting between representations has a higher degree of coverage- than a person who can only do the first.

Radius of action is the spectrum of contexts and situations in which the competency can be activated. The degree to which the student is possessing representation competency is to be measured by the extent to which the student can solve tasks in routine and/or new situations; in relation to internal mathematical situations and/or application-oriented situations; use fractions in different situations. The technical level deals with conceptually and technically advanced conditions and tools the person can activate the competence towards. The student's responses are used to identify development opportunities so that the student's next set of tasks can help further development the competencies radius of action.

During the third iteration, both task design and the assessment tool will be tested on a larger number of students to further inform both the task design and the assessment tool.

Matematikfessor.dk makes their online assignment portal available for testing of tasks and evaluation tool.

This paper presents the first findings from a survey, administered to 421 Italian in-service primary teachers, on their beliefs regarding the knowledge and skills investigated by the national standardized assessment (INVALSI) tests, their proximity to didactic practices in Mathematics and the role they assume within the school context. The case presented in this paper is discussed in order to investigate the way teachers interpret data coming from standardized assessment and if/how they use them in their teaching practice. Findings show an overspread meta-didactic conflict generated by teachers' difficulties in interpreting INVALSI tests and in using them coherently with the framework on which the tests have been designed.

Keywords: Standardized assessment, meta-didactic conflict, primary teachers.

Rationale and theoretical framework

At international level, the strictly link between standardized assessment and mathematics education is increasingly emerging (De Lange, 2007). Standardized assessment has the main purpose of system evaluation and its repercussions within social, political and educational fields, is increasingly taking hold, both at the level of the school system, and at the level of impact on classroom practices (Looney, 2011). There is a growing interest in broadening standardized assessment beyond the evaluation of school systems to mathematics education research as a new methodological tool (De Lange, 2007; Meinck, Neuschmidt, & Taneva, 2017). In Italy, the INVALSI national agency is responsible of the standardized mathematics assessment (INVALSI tests) that occurred, for the first and second cycle of education, since 2008. The INVALSI tests are administered at a census nationally and the results, elaborated on a valid statistical sample, are returned to the schools and publicly discussed every year. The theoretical framework of the INVALSI tests is in line with the main research results in mathematics education and with the National Curriculum Guidelines (INVALSI, 2018). This ensures that the macro-phenomena highlighted in the standardised assessment can be framed with the main research lenses and that they highlight new characterisations or phenomena (Bolondi, Ferretti, & Santi, 2019, Ferretti, & Bolondi, 2019, Ferretti, & Gambini, 2018). Several researches show how the results of the standardized assessment can be used in a formative perspective within didactic practices and as a tool within teachers' professional development paths (i.e., Doig, 2006; Di Martino, & Baccaglini-Frank, 2017; Ferretti, Gambini, & Santi, 2020). The research project within which this study moves, is in tune with these strengths of thought and aims to identify training needs of Italian teachers and to propose guidelines for the improvement of teaching practices, regarding the use of mathematics INVALSI tests. In particular, we investigate the presence of any conflicts, in the sense of Sfard (2008), that might exist between the "language of standardised assessments" and mathematics teachers' interpretation of it (Arzarello, & Ferretti, 2021). As we will explain in the following section, one of the main aims of this research is to understand the role and meanings that teachers attribute to the INVALSI tests, investigating how they interpret, consider and use the INVALSI tests and their results.

The interdisciplinary research project and our research questions

Herein, we analyse the first results of an interdisciplinary research project aimed at investigating the link between the INVALSI tests in Mathematics with the teaching and learning processes of Mathematics, in particular with teaching practices. The research project is conducted by the INVALSI Disciplinary Didactics Group of the Italian Society of Research in Didactic S.I.R.D., composed by mathematics education researchers and pedagogists. The interdisciplinary collaboration consisted in the design and in the administration of a tool for detecting teachers' attitudes towards INVALSI agency with its aims and working methods, as well as its tests in Mathematics and their repercussions on teaching practices. We are interested to understand what are the “tools” possessed and used by the teachers: to read and interpret INVALSI tests and their results; to identify possible effects of the INVALSI tests on their Mathematics teaching practices. The analysis of data coming from the results of the INVALSI standardized assessment is not enough to identify training needs in this direction at a national level within schools and to propose guidelines for the improvement of practices regarding the use of INVALSI tests. Rather, to reach these goals, we intend to develop a meta level analysis focusing on the way teachers interpret and use these data in their teaching practices. To do that, a survey was designed and administered to investigate primary teachers' beliefs regarding the knowledge and skills investigated by the INVALSI tests, their proximity to didactic practices in Mathematics and the role they assume within the school context.

In this paper we analyse data concerning the Mathematics Education section of the survey. The section focuses on 7 tasks of the INVALSI tests, chosen because considered suitable to highlight different didactic macro phenomena. With respect to each of the 7 tasks, teachers are asked to answer questions aiming to investigate: their ability to read INVALSI data and identify the reasons of students' mistakes; how suitable an INVALSI task is considered for assessing students learning and how commonly it is used in assessment practices. The final part of the Mathematics Education section of the survey contains some transversal questions that aim at investigating how the mathematical contents and the skills detected with the INVALSI tests are more or less close to the daily personal didactic practices and perceived as consistent/inconsistent with the National Curricula Guidelines. All these variables represent the focus of the survey and are the object of the analysis proposed in this study. In what follows we will exemplify our study presenting and analysing teachers' responses to some of the questions of the survey. More specifically, we intend here to answer the following research questions:

Q1: to what extent teachers' interpretation of the INVALSI tests and their results is coherent with the framework on which the tests have been designed?

Q2: to what extent the mixed (qualitative and quantitative) investigation based on our survey results to be a tool to answer Q1?

The crochet placemats task

This paper focuses on some questions of our survey, which refer to the INVALSI task of Figure 1.

To make 4 crochet placemats, grandmother uses 6 balls of cotton.
a) How many balls of cotton of the same type she has to use to make 20 placemats?
Answer:............
b) Write how you did to find the answer.

Figure 1: Task 11, Mathematics INVALSI test Grade 05, s.y. 2012-13

Teachers were given a set of students' answers to the task, consisting in both the numerical result and the solution strategy. For each of the proposed student answers, teachers were asked to choose its degree of correctness (*Completely Incorrect, Partially Incorrect, Mainly Correct, Completely Correct*). These 4 possible options are given to the teachers without an explanation of the difference between *Partially Incorrect* and *Mainly Correct:* to the teacher's choice of *Partially Incorrect,* we attributed the feeling that what is important for the teachers in that answer of the student is the fact that it is incorrect (even if only partially), rather *Mainly Correct* is the answer that we expected to be chosen by the teachers which consider the answer of the student to be correct (even if not completely).

The proposed student answers are:

1) 30, I calculated 20+6+4
2) 24, I multiplied 6 balls by 4 placemats, and I got 24
3) 120, I have multiplied 6 balls by 20 placemats
4) 30, Since for 4 placemats we need 6 balls of cotton (so 2 more), for 20 placemats we just need to do plus 10
5) 30, The grandmother uses a ball and a half to prepare a placemat, so I did this = 20 x 1.5 = 30
6) 30, To do 20 placemats I have to do 5 times 4 placemats, so I need 30 balls
7) 24, I have multiplied 20 placemats by 1 ball and a half, and I got 24.

As we can notice, option 1) reports a correct numerical answer supported by a wrong strategy; on the contrary, option 7) reports a correct strategy with a wrong numerical result. Only the options 4), 5) and 6) are correct. Despite the solution strategies reported in these three options are all correct, they are characterized by different approaches. Options 5) and 6) mainly follow a multiplicative model of reasonings, whereas option 4) makes use of a mixed additive-multiplicative model (Arzarello, 2018).

Results

The survey, that has been offered to be voluntarily filled on-line, involved 421 Italian in service primary teachers: most of them teach since more than ten years.

Table 1 shows the valid percent of the teachers' responses inherent to the wrong student answers proposed in the survey. A first look at the responses given by the teachers shows that most of them (more than 80%) recognised the first three options to be incorrect (Table 1). In particular, it seems to be reasonable that the correct numerical result (30) of the student answer, even in presence of a wrong strategy, can justify the fact that the number of teachers, who marked option 1) as *Completely Incorrect* is slightly lower with respect to those who considered *Completely Incorrect* options 2) and 3). Conversely, student answer 7) was considered *Incorrect* (*Completely* or *Partially*) by the 68.9% of the teachers (Table 1), even in presence of a correct strategy. A deeper analysis of data reveals that the 90% of the teachers which evaluated option 1) to be *Correct* (*Completely* or *Mainly*), considered *Completely Incorrect* option 7), and at the same time, the 99% of those who evaluated option 7) to be *Correct* (*Completely* or *Mainly*), considered *Incorrect* (*Completely* or *Partially*) option 1). This inverse correlation between teachers' responses given to student answers 1) and 7) is also confirmed by the factorial analysis we will present below (see Table 2).

Table 1: Valid percent of teachers' responses

Solution	Valid Percent			
	Completely incorrect	Partially incorrect	Mainly correct	Completely correct
1) *30, I calculated 20+6+4*	81.9	14.9	2.6	0.6
2) *24, I multiplied 6 balls by 4 placemats, and I got 24*	84.9	11.9	2	1.2
3) *120, I have multiplied 6 balls by 20 placemats*	85.5	12.5	1.2	0.8
4) *30, Since for 4 placemats we need 6 balls of yarn (so 2 more), for 20 placemats we just need to do plus 10*	23	32	34.8	10.2
5) *30, The grandmother uses a ball and a half to prepare a placemat, so I did this = 20 x 1.5 = 30*	4.7	5.2	18.8	71.3
6) *30, To do 20 placemats I have to do 5 times 4 placemats, so I need 30 balls*	6.9	8.3	21.4	63.4
7) *24, I have multiplied 20 placemats by 1 ball and a half, and I got 24*	46.3	22.6	29.7	1.4

Concerning the other three given answers, number 5) is mostly considered *Completely Correct*. A high percentage of teachers also recognised solution strategy 6) to be *Completely Correct*, while the teachers' responses inherent to solution strategy 4) reveal to be much noisier than numbers 5) and 6).

Also for the three correct student answers, some interesting results can be found observing data more in details. First of all, it seems worth of note that among the 192 teachers (45.6% of the total) which considered both the options 5) and 6) to be *Completely Correct*, only 29 also saw option 4) as *Completely Correct*. That is only the 6.9% of the teachers considered all the three student answers 4), 5 and 6) to be *Completely Correct*. Among the teachers who considered *Completely Correct* both options 5) and 6), we have also found out the number of those who saw option 4) as at least *Partially Incorrect*: they are 82 (the 19.5% of the total). This means that the 42.7% of those teachers, who considered *Completely Correct* answers 5) and 6), judged *Incorrect* (*Completely* or *Partially*) the mixed solution strategy presented in answer 4). Conversely, focusing on the total number of teachers

(232), who considered *Incorrect* (*Completely* or *Partially*) option 4), we can observe that 82 of them (that is the 35.3%) judged *Completely Correct* student answers 5) and 6).

The bivariate factor analysis (Suhr, 2006), using the Varimax method (SPSS software), allows the identification of two factors that saturate 44% of the total variance (Table 2). These results are interesting: in fact, option 1) and option 7) are in the same component with opposite signs; option 3) and option 2), both reporting wrong multiplicative model of reasoning, are in the same component; the first component also contains the two correct options 5) and 4) with opposite signs with respect to options 3) and 2); also the two most recognised correct strategies in options 5) and 6) belong to the the same component. However, some options reveal low factorial coefficients, so highlighting the presence of some critical aspects. These critical aspects are worthwhile of a further investigation, which we are now pursuing using qualitative methods of analysis.

Table 2: Varimax Rotated Factor Matrix with Kaiser normalization applied to teachers' responses

	Components	
3) *120, I have multiplied 6 balls by 20 placemats*	.721	
2) *24, I multiplied 6 balls by 4 placemats, and I got 24*	.715	
5) *30, The grandmother uses a ball and a half to prepare a placemat, so I did this = 20 x 1.5 = 30*	- .567	.508
4) *30, Since for 4 placemats we need 6 balls of yarn (so 2 more), for 20 placemats we just need to do plus 10*	- .424	
7) *24, I have multiplied 20 placemats by 1 ball and a half, and I got 24*		.751
1) *30, I calculated 20+6+4*		- .490
6) *30, To do 20 placemats I have to do 5 times 4 placemats, so I need 30 balls*		.449

Teachers were also asked to answer two other questions about their awareness of the validity of the task in order to assess students' learning and the extent of the use they make of similar tasks in their assessment test. Diagrams in Figure 2 show the valid percent of teachers' answers to these questions.

As those above, also these data show some unexpected correlation. We will discuss this issue in the next Section.

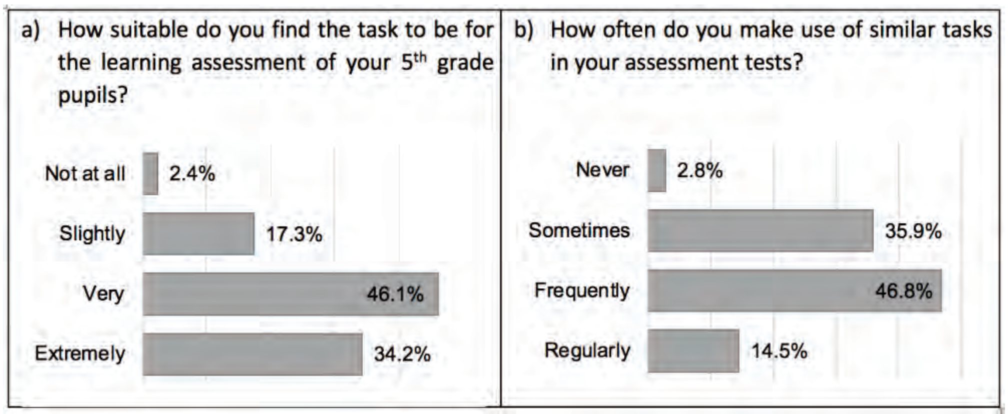

Figure 2: Teachers' responses to the questions about the validity of the task to assess students' learning and the use of similar questions in their assessment test

Discussion

We have already pointed out some contradictory aspects within teachers' answers to our survey. Figure 2 is emblematic for that. In fact, with respect to the two questions in it, we can see that, for the 80.3% of the teachers, the crochet placemats task is (*Very* or *Extremely*) suitable for the students' learning assessment, while the 61.3% of the teachers declared to make use (*Frequently* or *Regularly*) of similar questions in their assessment test. A first possible interpretation of this discrepancy might be connected with the perception of a higher difficulty embedded in the assessment of argumentative and problem solving skills, especially using open questions: although teachers recognize that the crochet placemats task is suitable to assess students' learning, in their usual assessment tests they prefer to assign more procedural exercises. However, we believe that the discrepancy highlighted by our data can be also considered in the light of the mentioned teachers' difficulty in recognising the correctness of “unusual” solution strategies.

We can interpret all these results basing on the concept of *meta-didactical conflict*, elaborated by Arzarello and Ferretti (2021). It exploits an analogy between the answers given by teachers in surveys like that illustrated here and the “incommensurable discourses” described by Sfard (2008). She shows how, in classroom interactions, interlocutors many times share the same words but with a different, incommensurable, meaning, of which they are not aware: a conflict is so generated. Something very similar we found when we analysed the answers to our questionnaire: here we found incommensurable languages. As the name we adopted suggests, this conflict consists of three components and is meta-didactic. We have defined it as meta-didactic because it is inherent in discourses about didactic processes such as assessment, students' skills and mistakes.

In this study we have highlighted how a twofold conflict emerges in many teachers' answers, because they interpret: (i) the difficulties of students in the INVALSI tests in a way that is completely different from what unquestionably appears from the data of the survey; (ii) the rationale of the INVALSI tests in a contradictory way (e.g., in the way how they couple the dyads suitable/not suitable Vs most used/ not used in the examples with respect to what appears in the survey data).

To summarize our findings, we can say that teachers' answers to our survey show an overspread meta-didactic conflict. We consider worth of note, that even if teachers declare to consider the task highly suitable to assess students learning, they do not say to make an extensive use of this kind of task and, above all, in most of the cases, they are not always able to recognise all the suggested correct solution strategies. These observations can give a negative answer to our research question Q1. Furthermore, the case of the crochet placemats task is an example of how our survey resulted to be a useful tool in order to investigate teachers' interpretation of INVALSI data and their use in the teaching practices. In this sense, our result can give an answer also to research question Q2.

Conclusion

In the paper we have presented the first findings from a survey aimed at investigating the way primary school mathematics teachers read, interpret and use INVALSI Italian standardized assessment. According to the INVALSI theoretical framework (INVALSI, 2018), the crochet placemats task has been designed with the aim to evaluate if fifth grade students were able to solve a given problem of direct proportionality and to describe their solution strategies. At a meta level, in order to evaluate the correctness of the solution to the task, teachers have been requested also to recognise the correctness of the strategies employed by the students. This needs a deep understanding of the underlying conceptual field of the multiplicative structures. Analysing teachers' responses to the survey, we have observed a basic meta-didactical conflict. The necessity of overcoming this conflict can suggest suitable designs for professional development programs for in-service teachers in order that they develop a correct culture of assessment and base their teaching practices on a correct interpretation of the data in national surveys. If we want to overcome the risk that standardised assessment is limited to classifying students, schools and nations, we need to develop the dialogue between standardised assessment and mathematics education. To fully recognise the potential and educational goals of standardised assessment, there is a need to develop and disseminate effective theoretical tools for interpreting the quantitative data and the macro phenomena emerged.

Moreover, our data provide several elements to be further analysed, both quantitatively and qualitatively, to shed light to critical aspects connected with teachers' perception of the usefulness of standardized assessment in their professional activities, that is the main general aim of our interdisciplinary research project.

Incorrect responses to the national assessment of mathematics: Gaining insights into mathematical proficiency at middle school

Francesca Ferrara[1] and Stefania Pozio[2]

[1]Università degli Studi di Torino, Italy; francesca.ferrara@unito.it

[2]INVALSI, Roma, Italy; stefania.pozio@invalsi.it

In this paper, we analyse the incorrect responses of grade 8 students to mathematical items of the national assessment of mathematics. We frame our study starting from an item which requires to write the perimeter formula for an isosceles trapezoid as a function of one variable. Focus is put on common features of groups of incorrect responses, which we look at as routes to algebraic thinking in this context and which reveal partially correct responses. Studying the mutual relationships between the routes and the students' proficiency levels reported via the assessment scores, we gain insights into the students' mathematical proficiency and the nature of their errors. Expansion of our route-based investigation to other items still highlights the inclusion of partially correct answers, which might entail a wider range of acceptable responses and more complex marking involving partial credit scoring.

Keywords: Assessment of mathematics, error, route, proficiency level, partial credit.

Introduction

In this paper, we first investigate the incorrect responses to a mathematical item by grade 8 students in a national assessment of mathematics. The item asks to write the formula for the perimeter of a simple figure as a function of one variable and had a very high percentage of incorrect responses. It has to do with the algebraic understanding of formulas, as part of the mathematical literacy required at the end of middle school. Specific focus on writing a formula is crucial, since formulas evoke problematic pairs of mathematical thinking, such as conceptual and procedural, relational and operational, and general and particular (e.g. Sfard, 1991; Arcavi, 1994). Each pair emphasises a tension between the semantic and the syntax of formulas, which usually remain bounded to applying static calculation instead of being conceived as versatile means to establish relationships, despite their role in transitioning from arithmetic to algebra and in mathematical modelling. A formula further requires the usage of letters as variables, of which students often reveal static images, as unknown values, or labels, with difficulties to conceptualise quantities in a problem context, how they can be related, how they vary together (Bush & Karp, 2013; Carlson et al., 2015).

We know that, despite their role in reasoning algebraically or functionally, formulas did not receive extensive attention in mathematics education research, especially in relation to student literacy. In considering the specific item mentioned above, we aim to investigate how formulas are (or can be) interpreted by middle school students and the corresponding difficulties in seeing them as algebraic relations or functions. To address this concern, we take a sampled group of grade 8 students, who took part in a national standardized assessment test, and we focus on their incorrect responses to the item to better interpret their approaches to the solution. We further an initial analysis of these answers, which showed types of emerging errors, related to known misconceptions or procedural forms of mathematical thinking (Pozio & Bolondi, 2019), to better see them in terms of conceptualisation processes about the mathematical task rather than as reasoning products.

We then briefly expand our considerations to other items, based again on central but different aspects of mathematics thinking and learning at middle school in our country. We overall frame this study with reference to the content of the initial item (algebraic knowledge) to introduce the reader to the idea of *route* as a methodologically relevant means to study the ways students can face mathematical items and produce incorrect responses, and to focus on their mathematical literacy.

Theoretical highlights

Arcavi (1994) offers the idea of symbol sense to discuss the versatile nature of algebra and its use as a tool to understand, express, and communicate generalizations, to reveal structure, and to establish connections. Symbol sense is difficult to achieve, especially in the early grades as it involves letter usage and understanding of the roles and multiple meanings of variables (Bush & Karp, 2013; Küchemann, 1978; Philipp, 1992). Küchemann and Philipp analysed misconceptions related to letter usage and observed that variables can be treated as labels or objects, constants, unknowns, generalised numbers, varying quantities or variables, parameters, or abstract symbols. Philipp focused on the difficulties students have with variables as related to an inability to recognize the role of the variable, and Küchemann studied how certain ways of using letters were typically perceived as less demanding than others. Following Küchemann, students understand the meaning of the use of symbols in algebra only when they can work with letters as variables. Usiskin (1988) pointed out misconceptions about a view of variables as simple labels and reported failure to grasp variables as varying quantities rather than missing values. Kieran (2007) argued that the meaning of a variable varies depending on the context, an obstacle when learners face problems involving this notion. Discontinuities with arithmetic are also implicated in work with variables, which uses number from a more structural point of view (Stacey & MacGregor, 2000; Warren et al., 2016). According to Stacey and MacGregor, difficulties in formulating and solving algebra word problems have often to do with a compulsion to calculate, which rests with arithmetic problem solving and accounts for many misconceptions of algebraic thinking at the early grades. These authors identified different “*routes*” to a solution of simple problems on equations by grade 10 learners. They associated non-algebraic routes to students using arithmetic reasoning or trial and error; superficially algebraic routes to students writing equations to solve the problem as formulas describing sequences of calculations; algebraic routes to equation writing and solving. Capraro and Joffrion (2006) further claimed that writing equations from word problems is difficult for middle grade students, whether concerned with misconceptions or literal translation.

These studies shed light on the fact that the inclination to misconceptions may be related to mainly procedural or operational approaches. Formulas, as algebraic statements that value the interplay of procedural and conceptual (relational), are instead a powerful means to mobilise symbol sense. Interestingly, the context of measurement teaching and learning shows confusion between area and perimeter, especially for rectangles, indicating weakness in grasping both formulas (Smith & Barrett, 2017). Similarly, even middle school learners still struggle to distinguish area from the length of the region’s boundary (Chappell & Thompson, 1999).

In respect to this body of literature, our first aim in this paper is to gain insight into how formulas are conceived by middle school students and to better understand difficulties and misconceptions related to formulas in context. To this aim, we focus on types of errors as critical to meaning making, and we look at them as generative of specific approaches to the solution of a mathematical item, that is, of "routes" to the solution, borrowing from Stacey and MacGregor's study. This helps us see ways that middle school students still struggle with seeing formulas as means to establish relationships. A second aim of the study is to shed light on the relevance of routes for the analysis of students' incorrect responses and related mathematical literacy. In the end, attention is therefore shifted to other items of the national assessment in which high percentages of students performed incorrectly.

Context and participants

The context for this paper is the national standardized computer-based assessment of mathematics administered in 2018 to grade 8 Italian students at the end of the school year, as part of the evaluation of their middle school-based education. The assessment is administered by the National Institute for the Evaluation of the Education System (Istituto Nazionale per la Valutazione del Sistema di Istruzione e di Formazione–INVALSI, in Italian). While the participation in the national computer-based test (CBT) is mandatory for all grade 8 students, a sample group is selected for the evaluation process. CBT uses a wide number of items (item bank) from which to extract clusters of items for creating multiple forms of the test. A peculiarity of the CBT is the development of empirically based proficiency levels to report student progress. Accordingly, students' mathematics proficiency and item difficulty are located along a shared scale, which is divided into five levels, 1 to 5, lowest to highest (therefore, a level refers both to student proficiency and to item difficulty). This approach allows describing what students can do with mathematical tasks at different levels of difficulty.

In this paper, we particularly draw on one mathematical item of the 2018 assessment of mathematics at grade 8. The item requires students to write the perimeter formula for a simple geometrical figure as described in the next section. Out of the 574506 students who completed the assessment test, 31300 constituted the sampled group. Of these, 4543 students answered the item under consideration. Some 2147 students out of our 4543 respondents gave an incorrect answer (47,2%), only 1561 students answered the task correctly (34,4%), and there were 835 missing answers (18,4%). Successful students were for the majority at a high proficiency level (4 and 5), while the 71% of students at low proficiency (levels 1 and 2) do not even attempt to answer.

A mathematical item about algebraic knowledge

The mathematical item, which is the initial point of this paper, is an open-constructed response item that involves an isosceles trapezoid given by a picture, as shown in Figure 1. Relational information for which the long base is twice the short base is presented in a textual stimulus at first (line 1). The picture additionally provides a number (5) and a letter (b) respectively for the leg's length and the short base's length. The task follows (line 2) asking the students to write a formula to express the trapezoid's perimeter "as a function of b". Apart from knowledge about simple calculation of the perimeter, the task therefore focuses on reasoning functionally on the formula, implying the use of the letter b to capture relationships beyond coordination among the different semiotic sets.

Domanda **Nel trapezio isoscele in figura la base maggiore è doppia della minore.** (1)  **Scrivi una formula che esprima il perimetro *p* del trapezio in funzione di *b*.** (2) *Digita la risposta alla domanda.* (3) **Risposta:** p =	1. In the isosceles trapezoid in the figure, the long base is twice the short base. 2. Write a formula that expresses the trapezoid's perimeter p as a function of b. 3. Type your answer to the question.

Figure 1: A mathematical item about algebraic knowledge

Data and method

We are interested in investigating the incorrect responses given to the item to better understand its complexity and the ways in which middle school learners approach it. For the analysis, we consider those incorrect responses (1759) which concern the use of letters to write the requested formula, leaving out only numerical values or expressions, and word answers as single letters. The data we use are quantitative and qualitative. Quantitative data are percentages of correct, incorrect, and missing answers, the students' proficiency levels and the item difficulty. Qualitative data are the written responses, which were accessible thanks to the expert correction that INVALSI uses for open constructed-response items.

Data are finally combined to study the relationship between the routes and the proficiency levels of the students. Our method can be seen as a qualitative method in principle. The analysis was developed by first looking at the incorrect responses to search for common features, for example reference to a single semiotic set, like natural language or numbers, and attention to the relationships implicated in the item. We then grouped the answers according to the identified features into those that we interpret as routes and sub-routes to the solution. The same method was applied to study incorrect responses to other items centred on different but crucial aspects of mathematical literacy at middle school. These items also share with the original one high percentages of missing and incorrect answers.

Findings

We recognised three major approaches to the formula item, essentially: there have been students who have tried to write the formula making explicit reference to the relationship between the bases (*Relational route*); students who have only partially referred to the given elements to write the perimeter (*Partial route*); who, on the other hand, has written an area formula (*Habitual route*). We also found another widespread approach, that of students whose answers present letters but seem to escape decipherable orientations, while still relating to elements in the item (*Murky route*). The routes are captured by the examples in Tables 1 to 4 as follows (the number of responses of a certain kind is in parentheses at the top).

Table 1: Examples of answers in the Relational route and its five sub-groups (228)

***R*1** (62)	***R*2** (32)	***R*3** (4)	***R*4** (66)	***R*5** (64)
Using a letter in place of number 5	Using only numbers for the formula	Using mainly words for the formula	Reversing the relationship	Using wrong typing for operation signs
*bx*3+2*l*	[6+(6*2)]+(5*2)	Short base plus short base times two plus ten	*B*+1/2*B*+ (5*2)	5*2+*b*+*b***b*

The students whose responses belong to the Relational route (Table 1) are essentially capable to orient themselves to the information presented across the different semiotic sets and the various degrees of relationship in the item. Beyond writing a relationship between the bases, in fact, these students know that they must find the perimeter of an isosceles trapezoid and consider all its elements, gaining information from the text and the picture. The route is made of 5 sub-routes (*R*1 to *R*5, Table 1).

Table 2: Examples of answers in the Partial route and its four sub-groups (676)

***P*1** (229)	***P*2** (276)	***P*3** (145)	***P*4** (26)
Using letter *B* for the long base	Multiplying *b* by 2 instead of 3	Seeing the perimeter as sum of any 4 sides	Writing the procedure in words
B+*b*+5+5	(5+5)+*b**2	*B*+*b*+*l*+*l*	Long base + short base + 2*5

The students who undertake the Partial route, which includes 4 sub-routes (*P*1 to *P*4, Table 2), are capable to understand the request of a formula even if they do not refer it to the entire context, which demands connection with various degrees of relationship. The responses in this route essentially share particular focus on writing a formula for the isosceles trapezoid's perimeter, while forgetting some of the elements in the task, like the relationship between the bases (*P*1) and the specific length of the leg (*P*3). *P*1 and *P*3 exemplify how letters *B* and *l* respectively are used as labels (Usiskin, 1988).

Table 3: Examples of answers in the Habitual route and its five sub-groups (293)

***H*1** (112)	***H*2** (35)	***H*3** (31)	***H*4** (28)	***H*5** (87)
Using letter *B* for the long base	Taking the relationship between the bases	Writing the area of a triangle	Using words to write an area formula	Using letter *h* in some way
(*b*+*B*)*xh*/2	[*b*+(*b**2)]**h*/2	*b***h*/2	*b* plus *B* times 5 all divided by 2	[(*B*+*b*)**h*]

The Habitual route contains the 5 sub-routes *H*1 to *H*5 (Table 3) and comprises answers that concern the writing of an area formula rather than a perimeter formula (the known confusion introduced above) and, therefore, are far from solving the item correctly. We can realise this by observing the use of letter *h*, which habitually labels the height of a geometric figure, multiplied–in most cases–by a base or by the sum of two bases. The students in this route seem to associate the trapezoid and the formula with the task of finding the area of the trapezoid as students learn to measure the area of specific figures, not the perimeter, by means of rote procedures. While some consider the relationship between the bases (*H*2), many show a vague awareness of an adequate area formula (*H*3, *H*5).

Table 4: Examples of answers in the Murky route and its 3 sub-groups (562)

***M*1** (202)	***M*2** (180)	***M*3** (180)
Taking essentially *b* and 5	Taking essentially *b* and 2	Taking *b* or other letters
5*2+2**b*+*B*-*b*	*b**2+*b**2+*b*+*b*	*l*+*l*=*b*+*B*

The Murky route, with its 3 sub-groups (*M*1 to *M*3, Table 4), basically shows attempts to examine information for producing an answer that still uses letters, revealing some reasoning albeit quite rough. Most of the answers are relatively oriented to partial elements of the item, in many cases they exclude the legs' length or the relationship between the bases. We often assumed that these students have little if any clear idea of which elements to use for finding the perimeter of the trapezoid. It may also be that the request of writing the perimeter in function of *b* had implied specific reasoning on how to use letter *b*, and other letters, in a formula, or particular focus on one or the other base.

Conclusive discussion

For the sake of space, we cannot elaborate on the routes further. We shift attention to the relationship between the routes and the students' proficiency levels, turning to graphical representations of the distribution of the routes across the five levels and of the levels across the four routes. Figure 2 shows how percentages of students in each route are divided into the five proficiency levels (the first graph).

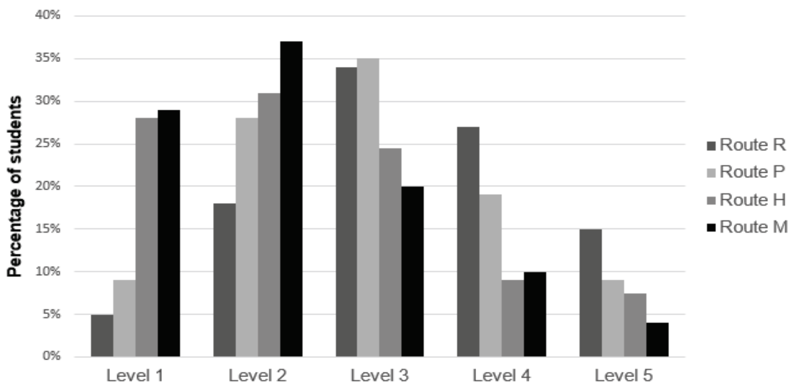

Figure 2: Distribution of routes across proficiency levels

A general trend emerges in the routes. In particular, the 29% of students at level 1 of proficiency and the 37% of students at level 2 belong to the Murky route (*M*), while students with medium proficiency (level 3) are present in both the Relational (*R*) and Partial (*P*) routes, with a percentage of about the 35% (shortly, the 70% of students who show medium proficiency are in the first two routes). Turning to high proficiency, we see that level 4 and 5 students are present at most for the 27% and the 15% respectively in *R*. We essentially see an increase of percentages of students with low proficiency as we pass from routes *R* to *M*, and a decrease for students at medium-high proficiency level. This trend is consistent with the assessment model, for which the closer an answer is to a correct one, or the more it includes steps toward the solution (partially correct answer), like reference to the relationship between the bases, the higher is the probability that the answer is given by a high proficiency student.

That less than 10% of students in *P* are at level 1 or 5, while the rest is at levels 2 to 4, also means that middle level students are basically capable to write a generic formula for the perimeter of a quadrilateral but may have troubles to write a more complex relationship between the given data. Most students in *H* are within the ranges of low proficiency, showing confusion between perimeter and area and, possibly, weakness in grasping both formulas, as outlined by Smith and Barrett (2017). Briefly speaking, the routes inform about the relative distance from solving the item correctly. The routes contain partially correct answers (especially *R*), which often satisfy the question intent and therefore might be considered for grading in the assessment. An additional aspect is the presence of all levels in all the routes. We can conclude that students make errors which reveal much about their algebraic proficiency in context, especially regarding the interpretation of formulas and the use of letters, which are still often conceived respectively as mere procedures or rules and labels or names.

After this first analysis, we moved to use our route-based approach to look at how other items of the national assessment in grade 8 were incorrectly answered and gain more insights into mathematical proficiency at middle school. Proportional reasoning and the relationship between simple geometric figures' area and perimeter are the core mathematical contents involved in these items. The incorrect responses are 1154 out of 2231 for the first item, and 6504 out of 8997 for the second item (300 and 777 missing answers respectively). Examined through routes, the answers highlight a multiplicity of approaches to single solutions, the impossibility of unambiguous interpretations in certain cases, and the inclusion of responses that are partially correct while satisfying the question intent. Again, the routes inform us about students' kinds of errors and misconceptions (and their mathematics literacy), which deserve specific attention from the educational point of view. The routes also help us reason about the importance of the question intent and the need for a wider range of acceptable responses and more complex marking by partial credit scoring, in line with the PISA and TIMSS assessment.

A general, conclusive observation relates to the fact that the sample we analyse is representative of the entire population of middle school students in grade 8 in our country. These students come from different classes of different schools spread across the national territory. Therefore, studying their incorrect answers is meaningful to the extent to which it allows us to better understand ways that specific aspects of mathematics thinking and learning are practiced at middle school in our country and conceptions that learners develop from them.

Opportunities for digitalization of the final examination of Math

Evelin Anna Geszler

Eötvös Loránd University, Institute of Mathematics, Budapest, Hungary; geszeve@student.elte.hu

Keywords: Final examination, digitalization, mathematics test.

Some research compares the final exam systems of compulsory education (between 16-18 years; Kákonyi, 2015), but no attempts have been made towards a comprehensive study about the level of digitalization of the mathematics tests. This poster highlights the main characterizations of the Math exam in four countries (Finland, Denmark, Georgia, and Germany) that made steps towards digital assessment. The long-term research purpose is using this international comparison to influence the practice in Hungary towards more digitalization.

In Finland, Mathematics test is not compulsory. It is organized on two different levels of difficulty, and any scientific, graphic, or symbolic calculator can be used that doesn't have a data transfer feature. Traditional test papers are no longer available as Finland achieved complete digitalization by 2019. The digital examination was not an adoption of the paper-based test onto a computer, but instead required the transformation of types of tasks. The list of measurable skills also changed, making it possible to detect the efficiency of information processing, critical thinking, and real-world problem solving by multiple-choice and open-ended questions (The Finnish Digital Matriculation Examination, 2021).

Mathematics is a compulsory subject in Denmark's school-leaving exams, which terminates lower secondary education. Computers have been involved in final exams in certain subjects since 1994. At first, only the paper-based examination booklet was adapted to digital environment and computers' text editor function dominated. During the test, examinees use their own laptops without an internet connection. The paper-based test's open-ended questions can be answered on paper or in a Word document in a digital environment. These documents then must be delivered on a USB-drive and printed. The final aim is the renewal of the complete process, to be able to measure creativity, critical thinking, and the ability to work in teams and to solve real-life problems (The Danish Ministry of Children and Education, 2019).

Georgia's national exams apply computer-based adaptive testing, where the test items are selected sequentially according to the correctness of a student's answers on previous items. The main reason behind digital testing is the prohibitive cost of a national paper-based examination system, but this also requires investments in school ICT infrastructure. Although the delivery of the test has become electronic, the answer sheet remained paper-based, even in 2020. The exam of Mathematics is optional, and the most controversial part of the system is the lack of measuring a wide range of competencies due to its multiple-choice test format (Trucano, 2015).

In Germany there is no unified school-leaving examination, as every federal state has its own Abitur. The mathematics test can be substituted with another subject among the mathematical-scientific fields. The exercises cover probability theory and statistics, have many arithmetic components, and require the knowledge of mathematical justifications and evidence. There have been some attempts to achieve centralized final exams. In 2017 a joint task pool was launched to improve the comparability of the Math exams in different federal states. Closed format tasks characterize the exam questions, which also show the influence of IT tools. Graphic calculators and Computer Algebra Systems, like GeoGebra's CAS, are legal aids. In Grade 12, all students must decide whether they want to take the CAS or the classic Abitur in Math. All solutions must be documented on paper (Csapodi, Filler, 2017).

In Hungary, there is a centrally standardized school-leaving exam, called *érettségi*. The same requirements apply all over the country. Mathematics is a compulsory subject, but candidates can choose the level of the exam; the intermediate level measures basic knowledge, while the higher level requires deeper analytic skills, and the questions are open-ended. Scientific calculators that cannot store and display textual information are allowed. The current tests are considered objective and valid, and therefore adequate for measurement, so it is not our intention to make changes in the types of items, as they did in Georgia. Within the framework of my PhD research, I'm working on developing tasks that can be set in the digital environment and focusing on the measurement of problem-solving skills.

In conclusion, there are numerous ways to involve a computer in the final exam of Math; from embedding the paper-based tasks without any modification to a digital environment, to computer-based adaptive testing and to problem-solving tasks, where creativity, skill of analyzing and assessing information objectively, and ability to mathematical modelling dominate. We would target the latter in Hungary, considering that final exams always have an active impact on education itself, so all the small changes must be made bit by bit, monitoring their effectiveness and providing constant feedback.

Real tasks in Italian mathematics standardized assessment

Chiara Giberti[1] and Simone Passarella[2]

[1]University of Bergamo, Department of Human and Social Science, Bergamo, Italy; chiara.giberti@unibg.it

[2] University of Padova, Department of Mathematics, Padova, Italy; simone.passarella@unipd.it

In this research we propose a criterion to classify real mathematics tasks in a standardized assessment. Specifically, we used this criterion to categorize the tasks of six, grade 5, standardized tests administered in Italian schools from 2009 to 2014 and we analyzed the psychometric features of these items. Results show a consistent presence of real tasks in Italian standardized assessment, indicating that one of the competences that these tests are intended to assess is the ability to develop and apply mathematical thinking to solve problems from everyday situations, as desired by the European Council and PISA. Moreover, the items classified as real are not necessarily difficult for students, but they are discriminative. The analysis at an item level of this kind of tasks could provide further information about how students face real tasks in a standardized assessment

Keywords: Standardized assessment, rasch model, real task, mathematical competence.

Introduction

In recent years, the growing attention given to national and international standardized assessment is promoting new reflections on how these tests are constructed and which information emerge from their results (Giberti & Maffia, 2020). The theoretical framework of each survey is fundamental to understand the aim following which the tasks are constructed and the mathematics that the test is going to assess. The most famous and discussed international survey is PISA, the Programme for International Student Assessment, promoted by the Organization for Economic Co-operation and Development (OECD). In PISA theoretical framework, Mathematical literacy is defined as “an individual’s capacity to reason mathematically and to formulate, employ, and interpret mathematics to solve problems in a variety of real-world contexts” (OECD, 2019); then all PISA mathematics problems are set in a context, which can be personal, occupational, societal, or scientific.

This contribution reports first results of an ongoing research project whose overall aim consists in studying how tests of Italian standardized assessment (administered by the Italian National Institute for the Evaluation of Educational Systems – INVALSI - every year at grade 2, 5, 8, 10 and 13) are built and what mathematical competencies and types of reasoning are aimed to be assessed. Specifically, the aim of this paper is to analyze INVALSI tests, proposing a criterion based on Palm’s framework (Palm, 2006) to evaluate the presence and quality of real tasks. Furthermore, the psychometrical features of those tasks previously identified as real will be analyzed.

Theoretical Framework

In the Italian context, the National Indications for the First Cycle of Education (MIUR, 2012), emphasize how mathematical knowledge should offer skills for perceiving, interpreting, and linking artifacts and daily-life events. Students are required to analyze situations and to translate them into mathematical terms and choose the actions to be performed to produce a solution to the problem.

These indications are reflected also in the European context. Indeed, the European Council (Recommendations of the European Parliament for lifelong learning (2018/C189/01)) recently defined as *mathematical competence* the ability to develop and apply mathematical thinking and the ability to use different representations (formulas, constructs, models, …) to solve problems starting from everyday situations. Despite the importance of including real-life experiences in mathematics classrooms, there is a strong discontinuity between in- and out-of- school mathematical experiences (Passarella, 2021). One of the possible causes of this fracture is the stereotyped nature of the problems proposed by textbooks and teachers, which, rather than serving as an interface between mathematics and reality, promote in students an exclusion of realistic considerations (Verschaffel et al., 2020). Instead, real and less stereotyped problems must be inserted in the school practice, in order to create a bridge between mathematics classroom activities and everyday-life experiences (Passarella, 2021; NCTM, 2000). Given the importance of real problems for mathematics classrooms, the following question emerges: when a mathematical task might be defined as *real*? Several studies delt with the concordance between mathematical school tasks and the corresponding out-of-school situations: Wiggings (1993) with the introduction of the term authenticity; Niss (1992) and the mathematical literacy framework of the OECD's Program for Student Assessment, PISA (OECD, 1999); Realistic Mathematics Education, that considers realistic and rich contexts as starting points for mathematization processes (Van den Heuvel-Panhuizen & Drijvers, 2014). In this contribution, we will consider the framework proposed by Palm (2006), that was developed to depict those aspects of real-life situations that should be considered important in their simulations (Figure 1).

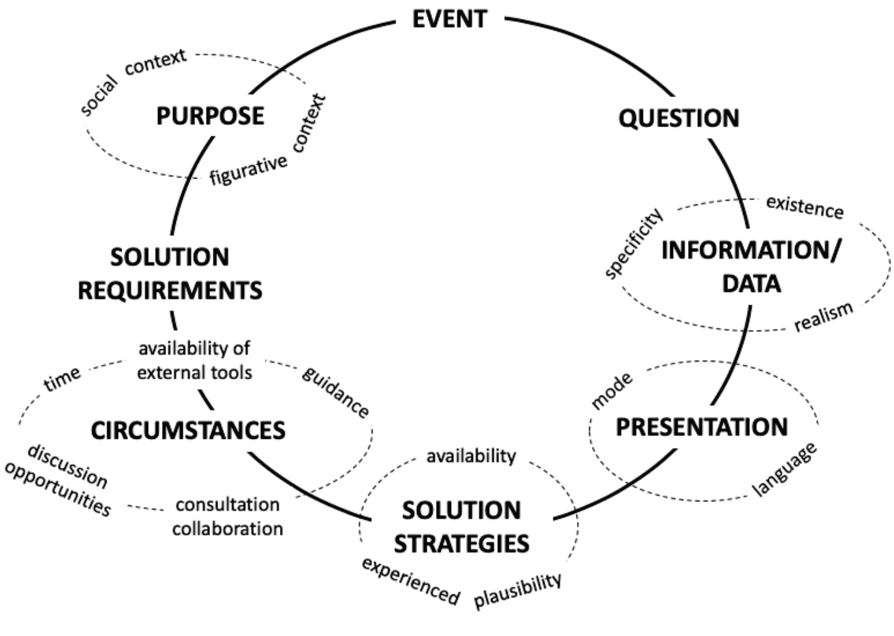

Figure 1: Palm's framework for simulations of real-life situations

A detailed description of these aspects can be found in Palm (2006). In Table 1 we describe those aspects that will be considered in the rest of the work, reporting for each of them a key question, in order to start reasoning on the concordance between mathematical school tasks and corresponding situations in real-life beyond the mathematics classroom. The framework proposed by Palm can enhance discussions amongst teachers and researchers on the characteristics of tasks that simulate real-world situations, and for the design and analysis of real tasks for mathematics classroom activities (Palm, 2006). Starting from Palm's framework, in this work we are proposing a criterion to evaluate the presence of real tasks in the Italian national tests in mathematics. Furthermore, using this criterion, we identify real task and analyze their psychometrical features to understand the behavior of the students facing these items.

Table 1: Key questions for some aspects from Palm's framework

Event	Could the event described in the school task take place in real-life?
Question	Does the questions in the school task might be posed in a corresponding real-life event?
Existence	Do the information available in the school task exist in a corresponding real-life event?
Realism	Are the values given in the school task close to values in a corresponding real-life event?
Specificity	Can specifications of the school task context be compared to a reasonably extent to the corresponding out-of-school situation?
Presentation Mode	Is the problem communicated orally or in a written form? Are the information presented in diagrams, tables, graphs, …?
Language	Does the language used in the school task not negatively affect the possibilities for students to use the same mathematics as they would have used in a corresponding real-life event?

Research Questions

The first aim of this contribution is to evaluate the presence of real tasks in the Italian national tests in mathematics (INVALSI tests), in order to investigate if INVALSI tests are intended to assess students' ability to develop and apply mathematical thinking to solve problems starting from everyday situations, as desired by the European Council and PISA. Consequently, our first research question is:

RQ1: Are there real tasks in the standardized INVALSI tests?

If the answer to the first research question is yes, considering that previous studies have highlighted that there is a strong discontinuity between in- and out-of- school mathematical experiences (Passarella, 2021), we would investigate the psychometrical features of the tasks classifies as real, in order to start understanding how students face these tasks.

Accordingly, our second research question is:

RQ2: If yes, which are the psychometrical features of these tasks? Are there some recurrent features that can be interpreted as a specific behavior of students facing a task of this type?

In this paper we will answer to this second research question considering the general psychometrical features provided by the Rasch Model, considering the whole set of items and providing an example of analysis at an item level.

Data and Methods

INVALSI tests are national standardized assessment administered every year in different school grades from primary to upper secondary school. In all grades INVALSI tests investigate students' competencies in mathematics and Italian language but, in upper grades, also an English test was included in the survey. In this work we decided to focus on grade 5 mathematics tests and compare the results in different years: from 2009 to 2014. INVALSI test are administered, for each grade, to the entire student's population. In this research our analysis is based on the probabilistic national sample drown from the entire population which is also considered for all the statistical analysis of the INVALSI Institute. For each test the sample includes approximately 30 000 students[1] and sample data are completely void of the effect of cheating because the test administration is conducted by an INVALSI inspector who guarantees the correctness and fairness of the process. All mathematics tests include different items in terms of typology (Multiple choice, Open-ended, Justification Open-ended, True/False), and mathematical content categories (Numbers, Data and Probability, Relationships and Functions, Space and Shape).

To answer to our first research question, we propose a criterion (Figure 2), based on Palm's framework, to classify mathematical tasks as to be real or not. In this direction, to evaluate the presence of real tasks in the INVALSI tests, we started categorizing each task of every INVALSI test in terms of its feasibility. Feasibility, in accordance with Palm (2006) is made by two aspects: *event* and *question*. Event refers to the possibility that the event described in the school task can take, or not, place in real-life. Question refers to the possibility that the posed question might be posed, or not, in a corresponding real-life event. Those tasks that positively reflected both the aspects of event and question had been categorized as real. Then, for those real tasks, their quality was evaluated. Quality refers to the degree by which a task is similar to a corresponding real-life event. Specifically, quality is defined considering five aspects from Palm's framework, namely *existence*, *realism*, *specificity*, *presentation*, *language*. For each aspect a score was given: 0 if that aspect had no correspondence in a real-life event; 1 if that aspect had a partial correspondence in a real-life event; 2 if that aspect had complete correspondence in a real-life event. In conclusion, to every real task was associated its level of quality by calculating the mean among the scoring (0, 1 or 2) given to its indicators (*existence, realism, specificity, presentation, language*).

To answer to our second research question, we analyzed data from each test using the Rasch model (Rasch, 1960) which is the one adopted also by INVALSI statistical team. The Rasch model is a simple logistic model belonging to Item Response Theory and it provides a joint estimate of the difficulty of the items of a test and of the ability of each student by placing them on the same scale from −4 to +4. Specifically, in this study we considered a parameter measuring the difficulty for each

[1] More precisely the sample was composed by 43586 students in 2009, 35567 in 2010, 31564 in 2011, 30870 in 2012, 24774 in 2013 and 25349 in 2014.

item (Delta) and a parameter measuring the fit of the item (Weighted). Other information could be identified observing specific graphs called Distractor Plots, output of the Rasch Model. The Distractor plot of an item allows the comparison between the Item Characteristic Curve (ICC, which expresses the probability of responding correctly to a specific item depending on the difficulty of the item itself and the ability of the respondent) and the empirical trend of each possible answer, as function of students' ability. Moreover, the software used to implement the Rasch Model (ConQuest) gives a parameter, belonging to the Classical Test Theory, which highlights how much each item discriminates between students with high ability levels and students with lower ones. All the items classified as real were then classified on the bases of difficulty (Delta), fit of the item with the Rasch model (Weighted), and discrimination. This analysis from a psychometrical perspective is performed at an item level: a single mathematical task might be composed by 1 or more items, and each item is identified by a request. Furthermore, we also considered the Distractor plot of each of these items and started investigating possible features such as under-discrimination/over-discrimination, particular distractor trends (for example humped performance trend - Ferretti, Lemmo & Giberti, 2018) but also guessing effect[2] (correct answers given regardless of being certain about its trueness).

FEASIBILITY		
	Yes	No
Event	The event described in the school task can take place in real-life	The event described in the school task can not take place in real-life
Question	The question posed in the school task might be posed in a corresponding real-life event	The question posed in the school task might not be posed in a corresponding real-life event

(Yes; Yes)

QUALITY			
	0	1	2
Existence	Data and information available in the school task do not correspond to the ones available in a corresponding real-life event	Data and information available in the school task partially correspond to the ones available in a corresponding real-life event	Data and information available in the school task correspond to the ones available in a corresponding real-life event
Realism	Values given in the school task are not close to values in a corresponding real-life event	Values given in the school task are partially close to values in a corresponding real-life event	Values given in the school task are close to values in a corresponding real-life event
Specificity	Specifications of the school task are not analogous to the ones in a corresponding real-life event	Specifications of the school task are partially analogous to the ones in a corresponding real-life event	Specifications of the school task are analogous to the ones in a corresponding real-life event
Presentation	The task is not presented and formulated in a manner analogous to reality	The task is partially presented and formulated in a manner analogous to reality	The task is presented and formulated in a manner analogous to reality
Language	The language is not analogous to the language that might be used in a corresponding real-life event	The language is partially analogous to the language that might be used in a corresponding real-life event	The language is analogous to the language that might be used in a corresponding real-life event

Figure 2: Classification of mathematical tasks

Results

In Table 2 results from the classification of tasks as real and in terms of their quality are reported. The distributions of real tasks vary between 24% and 45%. The quality of the real tasks was relatively high in every test. These results give some first suggestions concerning the theoretical framework on which the test is constructed and the type of mathematics that the test is going to assess. Indeed, the presence of a considerable number of real tasks, all of them of medium-high quality, shows how INVALSI tests stressed the importance to give students opportunities to face with real-life problems, in accordance with the definition of mathematical competence and the Italian National Guidelines.

[2] Indeed if we consider multiple choice tasks with 4 possible answers the probability for a student to answer correctly randomly is 25% but we have information regarding the intensity of this phenomenon considering the intersection between the Rasch model and the y axes of the distractor plot.

Table 2: Results from the classification of real tasks

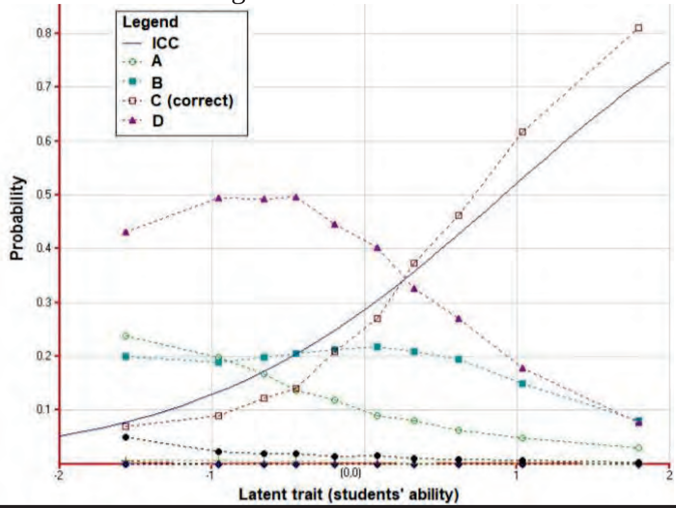
Year	Distribution	Total average of real tasks quality	SD
2008-09	24% (7/29)	1.4	0.3
2009-10	28% (9/32)	1.5	0.5
2010-11	33% (10/30)	1.7	0.3
2011-12	33% (11/33)	1.6	0.4
2012-13	31% (11/35)	1.7	0.3
2013-14	45% (13/29)	1.5	0.5

Then we classified on the bases of their psychometric features the 61 tasks (corresponding to 96 items in total) identified as real tasks. Considering items' difficulty (Delta parameter) we found that realistic tasks seem not to be a source of difficulty for students: the 35% of the items are easy with a delta smaller than -1; the 33% of the items shows a medium-low level of difficulty (-1<delta<0); the 27% of the items shows a medium-high level of difficulty (0<delta<1); and finally, we found only 4 difficult items (delta >1). The difficulty average is -0.61 highlighting that generally students are not particularly in trouble with real tasks. Furthermore, the item fit is considered good (values ranging from 0.8 and 1.2) for all the items except one, and the vast majority (84%) of the items identified have an optimal fit with values ranging between 0.9 and 1.1. Therefore, we can state that in the items identified the real context does not create a misfit with the model. The items identified as real are almost all discriminative items: the 81% have a good discrimination index (>0.3) and more than the 50% of the items have an optimal capacity to discriminate between students with lower ability levels and students with higher ones.

The items identified cover all item typology and all content domains but almost half of them belongs to the domain Data and Probability and only 5 items belong to the domain Space and Shapes, even if many real situations could become the stimulus for geometrical real problems.

In this research we started also to consider distractor plots of the identified real tasks, to detect possible recurring students' behavior facing a real task as function of their mathematical ability. This analysis will be the focus of further studies, but we report here an example of item analysis to explain its potentialities to investigate this issue. The task reported in table 3 was administered in the INVALSI grade 5 test in 2010. Accordingly to our proposed criterion, the task was classified as real with a quality of 1.2 (existence=1, realism=2, specificity=1, presentation=1, language=1). From a psychometrical perspective the item is medium-difficult with a difficulty index equal to 0.91 and the 32% of correct answers. The weighted index (0.9) highlights a good fit of the item. However, the distractor plot shows a little underdiscrimination of the item: the model overestimates the percentage of correct answers for students with medium-low ability and it underestimates it for higher ones. This characteristic might be linked to the influence of the real context that could give more difficulties for students of medium low ability levels due to the fact that they are not used, in the Italian school routine, to face numerous real problems. Moreover, also the trend of the incorrect answers is particularly interesting: distractor A decreases with students ability, this option might be chosen by students that find the correct answer “No” but they don’t link this answer to the correct argumentation; distractor B is constant for almost all ability levels; finally distractor D has an humped performance trend and is more attractive for students with medium-low ability levels. The guessing effect (probability for students of lower ability levels of choosing the correct answer randomly) is low as highlighted by the distractor plot.

Table 3: Example of a real INVALSI task (Task D14 grade 5 INVALSI test administered in 2010)

<table>
<tr><th>Task</th><th>Statistical data</th></tr>
<tr><td>Sandro has 20 dm of string to close four packages he needs to ship. For each package he needs 60 cm of string. Will he be able to close the four packages?
A. No, because 60 is greater than 20
B. Yes, because 20 dm are more than 6 dm
C. No, because 240 cm are more than 20 dm
D. Yes, because decimeters are larger than centimeters</td><td rowspan="3">Delta = 0.91 Weighted = 0.90 Discrimination = 0.51


</td></tr>
<tr><th>Our classification</th></tr>
<tr><td>Real task
Quality: 1.2</td></tr>
</table>

Conclusions

In this paper we reported the first results of an ongoing research project whose overall aim consists in studying what mathematical competencies and types of reasoning are intended to be assessed in the Italian standardized tests. Specifically, we focused on the presence of real tasks in INVALSI tests and on how students face with this kind of tasks. In order to find answers to our research questions, we firstly proposed a criterion, based on Palm’s framework (Palm, 2006) to classify real tasks. Results show that there is a consistent presence of real tasks in INVALSI tests. This fact suggests that one of the competences that these tests are intended to assess is the ability to develop and apply mathematical thinking to solve problems from everyday situations, as desired by the European Council and PISA. Concerning the psychometrical features, from a preliminary analysis of real task at an item level we can observe that, despite the limited use of real problems in didactical practices in Italy (Passarella, 2021), students do not reveal difficulties in these items, and most of them have a low or medium low difficulty level (Delta). This lack of work on real problems does not also influence the fit of these items except in a few cases. Indeed, real items are coherent with the latent trait measured by the whole test. An interesting outcome is that most of the real tasks are discriminative: students with high ability pass brilliantly these tasks, while students with low ability struggle more. Finally, we observe that in INVALSI test there is only a limited number of real tasks in geometry (Space and Shape), while this content domain could be one of the main interesting to promote this kind of tasks.

Future research is needed, particularly on: extending the analysis to tests up to 2019-20 and to the other grades of schooling, since in this study the focus was only on the fifth-grade; deepening the analysis of students' behaviors in facing real problems with some interviews to students and focus groups with teachers; investigating which other mathematical competencies are assessed in INVALSI tests; conducting a comparison with the PISA results in order to uncover and discuss differences or similarities between the two standardized tests.

From paper-pencil to tablet-based assessment: a comparative study at the end of primary school

Nadine Grapin[1] and Nathalie Sayac[2]

[1] Université Paris-Est-Créteil, Laboratoire de didactique André Revuz, Paris, France; nadine.grapin@u-pec.fr

[2]Université de Rouen Normandie, Laboratoire de didactique André Revuz, Paris, France; nathalie.sayac@univ-rouen.fr

Assessments are increasingly being designed on a digital artefact (computer or tablet), while in France the equipment rate in primary schools is still low. Some computer-based assessment tasks use specific software functionalities (the dynamic aspect of a geometric figure for example), while others "migrate" from paper and pencil (PP) to digital artefact without using specific functionalities of dedicated software. In this research, we are interested in the validity of assessment tasks designed on tablet (especially when students do not usually use a tablet in the classroom and/or in assessment situations) and in the effects of migration (from PP to tablet) on student performance and procedures from one medium to another.

Keywords: Assessment, validity, comparative analysis, tablet-based assessment.

Introduction

Most standardized large-scale assessments like PISA or TIMSS have ever migrated (or are going to migrate) from paper-pencil (PP) to digital artefact (DA), like computer or tablet. Several reasons could be quoted for justifying such evolution and designing digital tests like increasing efficiency and consequently reducing costs or giving instant feedbacks, especially in the case of formative assessments (Threlfall, 2007). In France, since 2019, at the end of elementary school (Grade 5), a representative sample of students takes with tablets (and not with paper-pencil, as they did before), a national test, which aims to assess mathematics skills and knowledge and to observe their evolution at six-year intervals.

All French elementary schools have been equipped with computers and Internet access, but students haven’t regular access to these digital environments: on average, there are 7.8 students per computer at elementary school (no data is produced about tablets) (Ministère de l’Education Nationale, 2018). These observations made us wonder about the validity of computer or tablet-based tests: if students are not used to doing mathematics with such artefacts, we can ask if the test assess really what it has to assess (mathematic skills and knowledge) or does it assess other competencies, like digital skills. More specially, is the test itself valid (especially when students do not usually use a tablet in the classroom and/or in assessment situations)? is longitudinal comparison performance (in the case of large-scale assessments) relevant? are mathematical processes to solve tasks the same when a similar problem is on PP or DA?

Previous research and theoretical background

In their review of assessment in mathematics education, Nortvedt and Buchholtz (2018) point to the development of digital assessments with parallel advances in psychometric models and the development of adaptive assessments. At the same time, they also highlight the limitations of such assessments, particularly because they often only assess knowledge on simple tasks (and do not allow for the assessment of students' problem-solving skills). The authors conclude that "technology can also limit what is assessed" (p. 560). In general, the design of digital assessments raises validity issues, and we will explain how we address them. We do not review in this text all the research about digital assessments, but we limit our subject to the comparison between paper-pencil and digital-based assessments.

Comparative research between paper-pencil-based assessments and digital ones

Numerous studies, especially the Anglo-Saxon ones, aim to compare success scores between PP and DA were carried out at different school levels and on various disciplines. First, we can observe that most of these studies are based on data analysis without considering students' procedures (see, for example, Hamhuis & al., 2020). Second, their results are divergent, and they do not allow us to conclude, on the fact that a medium (DA or PP) would promote or not student success (Lemmo & Mariotti, 2017). For example, in France, from the results of two large-scale assessments, Bessoneau, Arzoumanian, and Pastor (2015) identified two variables that particularly influence the success in a mathematical item depending on the medium used: the structure of the item (length of texts, number of documents, etc.) and the type of tasks proposed. In particular, the items presenting a syntactic and linguistic complexity relative to the statement are better succeeded on PP whereas, in the case of an item requesting a direct taking of information (in a table or on a graph), success is better on a DA. In addition, problems requiring several steps of resolution are more successful on PP.

About such performance comparisons, we share Lemmo and Mariotti's (2017) point of view: "task comparability cannot be measured only in terms of students' outcomes, but it is also established by the comparison between the solving strategies that they use" (p. 3541).

About validity and legitimacy, Threlfall et al. (2007) explore in their research several aspects of "what may be lost and gained by undertaking mathematics assessment on the computer" (p. 336) and their conclusion, based on student's performance is :

> It is not only that translating paper and pencil items into the computer format sometimes undermines their validity as assessments, it is also that some paper and pencil items are less valid as assessments than their computer equivalents would be. (p. 335)

Let us now explain how we study the validity of a test from a didactic point of view while considering the modality of assessing (PP or DA).

Validity and instrumental genesis

For studying the validity of assessment tasks, we have developed in previous research a methodology with two complementary approaches (Grapin, 2016): one epistemological and didactical and another psycho-didactical. The first approach provides us with evidence of validity based on the a priori analysis: for each task, we list, among other things, the different solving procedures, the possible errors, and their origins, but also the complexity of the tasks (Sayac & Grapin, 2015). This analysis allows us to study whether the solving of the task mobilizes the mathematical knowledge that we want it to assess. The psycho-didactical approach is focused on student activity, i.e., that they develop when carrying out the task; in our case, this includes their mathematical activity (their solving strategies), but it takes also into account the process of instrumental genesis (Rabardel, 1995). Moreover, “instrumental genesis is not the same for all students; it depends on their relationships with both mathematics and computer technologies” (Defouad 2000, as cited in Trouche (2005)). We hypothesize that students who use these artefacts routinely in the private sphere will have easier use of them in the school sphere; we also assume that students who have been able to use these artefacts in classroom situations will have a different instrumental genesis than others. So, to study the psycho-didactic validity of assessment tasks with a DA, it is therefore essential to determine students’ use of the artefact (whether at school or home) and to observe how they solve the task with this artefact.

For this comparative research, we also have to determine how and when two tasks could be considered equivalent. Riplay (2009) distinguishes migratory and transformative approaches to switch from PP assessment media to a digital one. The migratory approach consists of the transition of PP task to DA without any modification; in the transformative approach, the original PP-based tests are transformed with the integration of specific functionalities of the artefact. The migration of tasks also requires considering the functionalities of the software or the application used for the test.

Research goals
