We have chosen to focus our research on the comparison between PP and tablet-based assessment because one of the national large-scale assessments in France at the end of primary school migrated from PP to tablet in 2019. This raised questions about the comparability of results from one year to the next, but above all for us, several questions about validity. In this paper, we focus on two aspects of our research: the way we designed the test and analyzed its validity (1) and the analysis of the first results considered instrumental genesis (2).

(1) We have designed the test to compare the students’ strategies in the case of migratory and transformative approaches: even if only some knowledge related to general tablet functionalities (virtual keyboard, drag and drop, virtual eraser in the draft) are needed to write or to provide the answer, we have considered that there was a change to the task (we will give examples in the following sessions). Under these conditions, is, a priori, the student's mathematical activity the same when solving a problem on a tablet or with PP? what are the differences in terms of mathematical strategies? And finally, are the same knowledge assessed?

(2) Since French schools are still poorly equipped digitally, we assume that students who regularly use tablets at home may have more advanced instrumental knowledge than others; since the time required must be short in an assessment’s context, it is therefore possible that tests on a DA generate academic inequalities linked to the artefact itself. Is that so? How can the use (regular or not) of tablets impact students' scores and procedures? What are the implications for task validity?

The first question will be principally dealt with in the following part (methodology and design of the tests), and the second, in the part dedicated to results.

Methodology and design of the tests

To study more specifically the students’ activity in a tablet assessment situation and to be able to compare it with that on PP, we conducted in June 2021 a study at the end of Grade 5 with 80 French pupils from priority education schools and from “ordinary” schools (choosing two types of schools will enable us to observe whether inequalities are generated by the artefact itself).

Administration of tests and survey

All the students took the same two tests (PP and tablet). Each test consists of solving 23 tasks whose required knowledge of whole numbers and decimals, arithmetic, and problem-solving. The paper-pencil-based test took place during a regular classroom math session. The tablet-based test took place after PP one with the two researchers in the classroom. We observed how students were using the tablet and the difficulties they might encounter, depending on the tablet’s functionalities involved in certain items. During this observation phase, we focus on the student's instrumental genesis and study whether it interferes with the student's mathematical activity. We don't ask the students individually about their procedures because the a priori analysis of the tasks enables us to infer their strategies from the proposed answers.

Moreover, we ask students if they have a tablet at home and how often they use it (at home and in the classroom). The answers to this short questionnaire will also make it possible to judge the validity of the tasks and to ensure that they do not generate inequalities between students (especially those who have a tablet at home and those who do not).

Design of both tests

The choice of the didactic variables’ values made it possible to design mathematical equivalent tasks; we describe, in this paragraph, with examples, how we have designed such tasks in migratory and transformative approaches.

First, we have chosen, as equivalent tasks in a migratory approach, multiple-choice questions, as the example below (Table 1).

PP task	**Tablet task**
What is the result of 45,83 × 10 ? *Tick the correct answer.* □ 450,830 □ 450,83 □ 45,830 □ 458,3	Quel est le résultat de 23,85 x 10? *Coche la bonne réponse.* ☐ 230,850 ☐ 230,85 ☐ 23,850 ☐ 238,5

Table 1: Example of a QCM in PP and tablet environments

We can observe, in this first example, that the two tasks (PP and tablet) involve the same mathematical knowledge with the same level of complexity; the wrong answers correspond to the same type of errors both on the PP task (PPT) and on the tablet task (TT).

When the transition of an item from the PP to tablet involved the use of the virtual keyboard or drag and drop, for example, we considered these modifications to be in a transformative approach. Nevertheless, we were careful to design mathematically similar tasks by choosing appropriate values for didactic variables, but let us explain, using the following example, how this type of transition can impact student answers. For assessing knowledge about writing numbers and units, we design the two following tasks (Table 2):

PP task		**Tablet task**	
Connect each number on the left with its equal number on the right.		Move the left or right label so that the number on the left is equal to the number on the right	
		Fais correspondre chacun des nombres de gauche avec celui qui lui est égal à droite.	
372 centièmes	0,372	483 centièmes	0,483
372 dixièmes	3 720	483 dixièmes	4830
372 unités	37,2	483 unités	48,3
372 dizaines	3,72	483 dizaines	4,83
372 millièmes	372	483 millièmes	483

Table 2: Example of a task using tablet functionalities

In this example, in the case of the TT, students can forget numbers or make mistakes but he or they cannot rely on one label on the right with two others on the left (unlike with the PPT). The treatment of the answers, especially in this case, is also simplified with the tablet.

We also want to study how students solve arithmetic problems, especially to observe how they use a draft on a tablet: on PP, they can easily make a diagram, write the operation, and use paper as a draft. With the tablet, we had provided a draft zone, but students need to understand pictograms (Fig. 1) for being able to draw, erase, organize their calculations.

Figure 1: Pictograms for using draft zone

Two types of problems were designed: a division problem (text of problem 1 - PPT: *"9 students of 6 years old must share 1,557 masks. How many masks will each student have?"*) and a number problem (text of problem 2 - PPT: *"Six 4-year-old students must share 6,000 sheets of paper. How many sheets of paper will each student have?"*). Students cannot use a calculator either in PP or with the tablet. For solving problem 1, they have to use a draft for calculating 1557:9 but for problem 2 they can mentally answer. With problem 1, we'd like to study how students use the draft of the tablet, and with problem 2, we'd like particularly to observe whether the tablet promotes mental calculation procedures.

Results

Results for all students

For all 80 students, the average success score in PP is 16 correct answers (out of 23 tasks) and 14.5 on the tablet. Now let's look at the difference in success question by question: we studied the number of correct answers per question, and we calculated the difference between the number of correct answers of PPT and the number of correct answers of TT (Figure 2). We observe for example that 4 students out of 80 did better on question 21 (QCM – the task is given in table 1) on PP than on a tablet.

On the whole test, only 2 tasks (Q1 and Q19) of 23 are better performed on a tablet than in PP, but only by 1 or 2 more students.

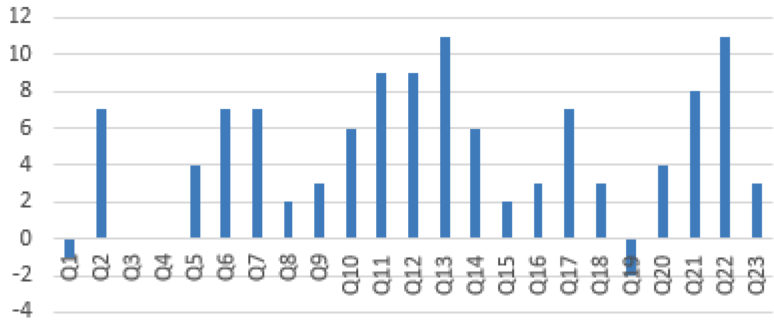

Figure 2: Difference between the success score in PP and on the tablet per question

It's not surprising that the division problem (problem 1 – Q13, quoted before) is more successful on PP than on a tablet, but we must study exactly what are the errors and procedures in PP and on a tablet for better understanding this result. We have the same analysis to do with other questions, especially when the difference between performance on PP and with the tablet is important. We'll then be able to determine the validity of such assessment tasks, whether PPT or TT.

Per student, we observe also that the difference in success score on the 23 questions between PP and tablet can vary between -8 and +14. 16 students have the same score in the two tests but 7 students have a score difference of 4 points (Figure 3).

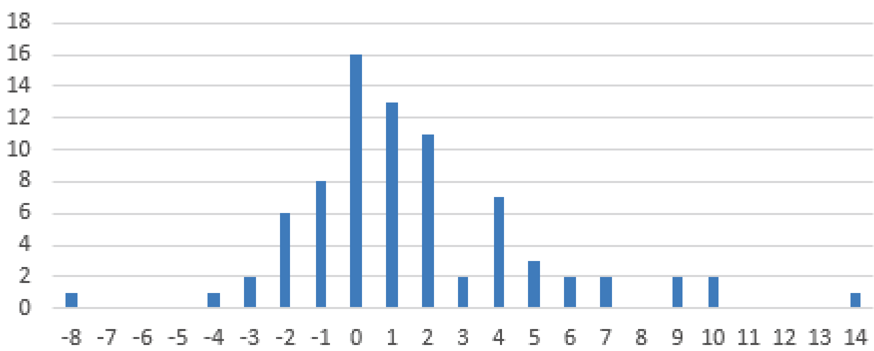

Figure 3: Number of students by the difference in success scores between PP and tablet

Results for students according to their use of the tablet

During the observation phase, we noticed that most students use the tablet by themselves, without help; only instructions on how to write the comma, use the “drag and drop” and erase in the draft have been given by the researchers. The answers of students confirm that 80% of the students regularly use a tablet at home (more than once a week) and only 17 students use a tablet less than once a month.

For these 17 students, we observe that the average success score both on PP (16,5) and tablet (14,5) is better than the average score of all students. We are currently further studying the responses and procedures of these students. We can observe for example, that, for problem 1 (division problem), which requires a little more advanced use of the tablet and the draft area, 4 students who had correctly solved the problem in PP were mistaken on the tablet (either because they did not answer anything, or because they made a mistake in the division or did not finish it). We cannot give general conclusions from this example, but during the presentation, we’ll present the detailed results, and we’ll try to show the relationship between the regularity of tablet use, the students’ mathematical activity, and their performance.

Conclusion

To complete these first results, we will reproduce this experimentation on a larger sample of students, taking care to change the order of the two modalities (PP then tablet *vs* tablet then PP). We also wish to integrate tasks that use other functionalities of the tablet (such as the zoom to place a number on a graduated line or the integrated calculator to perform operations in problem-solving).

The question of the validity of the assessment tasks is raised on the DA, as on PP. DA offers several possibilities for designing new types of tests especially diagnostic and formative ones with automatic feedbacks (for example, Sirejacob & al., 2019), but if the designers of these tests do not consider the specificities of the DA, the validity of the test is not guaranteed: students' mathematical knowledge is not correctly assessed and all the feedbacks are not suitable. Our research aims to identify points of vigilance about the validity of tablet-based assessment and the comparison between PP and tablet performance and strategy.

This research also allows us to better study *a priori* the complexity of a task on a tablet (Sayac, 2018; Sayac and Grapin, 2015) by adding a specific dimension related to the instrumental genesis and the functionalities of the support involved in the resolution of the task.

Zooming in mathematical conversations in the light of the formative assessment

Stine Holm Gundersen[1] and Iveta Kohanová[2]

[1]Former master student at NTNU, Norway; gundersen.stine.holm@gmail.com

[2]NTNU, Department of Teacher Education, Trondheim, Norway; iveta.kohanova@ntnu.no

This paper presents the results of a qualitative study focusing on characterisation of enactment of formative assessment during mathematical conversations by Norwegian primary school teachers. Two second-grade teachers working in a primary school in a large city in Norway were observed during mathematical conversations with their pupils in station teaching regarding various strategies for addition. We suggest a model that characterises the formative assessment enacted during a mathematical conversation from a teacher's perspective.

Keywords: Formative assessment, mathematical conversations, learning of mathematics.

Introduction

Assessment is vital to the education process and it has been on the political education agenda in many countries for several years, also in Norway. In 2010 the Norwegian Directory of Education and Training started a national programme The Assessment for Learning (AfL). The involved schools worked over a period of 16 months towards an overall goal, which was "to improve formative assessment practices in the classroom by developing distinct criteria to clarify how to reach curriculum goals" (Hopfenbeck et al., 2013, p. 28). This AfL initiative was a continuation of a previous programme (Improved Assessment Practice) and as Smith (2016) stated that "despite multiple initiatives, problems with implementation /of AfL/ have remained, and the changes in classroom practice have not gone as expected" (p. 182). Several Scandinavian researchers studied how teachers develop individual AfL literacy usually within an intervention (e.g., Engelsen & Smith, 2014; Andersson & Palm, 2017). However, little is known how Norwegian teachers from schools involved in AfL programme, are practicing formative assessment nowadays.

Assessment plays an important role also in the new Norwegian curriculum (LK20), which was launched in August 2020. The competence goals in mathematics are built around six core elements and assessment is described in a special paragraph for each grade (Utdanningsdirektoratet, 2019). As stressed in LK20, assessment should help promote learning and to develop competence in mathematics. Teacher should ensure good conditions for students' participation; provide guidance and adapt teaching so that students can use the guidance to enhance their learning. The role of both the teacher and the student in the assessment process is undoubtedly essential and although student's peers are not mentioned, we see signs of formative assessment (FA) here (Cowie & Bell, 1999), despite using the word "undervegsvurdering", which literally translates as "assessment along the way". In LK20 (Utdanningsdirektoratet, 2019) a particular emphasis is also given to oral skills when students should create meaning through conversation in and about mathematics. One way how to engage students into communication in mathematics is to lead mathematical conversations (MCs), which are "not only very good methods for teachers to elicit evidence of students' understanding and misunderstandings in order to inform the next steps in learning and teaching, they are in themselves powerful learning activities" (Swaffield, 2011, p. 443). The main purpose of a MC is to support and promote students' learning through a discussion in which students can clarify their own thinking and learn from others (Chapin et al., 2009).

In this context, and also in line with Bennet's (2011) criticism of FA related to its lack of conceptual understanding and exemplification in specific subject areas, we consider pertinent to shed a light on MCs in terms of FA. Thus, we seek to answer the following research question: *How can the enactment of formative assessment during a mathematical conversation be characterized for Norwegian primary school teachers who participated in the Assessment for Learning programme?* The study presented here was part of the main study, in which we, in addition, also tried to understand how the teachers who participated in the AfL programme, perceive FA in mathematics.

Theoretical framework

In the research field of mathematics education, several theoretical frameworks and models are designed to explain FA (e.g., Cowie & Bell, 1999; Wiliam & Thompson, 2007). Although the term *formative assessment* does not represent a well-defined set of artefacts or practices (Bennet, 2011), the following conceptualization by Cowie and Bell (1999) captures the meaning of many definitions found in the literature: FA is "the process used by teachers and students to recognise and respond to student learning in order to enhance that learning, during the learning" (p.101).

Wiliam and Thompson (2007) operationalized FA in a form where the three key processes of teaching and learning and the three agents in the classroom (teacher, peer and learner), are interconnected within the five key strategies. Cowie and Bell (1999) introduced a model (Figure 1) to describe and explain the nature of the formative assessment process in science education.

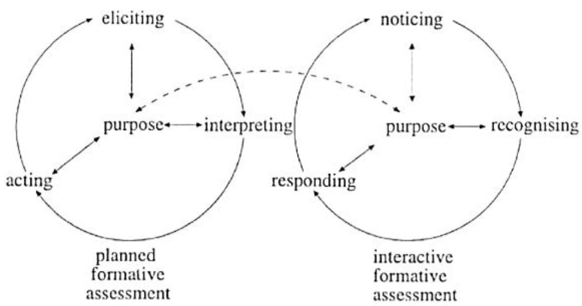

Figure 1: Model of formative assessment (Cowie & Bell, 1999, p. 113)

The model was developed from a consideration of the data collected through a research project investigating FA in science classrooms in New Zealand. It consists of two kinds of FA: *planned* and *interactive* (PFA/IFA). PFA involves *eliciting* assessment information using specific planned assessment activities, *interpreting* and *acting* on the information. The purpose for doing the assessment strongly influences the other three aspects of PFA process. IFA takes place in teacher-student(s) interactions that arise from the learning activity and are thus not planned. IFA, besides the purpose, involves also three aspects, *noticing* in the context of the learning activities, *recognizing* significance of what was noticed for the development of the student's understandings and immediate *responding*. It is usually used with individual students or small groups. Teachers switch between PFA and IFA as the purpose changes. The purpose of the PFA is to obtain information from the whole class about progress in learning as specified in the curriculum to inform the teaching. The purpose of the IFA is to mediate in the learning of individual students with respect to science, personal and social learning.

Although the second key strategy of Wiliam and Thompson (2007) mentions effective classroom discussions, the model of Cowie and Bell (1999) enables us to zoom into single episodes of MCs and study, how teachers support students' learning during the learning.

Methods

Research Context, Data Collection and Data Analysis

The data that constitutes the empirical base for this study is an observation of two second-grade teachers and their pupils during one mathematics lessons in late autumn 2018, as well as interviews with these teachers before and after the observed lesson. The interviews constitute the main source of data for other part of the earlier mentioned main study. For this study they play a supportive role, for example, regarding clarification of the learning goals of observed lessons, and additional information about typical way of performing FA, which helps us to answer our research question.

The chosen primary school in a large city in Norway was selected based on its participation in the AfL programme, as well as on its accessibility to the first author. Following criteria were used to select two teachers to participate in this study: (i) has worked as a teacher in the school for the last 8 years (participation in AfL); (ii) educated as a mathematics teacher (professional skills), (iii) teaches mathematics at the present time. Together with the headmaster of the school and the selection criteria, it was decided which teachers were asked to participate in the study. The names of pupils and teachers are altered; the teachers are called Jorunn and Hilde. In collaboration with Jorunn and Hilde and due to the purpose of the study, it was decided that station teaching was appropriate to observe. Station teaching is teaching divided into several learning activities. The teacher began the lesson by explaining the five learning activities and where in the classroom the assignments were located. Then the pupils were divided into five groups of 3-4 pupils, and the teacher decided which group to start with the different activities. The pupils worked on the same learning activity for 20 minutes. Switching from one activity to another was performed and controlled by the teacher. The content of the different learning stations was independent of each other but selected based on the teacher's thoughts on the balance between work and play. The observed station is called teacher-controlled station as the teacher participates in the pupils' learning work at that station, and none of the remaining four stations.

The learning activity the teachers chose for this station included a clue task (Figure 2), and it was for the first time Jorunn and Hilde used this type of task in a MC that focuses on addition strategies. The task consists of a text assignment and four clues. The teacher's guide to the clue task (Brataas, 2018) specifies that the teacher's role is to introduce the task, guide pupils, and lead a summary with the intention of having pupils present their solution suggestions. In other words, the learning activity is structured in a way that allows the teacher to gather information about the pupils' learning.

> The teddy bear tries to find out how many soft toys they are in Felix's room. Some are small, some are large, but all have a permanent position in the room. Can you help the teddy bear to find out how many soft toys there are?
>
> 1a. On the shelf above the bed are four cute penguins and two lurking foxes.
>
> 1b. On the bedside table, there is the teddy bear and four other soft toys waiting for Felix to come home.
>
> 1c. In the windowsill, there are twice as many soft toys as it is on the shelf above the bed.
>
> 1d. On the bookshelf, there are three times as many soft and scary dinosaurs as there are soft toys on the bedside table.

Figure 2: Clue task (Brataas, 2018, p. 2)

Both teachers used the same task in the teacher-controlled station, and both had the same structure during the lessons. The data in this study, therefore, consists of ten transcripts of MCs between the teachers and different pupils groups at the teacher-controlled station, five with Hilde (H1-H5) and five with Jorunn (J1-J5).

The analysis of the data was driven by deductive thematic analysis (Braun & Clarke, 2006) by using the four aspects (purpose; elicit/notice; interpret/recognize; act/respond) of FA from the Cowie and Bell model (1999) as codes. In the analysis we have chosen to disregard connection with PFA or IFA because our aim is not to focus on the type of FA, but its characterization during a MC.

Analysis

In this paper we present three episodes, as examples of enactment of FA during a MC. The first episode J1 is a conversation between Jorunn and a first group consisting of three pupils. Jorunn presented goals for the activity and equipment that was available on the table and gave a general description of the learning activity.

9	Jorunn:	And I have sort of a goal here, about what we are going to look at, it is about – can you three cooperate, we will look at this. Also, we will look whether you manage to double [the pupils answer yes along the way, nod and pay attention]
10	R:	What was double again?
11	Jorunn:	Yes, what was double?
12	pupils:	It's the same as plus.
13	Jorunn:	Yes, but can you give an example?
14	R:	Oh! Is it taking the same thing again?
15	Jorunn:	To take the same again, you knew it yourself! Very good. Also, there is to check if you guys had a little fun when we are done [the goal]. That's what I want us to do. Are we ready?

At the beginning of the activity, one of the pupils asked for an explanation of the term doubling (line 10). This episode may be an example of how Jorunn *noticed* and *recognized* the pupil’s input as a valuable contribution to the development of pupils’ understanding of the concept of doubling.

Her *response* was to give the pupil room to think, she repeated the question and also encouraged peers to help by asking for examples.

Four pupils participated in episode J3. As the pupils began working on the clue 1c, Jorunn elicited information about their learning. Large proportions of the conversation contain exchanges of meaning related to the concept of doubling.

150	Jorunn:	Yes, how many were there on the shelf above the bed then?
151	Z:	six, [counts further] seven, eight, nine, ten, eleven, twelve
152	Jorunn:	Yes, is anyone using a different strategy?
		[short break, accepting that pupil Z is counting further and actually calculating the number of toys in the windowsill]
153	Jorunn:	Do you think it was difficult and why did you write six plus five?
154	C:	I should actually have written six there [point to five on the sheet, the pupil C wrote 6 + 5]
155	Jorunn:	Okay, you can erase it. [pupil C erases it]
		[short break]
156	Jorunn:	But what strategy do you use to calculate six plus six then?
157	X:	six plus six
158	C:	ehm, I have a good one. Because .... eee sixes can be split into three
159	Z:	six
160	Jorunn:	mmm it can
161	C:	It can also be split into five, it can be split into five and five and two.
162	Jorunn:	Five and five and two yes, it works. Mmm very good.
163	Z:	six and six is
164	X:	if we have one, two, three, four,
165	Jorunn:	Was anyone using the doubling strategy then?
166	X:	five, five, six

In the episode J3, we see that Jorunn has deliberately tried to *elicit* information about the pupils' learning, but she received little response from them. It is possible to interpret it as an example of Jorunn adhering to the plan to elicit information about the pupils' doubling strategies (as expressed in the interview before the lesson), i.e. the planned formative assessment. But at the same time, it is necessary to be critical of what information Jorunn actually received and how she acted.

In the episode H3, four boys participated in the learning activity, and the episode is taken from the last part of the conversation, which is linked to the last clue 1d (in the Figure 2).

260	Hilde:	Then there's one clue left, boys, are we ready? [the boys nod] In the bookshelf there are three times as many soft and scary dinosaurs as there are soft toys on the bedside table. Wow…
261	Q:	three like that
262	Hilde:	if these are the soft toys [pointing to the pile they made with blocks to represent the soft toys] that are on the bedside table, and you should have

three times as much. [gasps a little] What does it mean when it's three times as much?

263 Q: three times as much

Pupil Q repeated the term with wonder in his voice (line 263), and further in the conversation several pupils tried to explain what they thought.

276 Q: So then I take three again, one, two, three, then I've come to nine.

277 Hilde: It sounds very clever, but it's not three, it's five. And five three times. [pupils think, and continue working for 2-3 minutes]

278 Q: five [holding up the hand] then to these I have ... I've done it two, ... fifteen!

279 Hilde: Fifteen! Oh, we have to make the last fifteen, you guys are ready?

Hilde confirmed the pupils' work before she told them that they had to start with the amount of five and not three (line 277). She praised the pupil's thinking and repeated the information about the amount with another wording 'five three times'. The *response* from the teacher led the pupils to continue to work. After a few minutes of work, the pupil Q addressed Hilde and explained 'five three times' by showing the amount of five with his fingers on his hand. The teacher responded by repeating the number and urged the pupils to add fifteen blocks to the pile they had made for the number of soft toys in the room. This episode is an example of Hilde's response when pupils worked to explore the concept of three times as much. The teacher let the pupils work on the assignment without interfering with the work process. If the teacher made a conscious choice by allowing pupils to explore the concept with the wrong amount, the choice can be seen in the context of interpreting information about the pupils. It is possible to interpret the episode as an example of Hilde *recognizing* the thinking of the pupils and giving the pupils confirmation of thinking before correcting the amount.

The interviews revealed that both teachers thought of MCs as a way of conducting formative assessment in their mathematics teaching, and especially with young students. It is their most typical and frequent way of conducting FA. They stressed the importance of getting feedback immediately:

> You have to do it /assess/ while they /pupils/ are in the process. ... we can always put a smiley face in the book or something like that, but it kind of does not become what is [pause for thoughts] … yes, in relation to pupils, because they are so much here and now. (Hilde)

> I would say that my practice has changed from being an "after-assessor" to being "along the way". So that I do not spend a lot of time on corrections afterward anymore, because, in relation to primary school, I think it has no sense. They /pupils/ are done. And when they are done, they are done. They do not look at what they did, so I try to put as much weight as possible along the way so they get the feedback as soon as possible. (Jorunn)

Discussion

In this paper we focused on characterization of enactment of FA during MCs. Our findings revealed that both teachers were continuously collecting evidence of pupils' learning by listening, asking questions, revising the learning goal according to elicited information, interpreting pupils' thoughts, rephrasing their questions, providing time for pupils to think, acting, etc. In other words, they modified teaching in relation to how pupils responded to the learning activity. FA enacted during a MC seems to be a dynamic process, in which its four aspects were interrelated, both in PFA and IFA. FA evolves like a spiral through these aspects, but at the same time back and forth through the aspects. Moreover, there is not always a straight forward process with one action following another, as rendered in Figure 3, which shows the circular characteristics of FA enacted during a MC.

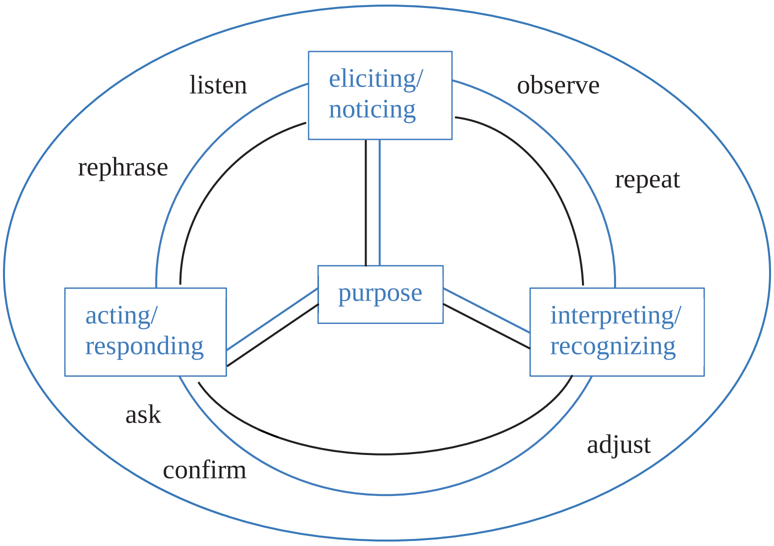

Figure 3: Our model suggestion of FA enacted during a MC, from a teacher's perspective

In Bell and Cowie's study (2002), science teachers indicated that eliciting and noticing were easier to do in the classroom than taking action and responding. Based on our observations, we concur with this finding, as the FA is "a complex, skilled task and it relies on the teacher's pedagogical knowledges" (Bell & Cowie, 2002, p. 92). Bell and Cowie (2002) suggest that "any future teacher development would need to focus on taking action and responding" (p. 94), as this determines whether the assessment is, in fact, formative or not. Bennett (2011) suggests that "to realize maximum benefit from formative assessment, new development should focus on conceptualizing well-specified approaches built around process and methodology rooted within specific content domains" (p. 5). Our study elucidates a MC as a specific way of conducting FA, which is in line with Ruiz-Primo (2011), who argues that assessment situations can occur in almost any learning activity if the teacher is aware of the student's learning. Faced with the new curriculum LK20, with an emphasis on speaking more mathematics, this study stands as an example of how two teachers assess "along the way" ("underveisvurderer") and/or act out FA during MCs. MCs are not FA per se. Our study contributes to the existing knowledge on teachers' FA practices when MC is the dominating teaching strategy.

This study was conducted to investigate the characteristics of algebra tasks that middle school preservice mathematics teachers developed at the end of a three-week training related to examining and categorizing algebra items in the previous high school entrance examinations (2018-2020). Twenty-nine third-year middle school preservice mathematics teachers participated in the study. The data of the study included 12 algebra tasks generated by preservice teachers at the end of the training and their characteristics. Findings showed that preservice teachers were able to develop cognitively demanding algebra tasks. Most of the tasks aimed to assess students' knowledge in geometry and measurement learning areas besides algebra. Lastly, most of the tasks were related to manipulating symbols, while four tasks focused on modeling problems using equations or algebraic expressions.

Keywords: Task development, preservice teachers, cognitively demanding algebra tasks, high stakes assessment.

Introduction

Assessment can be categorized based on its purposes. Formative assessment or assessment for learning is used purposefully for learning (Laud & Patel, 2013). It provides students and the teacher with a rich stream of information that can be used to adjust instruction to meet students' needs and enhance their learning (Wiliam, 2007). On the other hand, other potential actors such as universities, policymakers, and administrators need summative data since they cannot deal with the vast quantity of evidence collected through formative assessment (Burkhardt & Schoenfeld, 2018). Hence, summative assessment or assessment of learning is crucial to measure students' level of accomplishment, especially in countries where the result of high-stake exams may cause a big change in students' lives.

The results of students' performance in high stake exams directly impact teachers and students in some countries like the UK and the USA (Burkhardt & Schoenfeld, 2018), including Turkey. The types of tasks in the exams and the valued competencies influence teachers' actions in the classroom (Barnes et al., 2000) and therefore students' learning. In some cases, most classrooms' learning activities were reformed and became parallel to the task structures covered in the exams (Burkhardt & Schoenfeld, 2018).

In the case of Turkey, the High School Entrance Exam (HSE) system was changed in 2018. One of the fundamental changes made in the HSE was the structure of the items covered in the exam. Before the change, HSE measured basic skills at the level of knowledge, comprehension, and application. Now, high-level skills such as making interpretation and inference and analytical thinking are measured (Biber et al., 2018). Reports informing the results of the HSE exams held in 2018 and 2019 showed that mathematics tests had the lowest rate of correct response of all the subjects (Ministry of National Education [MoNE], 2018a; 2019). One of the reasons for this situation might be that mathematics teachers were unprepared for the cognitively demanding assessment tasks and could not find sufficient resources to use in their classrooms (Biber et al., 2018). Since tasks in the mathematics textbooks are not compatible with the HSE items and the resources teachers use in their lessons are insufficient, preservice mathematics teachers' awareness about the cognitively demanding HSE items needs to be improved. In addition, whether preservice teachers can generate cognitively demanding tasks is worthy of investigation since these tasks can be used as teaching tools as well as assessment tools.

This study aimed to investigate the characteristics of algebra tasks that middle school preservice mathematics teachers (PMTs) developed after participating in a three-week training related to examining and categorizing algebra questions in the previous HSE examinations (2018-2020).

Algebra is a bridge between mathematics and other branches of science (Erbaş et al., 2009). Research points out the importance of developing students' algebraic thinking starting from kindergarten (Stephens et al., 2017), and one of the ways this could be achieved is through professional development (Kieran et al., 2016). Although there are studies focused on investigating the questions that PMTs pose during diagnostic algebraic thinking interviews (e.g., van den Kieboom, 2014), limited research exists on examining PMTs' generation of cognitively demanding algebra tasks.

Kaput (2008) focusing on arithmetic and algebra problems proposed a framework that included two core aspects for algebraic thinking. The two core aspects of algebra were "(A): algebra as the systematic symbolizing of generalizations of regularities and constraints" and "(B): algebra as syntactically guided reasoning and actions on generalizations expressed in conventional symbol systems" (Kaput, 2008, p. 11). Kaput stressed that while both aspects of algebra are significant, school algebra generally focuses on Core Aspect B, more specifically reasoning and actions on generalizations. While in Core Aspect A, students are encouraged to notice regularities, generalize and represent those generalizations. In this study, Kaput's (2008) framework was used to categorize PMTs' algebra tasks with respect to the core aspects of algebra.

Measuring students' ability requires the classification of levels of thinking. Bloom's revised taxonomy provides a measurement tool for thinking and classifies thinking into six cognitive levels of complexity: remembering, understanding, applying, analyzing, evaluating, and creating (Anderson et al., 2001). In a similar way, Smith and Stein (1998) proposed four categories of cognitive demand; (i) memorization; (ii) procedures without connection (PW/oC); (iii) procedures with connection (PWC); and (iv) doing mathematics in order to help teachers select and create cognitively demanding tasks to increase students' ability to think and reason. They identified the first two categories as low-level demands while the last two categories as high-level demands. We used Bloom's revised taxonomy and Smith and Stein's (1998) categorization to categorize the cognitive levels of PMTs' algebra tasks in the study.

Methods

Basic qualitative research method (Merriam, 2009) was employed in this study in order to reveal the characteristics of algebra tasks generated by PMTs.

Participants and Study Context

The study participants were 29 third-year middle school preservice mathematics teachers who were enrolled in a four-year middle grades (grades 5-8) mathematics teacher education program at a public university in Ankara, Turkey. The program mainly offers introductory education and mathematics courses in the first two years. The departmental courses mostly start in the third year of the program. They include courses that focus on developing pedagogical content knowledge, such as the Methods of Teaching Mathematics in Middle Schools I and II. In their fourth and last year in the program, PMTs take School Experience and Practice Teaching courses. Related to the context of this study, a semester before this study was conducted, PMTs were enrolled in the Assessment of Learning in Science and Mathematics course. Throughout this course, PMTs were introduced to the different types of assessment, including formative, summative, and diagnostic assessment types. They were also asked to develop different assessment instruments, including multiple-choice, short response, true-choice, and open-ended with their rubrics.

Data Collection

The study's data were drawn from a study[*] that aimed to investigate middle school PMTs' conceptions of algebra, their awareness of the characteristics of algebra items in HSE, and their improvement in generating algebra tasks at the end of the training. The training was carried out in the Methods of Teaching Mathematics in Middle Schools II course, which focused on teaching "proportional and algebraic thinking", "statistics", and "probability", respectively. The Methods course was offered in the Spring Semester of 2020-2021 academic year by the first and second authors, and the researchers implemented the training of this study. The PMTs attended the course through online education via Zoom. The training took place as part of the algebraic thinking weeks.

The PMTs were asked to read the chapter on algebraic thinking by Van de Walle et al. (2013) and several other articles and a book chapter that were mainly intended for in-service and preservice teachers. These readings were discussed in class, and related activities were conducted in small groups. Usually, whole-class discussions took place after the small group discussions. At the beginning of the semester, two groups were assigned to design lesson plans focusing on algebraic thinking, choosing an objective from the curriculum. These plans were implemented through micro-teaching, and the groups received oral feedback from the instructors and their classmates. Then the training for this study started, which lasted for three weeks (12 class hours). PMTs were asked to analyze 2018, 2019, and 2020 HSE algebra items first individually and note the characteristics of the questions (objectives/contents addressed by the problems, and cognitive levels according to Bloom's revised taxonomy and Smith and Stein (1998), and their justifications). Then they discussed their analysis in the same groups of 4 or 5 each week. After small group discussions, whole-class discussions took place, and some sample items the researchers chose were discussed together. At the end of the training, groups were asked to generate two cognitively demanding open-ended algebra tasks in the same groups (6 groups and 12 tasks in total). They were also asked to write the related

[*]The research is funded by the Middle East Technical University Research Fund GAP-501-2021-10644.

objectives/contents from the curriculum, expected student responses (both correct and incorrect), and cognitive levels according to Bloom's revised taxonomy and Smith and Stein’s (1998) categorization.

Data Analysis

For the scope of this paper, we focused on 12 algebra tasks generated by PMTs at the end of the training and their characteristics. The data were analyzed through content analysis. Cognitive levels of the tasks were categorized based on both Smith and Stein’s (1998) framework and Bloom’s revised taxonomy (Anderson et al., 2001). We used Kaput’s (2008) framework to determine which core aspect (A or B) each task focused on. Kaput’s (2008) two core aspects and the cognitive levels of the tasks were determined separately by the researchers and later discussed to reach a consensus. Learning areas and contents were accessible from the national middle school mathematics curriculum (MoNE, 2018b).

Findings

Findings showed that all the tasks developed by PMTs were cognitively demanding algebra tasks according to Smith and Stein’s (1998) categorization and Bloom’s revised taxonomy. We classified all tasks developed by PMTs as PWC. Furthermore, according to Bloom's revised taxonomy, we classified PMTs’ tasks at two levels: nine tasks at the analyzing level, three tasks at the applying level. When we compared our and PMTs’ decisions about the levels, we found medium to a high inter-rater agreement. Specifically, out of 12 tasks, we found the level of the eight tasks the same using Blooms’ revised taxonomy (about 67% agreement); the disagreement was mostly between the levels of applying and analyzing. The agreement increased to about 92% for Smith and Stein’s categorization.

Most of the algebra tasks generated by the PMTs aimed to assess students’ knowledge in geometry and measurement learning areas. PMTs used geometric shapes to assess students’ ability in doing operations with algebraic expressions in almost all these tasks. More specifically, in these tasks, students were expected to measure the area/perimeter/length of a single or complex shape by making addition, subtraction, or multiplication with algebraic expressions. On the other hand, the remaining tasks were prepared to assess students’ understanding in only the algebra learning area. (See Table 1 for all 12 tasks)

To exemplify, in Task 11 (T11, see Table 1) generated by Group 6, students were required to use a proportional relationship to find the price of 1 L of Brand A and Brand B juice as algebraic expressions and solve first order inequalities with one unknown to reach the answer. This task assesses students’ knowledge only in the algebra learning area. We classified the task’s level of cognitive demand as PWC. Students need to engage with conceptual ideas, including using the information from the table provided, setting up an inequality to compare the prices of the juice brands for the same amount to complete the task and explain their reasoning. We also categorized it at the analyzing level considering Bloom’s revised taxonomy since it requires relating parts to one another and an overall structure (Anderson et al., 2001) and making connections between different contents, including integers, ratios, and inequalities.

Table 1: Characteristics of the tasks developed by PMTs

Groups	Ts	Smith & Stein	Bloom's Revised Taxonomy	A brief description of the contexts addressed by the tasks
G1	T1*	PWC	Analyzing	This task asks students to calculate the basal metabolic rate to decide on the number of calories people need to take to not gain weight and to propose a diet to have less/more calories.
	T2	PWC	Applying	This task asks students to find the shortest distance, which a goat can use to climb the top of the mountain using a right triangle.
G2	T3	PWC	Analyzing	This task asks students to divide a square field with one side $2x + 4$ cm into two equal parts to plant cotton to one part and corn to the other. Students are required to decide where two identical 360-degree rotatable fountains are set up to water the corn field's maximum area and find the least area in an algebraic expression where water cannot reach.
	T4	PWC	Analyzing	In this task, students are expected to form a T shape by using all tangram pieces in the square-shaped tangram board with an area of $16x^2 - 8x + 4$ cm^2 and write the algebraic expression for the height of the T shape.
G3	T5	PWC	Analyzing	Given a scenario, students are asked to create an Atatürk corner using rectangular materials whose areas and short side lengths were given algebraically. They are also asked to express the area of Atatürk's picture algebraically.
	T6*	PWC	Applying	This task gives a situation where the discount is applied for the amount of the tickets purchased and asks students to write inequalities that express the given situations. It also asks students to find the profit if two groups of students buy the tickets together instead of separately.
G4	T7	PWC	Analyzing	The task gives information that there are two gardens whose perimeters are equal. The area of one is $9x^2 + 18x + 9$ cm^2, while the other's area is 35 cm^2 and asks the sum of the values x can take. (Each side is a natural number).
	T8	PWC	Applying	In this task, a bus route is given on a map, and two different ticket types (students and adults) are defined. Ticket prices are given as algebraic expressions. Students are expected to find the cost of an adult ticket to go to a city in the route, examining two traveling situations and solving it.
G5	T9	PWC	Analyzing	This task asks students to create squares from cardboard with an area of $4x^2 - 8x + 4$ cm^2 and regular triangles and pentagons whose one side is half of the length of one side of the square. Students are expected to place these geometric shapes 3 cm apart on a rope with $15x + 45$ cm length and find how many geometric shapes are used.
	T10	PWC	Analyzing	This task gives a situation where the water pipes are laid in a square garden with a side of $3x + 6$ m. The length of pipes to be laid adjacent to the garden walls is $2x + 4$ m. Pipes narrow by half after 3 m. The narrowed water pipes pass over each other. Students are required to find the area in the garden where the water pipe is not laid.
G6	T11	PWC	Analyzing	In this task, two types of juice brands (Brand A 200 ml and Brand B 500 ml) are defined, and the price of each is given as algebraic expressions, $4x + 6$ and $5x + 40$ for Brands A and B, respectively. Students are expected to find how many Turkish Liras (TL) Ayşe paid for 1 L of juice at most if she bought Brand A juice and made a profit and to explain their reasoning. (The money she pays is an integer.)
	T12	PWC	Applying	In this task, students are given the information that the length of one side of a house with a square base is $2x + 2$ m, the area of one side of the house is two times the floor area, and the area of one window of the house is one-eighth of the side area. They are expected to find the area of the exterior of the house to be painted.

**Two groups developed questions that had multiple parts. For those questions, the highest level of cognitive demand or taxonomy level was noted as the levels of the questions.*

Task 7, (T7, see Table 1), created by Group 4, required to use algebra, geometry and measurement knowledge. Students were expected to factorize the algebraic expression to find the perimeter of the square and solve the resulting first-order equation with one unknown to find the sum of the unknown (x) values. We classified the task's level of cognitive demand as PWC since the solution requires cognitive effort, including setting up an equation to find the values for x. Students cannot follow procedures mindlessly, and they need to make connections between different learning areas, algebra, geometry, and measurement. We also classified the task as analyzing according to Bloom's revised taxonomy since the task requires analytical skills. Specifically, students were asked to find the possible values for x, using the information that the perimeters of the shapes were equal given the areas and factoring 35 to find the length of one side of the rectangle.

When we examined the tasks developed by the groups according to the framework put forward by Kaput (2008), most of the tasks were closely related to Core Aspect B, which was explicitly about manipulating symbols. Specifically, while four out of 12 tasks were categorized closely related to Core Aspect A, the rest were found more closely related to Core Aspect B. This finding could be because, based on our analysis, PMTs aimed to assess students' abilities to make operations with algebraic expressions in most of the algebra tasks generated. To exemplify, T11 was a task categorized more closely with Core Aspect A. Students are expected to use algebraic expressions to set up an inequality to model the problem context in the task. In comparison, we found T7 primarily concerned about solving equations to find the possible values for x. The other tasks related to Core Aspect A also involved modeling the problem context using equations or algebraic expressions.

Discussion

Mathematical tasks are at the center of students' learning since tasks give messages to the learners about what mathematics is and what doing mathematics includes (National Council of Teachers of Mathematics [NCTM], 1991). The tasks that mathematics teachers select, adapt, or develop and implement with their students have paramount importance since they also influence the level of students' learning. Hence mathematics teachers need to be aware of levels of demands to generate cognitively demanding tasks. On the other hand, some studies revealed that although higher-order thinking skills are crucial for education, what teachers understand from this and how they apply it in their instruction are unclear (Schulz & FitzPatrick, 2016). Turkish mathematics teachers can be an example of this situation since they had difficulty in finding resources for cognitively demanding tasks (Biber et al., 2018). This study showed that the algebra tasks PMTs developed were cognitively demanding. We classified all tasks generated as PWC. They were also at the analyzing (9 tasks) and applying (3 tasks) levels according to Bloom's revised taxonomy. This finding might indicate that PMTs were able to generate cognitively demanding algebra tasks. Even if PMTs created these tasks as possible HSE items, they might also be selective in the tasks they bring to the class and give place to the cognitively demanding tasks in the classrooms.

This study also showed that PMTs focused on geometry and measurement learning areas while generating cognitively demanding algebra tasks. They mainly preferred to assess students' learning in making operations with algebraic expressions by using geometric shapes. The same trend was also seen in HSE items. When we investigated the past HSE items, we observed that if the items were prepared to assess students’ algebra, geometry, and measurement knowledge, students were expected to do operations with algebraic expressions by using geometric shapes. Since PMTs investigated the HSE items of the last three years during the training, they might have been influenced by these items and tended to prepare similar items.

Regarding the analysis of core aspects of algebra, the findings showed that most of the generated tasks focused on calculation and solving instead of relating and representing. Kieran (2004) suggested several things to develop students’ algebraic thinking. These include “a focus on both representing and solving a problem rather than on merely solving it” and “a focus on relations and not merely on the calculation of a numerical answer” (p. 141). Although these tasks were developed for HSE, what is being asked in the examinations influences what teachers and students value in their classrooms (Barnes et al., 2000). Therefore, it is essential that PMTs also try to generate tasks that focus on generalizing, relating, representing, and solving, and calculating. We suspect that this finding might also be due to the tendency of the past HSE items that PMTs examined in the training. Although some tasks were related to Core Aspect A, we identified the majority associated with Core Aspect B.

As part of this study, PMTs only examined 2018, 2019, and 2020 HSE algebra items. Examining only the past HSE items might be a limitation that influenced the characteristics of algebra tasks generated by PMTs. Hence using different task sources can be recommended for future studies. Investigating the HSE items holistically, without differentiating the learning area, can also be suggested to see the general characteristics of items that are not specific to the learning area. Furthermore, since demanding tasks used in the classrooms positively affect students' learning, encouraging PMTs to develop cognitively demanding tasks in algebra and different learning areas can also be suggested.

In Hungary, assessment in school mathematics has always relied heavily on students' written work. Ensuring that only the student's own knowledge is manifested during the exam is a real challenge in distance learning. We combined the written test with verbal explanation by students. After writing down the solutions and sending them to the teacher, students also recorded short audio of each task. In this paper, we analyze students' oral explanations based on their written work, looking for additional information about students' thinking processes, furthermore, examine the quality of verbal communication.

Keywords: Curriculum based assessment, metacognition, online education, mathematical problem solving.

Introduction

During the pandemic, teachers experienced the differences between face-to-face and online instruction (Doucet et al., 2020). They realized worldwide that online schooling requires collecting and reviewing old teaching methods adaptable to the new situation or even searching for new approaches. It is true for the ways of assessment of students learning as well. In Hungary, assessment in school mathematics has always relied heavily on students' written work. Written responses to mathematical tasks are often the basis of summative and formative assessments. However, ensuring that only the student's own knowledge is manifested during the exam is a real challenge in distance learning. The written examination was not appropriate anymore, while the oral was too time-consuming and unusual for senior high school students. It was our starting point when we combined the written test with verbal explanation by students. After writing down the solutions and sending them to the teacher, students also recorded short audio of each task.

Taking not only aspects of teaching and learning but also researching into consideration, the so-called “loud test” seems to be a valuable tool to detect students' metacognitive activities as well. After the solution of the task is written down, the laud explanation forces the learner to deal with the looking back phase in problem-solving (Polya, 1945), which is the most neglected phase, as much research shows (Cai & Brook, 2006).

In this paper, we analyse students' oral explanations based on their written solution, looking for additional information about students' thinking process, furthermore, examine the quality of verbal communication. Qualitative analysis is done on a per-pupil basis. We formulated the following research questions:

1. Does the oral explanation contain more information about the learner's knowledge and thinking process than can be read from the written solution?

2. What types of metacognitive activities can be observed in the verbal explanations?
3. What characterizes senior high school students' professional language communication?

Theoretical background

In the educational process, we can distinguish three types of assessments: (1) assessment before instruction (diagnostic), (2) assessment during instruction (formative), and (3) assessment after instruction (summative). Formative and summative assessments are often characterized as assessments for learning and assessment of learning (Chigonga, 2020). It's clear that there is a significant overlap between assessment for and of learning. We designed summative assessment tasks to measure students' expected standards; however, we also aimed to get information about students' thoughts and possible misconceptions. It means that the assessment process was summative and formative at the same time.

The challenges to written assessments, especially that of problem-solving, are several. Most test situations require students to produce an extended written account explaining their problem-solving process and proposed solution. It is problematic because considerable skill is needed to make a clear and comprehensive description of the problem-solving process, a skill that students may or may not have (Monaghan et al., 2009). From this aspect, it seems that an oral explanation of the problem-solving process may be easier for students, as they do not have to transform their thoughts into a mathematically correct written form. Morgan and Watson (2002) argued that all mathematics assessment is interpretive in nature, so it also shows subjective features. Regarding the assessment of students' problem-solving ability, Teledahl concluded that ”The fact that there are different ways to interpret what the students have written further strengthens the conclusion that using this writing, to assess other mathematical abilities, may be problematic. ” (2017, p. 3602)

Huxham et al. (2012) note five main advantages to oral assessments: they (1) develop oral communication skills; (2) are authentic; (3) can be seen to be more inclusive; (4) can be a powerful way of evaluating understanding and (5) are more difficult to cheat in. Furthermore, in an oral exam, a small knowledge gap can be bridged with the teacher's help so that the student can solve a task that he/she would not be able to do in writing. Our “loud test” is similar to the oral exam in more aspects (see (1), (4), (5)), but the students have no opportunity to receive ongoing confirmation or help from the teacher. However, oral exams have not only advantages but also disadvantages. Anxiety and fairness are the most common concern (Iannone & Simpson, 2012). Since our “loud test” was not a typical face-to-face oral exam, we believe that anxiety did not significantly affect the results. As the evaluation did not coincide with the oral presentation, the teacher had the opportunity for a thoughtful assessment, so there was little harm to fairness.

Professional language communication is an essential element of both written and oral exams. The professional language of mathematics comprises technical terms (like geometric sequences or logarithms) and specific, often very concise, sentence structures. “In mathematics classes, we face the challenge of developing individual language use from orality towards literacy, in the direction of learning to speak and write mathematically.” (Marei, 2019, p. 1657)

Asking students to think aloud is naturally connected to metacognition because the situation itself contributes to rethinking the problem-solving process. According to Flavell et al. (2002), metacognition refers to people's knowledge of their own information processing skills, knowledge about the nature of cognitive tasks, and strategies for coping with such tasks. Moreover, it also includes executive skills related to monitoring, self-regulation, and evaluating one's own cognitive activities. Metacognition happens when students analyze tasks, set goals, implement strategies and reflect on their own learning (Spencer, 2018). Metacognitive experiences refer to a person's awareness and feelings elicited in a problem-solving situation (Schneider & Artelt, 2010). Libet's (2002) research suggests that roughly half-second time units can be associated with conscious decisions. From a pedagogical point of view, this means that if we make a decision during learning, it becomes conscious only a little bit later. It also follows that the speed of procedural metacognitive processes may prevent the individual from reporting them orally simultaneously as the process. However, the possibility of later conscious access and verbal reporting remains (Csíkos, 2017). According to our research setting, the oral explanation of the students took place later in time than the description of their thoughts.

Methodology

The target class consists of 29 high school students (Grade 12), 27 of whom participated in the research. They have four lessons per week taught by one of the authors of this article. The research was done in the school year of 2020/2021 autumn in a small town in Hungary. The schools were open from September 1 to November 11 of 2020, then online education started. The summative assessment fell on November 16, so most of the material was taught face-to-face. The topic of the assessment was geometric series. The first task was considered a routine task. Two terms of a geometric series were given, the first term, the quotient, and the sum of the first ten terms had to be calculated. The answer was two different geometric series. The second and third tasks were real-world problems, and the second was similar to the third but simpler. In this paper, the third task is highlighted:

> *The number of wild koalas in Australia is getting smaller and smaller. Surveys show that the number of koalas is decreasing by 9 % every year. In 2009, 43000 wild koalas were counted on the continent. Considering the same decrease, find the number of years after which the number of koalas in Australia falls under 60% of the 2009 data.*

Because of the school closure, the students responded to the written test at home. They also made audio recordings explaining how the tasks were solved (“Summarize and explain your proposed solution orally in 1-2 minutes.”). The time limit was 45 minutes to solve three tasks, scan the papers, record the oral explanations with mobile phones, and send them to the teacher. The students got scores for the written solution and the recording.

The recordings were investigated in the same way:

1. We identified the coding units; namely, we found those parts of the recordings which contain extra information, i.e., not just repeating or summarizing what is on the paper. (A recording may include more than one such unit.)
2. Using the content analysis method, these units were coded first according to three criteria: The extra information refers to A) one step of the solution, B) the entire solving process, C) the interpretation of the result obtained. For example, we coded the unit as A, if the student justifies one of the steps in the solution, B, if he/she explains the chosen strategy or model, or C if he/she notes

that his/her result is consistent with the problem situation or modifies it accordingly. These codes are closely related to the following metacognitive activities: A) monitoring, self-regulation, B) strategy, C) reflection, evaluation. (Not all extra information counts as metacognitive activity, but it creates the possibility of it.)

For each unit, a second code evaluates the quality of the oral explanation in terms of the mathematical language register: 1) Correct; 2) Sloppy (everyday language, but the mathematical content is clear); 3) Incorrect+ (incorrect terminology, but the mathematical content is recognizable); 4) Incorrect– (incorrect terminology, no recognizable mathematical content); 5) No (There is no mathematical content in the unit).

The recordings were analyzed independently by the two authors. In case of disagreement, the authors' consensus fixed the units and their codes. Figure 1 illustrates our coding system.

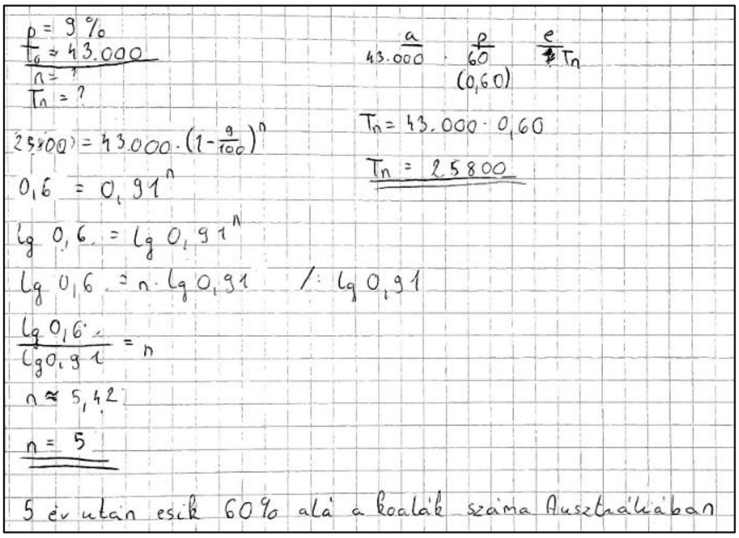

Figure 1: The written solution of Student S13

The associated sound recording with the codes, where the numbered units are written in italics:

"*In the 3rd task, we only know the rate of interest, the percentage, and the total value.* (S13-Unit 1, B, "Sloppy") and from these items, I calculated the value of T_n with percentage calculating. Then I got the result which I immediately substituted into the formula. *And here, in the parenthesis, there is a minus because there is a decrease.* (S13-U2, B, "Sloppy") I got the result 0,6 by dividing 25800 with 43000. The $0{,}91^n$ is the task in the parenthesis. *We brought in the base 10 logarithm because, with the use of it, we can get the result of n.* (S13-U3, A, "Sloppy") Then I arranged the things and calculated. I would rather say that I arranged the equation so that I could get the value of n. *I got a result of 5.42. Although the digit after the decimal point is less than 5, we have to lower the result because the task also includes a decrease.* (S13-U4, C, "Incorrect+") I also answered in a whole sentence because it was a word problem." (Student S13)

Findings and discussion

27 students wrote the test; each consisted of 3 tasks. Out of a total of 81 written solutions, 3 were not accompanied by audio recordings so that we could examine 78 audio recordings. There were 40 recordings, which contained extra information. These belonged to 19 students out of the 27. In their

audio recordings, 4, 9, and 6 students provided additional information to one, two, and three tasks, respectively. The number of coded units associated with the first task is the lowest, 18 units, while for Task 2 and 3, these numbers are 30 and 31. This result confirms that Task 1 was indeed a routine task for our students, in which the way to solve it was conventional, so the students did not feel the need to explain their answers in more detail. Task 2 and Task 3 were real word problems in which finding and matching a model was part of the solution strategy. Obviously, these problems required more thinking, and they provided more opportunities to express background information in the recordings. The coding results for the types of extra information (Table 1) are also related to this idea. In the routine task, the students did not interpret the answer at all, while in the case of world problems, the number of units where students tried to explain their way of thinking or interpret the result obtained is higher.

Table 1: The number of units according to what the extra information refers to

	A	B	C	Total
Task 1	10	8	0	18
Task 2	3	18	9	30
Task 3	10	13	8	31

The coded units were also examined according to the types of extra information and the number of students. Analysis of the audio recordings supports our hypothesis that students also perform metacognitive activities during the oral explanations. Table 2 shows some examples of this in connection with Task 3.

Table 2: The types of extra information and the number of students

Codes	Number of Ss	Examples in connection with Task 3
A: explanation of a certain step of the solution	14	“I brought in the logarithm because n was known. Because we can write the unknown n in front of the logarithm.” (S9) (self-regulation) “Then I got an exponential equation, but I don't have the same base, so I brought in the base 10 logarithm. This way, I got that lg1075 = n*lg1,09.” (S4) (self-regulation, monitoring)
B: explanation regarding the entire solving process	16	“In Task 3, I also calculated with geometric sequence.” (S27) (strategy) “The value of q is 0,91 because 9% can be replaced by 0,91.” (S25) (strategy)
C: the interpretation of the result obtained	11	“The answer is 6 years because I got 5,41641 and it is more than 5 years, so 5 years are not enough, that's why the result is 6 years.” (S25) (evaluation)

We can say that almost half of the class reached the goal of the recordings. Justifying certain steps, explaining the key elements of the solution process, and interpreting the result provides a great opportunity for some metacognitive activities.

Figure 2 presents the students' distribution regarding their scores on the written test and the number of coded units. The total score was 21; the red line in the figure shows the class average of 10.4. The blue points indicate the 19 students. The average score of the students who add extra information is 10.6 (deviation: 4.4), while the average score of the rest of the students is 9.9 (deviation: 5.0).

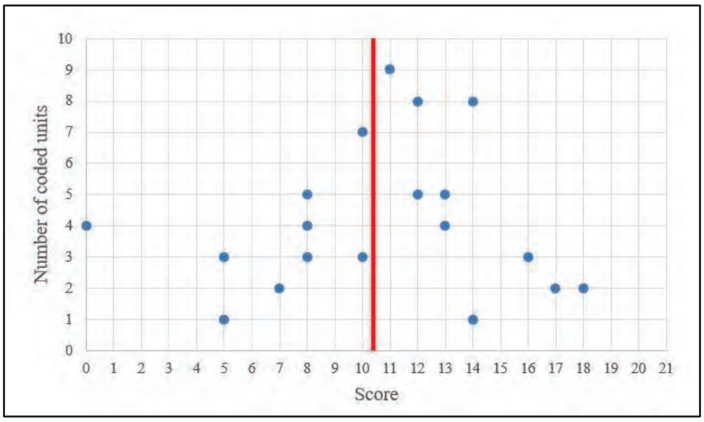

Figure 2: The scores and the number of coded units by students

The willingness to explain in detail does not appear to be closely related to the points achieved. The students whose points were close to the average provided the most extra information. Students with higher scores typically did not supplement their written solution with additional oral information, even if it was quite sketchy. We also found a lot of interesting and instructive information in the recordings of the students with weaker performance. The example below shows how S3 realized that his solution was wrong. He tried to modify but also incorrectly.

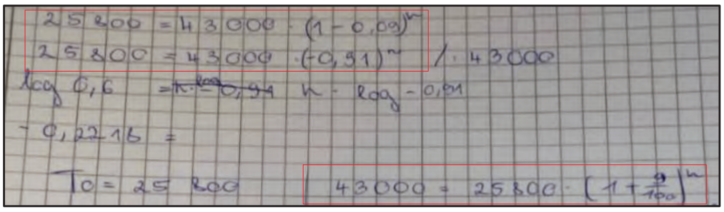

Figure 3: The written solution of Student S3

The explanation of S3: *"First, I did it with a minus, but it's sure didn't turn out well."* (C - reflection) *Then I made it with a positive and came up with 6 years, which I don't know … I don't think it is good either."* (C - reflection)

The quality of the professional language of the examined coded units in all three tasks is summarized in Table 3. The verbal expression of the coded units was mainly mathematically correct; there were no "Incorrect–" performances. It probably means that the students only dared to say things they were sure about to a certain extent. It is important because, in this way, they are reinforcing and deepening their right ideas, not their wrong ones. The laxity of the students encourages the teacher to further corrections, and some "Incorrect +" units bring the mistakes and misconceptions to the surface. These things remain unknown in the written tests, but they are considered mistakes in the oral explanation.

Table 3: The quality of the professional language

	Correct	Sloppy	Incorrect+	Incorrect-	No	Total
Number of units	26	28	15	0	10	79

The first example highlights the inaccurate formulation of one of the identities of exponentiation. The other points out the incomplete knowledge regarding the concept of even root power and the term of absolute value:

– Student S4 refers to one of the exponential identities as “$q^6/q^4=q^2$ because when dividing, we subtract the exponential value [instead of subtracting the exponents]”.
– Student S12 explained what he wrote ($q^4 = |16|$, then $q = 2$ and $q = -2$) as follows: “The value of q is 4 [instead of the exponent of q is 4)], and it is an even root power, that's why we have two quotients. We had to use the absolute value of 16 [instead of the absolute value of 2], so we got 2 and -2.”

Conclusion

We detected some positive impact of the “loud test”-method not only on learning but also on teaching. On the one hand, it was useful from the students’ point of view because students discovered errors in their written work during the recording that they modified, although not always correctly. On the other hand, at least half of the class prepared sound recordings that helped the teacher better understand their thought related to problem-solving and provided a more detailed error analysis, contributing to better future teaching (the effect of formative assessment). Furthermore, the “loud test” seemed to be a valuable tool to detect students' metacognitive activities. Loud explanations force learners to deal with the looking back phase in problem-solving, the most neglected step described by Polya (1945). However, the success was influenced by its quality and the student's content knowledge as well. The need to consciously apply the solution steps and use the appropriate professional language has also become apparent. In summary, we can state that the teacher gets a more detailed picture of students' current level of development, although the correction of students' works takes more time.

Norwegian primary teacher education: Prospective teachers' responses to short written feedback

Grethe Kjensli, Siri Krogh Nordby and Trude Sundtjønn

OsloMet – Oslo Metropolitan University, Norway
grethe.kjensli@oslomet.no, siri-krogh.nordby@oslomet.no, trude.sundtjonn@oslomet.no

This paper reports on a project in a mathematics course for prospective teachers, where the teacher educator modelled feedback based on formative assessment principles. We analyse and discuss the prospective teachers' responses when they are challenged to reflect from a teacher's perspective on how to use different models to compare fractions in a primary classroom setting. We find that the prospective teachers tended to use the feedback to move forwards in their teacher perspective, while some of them reflected on their uncertainty of how to use the models in a classroom. We argue that the prospective teachers got the opportunity to reflect on their own learning process.

Keywords: Formative assessment, teacher education, prospective teachers, feedback.

Introduction

Research on written feedback as formative assessment for mathematics teachers' education is sparse, however there is some work emerging. For example, Buchholtz et al. (2018) examined what learning opportunities could be identified when combining formative and summative assessment of prospective teachers' professional competence. Their findings showed that a significantly higher number of learning opportunities were perceived when these two forms of assessment were combined. In another study, Kastberg et al. (2020) found that mathematics teacher educators' written feedback could be described as effective when it gave prospective teachers the opportunity to build on their own answers; however, Kastberg et al. saw little evidence of feedback intended to help prospective teachers self-regulate their own learning.

Mathematics courses in teacher education aim to prepare prospective teachers to teach mathematics and provide experiences on which they can base their later pedagogical practices. Research suggests that prospective teachers benefit from experiencing for themselves the didactics the teacher educator intends for them to learn, especially if they receive an explanation of why certain practices are of value in classrooms (Rojas et al. 2021). Summative assessment is still the prevalent assessment method for teacher education courses (Mumm et al. 2015), which means that prospective teachers receive little prompt individual feedback during their day-to-day teaching and learning. This is also the case at our university, where, in our mathematics courses, students have one exam at the end of each semester (for a total of three exams over 1.5 years) and two or three longer written assignments (mostly in groups) each semester, for which they receive feedback. One way of giving students more continuous feedback is through formative assessment, which combines participants' awareness of learning goals, academic and process-oriented guidance such that it contributes to a community of learning (Black et al., 2003). Written feedback gives teacher educators and prospective teachers the opportunity to revisit the comments over time to reflect and discuss important points in their work (Kastberg et al., 2020). In this project we wanted to explore how short written feedback could be used in a mathematics education course. The research question discussed in this paper is: what characterises prospective teachers' answers to short written feedback intended to raise awareness of use of different fraction models for primary school teaching?

Theory

The concept of formative assessment is used in the literature with different interpretations (Mumm et al. 2015). In this study we use Black and Wiliam's (2009) framework which emphasise five aspects of formative assessment: clarifying and understanding learning goals, effective classroom learning activities, giving feedback that points forwards, using students in peer learning and getting students to own their own learning process. An assessment is formative if used as a guide to what the participants should learn, what they already know and where to go next (Wiliam, 2007). Short-written feedback can contribute to this process of learning, and Swaffield (2011) highlights for assessment to be fruitful, it is important that it is directed towards learning that occurs in activities that are taking place there and then. Furthermore, feedback has greatest effect when aimed at a particular task and have concrete suggestions for improvements (Hattie & Timperley, 2007). In a classroom, formative assessment can occur in two different ways: spontaneously or planned (Dixson & Worrell, 2016). Spontaneous formative assessment is characterised, for example, by the teacher taking hold of academic moments that appear in the teaching and allowing the participants to contribute with academic justifications and examples on the spur of the moment. Planned formative assessments allow teachers to become aware of participants' current competences, and such information can help facilitate and adapt further learning and teaching (Wylie et al., 2009).

Lunenberg et al. (2007) argue that teacher educators can model teaching in four different ways: implicit modelling, explicit modelling, explicit modelling by facilitating to classroom practice and connecting their own teaching with theory on how to teach. Implicit modelling is when the teacher educator uses themselves as good examples of how to teach. However, without an explicit discussion of why their teaching is a model for good teaching practices, there is a risk of prospective teachers not recognising the transfer value because they do not recognise the connection to practice and theory. Prospective mathematics teachers need to know not only the right answers to questions but also how to teach mathematics in appropriate ways to pupils. This can be achieved by teacher educators modelling, for example, how to use different models for teaching fractions. Olanoff et al.'s (2014) research summary showed that while student teachers often knew how to procedurally calculate with fractions, they struggled with knowing why the procedures worked and how to use number sense to understand fractions. The work developed in this study draws from the outlined theory, emphasising how formative assessment, using short written feedback contribute to guiding prospective teachers in their learning of teaching mathematics. Based on Hattie and Timperley's (2007) framework of effective feedback, which includes questions such as "where am I going", "how am I going" and "where to next", we see the goal of this study as an opportunity to identify prospective teachers use of such feedback.

Research design and context

Prospective teachers intending to teach in grades 1-7 (ages 6-12) in Norway have a mandatory mathematics course (equivalent to 30 ETCS), which is a blend of learning mathematics and learning how to teach mathematics. Pupils in Norwegian primary schools do not receive grades, so their own future assessments will be mostly formative. In this semester they studied 10 ECTS in mathematics (in addition to 10 ECTS in Norwegian and 10 ECTS in pedagogy). The course theme in this period was fractions; with the use of different fraction models (i.e., area model, set model, and place on a number line) and how to use visualisations and representations for pupils' understanding of fractions.

Each lesson started with an introduction to the intended goal, and at the end of the lesson, the prospective teachers were asked planned question(s) based on the lesson's teaching goal, in line with Swaffield's (2011) point that the assessment should be directed towards the activities at that point in time. The prospective teachers got about 10 minutes to independently answer these questions in a notebook and handed it in before leaving. The teacher educator would afterwards write short written feedback to their answers, in the form of questions and reflection notes. The notebooks were given back at the start of the next lesson. The prospective teachers got the opportunity to reflect and make written changes according to the feedback. The idea was to encourage them to evaluate their own work, challenge and explore their choices and teacher knowledge so that the gap between what the prospective teachers understood and what the teacher educator wanted them to understand decreased.

The teacher educator (one of the authors) was a teacher with more than 10 years teaching experience from both lower secondary school and teacher education. She was experienced in using formative feedback, primarily in lower secondary school, and familiar with Black and Wiliam's (2009) framework. During the project the authors of the paper discussed how to give feedback to the answers. All the prospective teachers in the class agreed to participate in this study; however, not everybody was present for each lesson. Data were collected during a five-week period, within a weekly session of three hours. However, in this paper we only analyse one cycle of feedback and answers after one lesson, in which the teaching had focused on how to visualise and compare fractions using different models. The stated learning goal of this was: ''you should be able to use different models for fractions and assess when the different models are suitable.'' The questions the prospective teachers answered at the end of the lesson was ''which of these fractions is larger, $\frac{9}{4}$ or $\frac{7}{6}$? Answer with as many visualisations as you know'' and the same question, with comparing the fractions $\frac{3}{7}$ and $\frac{4}{9}$.

Data analysis

The data analysed in this paper come from 30 prospective teachers who had answered the questions after the lesson and responded to written feedback. The feedback from the teacher educator was in the form of short questions and comments and varied from short encouraging answers, such as ''good'' to questions, such as, ''could you show this with more visual models?'' and ''could you show this more accurately?'' This included responses intended to encourage the prospective teachers to think about how to use their knowledge in a classroom setting, such as ''how could you show this for a 5th grade?'' and ''how could you do this if the pupil did not know how to find a common denominator?''

The coding and thematic analysis were done by all three authors. We read all feedback and answers individually. We discussed what we had seen and decided to code the feedback given by the teacher educator as ''mathematical feedback'', ''reflective teacher questions'', ''encouraging comments'' and ''other''. These categories were not mutually exclusive, some of the comments and questions were shared between content knowledge of fractions and how to teach fractions, while other questions and comments were focused on either content knowledge or teaching knowledge. The coding of the teacher feedback was afterwards done individually by the first and third author, and then compared and discussed until we reached consensus. In this paper we report on the analyses of the prospective teachers' responses to the questions and comments that gave them the opportunity to reflect and comment on the use of their knowledge in a mathematics classroom. We focused our analysis on the notebooks of prospective teachers who had been given what we coded as a reflective teacher question (22) and had in some way answered this question (16). These answers were then individually divided by the authors according to the prospective teachers' revisions and comments 1) with a focus on the mathematics content, 2) with a focus on how to teach, and 3) those that were either wrong or not in accordance with the feedback. Here we again compared and discussed for consensus in the grouping. These three categories enabled us to compare the prospective teachers' responses. Here, we report on three characteristic examples of the prospective teachers' answers.

Results

The analysis of the prospective teachers' answers to questions about how the knowledge could be implemented in a classroom showed that they answered quite differently to similar questions. The answers showed that the prospective teachers were unsure of how to use their knowledge in a teacher context, and some, in their reflections, also showed this uncertainty.

The first example is from a prospective teacher who answered the feedback ''which model do you think is best suited for explaining to a 5th grade'' which they had gotten in response to their answer to original question, ''which of these fractions is larger $\frac{3}{7}$ and $\frac{4}{9}$? Answer with as many visualisations as you know.'' There was also a comment on a more mathematical issue, where the teacher educator had drawn an arrow between the number lines and asked, ''what was important here?''

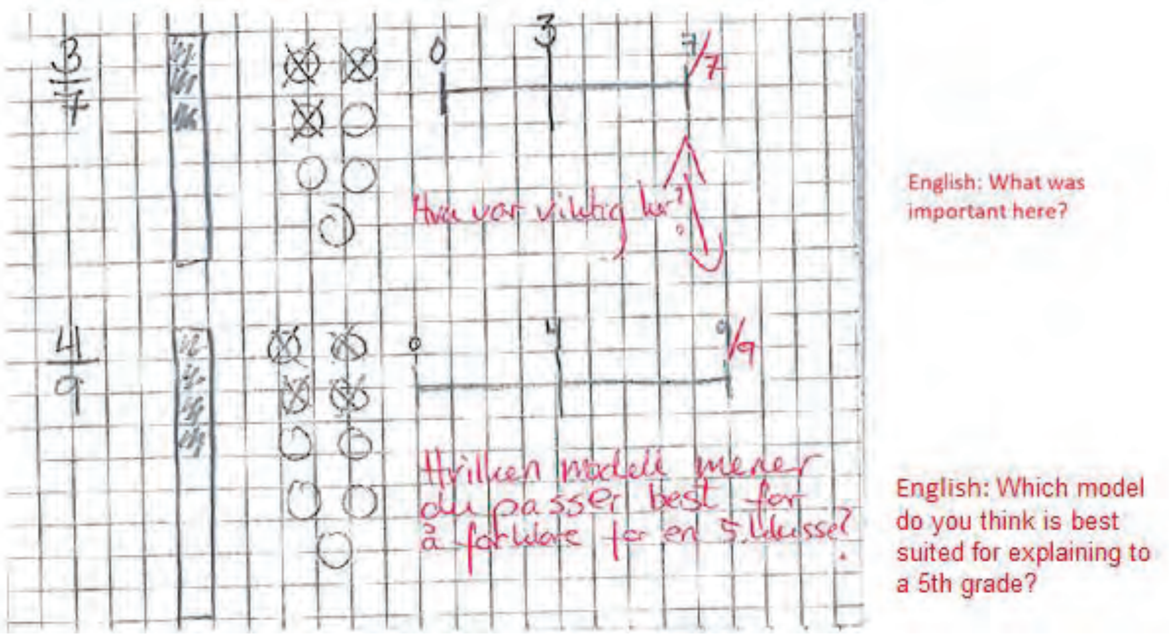

Figure 1: Prospective teacher's original answer, with feedback from teacher educator in red

In the prospective teacher's original answer, they used an area model, a set model, and a number line to visually represent the fractions $\frac{3}{7}$ and $\frac{4}{9}$. There was no written answer to which fraction is larger, and it was not clear from the answer how the prospective teacher's intended to use these to figure out which fraction is larger. They answered the feedback from the teacher educator and wrote

> To be best for a 5th grade it is important that the distance on the number line is the same for each value, and maybe it should have been marked [with] the numbers across…? Or maybe the most important [is] to show that 1 is $\frac{7}{7}$ so that it does not get confusing that $\frac{7}{7}$ is the value of one whole and not the value 7.

In their answer, the prospective teacher incorporated both the mathematical issue about a number line with 7 or $\frac{7}{7}$ and discussed what could be done when teaching pupils. They used the feedback to reflect on what could be important in a classroom, but they signalled uncertainty with their use of ''…? Or''.

Similarly, another prospective teacher had written in their original answer that their own drawing was inaccurate. The teacher educator challenged the prospective teacher to again think about how to compare $\frac{3}{7}$ and $\frac{4}{9}$ for pupils.

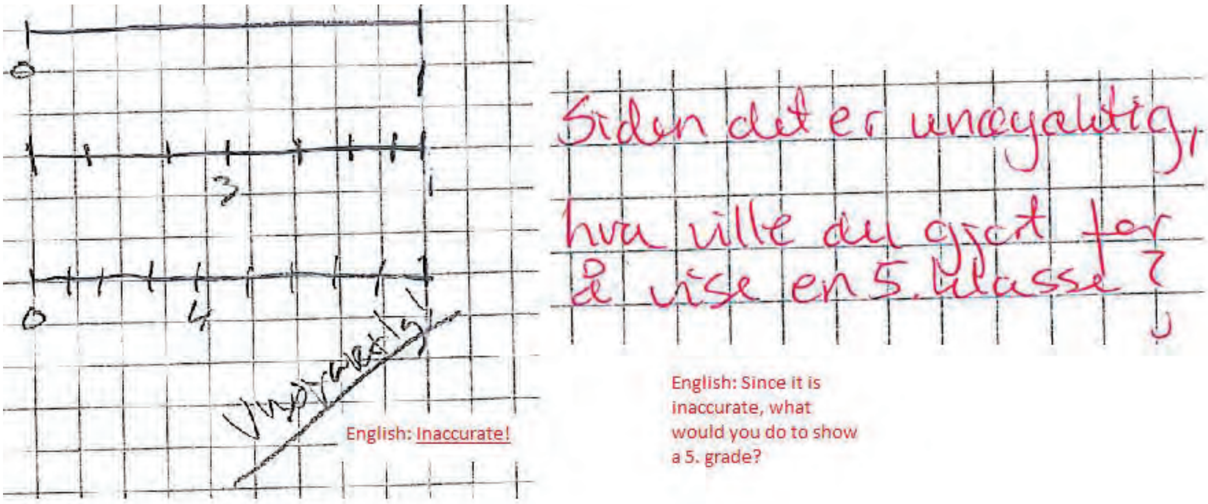

Figure 2: Prospective teacher's original answer (left) and teacher educator's comment (right)

This example shows how the prospective teacher used the feedback (see Figure 2), ''since it is inaccurate, what would you do to show a 5th grade?'', to answer, ''for explaining for a fifth grade I would focus on the explanation of parts and whole, and from there discuss these two magnitudes. I think. Difficult to answer this now.'' The answer shows that the prospective teacher's awareness that they could not fully answer the feedback and that they were still in a learning process.

The third example is from a prospective teacher who had gotten feedback on their answer to the question, ''which of these fractions is larger, $\frac{9}{4}$ or $\frac{7}{6}$? Answer with as many visualisations as you know.'' As seen in Figure 3 (left-hand side), in their original answer that they show knowledge about the different representations (i.e., circular and rectangular area models and number lines), but they did not show how these models could be used to compare fractions. Here, the teacher educator gave the feedback. ''Ok! How can you show this clearly for a 5th Grade which is larger?''

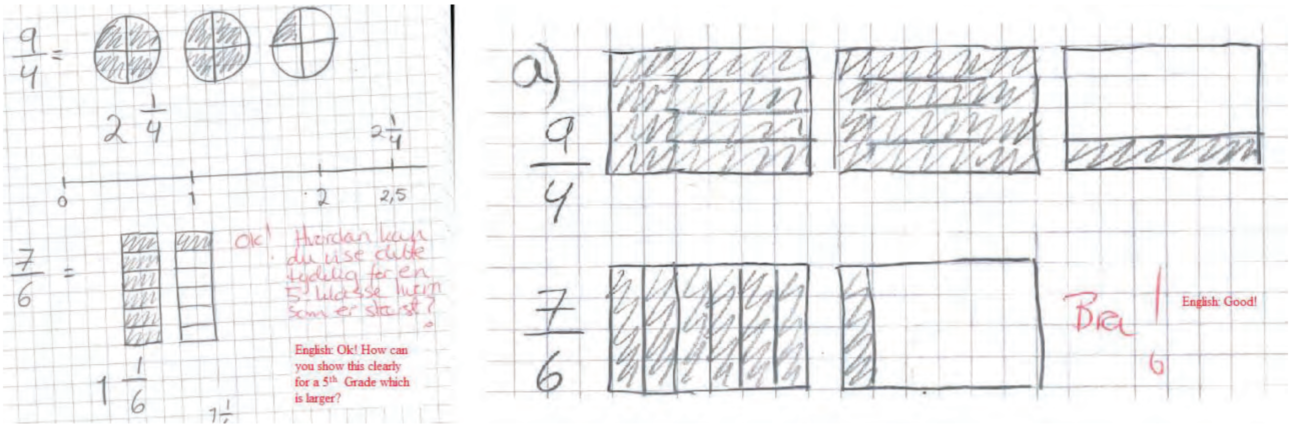

Figure 3: Prospective teacher's original area models (left) and revised area models (right)

The prospective teacher's revised answer (Figure 3, right-hand side) shows the fractions sketched using a rectangular area model, but here, they chooses the same shape and size for a unit fraction. Although there are no notes to accompany the drawing, the drawing is precise. It shows $\frac{1}{4}$ and $\frac{1}{6}$, and the rectangles are drawn above each other, which makes a comparison easy. However, in this question, it may have been obvious to the prospective teacher that $\frac{9}{4}$ was bigger than $\frac{7}{6}$, since $\frac{9}{4}$ is more than two wholes, and $\frac{7}{6}$ is just above one whole. Therefore, the shape of the area models may not have mattered to the prospective teacher in this case.

Discussion and concluding remarks

In this project, the teacher educator used implicit modelling for an assessment practice that the prospective teachers could use in their own classrooms. We saw that the teacher educator used different kinds of comments in the feedback, which ranged from encouraging remarks to mathematical comments, and comments directed at giving the prospective teachers a nudge towards thinking of their future classroom teaching. The three answers shown in this paper are examples of the prospective teachers' reflections after they had revived short written feedback intended to point forwards and help them take a teacher perspective. The prospective teachers, by answering the questions and receiving tailored comments, got the opportunity to reflect on how the fraction models could be used in teaching mathematics and experienced an assessment practice, which they also could use in their own teaching. This is in line with Rojas et al.'s. (2021) suggestion on how to improve learning processes in mathematics teacher education.

It seemed like that when first asked about comparing fractions in different ways, the prospective teachers answered with a focus on showing that they could draw different models. This may be a consequence of the question they were asked, which consist of two parts, both comparing the fractions and showing different visualisations. It may be that the prospective teachers focused on showing their knowledge of different fraction models and disregarded the point that they should compare the fractions. In the lesson the teacher educator had both showed how to visualise different fraction models and showed how to use them for comparison. With the original questions, the teacher educator's intention was that the prospective teachers should model ways that could be used in a classroom, so the questions in this case had two functions. The teacher educator could use the questions and answers with feedback to help the prospective teachers turn their attention towards 1) using the fraction models as teaching tools and 2) realise that there was a gap between the prospective teachers' answers and the teacher educator's intentions. For formative assessment it is important that learning goals are understood, and here the formative assessment gave both the teacher educator and prospective teachers the opportunity to adjust their understanding of the goal of the lesson. Such common understanding can contribute to a community of learning (Black et al., 2003).

The feedback they received gave the prospective teachers opportunities to assess and reflect on their previous answers. They showed that they were aware they were still in a learning process, and some of their answers communicated to the teacher educator their own uncertainty about how to respond to the feedback. We argue that the prospective teachers were in a process towards owning their own learning, which is an important aspect of a formative assessment (Black & Wiliam, 2009). The prospective teachers get little individual feedback during their mathematics courses in our institution. With such short-written feedback, they got the opportunity to reflect on if they could answer the questions related to the lesson. The feedback can use in their learning both immediately when they received the feedback and later while revising the course content on their own. We also found that the prospective teachers used this feedback loop to establish a rapport with their teacher educator and indicate where they were unsure about something, which was useful for both.

From a teacher educator's perspective, the formative assessment gives the teacher educator an opportunity to identify where the prospective teachers are struggling and provide feedback to help promote learning. This can be done for individuals as comments and by lifting problematic areas into the teaching of the whole class. In retrospect, we recognise that more thorough feedback could have been given in the answers. For example, this could be to point out more misunderstandings and give more specific positive remarks. However, because the project was intended to be carried out with teacher educators' busy schedule, it is important to reflect on which and how many comments are given.

Acknowledgment

A big thank you to the prospective teachers who worked diligently on their assignments and let us look into their answers, questions and reflections.

Differentiations and resources in assessing students' written texts in mathematics

Assessment plays a very important role in the educational process in the subject of mathematics. This study investigates the way 33 secondary school teachers who teach mathematics assessed students' written texts in mathematics as well as the resources they draw on when they assess such texts. The research tool is a questionnaire based on three authentic students' written texts, graded by the mathematicians and the grading justification that was given. Data analysis revealed strong differentiations in grading. The resources on which the mathematicians draw on to justify the grading relate mainly to their beliefs about the nature of mathematics and their expectations of 'communicating' mathematical knowledge.

Keywords: Assessment in mathematics, resources, grading.

Introduction

Assessment has been disputed for ages despite its importance in the educational process as it is considered to legitimize social inequalities reducing them to inequalities of individual abilities. Research in mathematics education distinguishes three types of assessment of students' work: diagnostic, formative and summative assessment (van de Walle et al., 2017). Summative assessment has begun to be challenged at an institutional level while the usefulness of formative assessment has been highlighted.

In recent years, research has focused on teacher's pedagogical discourse regarding the assessment of students' work, i.e. the set of knowledge he/she uses and the practices he/she adopts when participating in the assessment process, and offers a framework that allows the identification of the concepts attributed by the teacher (Tang et al., 2012). While assessing, the teacher draws on resources, that is, structures of accumulated knowledge, which include language, representations, values and beliefs, to produce or interpret texts. Morgan and Watson (2002), considering the purpose of assessment to be the evaluation of students' achievements, highlight the complexity of the process, as teachers' judgments are influenced by various factors that 'force' them to draw on different resources every time. In this sense, it is to be expected to observe variations in assessment, which are due, among other things, to the assumption that there is not necessarily a 'relationship' between the text produced by a student and the meanings that the teacher, as a reader of this text, creates (Morgan & Sfard, 2016).

Earl (2006) adds students' perceptions of their capabilities. As a result, the feedback provided motivate the development of their self-image/self-concept. In addition the teacher's expected cognitive skills for the students, sometimes positively or negatively at times, affect the objectivity that assessment in mathematics, needs to promote. Zhao et al. (2016), in their study, refer to the assessment criteria adopted in mathematics curricula as important. Finally, Buchholtz and Nortvedt (2018) include in their assessment resources the different expectations and beliefs of teachers about students' 'cognitive-learning achievements' in relation to gender or the 'categorization' of students into 'majority and minority students'.

The focus of the present study is on the interpretative nature of the assessment of students' written mathematical texts, as well as the resources linked with these interpretations. The aim of the study is to show these resources used by teachers when assessing students' written mathematical texts.

The assessment of students' written texts in mathematics: theoretical framework

Morgan (2000) investigated the relationship between the mathematical knowledge 'shown' in students' texts and the mathematical text assessed by assessors. By identifying the features of the texts that were important for the teachers and the resources they used for assessing, Morgan (2000) categorized the resources and concluded that identical student's texts receive different ratings from teachers and she has identified the resources that teachers used to understand and assess students' written texts as follows: (a) a teacher's personal knowledge (PK) of the subject of mathematics and the relevant curriculum, combined with the affective aspects that are evident as a teacher's personal 'story' in relation to mathematics is written out, (b) teachers' beliefs about the nature of mathematics (NM) and the ways in which it is linked to assessment, (c) teachers' expectations of the ways in which the individual involved in the educational process can 'communicate' mathematical knowledge (ECM), (d) teachers' experience and expectations of their students and the classroom as a whole (EEC), (e) teachers' experience and their impressions and expectations of students individually (EES), (f) teachers' cultural background and language skills acquired (LC).

In the study of Morgan and Watson (2002), informal assessments appeared to be influenced by a variety of factors that had little to do with students' mathematical achievement, while the use of different resources, such as expectations about the nature of mathematics or personal mathematical understanding, including experiences, knowledge, beliefs and priorities can lead to very different judgments for individual students. Klothou and Sakonidis' research (2011) attempted to study the pedagogical discourse that primary teachers develop about students' mathematical achievement. The analysis revealed that different teachers can interpret the same or similar students' texts in many different ways, either by considering different elements as important or by assigning different value to similar features. Teachers' assessments are mainly fuelled by the resource about beliefs of the nature of mathematics and its connection to assessment, and tend to be informal in nature and clearly lack certain criteria. Assessment is perceived in different ways by teachers, with the main influencing factors being the curriculum, parents' perceptions of students' grades, cognitive criteria and personal relationships with students. Stagnation in the field of assessment was also evident, as grading is based on formal exercises and closed-ended questions.

The study

Traditional forms of assessment are now challenged by (a) the belief that mathematical knowledge is complex, so traditional forms of assessment are almost impossible to 'measure' it successfully, (b) the strong sense that even the most objective tests contain and record cultural biases, (c) the recognition of the dominant influence of the assessment system on the curriculum (Klothou & Sakonidis, 2015).

Given the importance of assessment in the cognitive, social and emotional development of the student, research findings point out that the same student's text can be read and assessed very differently by different teachers or even by the same teacher in different circumstances and moments depending on the resources that each one uses, take on greater significance. The different experiences, expectations, personal 'stories' of each teacher, as well as the epistemological consistency of each teacher, makes the meaning he/she attributes to and extracts from each text different.

In the Greek educational system, the importance attached to students' written mathematical texts is undeniable, however there hasn't been sufficient research in the field on secondary education. Focusing on secondary education and based on authentic written mathematical texts of students, we try to open a discussion by posing the following research questions.

1st research question: Are there differences in the assessment of the same written mathematical texts of high school students by mathematicians in secondary education?

2nd research question: What resources do mathematicians in secondary education draw on when grading an unknown student's written mathematical text?

The sample consisted of 33 mathematicians who taught mathematics in public schools and were selected by convenient sampling. Specifically, the sample consisted of 14 women and 19 men, from different places of Northern Greece. 16 of them have a postgraduate degree while 6 are in the process of obtaining one. Three of them have a doctoral degree and another 3 are in the process of obtaining it. 2 of them have 0-5 years of teaching experience, 4 have 6-10 years of teaching experience, 4 have 11-15 years of teaching experience, 11 have 16-20 years of teaching experience, 5 have 21-25 years of teaching experience and 7 have more than 25 years of teaching experience.

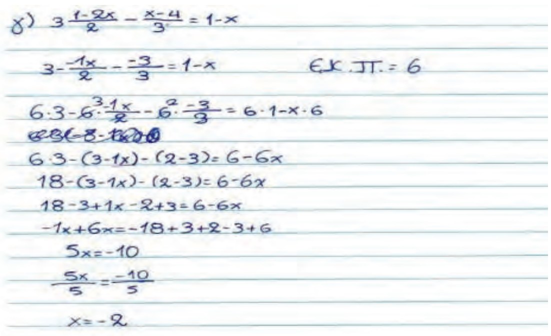
The research tool of the study was a questionnaire, which consisted of (a) 18 questions about their beliefs about the nature, learning, teaching and assessment of mathematics and (b) three authentic student' texts, which were graded by the teachers as well as the reasons for the choice of grade that was given. The present study investigates the second part of the questionnaire in order to study the resources adopted by the teachers in their assessment process in mathematics. This questionnaire was also used in a relevant related study with primary school teachers in order to compare possible differences in assessment between primary and secondary teachers.

This paper presents the results regarding the grading and the justification of the three authentic students' mathematical texts that was given by the mathematicians of the sample.

Mathematicians were asked to grade three authentic students' writing assignments in mathematics that involved: the first, solving a first-grade equation, the second, solving a problem and the third, solving a geometry exercise. The first of the three written texts was chosen because it is typical in written examinations in the Greek educational system for students in the second grade and it combines algebraic and arithmetic knowledge. The second one was chosen as a typical example of mathematization of a problem. The third one is a geometry problem including the drawing of a geometrical shape. All three written texts included parts that were answered wrongly as well as parts that were answered correctly because we wanted to see how teachers assess when they have dilemmas.

The questions to the mathematicians and the students' texts are presented below:

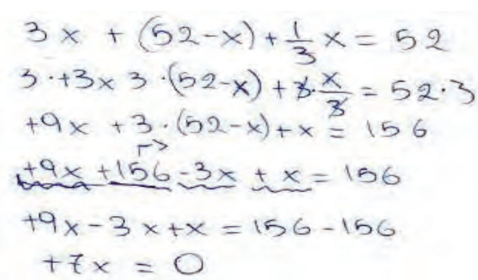
Question to the mathematicians: "Study a 14 year-old student's response to an exercise given on a written exam at the end of a school year. Score from 0 to 4 points and justify the mark given (decimal values are also acceptable)".



γ) $3\frac{1-2x}{2} - \frac{x-4}{3} = 1-x$
$3 - \frac{1x}{2} - \frac{-3}{3} = 1-x$ ΕΚΠ. = 6
$6\cdot 3 - 6\cdot\frac{1x}{2} - 6\cdot\frac{-3}{3} = 6\cdot 1 - x\cdot 6$
$6\cdot 3-(3-1x)-(2-3)=6-6x$
$18-(3-1x)-(2-3)=6-6x$
$18-3+1x-2+3=6-6x$
$-1x+6x=-18+3+2-3+6$
$5x=-10$
$\frac{5x}{5}=\frac{-10}{5}$
$x=-2$

Figure 1: Student's text 1

Question to the mathematicians: "Below is the response of a 15 year-old student to a test. The problem was as follows: Demis, Kostas and Maria have a total of 52 euros. Demis has three times as much money as Kostas and Maria has 1/3 of Kostas' money. (a) If Kostas has x euros, then how can we symbolize the money that Demis and Maria have? (b) Find how much money has each. Mark from 0 to 3.5 points for this text and justify the grade you have given (decimal values are also acceptable)".



$3x + (52-x) + \frac{1}{3}x = 52$
$3\cdot +3x \; 3\cdot(52-x) + 3\cdot\frac{x}{3} = 52\cdot 3$
$+9x + 3\cdot(52-x) + x = 156$
$+9x + 156 - 3x + x = 156$
$+9x - 3x + x = 156 - 156$
$+7x = 0$

Figure 2: Student's text 2

Question to the mathematicians: "Below is a response to a test from a 15 year-old student. The exercise was as follows: Given an isosceles triangle ΑΒΓ (ΑΒ = ΑΓ) and its bisectors ΒΔ and ΓΕ. After drawing the shape, prove that (a) triangles ΒΔΓ and ΓΕΒ are equal, (b) ΑΔ=ΑΕ. Grade this text from 0 to 4.5 points and give reasons for the grade you gave (decimal values are acceptable)".

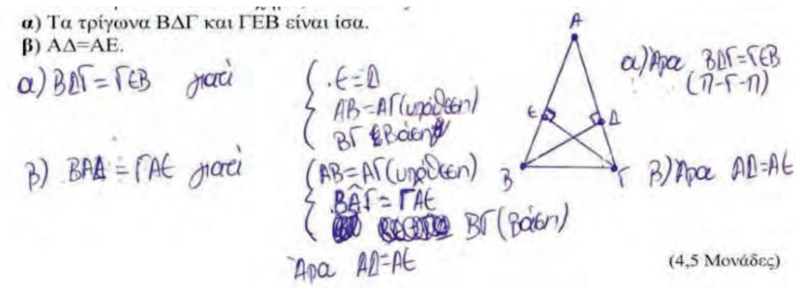


Figure 3: Student's text 3

Techniques of Grounded Theory combined with Morgan's (2002) categorization of resources were used in order to analyze the data. Careful readings of the data were carried out to identify the resources to which the teachers referred when assessing students' texts.

The abbreviations used for the resources on which the mathematicians drew on are: NM: teachers' beliefs about the nature of mathematics and the ways in which these are linked to assessment; ECM: teachers' expectations of the ways in which students can 'communicate' mathematical knowledge; NM+ECM: a combination of NM and ECM. The resources 'teachers' personal knowledge of mathematics and curriculum combined with the affective aspects of their personal 'story' in relation to mathematics (PK), 'experience and expectations for pupils and classes in general' (EEC), 'experience, impressions and expectations for specific pupils' (EES) and 'language skills and cultural background' (LC) appeared a few times, always in combination with the resources NM and/or ECM, were grouped under the name COMB.

Results

1st research question: The mathematicians' grades were converted into the scale of 0 to 10. The average of the three scores per teacher was also calculated. The grades are shown in Table 1, grouped within a range of 2 points.

Table 1: Descriptive statistics of teachers' scores

Grading	1st text	2nd text	3rd text	Average of the 3 written texts per mathematician
[0-2)	2 (6%)	4 (12.1%)	7 (21.2%)	3 (9.1%)
[2-4)	9 (27.3%)	3 (9.1%)	16 (48.5%)	10 (30.3%)
[4-6)	12 (36.4%)	14 (42.4%)	7 (21.2%)	14 (42.4%)
[6-8)	9 (27.3%)	8 (24.3%)	3 (9.1%)	6 (18.2%)
[8-10]	1 (3%)	4 (12.1%)	0 (0%)	0 (0%)
Total	33 (100%)	33 (100%)	33 (100%)	33 (100%)

Average	4.54	5.32	3.3	4.39
Standard Deviation	2	2.39	1.82	1.64

From Table 1 it is clear that there were strong differences in all 3 texts. The 2nd text was graded the highest and the 3rd text was graded the lowest. In the 1st text more than 1/3 of the teachers (33.3%) graded below 4, while 1/3 of the teachers (30.3%) graded more than 6, in the 2nd text about 1/5 of the teachers (21.2%) graded below 4, while more than 1/3 (36.4%) graded above 6; in the 3rd text 1/5 of the teachers (21.2%) graded below 2, while 1/3 of the teachers (30.3%) graded more than 4. In the average below 4, slightly less than half (39.4%) graded below 4, while less than 1/5 (18.2%) graded above 6.

2nd research question: Teachers were asked to justify their grades and specifically to mention any necessary information regarding their thoughts, opinions so that we could understand how they graded each text. The analysis was carried out by carefully reading the justifications and placing them in one or more resource categories.

Below there are some characteristic extracts from the discourse mathematicians used in the categorization. For the category NM: “most part of the equation is correct as well as the result”, “the student knows enough about the concepts, he can create an equation”, “the student did not understand that the answer is not ‘realistic’. For the ECM category: “the student does not state the criteria”, “the student does not justify the equations”, “the student does not use symbols”, “the student does not solve the problem questions”. For the categories NM and ECM the same mathematician stated: “the student does not write all the elements in the shape, ignores basic solving practices, has not understood the meaning, does not know basic things of geometry, does not adequately justify what he reports”, “the initial thought is correct, he did not clearly answer the questions and got the wrong result”. For the COMB category: “the student acquired the necessary procedures for solving”, “the steps for solving are correct, some misinterpretation in the operations, I could have given a slightly higher grade, if I judged that the student made a serious effort and I wanted to encourage him”.

Table 2 presents the results of the analysis on the resources used by the mathematicians.

Table 2: Frequency of mathematicians by resource

Resources	1st text		2nd text		3rd text	
	N	%	N	%	N	%
NM	23	69.7	15	45.5	6	18.2
ECM	0	0.0	2	6.1	2	6.1
NM+ECM	1	3.0	14	42.4	19	57.6
COMB	9	27.3	2	6.1	6	18.2

Table 2 shows that, for the first text, the majority of the mathematicians (69.7%) used resources related to the nature of mathematics, assessing understanding of the solution process and fluency in operations. Slightly less than one-third of the mathematicians (27.3%), in addition to beliefs about the nature of mathematics, drew on pedagogical-emotional resources, such as expectations for the classroom or for a particular student, either in the positive direction ("I give him/her a graceful grade for trying to get to the end of a process he/she does not understand") or in the negative direction ("mistakes that may have been allowed in earlier grades, but not now").

For the second text, the results are different. Almost half of the mathematician (45.5%) focused on whether the student knew how to mathematise the verbal description and then solve the equation. The other half (42.4%) additionally assessed how the student 'communicated' this knowledge and considered the absence of an answer to question (a) to be significantly negative. In relation to the third text, more than half of the mathematicians (57.6%) drew on their beliefs about the nature of mathematics and also on their expectations about how mathematical knowledge was 'communicated'. Symbolism, having justification and using one question to solve the next were highlighted as desirable elements. For the last one, one mathematician even stated that he does not take the "trivial solution" into account at all. Less than 1/5 of the mathematicians (18.2%) drew only on their beliefs about the nature of mathematics and 6.2% only on the way the student 'communicated' his knowledge. Almost 1/5 drew on other resources and one mathematician commented on the part of the answer that the student had erased. Finally, the mathematicians rated the construction of the shape from 0 to 1.5 when the perfect total grade was 4.5.

Discussion and concluding remarks

1st research question: Teachers graded the three students' texts very differently, which is consistent with the findings of other studies (Morgan, 2002) that the same text can be graded very differently by teachers who teach mathematics because it depends on the resources they use and thus the meaning that each assessor gives to the written text is not unique.

2st research question: Almost all mathematicians drew on resources relevant to their beliefs about the nature of the subject matter. In the two texts, 2 and 3, the mathematicians also referred very frequently to what they would like a mathematical text to include when the students communicate their knowledge. In a similar study concerning primary education (Klothou & Sakonidis, 2011), in all cases the teachers drew primarily on resources related to their expectations of how mathematical knowledge can be 'communicated' and then on resources related to their beliefs about the nature of mathematics. In this study, beliefs about the nature of mathematics, either alone or in combination with expectations about 'communicating', emerged as the dominant resources on which teachers primarily drew. Finally, the results of this study also show that the resource pattern used in primary schools, namely that of the expectation of 'communication', does not appear. The assessment of each text was recorded with its own characteristics, significantly different from the others.

Despite its limitations, this study essentially aimed at investigating the assessment process in mathematics in secondary education. It highlighted the complexity of factors that influence the outcome of student's assessment in mathematics and are equally related to the subject matter itself as well as to socio-emotional aspects of those involved, leading them to use resources that are in fact unique to each individual.

This interpretative nature of assessment, combined with the importance of its results for student' development and the criticism regarding its contribution to the reproduction of social inequalities, create a field that needs further study in order to bring to the fore the weaknesses and strengths of existing assessment frameworks. Such knowledge being shared in the educational community is a step towards the search for and adoption of frameworks that value the learning achievements and potential of each individual student.

Handwritten math exams with multiple assessors: researching the added value of semi-automated assessment with atomic feedback

Filip Moons[1] and Ellen Vandervieren[1]

[1]University of Antwerp, Antwerp School of Education, Belgium; filip.moons@uantwerpen.be

Digital exams often fail in assessing all required mathematical skills. Therefore, it is advised that large-scale exams still feature some handwritten open answer questions. However, assessing those handwritten questions with multiple assessors is often a daunting task in terms of grading reliability and feedback. This paper presents a grading approach using semi-automated assessment with atomic feedback. Exam designers preset atomic feedback items with partial grades; next, assessors should just tick the items relevant to a student's answer, even allowing 'blind grading' where the underlying grades are not shown to the assessors. The approach might lead to a smoother and more reliable correction process in which feedback can be communicated to students and not solely grades. The experiment took place during a large-scale math exam organized by the Flemish Exam Commission, and this paper includes preliminary results of assessors' and students' impressions.

Keywords: Assessment, computer-assisted assessment, state examinations, feedback, inter-rater reliability.

Introduction

Regardless of all the practical advantages digital exams offer, Hoogland and Tout (2018) warn that digital questions focus on lower-order goals (e.g., procedural skills). They argue that handwritten questions are better suited to assess vital higher-order goals (e.g., problem-solving skills). Lemmo (2020) highlights substantial differences in students' thinking processes when the same question is asked digitally or paper-based. Bokhove & Drijvers (2010) point out that handwritten questions allow students to express themselves more freely. For all these reasons, Threlfall et al. (2007) advise deciding for each question individually whether the digital or handwritten mode is appropriate, leading to exams that are a mixture of both.

One major issue with handwritten questions is to find ways to assess them efficiently and reliably. Indeed, when the correction work is distributed among several assessors, guaranteeing grading reliability (Billington & Meadows, 2005) and consistent feedback (Baird et al., 2004) is challenging. Most exam designers try to ensure reliability by pre-developing a solution key with grading instructions for assessors (Ahmed & Polit, 2011).

General idea

In this paper, we introduce a novel approach to assess handwritten students' solutions with multiple assessors in a *semi-automated*[1] (SA) way: students solve these questions the classical way by writing on a sheet of paper. Next, these sheets are scanned, and assessors use the SA-system to correct the

[1] In the rest of this paper, we use the abbreviation **SA** to refer to our semi-automated assessment approach with reusable feedback.

solutions on a computer. Exam designers provide a solution key for each question consisting of different feedback items, written in an *atomic way* (see below), anticipating the most common mistakes. These feedback items can be linked to partial points for grading. When correcting a student's solution, the assessors have to select the appropriate feedback items, so the same feedback items are reused repeatedly. If a certain solution approach by a student is not covered in the available feedback items, an assessor can add a new feedback item. This new item is immediately available to all other assessors, leading to a *dynamic solution key* that expands as more and more corrections are made. When all assessors finish their job, the system produces individual reports for all students, including the grades and feedback.

In the following subsections, we discuss atomic feedback, the link with adaptive grading, and the idea of 'blind' grading.

Atomic feedback

Classic written feedback has traditionally consisted of long pieces of written text (Winstone et al., 2017). With its long sentences describing all of the errors in a student's work, classic written feedback is intrinsically not very reusable, as it is too explicitly targeted toward specific students. To overcome this difficulty and maximize the reusability of feedback, one of the key ideas underlying the proposed SA system is that it allows exam designers and assessors to write *atomic feedback* (see Figure 1). To write atomic feedback, one has to (1) identify the possible independent errors occurring and (2) write separate feedback items for each error, independent of each other. These atomic feedback items form a point-by-point list covering all items that might be relevant to a student's solution. The list can be hierarchical to *cluster* items that belong together (see Figure 1).

We have intensively studied atomic feedback in the first study of this PhD-project in the context of individual math teachers giving feedback to their students (Moons et al., 2020). The results of this study (Moons et al., in press) indicated that atomic feedback is significantly more reused than non-atomic feedback, so we found formal requirements to write feedback that can be reused. Teachers also tend to give more feedback when writing and reusing atomic feedback instead of saving time. However, since the atomic items are shared across multiple assessors in this second study, an additional criterium for atomicness is added: (3) a knowledgeable assessor must be able to determine unambiguously whether an item applies to a student's answer or not. As such, each item implicitly represents a yes/no question. Related atomic feedback items and intermediate steps in a solution key can share the same color to visually clear their connection (see Figure 1).

Adaptive grading

To obtain grades, exam designers can associate atomic feedback items with partial points to be added (green items in Figure 1) or subtracted. It is also possible to associate items with a threshold (e.g., 'if this feedback item is ticked, no points', red items in Figure 1).

The point-by-point list of atomic feedback items ultimately forms a series of implicit yes/no questions to determine the students' grade. Dependencies between items can be set, so items can be shown, disabled, or changed whenever a previous item is ticked, implying that assessors must follow the point-by-point list from top to bottom. This adaptive grading approach resembles a flow chart that automatically determines the grade, but – by ticking the items that are relevant to a student's answer – might at the same lead to several other envisioned benefits: (1) a deep insight into how the grade was obtained for both the student (feedback) as well as the exam committee and (2) a straightforward way to do correction work with multiple assessors as personal interpretations are avoided as much as possible (inter-rater reliability).

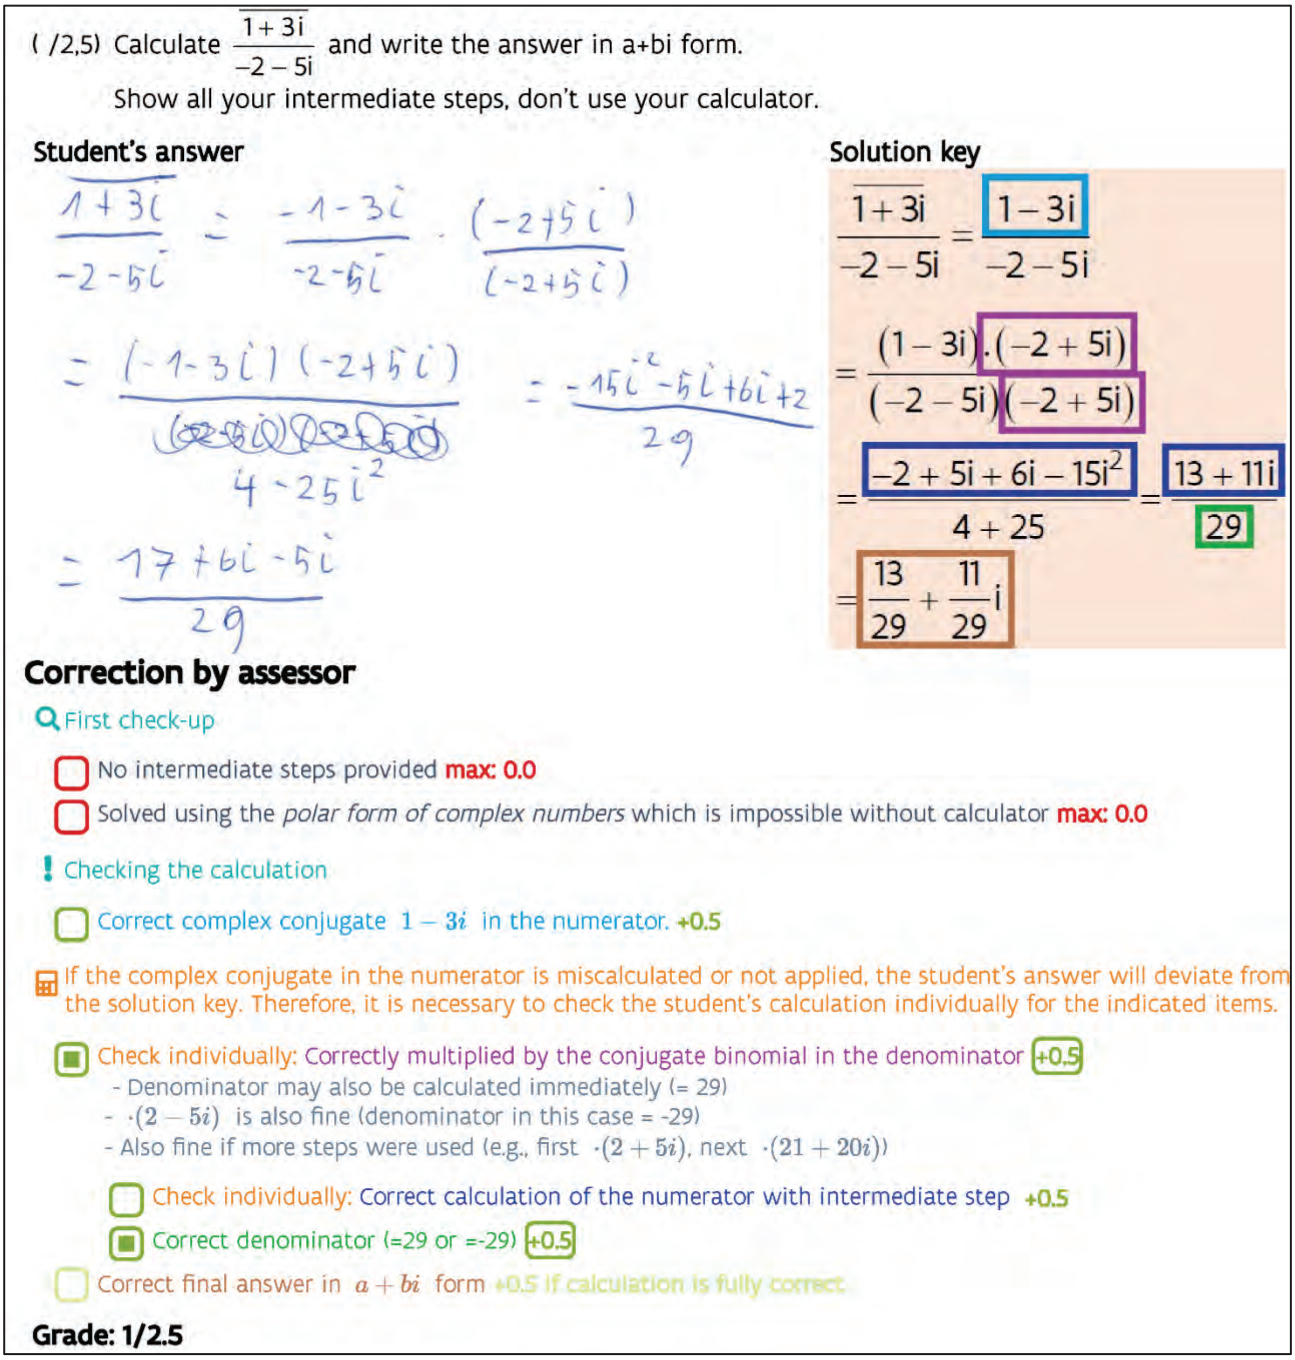

Figure 1: An example of adaptive SA grading with atomic feedback

In Figure 1, an example of the SA approach is given. The students' answer survives the 'First check-up' items; checking one of them would otherwise disable all of the following items. As the item 'Correct complex conjugate 1-3i' is unticked, the computer knows that a mistake happened; however, assessors should continue their assessment of the answer by taking into account that the students' steps will now deviate from the solution key for some items; these items are indicated by 'Check individually.' All the orange content would have disappeared when the item 'Correct complex conjugate 1-3i' had been ticked. The item 'Correct final answer in a + bi form' only gets enabled when all previous green items are ticked. The two ticked items each add 0.5 points to the grade, leading to a total of 1 out of 2.5.

Blind grading

Imagine that all references to points/grades disappear in Figure 1. This leads to the experimental idea of '*blind grading*' where the assessor chooses the appropriate feedback items without seeing the associated scores. The system still calculates the grades, but these are invisible to the assessors. The envisioned advantage of this grading approach is that assessors only need to focus on the content of a student's answer; any emotional barrier to select a feedback item disappears, possibly leading to higher grading reliability. Indeed, Ahmed & Pollit (2011) already indicated that deviations from a traditional solution key often occur when assessors disagree with the obtained grade. A possible disadvantage is that assessors might be afraid of being too lenient or too harsh. They lose an important frame of reference since they cannot compare if the calculated grade matches their sense of fairness.

The opposite mode of *blind grading* will be called '*visible grading*' in the rest of the paper; this is the standard mode where assessors can see the associated points for every feedback item and the calculated total grade (see Figure 1). Note that blind grading should not be confused by anonymous grading (Hanna & Leigh, 2012); in anonymous grading, assessors do not see the student's names to avoid certain biases (e.g., gender, ethnicity,...).

Research questions

After introducing the general idea and the key concepts, we present the first two research questions associated with preliminary investigations on assessors' and students' impressions of SA grading.

- (RQ1) How did assessors appreciate the SA system with blind/visible grading regarding perceived usefulness and ease of use?
- (RQ2) How did the students perceive their personal atomic feedback with grades?

Methods & Materials

The experiment is being executed in association with the Examination Commission of the Flemish government. Flanders is the Dutch-speaking part of Belgium. Flanders is a region without any central exams (Bolondi et al., 2019): every secondary school decides autonomously on the assessment of students. Consequently, the Examination Commission does not organize national exams for all Flemish students but organizes large-scale exams for everyone who cannot, for whatever reason, graduate in the regular school system. This way, students who successfully pass all their exams at the Examination Commission can still obtain a secondary education diploma. Students participating in these exams prepare autonomously or use a private tutor/school. The Examination Commission only provides clear guidelines for students on the content of the exams, carries out all the exams, and awards diplomas, but does not provide any teaching activities to students. We received ethical clearance from the ethical committee of the faculty of social sciences from the University of Antwerp.

Materials

Development of the ‘group’ SA-system

We developed an adaptation of the SA tool (described in Moons et al., in press) ready for handwritten assignments with a group of assessors. The tool is integrated as an advanced grading method in Moodle, an open-source e-learning platform. As Moodle is a framework offering many readily available components (such as a grade book, log in and uploading assignments,…), it guarantees rapid application development. The group assessment tool contains all the features explained in the introduction of this paper.

Mathematics exam

The mathematics exam for this experiment was developed by the exam designers of the Flemish Examination Commission in the way they always develop exams. Their solution key was turned to atomic feedback items for SA grading in close cooperation with us. The exam was one of the two math exams for the advanced mathematics track of Flemish secondary education and features complex numbers, matrices, space geometry, discrete mathematics, statistics, and probability. Interestingly, the exam is already a mixture of fully automated and handwritten questions: 46% of the exam grades are obtained with digital questions. Our experiment will only focus on the 54% part that consists of 10 paper-based questions with an open-answer format.

Survey based on the TAM model for assessors

We developed a short, validated survey based on the Technology Acceptance Model (Davis, 1989) to measure how assessors experienced the SA system’s usefulness and ease of use. The survey distinguished between the SA system using visible grading and the SA system using blind grading.

Survey based on feedback perceptions for students

We constructed a questionnaire loosely based on Weaver (2006) to measure how students perceive the personal atomic feedback they received.

Participants

60 students participated in the math exam linked to this study. The grading work was distributed among the 3 exam designers (employees responsible for the math exams of the Flemish Examination Commission) and 7 external assessors. These external assessors are mathematics teachers across Flanders who do this as a side job.

Methods

The Examination Commission designed the exam in August 2021. Next, their correction key was transformed to atomic feedback for SA grading in close cooperation with us. In October, all assessors received training with the SA system using a demo exam. The students took the exam on the 29th of October, 2021. All their answers were scanned and made available in the SA system. Every assessor had one month to correct the exams with the SA system. All student’s exams were distributed among the assessors. Especially for this experiment, all assessors got 30 randomly selected exams on top that were corrected by all (assessors were not aware of this). Half of the assessors corrected the even question blind, the other half the odd questions. Correctors filled in the survey based on the TAM model when they finished their assessment work. At the end of November 2021, all exams were corrected, and a personalized survey was sent out to the students. In this survey, students got access to their solutions to the questions, together with the provided atomic feedback (see Figure 1). The survey probed students' understanding of their feedback, how they liked the atomic form of the feedback, and the usability of getting feedback along with grades. After completing the survey, the students were invited for an in-depth interview on the same topic as the survey.

In February 2022, all assessors will re-correct the 30 exams corrected by all, but this time in the traditional way of the Examination Commission. In this traditional way, they must just communicate a grade for each question based on a paper-based solution key. This re-assessment will give deep insights into the inter-rater reliability of (visible/blind) SA grading versus traditional grading.

Results & Discussion

The results of (RQ1) on the assessors' views measured using the TAM model are shown in Table 1. The scales are measured on a 7-point Likert scale.

Table 1: Results of the TAM model by the assessors for both visible as well as blind SA grading

Scales	**Visible SA grading** M±SD	**Blind SA grading** M±SD
1. Perceived Usefulness	5.7 ± 0.7	4.6 ± 1.5
2. Perceived Ease of Use	5.4 ± 1.0	4.5 ± 1.4
3. Anxiety	2.5 ± 1.1	3.6 ± 1.7
4. Attitude Towards Using	6.1 ± 0.8	4.4 ± 1.7
5. Behavioral Intention to Use	5.6 ± 1.2	4.4 ±1.7

Table 1 shows that assessors have a strong attitude towards using visible SA grading, meaning that they like working with the visible SA grading system. Assessors rated their anxiety for visible SA grading as low and gave a high rating to the perceived usefulness, perceived ease of use, and the behavioral intention to use for visible SA grading. Blind SA grading was less appreciated on all scales. All assessors (100%) indicated they preferred visible over blind grading. Reasons given include the lack of control (71.4%), an alienated feeling (57.1%), and fear of missing items to be ticked (42.8%).

For (RQ2) on the student's perceptions of their received personal feedback (see Figure 1 for an example), the corresponding survey items are listed in Table 2. Of the 60 students who took the exam, 36 students participated in this online survey (60%). Results are expressed on a 7-point Likert scale and indicate that they would greatly appreciate if the Examination Commission would adopt this approach. Students feel that they understand their atomic feedback, learn from it, and see the connection with the obtained grades. It is important to remember that these results are entirely based on self-reporting, and other qualitative techniques (which are being carried out) are necessary to check if students indeed understand the given feedback.

Table 2: Overview of the students' survey items corresponding to their personal feedback

Students' survey item	M±SD
1. My feedback was too uninformative or brief to be helpful	3.6 ± 1.9
2. My feedback encouraged me to improve	4.7 ± 1.7
3. I will make even better exams based on my personal feedback	4.9 ± 1.6
4. This personal feedback helps me to reflect on what I have learned	5.0 ± 1.3
5. My feedback indicated clearly how my scores were calculated	5.5 ± 1.1
6. I understand most of my feedback	5.3 ± 1.4
7. It would be great if the Examination Commission always gave this type of feedback	6.3 ± 0.7
8. I feel demoralized or angry after reading my feedback	2.8 ± 1.8
9. The relationship between the feedback and the score is clear	5.2 ± 1.2

Conclusion

This paper introduced preliminary results of the second study of this PhD-project, investigating the possible added value of semi-automated assessment with atomic feedback when multiple assessors have to correct the same mathematics exam. The first results indicate that assessors rate visible SA grading highly but are less keen on using blind SA grading. On the other hand, students seem happy with the atomic feedback SA grading produces. Nevertheless, there are still many facets to this research study that have not been highlighted: the inter-rater reliability (comparison between blind SA, visible SA, and traditional grading), measurements for assessor reliability, the effect of the dynamic solution key,… are still uncultivated territory in the exciting universe of SA grading in mathematics education.

Looking back for understanding: formative assessment strategies and inclusive activities for conjecturing and proving

Francesca Morselli[1] and Elisabetta Robotti[2]

[1]University of Genova, DIMA Department of Mathematics, Italy; morselli@dima.unige.it

[2]University of Genova, DIMA Department of Mathematics, Italy; robotti@dima.unige.it

In this contribution we discuss a teaching and learning sequence on conjecturing and proving in grade 7. We rely on the Universal Design for Learning principles to design inclusive educational activities and we also promote the activation of formative assessment strategies, so as to create an educational path where the teacher monitors and, if necessary, refines the learning trajectory of each student of the class. Focusing on one formative assessment activity, we discuss the effectiveness of the sequence in terms of proof understanding and inclusion.

Keywords: Conjecturing and proving, formative assessment, inclusion.

Introduction and background

In this contribution we discuss the design and implementation of a teaching and learning sequence aimed at fostering students' first encounter with conjecturing and proving in lower secondary school (grade 7). The sequence is designed considering the principles of Universal Design for Learning, so as to realise an inclusive activity, and adopting formative assessment strategies.

In order to frame our teaching and learning sequence, firstly we refer to the specific mathematical process at issue, that is **conjecturing and proving**. There is a wide body of research on the teaching and learning of proof, see the work of Stylianides et al. (2016) for an overview. Here we focus on the first approach to proof, encompassing both understanding what a proof is and in learning how to prove (Balacheff, 1987). As De Villiers (1990) points out, it is crucial to make students aware of the different functions that proof has in mathematical activity: verification/conviction, explanation, systematization, discovery, communication. Lin et al. (2012) present a series of principles for task design aimed at promoting conjecturing, proving, and the transition between conjecture and proof. In relation to conjecturing, it is important to provide students with an opportunity to engage in: C1) observing specific cases and generalizing; C2) constructing new knowledge based on prior knowledge; C3) transforming prior knowledge into a new statement; C4) reflecting on the conjecturing process and on the produced conjectures. Concerning the transition from conjecture to proof, the teacher should propose tasks that raise students' need to prove. Moreover, the teacher should establish "social norms that guide the acceptance or rejection of participants' mathematical arguments" (p. 317), emphasizing that the acceptance /rejection is based on the logical structure of the argument and not on the authority of the instructor. In relation to proving, it is important to guide students: P1) to express in different modes of argument representation (verbal arguments, symbolic notations, etc.); P2) to understand that "different modes of argumentation are appropriate for different types of statements" (p. 318); P3) to create and share their own proofs and to evaluate proofs produced by the teacher, thus "changing roles"; and P4) to become aware of the problem of sufficient and necessary proof.

In particular for algebraic proof, Boero (2001) describes the fundamental cycle of *formalization*, *transformation* and *interpretation.* Performing a proof by algebraic language encompasses the following crucial issues: the choice of the formalization, that must be correct but also goal-oriented; the validity and usefulness of the transformations; the correct and purposeful interpretation of algebraic expressions in a given context of use.

As previously outlined, our aim is to design an inclusive teaching and learning sequence. **Universal Design for Learning** (UDL) is a multifaceted theoretical framework of learning that conceives teaching and learning as a dynamic system that must face the needs of all the learners (Rose & Meyer, 2006). CAST (Center for Applied Special Technology), a non-profit education research and development organization, created the Universal Design for Learning framework and the UDL Guidelines (https://udlguidelines.cast.org/more/research-evidence), offering a set of concrete suggestions that can be applied to any discipline or domain to ensure that all learners can access and participate in meaningful, challenging learning opportunities. UDL principles are deeply rooted in the foundational works of Vygotsky or Bruner. For example, through Vygotsky's theory UDL emphasizes one of its key points of curricula—the importance of graduated “scaffolds”.

The first UDL principle (UDL1) focuses on **providing multiple means of engagement**: indeed, besides recognizing the necessity of recruiting students’ interest, one must know that not all learners will find the same activities or information equally relevant or valuable. To reach this aim, the UDL framework suggests to:

- UDL1.1 Vary activities and sources of information;
- UDL1.2 Design activities so that learning outcomes are authentic, communicate to real audiences, and reflect a purpose that is clear to the participants;
- UDL1.3 Provide tasks that allow for active participation, exploration and experimentation;
- UDL1.4 Invite personal response, evaluation and self-reflection to content and activities;
- UDL1.5 Include activities that foster the use of imagination to solve novel and relevant problems, or make sense of complex ideas in creative ways.

The second UDL principle (UDL2) focuses on **providing multiple means of representation**. As far as representation of math objects is concerned, this principle suggests to provide options for perception in terms of alternative options of the registers of representation (algebraic language, for instance) through which the mathematical object can be represented. This allows students to improve comprehension about information at disposal, activating background knowledge, highlighting big ideas and new ideas to answer tasks and to guide information processing and design strategies of solution. We note that this is also in line with research in mathematics education, addressing the use of physical and digital artifacts for students with low achievement in mathematics and students with Mathematical Learning Difficulties (Robotti et al., 2015).

Providing **multiple means of action and expression** is the third UDL principle (UDL3). Physical action on some of these mathematical objects’ representations can support mathematics thinking. Similarly, the action supports communication (thus, not just writing but also gestures, or moving objects). This enhances the management of information, resources and ideas in order to develop mathematical thinking, supports the executive functions which are essential in guiding appropriate goal setting and progress monitoring.

Such a focus on goal setting and progress monitoring establishes a natural link with **formative assessment**, conceived as a method of teaching in which "evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited" (Black & Wiliam 2009, p. 7). A key element of formative assessment is feedback, that is any "information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding" (Hattie & Temperley, 2007, p.81). Wiliam and Thompson (2007) provide a description of five main formative assessment strategies: (FA1) clarifying and sharing learning intentions and criteria for success; (FA2) engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; (FA3) providing feedback that moves learners forward; (FA4) activating students as instructional resources for one another; (FA5) activating students as the owners of their own learning. Such strategies may be activated by the teacher, but also by the peers and by the student himself. Indeed, formative assessment should in principle lead to auto-regulation.

Method

From a methodological point of view, the sequence is the result of cycles of design, enactment, analysis and redesign, according to the design-based approach (DBCR, 2003). Following this approach, we take as a starting point specific theoretical claims concerning the teaching and learning process (guidelines for conjecturing and proving, UDL principles, formative assessment strategies) and we aim to understand "the relationships among theory, designed artifacts, and practice" (DBCR, 2003, p. 6), also considering the design of the teaching and learning sequence as an outcome of the research in itself. Moreover, the research is characterized by a strong interaction and collaboration between researchers and teachers, who take part in the design, implementation and a posteriori analysis. The teaching and learning sequence we present is the result of cycles of design, enactment, analysis and redesign that started in 2012 and involved four teachers of a lower secondary school in the North of Italy. At present, five cycles were performed in grade 7 (pupils' age: 12-13). During the implementation we collected teacher's notes, observer's notes, video recordings of the class discussions and written productions of the students. In this contribution we mainly rely on students' written productions.

In the subsequent paragraphs we illustrate the design of the sequence, guided by our theoretical tools, and we focus on the last formative assessment activity (Step 6), with the aim of exploring two research questions. The first question concerns the efficacy of the designed sequence to promote a first encounter with conjecturing and proving. The second question concerns the efficiency of the sequence in terms of inclusion.

The sequence

The teaching and learning sequence concern isoperimetric rectangles. At the core of the sequence is the conjecture and explanation of the fact that, among all the rectangles with fixed perimeter, the square has the maximum area. In the designed sequence the students, starting from the empirical evidence, grasp the idea of variation of the area according to the length of the sides. Students are asked to conjecture about the maximum area. Afterwards, they are guided by the teacher to feel the need for a general explanation and to appreciate the power of algebra in leading to a proof. The task sequence is organized in the following steps.

Step 1: Students address individually an explorative task in paper and pencil: "*Draw four rectangles with a perimeter of 20 cm*". Afterwards, students are asked to work in small groups: "*Compare the methods you used to draw the rectangles and synthesize*".

Step 2: Students work in groups and cut cardboard to create a set of isoperimetric rectangles.

Step 3: Students work in groups, aided by paper and pencil and cardboard, on the following questions: "*Do you think all the rectangles have the same area? If not, what is the rectangle with the biggest area?*". After each of the steps 1, 2, 3 the teacher promotes mathematical discussions.

Step 4: Once established that the square is the rectangle with the biggest area, the teacher guides the students to prove it. The proof, carried out in algebraic language, is presented at the blackboard, with the teacher involving the students via open questions. When presenting the proof, the teacher refers to the previous steps and highlights the crucial steps of the proving process. For instance, the teacher underlines that using algebra allows one to generalize from a specific rectangle to the generic rectangle, that is a rectangle with the same perimeter as the square.

Step 5: Each student receives a sheet containing the written proof of the property, and is asked to fill some open sentences concerning the proving process (for instance: "I put the rectangle over the square in order to…" ; "I use letters because….."). After step 5, the teacher collects written answers from the students and promotes a discussion amongst them.

Step 6: Each student is asked to answer to the following open question: "*Looking back at the previous steps, you may note that we worked on the problem of isoperimetric rectangles by means of different approaches: we used paper and pencil, cardboard, we drew a rectangle over a square on the blackboard, we used letters. What does each approach tell you? Do they make you understand the same thing? Were they equally easy to follow and understand?*".

The sequence is conceived according to the principles by Lin et al. (2012): students observe specific cases and generalize, so as to formulate a conjecture (C1); concerning the transition to proof, the teacher proposes different modes of argument representation (P1), paying special attention to the link between geometric and algebraic representations. During the guided proof and the subsequent individual reconstruction, students are led to reflect on the cycle of algebra, from the formalization (using letters to express relations) to the transformation and interpretation of algebraic expressions.

The sequence is also conceived according to the UDL principles: the steps involve different registers of representation, hence many channels of access to information (UDL2). Throughout the sequence, each student may address the problem on the basis of the privileged channel. For instance, the student may do some conjecture on the biggest area on the basis of the drawing, or on the basis of the manipulation of cardboards. In line with the UDL principles, modes of representation alternate so as to scaffold the solving process of any student. Working on different modes of representation (UDL3) is a support for reasoning, and also promotes motivation (UDL1). Each student can ground his/her reasoning on the mode of representation that is most suitable for him/her. This fact, giving the students autonomy in the choice of the way of tackling the problem, promotes sustaining effort and persistence and provides multiple means of engagement (UDL1).

From the perspective of formative assessment, we may note that during the designed sequence many formative strategies are activated. In steps 1 and 3, the student is asked to explain respectively the procedure for drawing isoperimetric rectangles and the conjecture. Explaining makes the student responsible for his/her learning (FA5). During the group work and all the class discussions, students act as instructional resources for their classmates (FA4). During the guided proof of the statement (step 4), the teacher explains the learning objectives of the activity (FA1). During steps 5 and 6, students are encouraged by the task itself to become responsible for their own learning (FA5); the teacher may gather information on the learning process, and use it to provide individual feedback (FA3).

Analysis

We focus on Step 6, which is a veritable formative assessment activity, where students are asked to give meaning to all the sequence, and also to reflect on their understanding and possible difficulties. Besides being responsible for their own learning (FA5), students also prove to be aware of the learning intentions of the activity (FA1). Moreover, encouraging students to make a self-reflection on the experienced learning sequence is in line with UDL1.4.

We selected some excerpts that provide evidence of the efficacy of the sequence in terms of first encounter to proof, and also in terms of inclusion.

> **Camilla**: In the first approach I understood well what is the meaning of isoperimetric rectangle. In the second approach I understood well which was the rectangle with the biggest area because overlapping the cardboards one group created a square which is a special rectangle. We understood that [the square] has the biggest area. In the third approach we specified better why the square has the biggest area.

Camilla describes the journey from discovery to explanation. Moreover, Camilla ascribes to each approach a specific role in terms of construction of meaning: the first one (figural) makes the students understand the problem and the relations at issue, the second approach (kinesthetic) leads to the conjecture and its perceptive verification, the third approach (verbal, non-visual, symbolic) allows to generalize and reach an explanation.

> **Erika**: The first approach was not very useful to me because, since we used a particular measure, I did not know whether what I understood could be applied to any rectangle. Moreover, it was not very useful because just drawing you could not see anything special and if you noticed something, you could hardly see it. The second method was very useful because we all had the idea of overlapping them to see which was the one with the biggest area and we understood it was the square. And also thanks to a sort of "ladder" with the square as a starting point and each step was a rectangle with longer basis and shorter height in comparison with the side of the square. But in this way you don't understand why the square is the rectangle with the biggest area. The third

method was the most important because it gave motivation to the fact that the square is the rectangle with the biggest area.

Erika proposes meta-level reflections on the function of each approach towards meaning construction: for instance, she points out that the drawing is too specific and static and doesn't allow seeing invariants. On the contrary, the dynamic actions on concrete figures in cardboards allowed her to see invariants and relations. Erika is aware of the fact that the cardboard figures give a perceptual evidence for the conjecture ("*also thanks to a sort of "ladder" with the square as a starting point*") but do not provide a general explanation ("*in this way you don't understand why the square is the rectangle with the biggest area*"). Erika also recognizes the value of the algebraic language as a generalizing tool ("*The third method was the most important because it gave an explanation*"). Erika also explicates a link between action on cardboard figures and algebraic transformation. We point out that Erika judges the approaches in terms of "usefulness", thus expressing her personal preference and functionality in relation to the objective of conjecturing and proving. Erika seems to be fully aware of the learning intentions and criteria for success of the activity (FA1).

Gaia: I had more difficulties understanding the last activity because with the cardboards and without letters it is easier… you can move figures, you cut the pieces that are left, you add to what is missing… but the concept is not as accurate as the one with the letters.

Gaia points out that the concrete representation on cardboards allows action (thus promoting conjecture) and communication to the classmates. At the same time, the concrete representation does not hinder the necessity of moving to another representation (algebra) in order to generalize.

Beatrice: we did many approaches, but the easiest was the one where we had to draw four rectangles with the same perimeter but drawn in different ways; the approach of cutting cardboards was not difficult, the only problem was to draw rectangles that were equal to those on the cardboard; the method on the blackboard seemed to me more difficult to understand. On the blackboard there were a square and a rectangle overlapped, they had the same perimeter and, by means of calculation, we had to explain why the area of the square is bigger than the area of the rectangle. They all say the same thing, but in different ways, for example they want to make understand that rectangles that are isoperimetric to the square are infinite, but with drawing and the cutting you understand less because you cannot draw infinite ones, whilst with the mind and numbers you can go on to infinity. For me, a student in difficulty should try the first two methods, but a student not in difficulty should try the third one. With the third method I had difficulty because I could not understand well, while with the first two methods I understood the concept of area, but I could not immediately grasp the idea of infinity but it was not possible to do it. The first two approaches are also more amusing because you can compare your ideas with the ones of your classmates and if you don't understand your classmates can help you, while if you are alone you have to understand by yourself, which is more difficult. […] Not everybody understands letters and figures and calculations, but with the drawing and easier explanations you understand more.

Beatrice recognises that the sequence was organised in terms of evolution of generality. She is also aware at metacognitive level of the fact that the algebraic approach, although valuable in terms of generality, is more demanding in terms of cognitive load. She adds considerations in terms of engagement and points out the different methods are suitable for different students.

> **Ivan**: They are all useful and each of us can use their own method but they all take the same result, so there is not a wrong method among them. They all take to the result and each of us may use their own.

Ivan, in a very synthetic way, seems to confirm that the designed sequence achieved its main goals: provide all students with multiple modes of representation, occasions of action and motivations to address the problem, and construct the meaning of algebraic proof.

Discussion and conclusions

The students’ reflections in step 6, conceived as a formative assessment occasion, prove to us that the designed sequence promoted an inclusive approach to conjecturing and proving. We observe that students were able to report the evolution from exploration, to conjecture, to proof. Moreover, they were generally aware of the need for a general explanation and appreciated the proving power of algebraic language.

From the point of view of inclusion, we saw the effectiveness of the three principles of UDL “in action”. A crucial issue is that in the teaching and learning sequence each register has its own status (and students prove to be aware of this), but for each student a register may play a specific function with respect to the learning objective. Some students construct the meaning by means of the kinesthetic register, other students by means of the algebraic one. Some students are completely aware of the generalising power of algebra, other students appreciate the necessity of algebra after having dealt with the dynamism of cardboard figures. In general, cardboard figures are efficient in activating the reasoning that leads to the conjecture, because the dynamic work on the figures allows one to identify geometric invariants. Interestingly, students themselves are aware of the two dimensions of the registers (status in reference to the designed teaching sequence, function in relation to the personal learning experience throughout the sequence). This suggests that providing multiple registers of representation enriches and makes the teaching and learning sequence really inclusive, without losing the content-related objectives of the activity (approach to proof). Moreover, we observed that students link their appreciation of one register to the fact that working in that register fosters understanding.

In the previous analysis we used the formative assessment activity (Step 6) to discuss the “inclusiveness” of the sequence. Conversely, we argue that the formative assessment activity performed in Step 6 was a way of fostering engagement and self-reflection. UDL principles suggest to promote also self-reflection on the performed activities (UDL1), and this clearly coherent with FA1 and FA5 that are activated in Step 6. Thus, we may argue that the formative assessment acted as a means of inclusion.

Can fluency as a factor of creativity be measured simply by means of a Fermi problem, and what influence does academic performance in mathematics have on this?

Hidemichi Okamoto

Tarui Municipality Fuwa Junior High School, Japan; hidemichiokamoto@gmail.com

The assessment of creativity has been studied much in the field of psychology. However, there is little research on easy-to-use assessment methods for schools in mathematics education. The goal of this study was to analyze the correlation between fluency measured by a Fermi problem and fluency in general creativity. Furthermore, it is to examine the possibility that Fermi problems can be used as a simpler way to measure fluency in mathematics education. As a result of surveying Japanese junior high school students (n = 291) and analyzing the results, a strong positive correlation was found. In addition, the results of the multiple regression analysis showed that fluency measured by a Fermi problem is a relatively strong factor when fluency in general creativity was the dependent variable, even when controlling for academic performance in mathematics and age.

Keywords: Creativity, fluency, fermi problem, mathematical modelling.

Introduction

Fostering creativity is required around the world. In the United States, for example, the educational goal is to develop 21st century skills. One major skill is creative thinking (Piirto, 2011). In Europe, the goal is to develop key competencies. Creativity is said to be built into all key competencies. Other countries are also trying to develop skills and competencies like those listed above. Fostering creativity is also a goal of mathematics education in Japan. The Japanese National Curriculum Standards (2017) guidelines propose that creativity should be fostered in each subject, nevertheless, clear guidance does not exist. Moreover, it is also not explicitly stated how creativity would be assessed. Because of this situation, a method should be developed that can be handled in mathematics education and can be used in schools to assess creativity in a simple way. Previous studies have shown that Fermi problems require creative thinking, and they seem to be useful to utilize as teaching materials to foster creativity. Additionally, it is hypothesized that there is a strong relationship between creativity and the richness of aspects considered in a Fermi problem. It would be possible to measure creativity by means of Fermi problems. The present study has two purposes. The first is to investigate the correlation between fluency measured by the richness of aspects solving a Fermi problem and fluency in creativity in general. The second is to examine the possibility that Fermi problem can be used as a simpler way to measure creativity in mathematics education.

Theoretical Frame

Fermi Problem

“Fermi Problems” were named after the Italian nuclear physicist Enrico Fermi. He had a special way of raising problems and probably the most famous of them is “How many piano tuners are there in the city of Chicago?”. Morrison described Fermi problems as “That is the estimation of rough but quantitative answers to unexpected questions about many aspects of the natural world" (Morrison, 1963, p. 627).

Fermi problems have been used in many areas of mathematics learning such as mathematical modelling. For example, Ärlebäck (2009) used of Fermi problems in a study conducted with high school students and Andrea (2005) used Fermi problems with pupils at the primary stage of education.

Fermi problems have also been found to be valuable as a learning material for mathematics. According to Silver:

> The development of students' creative fluency is also likely to be encouraged through the classroom use of illstructured, open-ended problems that are stated in a manner that permits the generation of multiple specific goals and possibly multiple correct solutions, depending upon one's interpretation. For example, consider the following "Fermi-style" problem […] (Silver, 1997, pp. 77).

If the relationship between Fermi problems and creativity becomes more clear, the value of dealing with Fermi problems in mathematics education will also be explained. Furthermore, it is also hypothesized that it would be possible to measure creativity by means of Fermi problems.

Creativity

Previous studies have expressed various definitions of creativity. Treffinger (2011) reviewed the literature for definitions of creativity up to 2011 and collected more than 100 references which discusses creativity from different perspectives. The present study focuses on fluency, as one of the elements of creativity. Guilford is a pioneer in the study of creativity since the 1950s. Guilford (1954) hypothesized that creativity has the following factors: sensitivity to problem, fluency, flexibility, originality, penetration, analysis, synthesis and redefinition. In the course of his research, Guilford refined these creativity factors and defined the factors while testing his hypothesis. In Guilford's study, fluency is defined as "The ability to think of many ideas; many possible solutions to a problem" (Guilford, 1973, pp. 2). Tests have also been developed to measure these factors. For example, based on research by Guilford, Torrance developed tests to measure the creativity factor. In Torrance's study, the measure of fluency is "In all tasks, fluency is defined as the total number of relevant responses, relevancy being defined in terms of the task assigned" (Torrance, 1963, pp. 9). Even in the 2000s, the research on creativity tests continued. Kim's (2006) critical examination of the Torrance Creativity Test and his research on the effective use of the Torrance Creativity Test and showed that fluency is one of the elements of creativity.

Fermi problems are seen as a form of mathematical modelling therefore the present study focuses on creativity in mathematical modelling. Mathematical modelling is the process of translation between the real world and mathematics in both directions (Blum & Borromeo Ferri, 2009) and some there some studies have investigated the association between mathematical modelling and creativity. Dan and Xie state that "We evaluated 33 engineering students in a class and obtained the distributions of the students' mathematical modelling skills and their creative thinking levels. The data from the experiments show that there is a strong positive correlation between these two kinds of competencies" (2011, pp. 457). Thus, it was assumed that mathematical modelling seems to have a positive impact on creativity. Wessels' (2014) study also discusses the relation between creativity and mathematical modelling. Wessels identifies the following four elements as a measure of the association between mathematical modelling and creativity:

- Fluency that refers to the generation of different solutions.
- Flexibility that entails the change of shift that takes place in the emphasis, direction, or approach of creative problem solvers.
- Novelty that refers to the level of originality in the development of new and unique solutions.
- Usefulness that is grounded on the relevance, adaptability and reusability of solutions in other real-world situations.

Wessels states that "A framework with four criteria for the identification of creativity was successfully used to evaluate levels of creativity in the solutions to the MEAs (model-eliciting activities)" (2014, pp. 1). Lu and Kaiser (2021) also state the relationship between mathematical modelling and creativity. They defines the three elements of creativity in the modelling cycle as Usefulness, Fluency, and Originality. They suggest that when assessing modelling competency, it is better to include the perspective of Usefulness among the three elements in the assessment items.

Thus, previous studies have discussed creativity and mathematical modelling. However, only a few studies have discussed the connection between fluency in general creativity, fluency measured by a Fermi problem and academic achievement in mathematics in detail. Additionally, previous studies have shown that assessing creativity in mathematics education is time-consuming. Therefore, a simpler way to measure creativity will need to be developed.

The present Study

In this paper, two research questions are considered.

1. Is there a correlation between fluency in the Fermi problems and fluency in creativity in general?
2. If there is a correlated, can the Fermi problem measure fluency in general creativity without being influenced by academic performance in mathematics, age, or gender?

Therefore, the purpose of this study is to determine whether there is the relationship between fluency in general and fluency measured by the richness of aspects in solving a Fermi problem. Additionally, it is investigated whether the Fermi problem can be a simpler measure of fluency in general creativity, when controlling for factors such as academic performance in mathematics, age and gender.

Participants and Procedure

A total of 291 Tarui Municipality Fuwa Junior High School (public junior high school) students participated in the survey (100 seventh graders, 169 eighth graders, 22 ninth graders). The academic level at this school is slightly lower than the national average. First, students received a mathematical performance test with a time limit of 50 minutes. Then they took the test for creative thinking and the Fermi problem test, which were both 10 minutes. Mathematical performance tests such as the one used in this study are part of the school curriculum and take place at the end of every school year. The students took the test in a relaxed state, as it was explained to them that the results of the test for creative thinking and the Fermi problem test would not affect their school grades in mathematics or any other subject at all.

Mathematical Performance Test

This is a test given regularly to measure the academic performance in mathematics and the author of the study was not involved in its design because the test was prepared by an educational publisher. In seventh grade students are tested on positive and negative number, equation, proportional and inversely proportional, figure problems, such as surface area and volume. In eighth grade, in addition to the aforementioned items, they are also tested on polynomial calculation, linear functions and proof problems for congruent figures. In ninth grade simultaneous equations and proof problems of similarity are added. These problems are asked in approximately the same proportion.

Test for Creative Thinking (TCT)

The Takano's TCT (1989) to measure fluency in general creativity was used in the present study. The TCT is based on Guilford's TCT (1959) and was adapted by Takano for Japanese students. The questions are as follows. A picture of an empty can was shown, and the students were asked, "What are the possible uses for the objects in this picture? Please think of as many as you can." The intention of this question is to figure out how many ideas the students can write. The number of possible uses of the empty can that the participants could think of was defined as fluency. For example, if a student gave two responses, "I use it as a vase" and "I use it as a tool for drawing circles", the fluency is 2. If no answer is given, the score is 0. In the following there are some examples of students' responses to the question: using it as a container, using it as a musical instrument, using the lid of the can as a cutter, using it to play bowling, using as a penholder, putting a stone in it, then using it as a weapon etc.

Fermi Problem Test

The Fermi problem used in the present study is "How many liters of water does one person use in a year?" In this Fermi problem, fluency is defined as "the richness of aspects solving a Fermi problem." This definition is different from definition of Wessels (2014) or Lu and Kaiser (2021). For ease of the evaluation in school, the number of ideas that can be evaluated more clearly and simply was used as the definition. For example, if a student considered "the amount of drinking water" and "the amount of water used in the shower" as the elements needed to solve the problem, the fluency is 2. If a response was "I use 10 liters in the morning, 20 liters in the afternoon, and 30 liters at night." Then the day was divided into three parts in chronological order the score was three. If there was no number to assume or only the answer, it was determined to be 0. After considering many problems in my preliminary research and discussing them with some pedagogy professors, it this problem was adopted.

Results

The statistical analysis was conducted to investigate the first research question, "How much of a correlation is there between fluency in the Fermi problem and fluency in creativity in general?" The correlation between fluency measured by the richness of aspects solving a Fermi problem (fluency of a Fermi problem), fluency in general creativity by TCT (fluency by TCT) and academic performance in mathematics was examined. Correlations with mathematical performance were also investigated, as previous research suggested that creativity and the Fermi problem have a strong relationship with mathematical performance. As can be seen (Table 1), there is a strong positive correlation between fluency of a Fermi problem and fluency by TCT. There is also a weak positive correlation between academic performance in mathematics and fluency by TCT. Similarly, there is a weak correlation between academic performance in mathematics and fluency of a Fermi problem.

Table 1: Correlation between Fluency by TCT, Fluency of a Fermi problem, and Math-Performance

	Fluency by TCT	**Fluency of a Fermi problem**	**Math-Performance**
Fluency by TCT	1		
Fluency of a Fermi problem	0,614**	1	
Math-Performance	0,247**	0,278**	1

*p<0,05;**p<0,01 Math-Performance (Mathematical performance test scores)

A multiple regression analysis was then conducted to further investigate the connection between the fluency in general creativity and the fluency in a Fermi problem, which was investigated in the present study. Fluency in general creativity was used as the dependent variable to determine the extent to which fluency as measured by the Fermi problem is a construct of fluency in general creativity. As can be seen (Table 2) two models were created for analysis. No multicollinearity was found in the two models. Model 1 adds age and gender as well as math-performance as control variables. Model 2 uses only math-performance as a control variable. Both models also show significant differences. In addition, there is a significant difference fluency of a Fermi problem and academic performance in mathematics in both models.

Table 2: Results of multiple regression analysis with fluency by TCT as the dependent variable

	Regression coefficient	**Standard error**	**Standardized regression coefficient**
Model 1: Dependent variable is fluency by TCT and 4 variables (Adjusted R^2= 0.297,F(4,286)= 31.58,p<0.001)			
Fluency of a Fermi problem	0.435***	0.045	0.492
Math-Performance	0.012*	0.005	0.124
Age	0.383*	0.195	0.099
gender	-0.275	0.229	-0.061
Model 2: Dependent variable is fluency by TCT and 2 variables (Adjusted R^2= 0.290,F(2,288)= 60.29,p<0.001)			
Fluency of a Fermi problem	0.444***	0.045	0.503
Math-Performance	0.011*	0.005	0.115

*p<0,05;**p<0,01; ***p<0,001 Math-Performance (Mathematical performance test scores)

Discussion and Conclusion

Analysis of the data showed a strong correlation between fluency in general creativity and fluency measured by the richness of aspects in solving a Fermi problem. The result of the multiple regression analysis in Table 2 also show that fluency of a Fermi problem is a relatively strong factor when creativity in general creativity was the dependent variable, even when controlling for academic performance in mathematics and age. Thus, it is predicted that the Fermi problem can measure fluency in general creativity without much effect from factors of age and academic performance in mathematics. Previous studies of the relationship between mathematical modelling and creativity have defined fluency as the number of different solutions or the number of different models considered. In addition, the mathematical modelling problems used in these studies were modelling problems of relatively high challenging level (Wessels, 2014; Lu & Kaiser, 2021). If the problem is a mathematical modelling problem at a challenging level, it is possible that it may take longer time to solve the problem, or that students seem to be satisfied if they can find one solution or model for the problem. This makes it difficult to measure fluency appropriately. To avoid such difficulties, the present study assessed fluency from a different perspective. By defining fluency as "the richness of aspects of solving a Fermi problem", it is possible to evaluate fluency more openly in terms of the items students have created and thought about in order to solve a problem, even if they cannot create a complete single solution or model. Additionally, Fermi Problems require to consider a large quantities of scenarios quickly (Ärlebäck, 2009). In fact, the Fermi problem used in this study showed that most of the students were able to answer or came up with ideas to solve the problem within 10 minutes. Thus, the Fermi problem can be handled in a short time. Therefore, the assessment using the Fermi problem, as in the present study, is simpler than the assessment used in previous studies. Hence, this suggests that Fermi problems can be simply used as one of the fluency assessments in school.

Focusing on the relationship between academic performance in mathematics and fluency, there is a weak correlation. There are two possible reasons for the weak correlation. First, Japanese junior high school students are not familiar to modelling problems like the Fermi problem. Therefore, it is predicted that even students who have a high academic performance in mathematics were not able to achieve a high level of fluency. Second, the issue seems to be the nature of mathematics problems. Just presenting ideas is not enough to solve a mathematical problem. It is necessary not only to come up with ideas for solutions, but also to be able to change the solution method to a better one to handle them properly, and to calculate without making mistakes. These reasons are considered to be the cause of the low correlation. In the present study a low relationship between the fluency and academic performance in mathematics was found, but one cannot deny the possibility that there is a strong relationship when looking from another perspective.

There are some limitations to the present study. First, in the present study, the reliability and validity of the test to measure fluency with the Fermi problem was not verified. Therefore, it is not possible to state that fluency in general creativity can be completely measured by means of this Fermi problem. Second, students dealt with "How many liters of water does one person use in a year?" In this case, results showed the relationship between fluency in general creativity and fluency measured by the richness of aspects solving a Fermi problem. However, it was not possible to shown whether there is the relationship between fluency in general creativity and all other Fermi Problems. It could be the case that there are some Fermi problems that limit fluency in the first place. Furthermore, the survey was only conducted with Japanese students in one school. It is possible that other countries will have different results. Moreover, the present study was only focused on fluency, which is one of the factors of creativity. It cannot be conclude from the results of the present study that Fermi problems is strongly related to all factors of creativity.

Although there are some limitations, it was suggested that the existing definition of fluency in mathematical modelling could be reconsidered, and that Fermi problems could be used to measure fluency in a simpler way. In the future, it will be examined the validity and reliability of a test to measure creativity using the Fermi problem. Additionally, the relationship between general creativity factors other than fluency and Fermi problems will be investigated to complement and extend the results of present study.

Fostering self-regulated learning by increasing student agency in assessment – student perceptions

Johanna Rämö[1], Jokke Häsä[2], Liisa Myyry[3] and Zi Yan[4]

This study investigated students' perceptions of different assessment methods in an undergraduate mathematics course. Each student could choose from two summative methods, exam and self-assessment, for their course grade. Embracing this form of agency, most the students chose self-assessment. A content-based analysis of the reasons students gave for their choice produced a variety of expressions of self-regulation. Many students recognised the value of self-assessment for their continuous learning and were motivated by it. Others acted from affective reasons, enjoying or agonising about one or the other method. Still others aimed to control their behaviour by challenging themselves or managing their workload. Choices were also made from purely practical reasons. The results give teachers valuable information on what students consider important in assessment. They also point to the usefulness of the study design for studying student agency and self-regulation.

Keywords: Undergraduate mathematics, self-regulation, agency in assessment, students' perceptions, self-assessment.

Introduction

There is a growing consensus among pedagogical researchers and policy-makers that university students should be involved in assessment processes as agents, not just passive assessees (e.g., Falchikov, 2004). This would improve students' engagement with the learning goals and assessment criteria, as well as their self-regulation skills, including monitoring and reflecting on their own learning (e.g., Adie et al., 2018). In this study, we enhanced student agency in assessment by giving them the possibility to choose between a traditional and a novel, student-centred assessment method for their course grade. By analysing the reasons students give for their choice, we aim to obtain in-depth information about students' self-regulation, as well as their perceptions of novel summative assessment methods in mathematics.

Student agency is usually restricted to formative assessment, which takes place during learning and usually does not involve high-stakes grading. Students may, for example, be involved in self-assessment or peer review processes. On the other hand, Nieminen and Tuohilampi (2020) suggest that student agency in summative assessment may in some contexts offer benefits that are not accessible through formative assessment. They reason that some students may not see the benefit of formative assessment to themselves but consider it instead to be conducted for someone else. However, involving students in summative assessment presents many challenges, for example regarding validity and fairness. Also, summative assessment has traditionally been in control of the teachers, and students may end up resisting any change that they consider a risk for their grades.

Hence, it is important to study students' reasoning around assessment choices in order to find ways to promote student agency also in summative assessment.

Assessment in mathematics is very traditional through all levels of education. In the UK, the most common assessment method in university mathematics is the closed book exam, and there has been no significant change in this in the last 10 years (Iannone & Simpson, 2021). Also, in schools assessment in mathematics is often traditional. In Finnish schools, the most common assessment method in mathematics is the exam, and alternative assessment methods are not used as frequently as in other subjects (Atjonen et al., 2019).

This study is the first step in a larger project concerning self-regulation and student agency in assessment. We let students in an undergraduate mathematics course choose the summative assessment method from two options: exam and self-assessment. The students made the choice in the beginning of the course but were able to change their choice before the assessment took place. The pedagogical motivation for this setting was to enhance students' agency by giving them power over their own assessment. We also presumed that students' perceptions of the assessment methods would be more authentic if they had to commit themselves to a particular method (as opposed to asking them about assessment that they were not engaged in). Our research questions are the following:

Research question 1: How do mathematics students perceive a novel summative assessment method compared to a traditional one?

Research question 2: What characteristics of self-regulation are expressed in the justifications students give for their choice of assessment method?

Self-regulation and student agency in assessment

Self-regulation refers to monitoring, controlling, directing and evaluating one's own thoughts and behaviour in order to achieve desired outcomes (e.g., Zimmerman & Schunk, 2001). Self-regulation of learning is considered an important skill in higher education and life-long learning (e.g., Zimmerman, 1990; Heikkilä & Lonka, 2006). Pintrich (2000) introduced a model of self-regulation that identifies four areas of regulation: cognition/metacognition, motivation/affect, behaviour, and context. For example, regulation of motivation may include assessing the value of a task and one's capacity of succeeding, and regulation of context may include changing the task or leaving it.

In order to cultivate self-regulation skills, students must achieve *agency*, in other words they must be able to make decisions and act autonomically towards a desired goal. One way of increasing student agency is to involve students in assessment. Assessment has traditionally been in control of the teachers, but recently, student agency in assessment – in particular, formative assessment – has been emphasised in international policy (Adie et al., 2018). Adie et al. (2018) proposed a definition of student agency in assessment based on Emirbayer and Mische (1998): agentic students (1) make choices and take action in assessment (2) within the boundaries of different contexts, environments and timeframes (3) thereby reproducing or transforming traditional assessment structures.

Self-assessment is a typical way of transferring control to students. Panadero et al. (2018) note that self-assessment has long been studied as a link between formative assessment and self-regulated learning. They point out that although self-assessment is theorised to support self-regulation, empirical evidence is mixed. On the other hand, Nieminen and Tuohilampi (2020) compared student perceptions of their agency in formative and summative self-assessment contexts. They observed that only those students who were randomly selected to perform summative self-assessment for their course grades, perceived the self-assessment useful for their future studies or working life. Compared to students assessed with an exam, they also expressed a feeling of 'studying for themselves'.

Students' perceptions of assessment

It is essential to understand students' perceptions of assessment in order to enact the positive impact of assessment on learning (Conlon, 2006; Guo & Yan, 2019). Past studies have shown that students tend to have mixed perceptions of assessment, and the purposes of assessment (formative vs. summative) might greatly influence their perceptions (Brown & Harris, 2016; McMillan, 2016). With regard to self-assessment, there is no consensus among students either. Some believe self-assessment to be useful, while others doubt its effectiveness in improving their learning (Hung, 2019; Lew et al., 2010). The learning environment can have a significant influence on students' perceptions of assessment (Gijbels et al., 2008) and self-assessment (Hill, 2016). Hill (2016) found that students seldom conducted self-assessment without explicit encouragement. However, once given the opportunity to practice, their attitude towards self-assessment became more positive and they were willing to continue to carry out self-assessment in their future learning.

Undergraduate mathematics students' perceptions of assessment have been found to be different from other fields. In their review, Struyven et al. (2005) found that higher education students find alternative assessment methods to be fairer and to lead to deeper learning than traditional methods. However, the review does not include any studies on mathematics students. Indeed, Iannone and Simpson (2015) found that in the UK, mathematics students prefer traditional assessment methods such as closed book exams. Iannone and Simpson (2017) have also compared mathematics and education students' perceptions of assessment in two universities in the UK. Students in both groups preferred assessment methods that, in their view, discriminated with respect to academic ability. However, their perceptions concerning discrimination differed. Education students preferred projects and dissertations, and mathematics students preferred closed book exams. It can be concluded that disciplinary factors need to be considered when studying students' perceptions of assessment.

Context and method

The context of this study was an undergraduate mathematics course taught at a research-intensive Finnish university. The topic of the course was linear algebra, and it was one of the first mathematics courses students take. The course lasted for 7 weeks and was worth 5 credits (ECTS). Typical major subjects among the students who took the course were mathematics (including teacher education), computer science, economics and statistics.

The course was taught using an inquiry-based teaching method (see Rämö et al., 2020). During the course, all students took part in formative self-assessment exercises which followed the DISA self-assessment model (Häsä et al., 2019). In the exercises, the students assessed their competencies using a detailed rubric written by the teacher and received automated feedback on their assessments.

For the summative assessment that took place at the end of the course, students could choose from two options: exam and self-assessment. In the former case, the grade was determined by the exam together with bonus points received from weekly tasks. In the latter case, the students self-graded their course according to the DISA model. In this model, a student's self-assessment is checked against the tasks they had completed during the course. The teacher can step in if the self-assessment is not in line with the student's weekly performance.

In the beginning of the course, students were explained the teaching arrangements of the course. As self-assessment was assumed to be a new assessment method to many students, and all students had to complete formative self-assessment exercises during the course, the teacher explained what the benefits of self-assessment are considered to be. After this, the students had to choose the summative assessment method, but they were told that they could change the assessment method before the end of the course if they wanted to. The students were asked to give a reason for their choice.

The participants in this study are 333 students who participated in the linear algebra course and gave consent to use their answers in the study. The data consists of two datasets. Firstly, it contains the reasons students gave for their choice of assessment method in the second week of the course ("On what basis did you make your choice?"). Secondly, it contains reasons students gave for changing their choice in the last week of the course ("Justify carefully why you wish to change your choice."). Students' answers were gathered via the Moodle platform that was used for teaching the course. In the beginning of the course, 83% (n=275) of the students chose self-assessment and 17% (n=58) examination. There were 18 participants who changed their choice: 14 from examination to self-assessment and 4 from self-assessment to examination.

The data was analysed using abductive content analysis, in which identified categories are related to theoretical concepts but not directly based on them (Timmermans & Tavory, 2012), and it was coded with an Atlas-ti programme for qualitative data analysis. The justifications varied in length from a few words to several sentences and each justification could include several reasons for the choice. For the students' choices in the beginning of the course, altogether 16 codes were identified, forming five main categories: self-assessment enhancing learning; examination preventing learning; external reasons for self-assessment; negative aspects of self-assessment and examination enhancing learning.

Results

The most common reason to choose self-assessment was that **self-assessment enhances learning**. Half of the justifications endorsing self-assessment were related to this category. Participants for instance argued that *they learned more by self-assessment*:

> I feel that I invest in the tasks more when I know that the self-assessment is based on them. And when I do tasks with thought, I learn the course content better.

They also stated that *self-assessment was a more efficient and beneficial way of learning*:

> In my view, self-assessment supports deeper learning to a greater extent, because often when you study for an exam, learning may remain superficial.

> I choose self-assessment, because I believe that it challenges me to study things properly during the course but also gives me information on how I have understood things and what is my level of mastery.

Self-assessment was *seen to balance the workload during the course*:

> Moreover, you can do the final assessment a bit earlier which makes it possible to focus earlier on other final assessments and Christmas holidays.

In addition, self-assessment was reflected to *be a more holistic and a long-term way of learning compared with examinations*:

> I want to learn to better interpret my learning in practice and I believe I'll get a more realistic outline of what I learned in the course by means of a long-term follow-up process than through an exam at the end of the course.

Some participants also mentioned that self-assessment caused less stress than examination: "Self-assessment is less stressful."

More than one quarter of the participants endorsing self-assessment as a first choice, considered that **examination prevented their learning**, not just because it can be stressful, but because it focused on only the limited aspects of what have been learned:

> In self-assessment I must really evaluate the work I've done, whereas the exam seems to be just one performance in which you can succeed (pass) even when you don't completely comprehend things.

Approximately 23% of the justifications for choosing self-assessment were related to **external reasons**, mostly referring to timing issues, and not taking a stand on effects on learning: "It is better for my timetable."

Participants endorsing examination for the first choice reasoned most often that **examination enhances their learning** by challenging and motivating them to learn.

> I choose the exam because I regard it as a more challenging alternative to myself.

> I feel the exam is a motivating and pleasant way of assessing mastery.

Examination was also considered to accomplish long-lasting learning outcomes and to be a good way to validate what one has learned.

> The exam creates extra motivation to permanently learn the content. It is also, in my opinion, a good way to validate one's level of mastery.

Negative aspects of self-assessment were also reasons to choose examination as the assessment method. Some participants had had negative experiences of self-assessment before and found it laborious and difficult: "Self-assessment is repulsive and difficult" or they were reluctant to try new experiences: "I'm not open to new experiences."

Those students who changed their initial choice from examination to self-assessment (n=14) did it often based on practical reasons, such as a more flexible timetable. Some students changed their mind because during the course they found that self-assessment was beneficial for them or they wanted to try something new. Those four students who changed their choice from self-assessment to examination argued for instance that they felt they could perform better in the examination than by doing self-assessment.

Discussion

In our study, most students chose self-assessment instead of exam. This is in line with several previous studies in which students have been found to prefer novel assessment methods over traditional ones (Struyven et al., 2005). However, it contradicts previous studies in which mathematics students in the UK have been found to prefer exams (Iannone & Simpson, 2015, 2017). The cultural context of these studies may explain the different results to some extent. In Finland, assessment is not high-stakes: exams can be retaken easily and single course grades do not affect students' studies or future careers. In the UK, assessment is often high-stakes, and this may lead students to view alternative assessment as risky. Finally, in the case of our study, the teacher informed the students about the benefits of self-assessment, which may have affected students' choices.

In previous studies, mathematics undergraduate students have been found to prefer assessment methods that they perceive to discriminate according to academic ability (Iannone & Simpson, 2017). We found similar perceptions in our study when students described how a certain assessment method enhances or prevents learning. What is notable is that some students linked the discriminating ability with exams but others with self-assessment.

Our study design allowed students to achieve agency in assessment in several ways. Practising self-assessment in a formative setting is itself a typical way to include students in assessment (Panadero et al., 2018). Also, some students opted for summative self-assessment, which has been reported to enhance future-driven agency and ownership of learning more than formative self-assessment (Nieminen & Tuohilampi, 2020). Thirdly, students were given power to choose the assessment method themselves.

Students' reasons for choosing the assessment method give information on how they regulate their learning in Pintrich's model for self-regulation (2000). Students who chose the exam expressed regulation of affect or behaviour: they enjoyed exams or found self-assessment disagreeable, or they felt that exam would challenge them to study harder. Students who chose self-assessment expressed similar regulation: self-assessment was more flexible in terms of scheduling (behaviour) or less stressful (affect). However, they also mentioned aspects of motivation and cognition, stating that they would learn more or in a more holistic way, and even metacognition, claiming that self-assessment would enable them to monitor and learn about their own learning.

From the teacher's point of view, it is valuable to understand not only what kind of assessment students prefer, but also what they would consider important given the chance to choose a method themselves. This knowledge will help in designing new, student-centred assessment structures. Allowing students to make the choice also revealed detailed information about what they focus on when regulating their own learning in an authentic situation. However, since it was the teacher of the course who collected the students' choices and justifications, some students may have embellished their reasoning, even though they knew that their answers would not affect their grades. This must be taken into account when drawing conclusions from the results.

The current study design offers several possibilities for future research concerning student agency in assessment. We will continue by analysing students' justifications further and by linking them to quantitative data on self-regulation and approaches to learning. As another direction that could be based on a similar design, we recommend studying the effects of increased agency in assessment on students' academic achievement or well-being.

Judgment bias in diagnosing misconceptions with decimal fractions

Andreas Rieu[1], Timo Leuders and Katharina Loibl

[1]University of Education, Freiburg, Germany; andreas.rieu@ph-freiburg.de

A prerequisite for remediating student misconceptions is their accurate diagnosis by the teacher. However, studies on judgment accuracy show that teachers differ substantially regarding their judgments even though little is known about the reasons so far. The present study investigates whether teachers' diagnosis of misconceptions with decimal fractions is subject to judgment biases. For this purpose, we propose a cognitive model for diagnosing misconceptions based on the process of hypothesis testing. The study results show that the formulation of alternative hypothesis and the processing of relevant information are predictors of high judgment accuracy when diagnosing misconceptions. Furthermore, normative and confirmatory biased judgment processes could be distinguished. Implications for teacher education are discussed.

Keywords: Assessment, misconceptions, confirmation bias, cognitive processes.

Judgment processes in diagnosing misconceptions

The term misconception suggests that students commit a systematic error due to a naïve theory. From a student's point of view, it is rather a strategy based on a hitherto reasonable idea. In mathematics education, various student misconceptions are well researched (cf. Confrey & Kazak, 2006), such as the assumption that "multiplication makes bigger, division makes smaller" which is correct with natural numbers and is thus often overgeneralised to fractions. From a teachers' perspective, misconceptions are constructs that emerged as a result of the learners' experiences in different contexts but that no longer function correctly when transferred to another area of knowledge (Fujii, 2014). In order to create adaptive learning opportunities, learner misconceptions must first be diagnosed. Then the teacher can trigger a cognitive conflict and resolve it by introducing the actual mathematical concept (Corno, 2008). Thus, teachers' judgment accuracy when diagnosing misconceptions – that is to determine it precisely - seems crucial for student learning. However, various studies have shown that teachers' judgment accuracy on student performance varies widely (mean effect size between teachers' judgments of students' academic achievement and students' actual academic achievement of r = 0.63 in the meta-analysis by Südkamp, Kaiser, & Möller, 2012).

In their framework, Loibl et al. (2020) conceptualise diagnostic judgments in pedagogical contexts as a teacher's inference about learners (e.g., their abilities) or materials (e.g., task difficulty) based on the information that is explicitly or implicitly present in a diagnostic situation. This definition locates diagnostic judgments within the larger field of social judgment and cognitive information processing and allows investigating the genesis of (correct and incorrect) diagnostic judgments. In this line of research, recent studies focus their research interest on the judgment processes and examine which information teachers actually gather and process to form their judgment (e.g., Rieu et al., 2022).

The judgment process can be influenced by personal expectations (often leading to erroneous diagnoses), which have already been documented in the area of ethnicity, socioeconomic status, and gender (McKown & Weinstein, 2003; Rubie-Davies, Hattie, & Hamilton, 2006; Südkamp et al., 2012). Biases like the confirmation bias – the tendency to selectively choose and process information supporting the initial hypothesis – influence the judgment process when the diagnostic judgments are based on hypothesis testing (Herppich et al., 2018; Oswald & Grosjean, 2004; Westhoff & Kluck, 2014).

The current study

One diagnostic situation in which the teacher's cognitive processes can be modelled as hypothesis testing (Trope & Liberman, 1996), is the detection of misconceptions in decimal fraction (e.g., *longer-is-larger, shorter-is-larger*, Stacey, 2005). In this process, an erroneously solved task often cannot be clearly assigned to one single misconception, but only the structured processing of several tasks and its solutions by the student allow the precise diagnosis of the misconception.

We assume that cognitive biases occur in this knowledge-based process and that these biases systematically favour the confirmation of a hypothesis and make its rejection unlikely (overestimation of the a priori probability of the hypothesis, selective gathering of hypothesis-confirming information, hypothesis-consistent interpretation of ambiguous information according to Schulz-Hardt & Köhnken, 2000, figure 1).

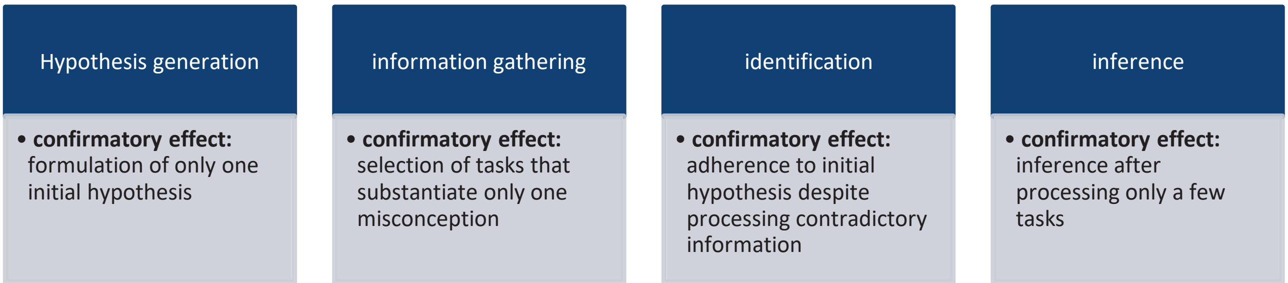

Figure 1: Hypothesis testing process and confirmatory effects in the domain of diagnosis misconceptions

The present study defines diagnostic judgments as information processing and analyses the causes of diagnostic errors. The collection of external indicators such as the formulation of the initial hypothesis and the number and type of information processed allow conclusions to be drawn about the genesis of diagnostic judgments (Loibl et al., 2020).

Specifically, it is assumed that in the ambiguous diagnostic situation of detecting misconceptions in decimal fraction comparison, confirmatory biases occur and prevent an accurate diagnosis. To this end, the following research question is investigated:

> *Is the diagnostic process of misconceptions in decimal fractions subject to confirmation biases?*

Based on the modelled judgment process and the theoretical assumptions, it is assumed that

① the generation of the initial hypothesis reveals if the (prospective) teachers recognise the ambiguous situation when diagnosing misconceptions in the area of decimal fractions based on one erroneously solved task and that

② the amount and type of processed information indicate possible confirmatory biases when gathering and identifying information. The processed information influences the accuracy of judgments when diagnosing misconceptions in the area of decimal fractions.

Method

To test these assumptions, prospective mathematics teachers (N = 79, average age = 21,7 years, 85% were female) at the beginning of their studies were confronted with one erroneously solved task by a virtual student in the domain of decimal fraction comparison (cf. figure 2). The first task and its incorrect solution represent an ambiguous diagnostic situation, as several misconceptions can be responsible for the student error. The diagnostic goal for the participants was to clearly determine the existing misconception of the presented student who consistently solves tasks according to a precise misconception. For this purpose, the necessary specific PCK concerning the misconceptions was visible to the participants and in total, 7 standardised cases had to be diagnosed.

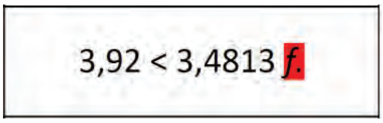

Figure 2: erroneously solved task in the domain of decimal fraction comparison

In an online survey, the prospective teachers first formulated an initial hypothesis about the misconception based on the erroneous student solution to one task. Afterwards they could choose further tasks which were solved by the student after their selection. That is, after clicking on it, teachers saw the solution to this task generated according to the misconception. Finally, the teachers submitted their final diagnosis.

The tasks offered for selection were shown in groups of four. The tasks differed with to the relevance of their information for the diagnosis. Tasks with relevant information for diagnosis allowed to distinguish between two possible misconceptions in the ambiguous diagnostic situation (i.e., these tasks are typically solved correctly with one misconception, but not with the other). Tasks with irrelevant information for diagnosis are either solved correctly by all learners despite the presence of a misconception or do not provide any additional information to the incorrectly solved tasks presented at the beginning.

A digital questionnaire was used to collect the initial hypothesis (single hypothesis or alternative hypotheses) and the number and type (diagnostically relevant or irrelevant) of information the participating persons used to get to their final diagnosis.

Results

Due to floor effects, two case diagnoses were excluded from the calculation. The judgment accuracy for the diagnosis of 5 cases over all participants was 63.3% (SD = 0.48) which designs the ratio of correct diagnoses of the presented students' misconception.

In a first step, the predictors for high judgment accuracy for the diagnosis of misconceptions in the area of decimal fractions are to be determined. Based on the theoretical modelling of the diagnostic process as hypothesis testing, the formulation of the initial hypothesis, the amount of information processed and the proportion of relevant diagnostic tasks are examined. Table 1 gives an overview of the average values of the three predictors.

Table 1: Representation of the average values of the assumed predictors for judgment accuracy according to accurate or incorrect diagnoses

	accurate diagnoses (n = 250)	incorrect diagnoses (n = 145)
average number of alternative initial hypotheses (SD)	0.26 (0.44)	0.15 (0.36)
average number of processed further tasks (SD)	2.73 (2.28)	2.94 (2.73)
average proportion of processed further relevant diagnostic tasks (SD)	0.68 (0.31)	0.54 (0.36)

The influence of the type of initial hypothesis (single hypothesis or alternative hypotheses) on the accuracy of the judgment was compared for accurate and incorrect diagnoses. The one-factor ANOVA indicates that significantly more accurate judgments are given after the formulation of an alternative hypotheses ($F(394) = 6.333$, $p = .012$, $d = 0.263$).

In addition, it was hypothesised that the amount of information processed, i.e. the number of tasks selected to see further solutions of the student, would also have an impact on judgment accuracy. To calculate this influence, the average number of processed tasks was compared for accurate and incorrect diagnoses. Group comparison using an ANOVA indicates no significant difference between accurate and incorrect judgments ($F(394) = 0.647$, $p = .422$, $d = 0.084$).

As a final predictor of judgment accuracy, we examined whether the type of information selected had an impact on judgment accuracy. For this purpose, the proportion of processed tasks that provide relevant diagnostic information was examined. The one-factor ANOVA indicates that accurate judgments, compared to incorrect judgments, are obtained by processing a significantly higher proportion of diagnostic tasks ($F(394) = 18.025$, $p \leq .001$, $d = 0.444$).

In a second step, the study aims to differentiate between different categories of information processing. Based on the finding that one of the predictors of high diagnostic accuracy is the formulation of an alternative hypothesis, different categories of judgment processes can be distinguished. First, after formulating an alternative hypothesis, a correct or incorrect diagnosis can be made. Secondly, a correct initial hypothesis can lead to correct or incorrect diagnoses. Thirdly, a correct or incorrect diagnosis can also be made after an incorrect initial hypothesis. Altogether, 6 different categories of judgment can be distinguished.

Out of the 6 possible judgment categories, two seems of special interest: On the one hand, the process that maps the ambiguity of the situation and subsequently leads to a correct result. Founded on the model assumptions, the ambiguous diagnostic situation should start with the formulation of alternative hypotheses and the given information (the tasks to select) must be processed as hints to correct diagnoses (normative judgment process). On the other hand, and taking into account the research interest, the process that starts from a single confirmatory misguided hypothesis and despite contrary information leads to an incorrect diagnosis (confirmatory-biased judgment process). Table 2 provides the descriptive overview on these two judgment categories concerning the number of processed information and the proportion of relevant diagnostic information.

Table 2: Descriptive overview of the information processing of the two judgment categories correct diagnoses based on alternative initial hypothesis and incorrect confirmatory diagnoses

	N	average number of processed information (SD)	average proportion of relevant diagnostic information (SD)
Normative judgment process: correct diagnoses based on alternative initial hypothesis	65	2.51 (2.02)	0.72 (0.28)
Confirmatory-biased judgment process: incorrect confirmatory diagnoses	84	2.48 (2.05)	0.47 (0.36)

The comparison using a one-factor ANOVA shows that the two judgment processes do not differ in the amount of information processed ($F(148) = 0.009$, $p = .926$, $d = 0.016$). Significant differences are shown, however, in the proportion of relevant diagnostic information processed and in the certainty of the final diagnosis: correct judgments based on an alternative hypothesis are made using a greater proportion of relevant information ($F(148) = 1.734$, $p \leq .001$, $d = 0.219$).

Discussion

Accurate diagnosis of student misconceptions by the teacher is crucial for building resilient conceptions in learners (Bradshaw & Templin, 2014). The research interest of the present study focuses on the emergence of such judgments via the investigation of the underlying cognitive processes (Loibl et al., 2020; Rieu et al., 2020). For such a complex judgment situation, it is assumed that biases take place and have a negative impact on judgment accuracy (Oswald & Grosjean, 2004).

The present study defines diagnostic judgments of misconceptions in decimal fractions as information processing in form of hypothesis testing and examines the impact of the created initial hypothesis, the number and type of processed information on the final diagnosis. It is expected that the information processing of the participating persons indicates the presence of confirmatory biased diagnoses.

In a first step, the formulation of alternative hypothesis and the processing of relevant information could be identified as predictors for the accuracy of judgments in the assessment of misconceptions in the area of decimal fractions. Due to the fact that all participating students had the necessary specific PCK about the misconceptions, these results show that the ambiguity of the diagnostic situation must be perceived and subsequently appropriate strategies must be used to cope with it. These findings complement previous studies on knowledge-guided information processing in diagnostic situations (Ostermann et al., 2018; Rieu et al., 2022) and person-dependent diagnostic sensitivity as a disposition (Kron, Sommerhoff, Achtner, & Ufer, 2021).

In a second step, categorising and contrasting the normative process with the confirmatory process highlights the differences between the two approaches concerning the type of information processed to obtain accurate judgments. These results indicate that an information-integrating strategy leads more often to a correct diagnosis (Böhmer, Hörstermann, Gräsel, Krolak-Schwerdt, & Glock, 2015; Fiske & Neuberg, 1990).

Despite several limitations, the results of the present study allow first insights into the judgment processes of prospective teachers when diagnosing misconceptions in the area of decimal fractions. The categorisation carried out on the basis of the type of initial hypothesis and further information processing permits an initial distinction between normative-accurate and confirmatory-biased judgment processes. The normative procedure, which processes relevant information based on alternative hypotheses in order to obtain an accurate diagnosis, should be incorporated into teacher training as a judgment strategy in complex situations to achieve a higher diagnostic accuracy and thus increase the adaptivity of teaching.

Initial phase of a study on assessment and argumentation: students' answers analysis and selection

Marta Saccoletto

University of Turin, Italy; marta.saccoletto@unito.it

Keywords:Argumentation, assessment, answers selection.

Introduction and Theoretical framework

This poster presents the first phase of an on-going study. The aim is to investigate features that are considered by Italian secondary school teachers when assessing the answers to tasks that require a justification. A small group of about ten teachers with different years of experience will be involved and asked to assess some students' responses during in-depth interviews. In this work, we focus specifically on a reflection about students' answers selection. We assume that the students' text that will be considered by teachers could highly influence the characteristics that will emerge and consequently impact on the whole study. Our aim is not to select *correct* answers, but to highlight texts differences that could help us to point out some specific aspects of teachers' points of view. To this aim we consider two theoretical constructs. Drawing from Habermas' concept of rationality (Habermas, 2003/1999), as adapted in Morselli and Boero (2009), we mainly consider three aspects. The epistemic aspect, which regards statements validation in respect to accepted premises and ways of reasoning; the teleological aspect, related to the problem-solving strategies and choices; and the communicative aspect, concerning both the expression of the reasoning and the adhesion to mathematical culture standards. In addition, we consider the three assessment criteria of argumentation conceived during a European Project focused on Formative Assessment by the Italian research group (Cusi et al. 2019). These are: correctness, related to the absence or presence of mistakes in the result, in the resolution process, or in the theoretical recalls; completeness, inherent to the presence of sufficient information leading to the conclusion; and clearness, concerning the way of expression and the reader's ease of understanding. To better characterize the data, we expand the criteria of correctness including the idea of *pertinence* of the mathematical knowledge used in the task resolution. These three criteria have not been used as an analysis instrument, rather as a tool to trigger classroom discussion about argumentation. We tried to include these three criteria with the idea that they could be more easily shared and discussed during teachers' interviews.

Methodology and Results Discussion

Figure 1 represents the chosen task. It was administered during the 2018- Italian Standard National Test (SNV) to 10^{th} grade Italian students, and it is related with the process "Arguing and Proving" in the SNV framework. We refer to the work of Garuti and Martignone (2019) for more details about content and influences of SNV framework. We selected this task as it offers the opportunity of working with a great variety of answers proposed by the Italian students. The qualitative analysis is conducted on 500 responses randomly selected from all the 15 233 answers. Answers are coded in relation to the three aspects of Habermas' concept, each of them being characterised with respect to different components emerging from the study of students' productions.

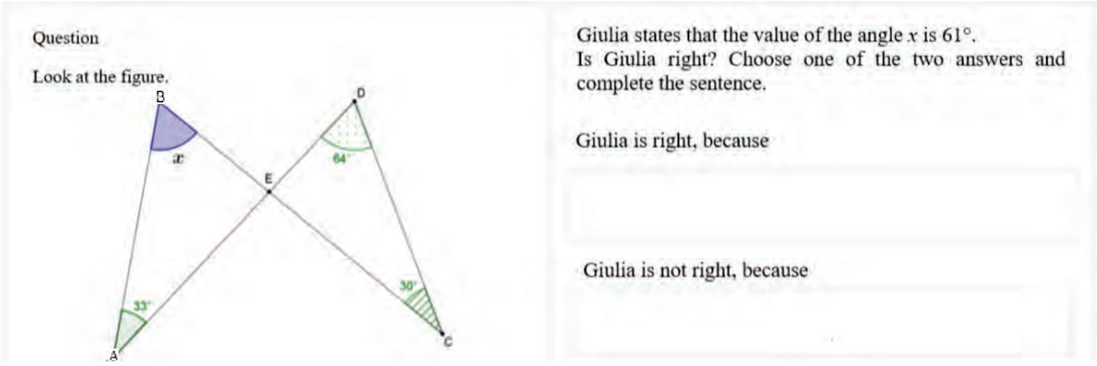

Figure 1: Task from SNV 2018, grade 10 (translation by the author)

Analysis led to the characterisation and selection of different responses. In respect to the teleological aspect, answers are characterised by the strategies used by students, as for example the choice to use a protractor, computational strategies, or to base on visual perception; the ways of implementing the chosen strategies (considering, when possible, the *correctness*) and the way of representing the steps of the procedures or strategies used (*clearness* and *completeness*). The epistemic aspect is shaped by the presence of specific theoretical justification (also referring to the *completeness* of the answers), and the *correctness* of the explicit theoretical references (taking into account also wrong premises that lead to the correct answer, as in the case of students considering the sum of the measures of the interior angles of a triangle being equal to 120°). As far as the communicative aspect is concerned, the different answers show different awareness of the mathematical culture standard, and attention to audience comprehension (considering *clearness* and *completeness*). To sum up, using these two theoretical concepts allows us to characterise the different answers, the selection of which could be a good starting point to discuss with teacher about possible evidence for acceptable answers.

Factors that influence the difficulty level of digital arithmetic assessment items for first-grade students

Gunnhild Saksvik-Raanes[1] and Trygve Solstad[1]

[1]Norwegian University of Science and Technology, Norway;
gunnhild.b.saksvik@ntnu.no, trygve.solstad@ntnu.no

Digital technologies enable new possibilities for the assessment of mathematical competence. When designing an assessment, it is essential to know how different design elements affect both the item difficulty and the strategies used by the children. In this paper, we investigate digital items that were designed to measure arithmetic competence as a component of the Foundational Number Sense (FoNS) framework for five- and six-year-old children. A Rasch analysis of the performance of 302 Norwegian children showed that the type of arithmetic problem and the magnitude of the answer strongly affected an item's difficulty level. Our qualitative observations indicated that certain additional design elements of the items might have influenced both the items' difficulty and the children's solution strategies. From a mixed methods perspective, we discuss the potential of different design elements to better assess children's understanding of numbers.

Keywords: Assessment, digital technology, numbers sense, arithmetic competence, primary school.

Introduction

Digital technologies bring both constraints and affordances to assessment in mathematics education (Threlfall et al., 2007). When assessing young children's mathematical competence, using a digital medium can alleviate the effect of irrelevant demands, such as reading or writing skills. At the same time, we might add elements in the design process of a digital item that could affect the assessment in unintended ways. Carefully designing digital assessment items might enable us to improve assessments and tell us more about the children's solution processes (Saksvik-Raanes & Solstad, 2021). To realise the full potential of digital assessments, we need to know more about how children perceive the different design elements of digital items and what strategies they use to solve them.

In this paper, we investigate digital arithmetic items for five- and six-year-olds from a mixed methods perspective and pose the following research question: Which design elements influence the level of difficulty of digital arithmetic assessment items, and how do the design elements influence the strategies that first-grade children use to solve these items?

Frameworks

Arithmetic competence as a part of the FoNS model

The Foundational Number Sense (FoNS) model describes the number-related skills that require instruction (Andrews & Sayers, 2015). In FoNS, the number sense concept is defined as multi-layered, flexible and relational. The FoNS model divides the number-related skills into eight interrelated categories: number identification, systematic counting, number–quantity relationships, quantity discrimination, representing numbers, estimation, simple arithmetic competence, and awareness of number patterns. In this paper, we focus on simple arithmetic competence, which is described as a child's ability to manipulate small sets through addition or subtraction.

Item design

The arithmetic items presented in this paper were designed based on four main categories: change and combine (sum items) as well as compare and equalise (difference items) (Carpenter & Moser, 1984). Previous studies have shown that children in kindergarten are highly capable of solving such items through modelling the situations in the problem (Carpenter et al., 1993). Sum items are composed in two ways. Either with one initial quantity and an action that causes a change (join), or with two initial quantities that may be considered separately or as a part of a whole. Difference items involve comparing two quantities to determine the difference between them. Equalise problems include an additional action that is to be performed to make the two sets equal.

In addition to problem type, the difficulty of the items was expected to depend on three further design elements. Some items used pictorial representations of numbers, and other items used symbolic representations of numbers. The items involved different numerical values between one and twenty. We balanced the number of items involving small (< 10) and large (≥ 10) numbers and items having ordered and unordered response buttons (see Figure 3).

Methods

Participants and procedure

Fifteen arithmetic items were solved by 302 first-grade children who were a part of a larger study that investigated 368 children's number sense using digital assessment tools. To select participants for the project, we invited about 50 elementary schools in and around Trondheim municipality in Norway to participate in the project. Eight of the interested schools were chosen to participate and all the 1st grade children in these schools carried out the assessment. The children were five and six years old.

A researcher visited the schools over a period of two months at the beginning of the school year. Groups of six to eight children carried out the assessment on separate tablet computers. The participants were seated in such a manner that they would not be disturbed by each other's screens or sounds. All children were given the same instructions before they started the assessment and were free to finish it at any time. Pre-recorded voice instructions were given for each item. The arithmetic items appeared at the end of the full assessment. There was no time limit for the items, but the time taken for each item was recorded. The children typically spent between 15 and 25 minutes on the full assessment, of which about one-fifth comprised arithmetic items.

Qualitative data from individual interviews conducted with 19 first- grade children solving the arithmetic items, were collected independently as a part of a master's degree project (Schjølberg, 2021). The goal of the interviews included in the master's project was to get an overview of the children's strategies. One of the strategies applied by one of the students who participated in the master's project is included in this paper. The interviews were carried out at about the same time as the main data collection.

All the described studies have been approved by the Norwegian Centre for Research Data, and the necessary guidelines related to depersonalisation and parental consent have been followed.

Items

The 15 arithmetic items were designed to investigate the different aspects of the children's arithmetic competence that could influence item difficulty. Four items involved the difference between two numbers. Two of these 'difference items' were compare problems, and two were equalise problems (Carpenter & Moser, 1984). The compare items involved small numbers (< 10), while the equalise problems involved large numbers (≥ 10).

Eleven items asked for the sum of two numbers. Eight of these 'sum items' included the systematic variation of three design elements: (i) small (< 10) or large (≥ 10) answer, (ii) symbolic or pictorial representation of the problem and (iii) ordered or unordered response buttons (see Figure 3).

A priori, we expected the difference items to be more difficult than the sum items, the items with large numbers to be more difficult than those with small numbers, the items with symbolic representations of numbers to be more difficult than those with pictorial representations and the items with unordered response buttons to be more difficult than those with ordered response buttons.

Analysis

All items were scored dichotomously, meaning that the children received one point for a correct answer and zero points for a wrong answer. Rasch measurement was used for the quantitative analysis of the children's responses using the Winsteps software (Linacre, 2017). The Rasch model is a probabilistic measurement model that provides interval-scale measures of item difficulty and person skill on the same measurement scale in units of logits (Wright, 1977). The probability that person v scores 1 point on item i depends on the difference between the skill of person v, β_v and the difficulty of item i, δ_i according to

$$\boldsymbol{P}\,\{\boldsymbol{X_{vi}} = \boldsymbol{1}|\boldsymbol{\beta_v}, \boldsymbol{\delta_i}\} = \frac{\boldsymbol{e}^{(\boldsymbol{\beta v} - \boldsymbol{\delta i})}}{\boldsymbol{1} + \boldsymbol{e}^{(\boldsymbol{\beta v} - \boldsymbol{\delta i})}}$$

Winsteps implements the joint maximum likelihood estimation (JMLE) algorithm to estimate the parameters of this model.

The excerpt from the individual interviews demonstrates how some children used the available resources on the screen to find the right answer to the problems. The qualitative data was analysed using a thematic analysis (Bryman, 2016).

Results and discussion

Task type

From Figure 1, we see that the type of task strongly influenced the difficulty of the items. As expected, the four difference items were also the four most difficult arithmetic items (Figure 1, orange markers). An independent samples t-test between the four difference items and four comparable summation items (symbolic representations involving large and small numbers and ordered and unordered response buttons) showed that this difference was significant ($p = 0.026$; $df = 6$).

Surprisingly, within the difference category, both compare items had higher difficulty than the two equalise items. The compare items were more difficult despite involving small numbers, while the equalise items involved large numbers and came with more complex voice instructions.

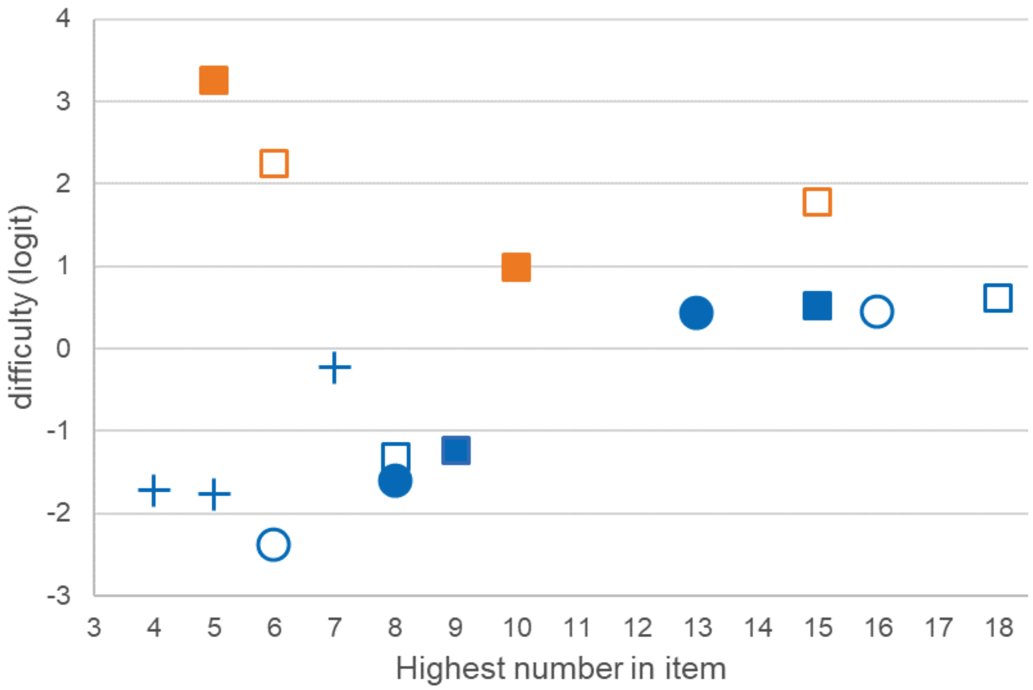

Figure 1: Item difficulty ordered by the highest number involved in the item

The items are categorised as (i) sum item (blue markers) and difference item (orange markers), (ii) pictorial representation (circular markers) and symbolic representation (square markers), and (iii) ordered response buttons (open markers), unordered response buttons (filled markers) and no response buttons (plus markers)

The compare and equalise items were visually identical (Figure 2), and three design elements differentiated them: the magnitude of the answer, the order of the response buttons and the voice instruction given. The answer was less than 10 for both compare items, while the answer was greater than 10 for both equalise items. The following voice instruction was given for the compare items: “How many more marbles are there in the blue box?”. For the equalise problems, the following voice instruction was given: “There should be an equal number of marbles in each box. How many more should the red box have?”.

In the design process, the difference items were challenging to create in a way that would enable all children to understand the given voice instructions. We wanted to keep the instructions as simple as possible to adapt to the attention span of the target group. At the same time, the compare and equalise problems represent two semantically different problems. The equalise problems involve one more step than the compare problems, as an action is performed on one of the two groups when comparing the quantities. We therefore expected that the equalise items would be more difficult. However, Figure 1 shows that the compare items were the most difficult.

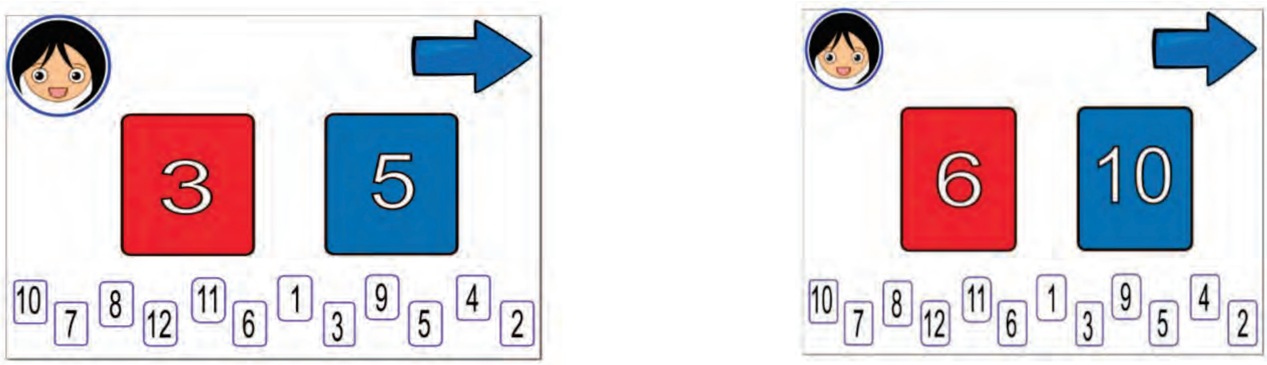

Figure 2: Two difference items

Left: item 13 (compare). Right: item 15 (equalise)

One reason why the compare items appear to be more difficult could be that the added action in the instructions for the equalise items make them more concrete, and this might have aided the children's comprehension of the items. Carpenter et al. (1993) found the kindergarteners in their study to be highly competent in solving compare problems through modelling. It is also possible that some children ignored the "more" word in the instructions for the compare tasks and interpreted it to mean "how many marbles are there in the blue box?". These results indicate that simplified instructions in word problems may lead to more misunderstandings and reduce the child's possibilities for modelling the situation.

The level of abstraction in the illustrations of these four items might also have contributed to their relatively high difficulty compared to the sum items. The children's previous experiences could also have played a role in determining the level of difficulty, as it seems that they were more familiar with the language-related problems that involved addition than subtraction.

Taken together, these results underline the importance of carefully investigating the various design elements when developing digital assessment items.

Magnitude of the answer

For the sum items, we found that difficulty was strongly correlated with the magnitude of the answer of an item. The Pearson correlation between difficulty and answer magnitude was $r = 0.88$ ($p < 0.001$) for all 11 sum items and $r = 0.96$ ($p < 0.001$) for the eight sum items that had a shared problem structure (Figure 1). In particular, the four sum items with a large answer were 2.1 logits more difficult than the corresponding four sum items with a small answer on average. An independent samples t-test showed that this difference was significant ($p < 0.001$; df = 6).

Number representations

A pictorial representation of a number is often thought to be easier to understand than its more abstract, symbolic representation. However, in the group of the eight sum items that shared a problem structure, we found no significant difference in the difficulty between the four items with symbolic representations (blue squares in Figure 1) and the four corresponding items with pictorial representations (blue circles in Figure 1) ($p = 0.65$; df = 6; independent samples t-test). One reason for this might be that the response buttons were written in the symbolic representation. Thus, knowing the correct answer only verbally would not be sufficient to provide a correct response. Indeed, from the qualitative data, we observed that some children knew how to verbally count to 20 without recognising the corresponding written numerals (see the next section).

Order of the response buttons

Based on pilot studies, we had the a priori expectation that unordered response buttons would increase the difficulty of the items because they do not easily allow children to rely on verbal counting strategies. However, at least at first glance, the structure of the response buttons did not seem to strongly influence the difficulty of the items (Figure 1; open vs filled markers). An independent samples t-test between the four sum items with ordered response buttons and the four sum items with unordered response buttons was not significant ($p = 0.88$; df = 6).

On closer inspection, the four sum items with large answers were found to be of similar difficulty (Figure 1) even though the two items with ordered response buttons had larger answers than the two items with unordered response buttons. It is therefore possible that the ordered response buttons made the two tasks with the largest answers easier to solve. The latter interpretation is substantiated by qualitative analyses of the children's solution strategies. One example is item 10, which involved numbers that some children were not very familiar with. After the voice instruction "What is sixteen and two altogether?", the child was to choose the correct answer from the response buttons at the bottom of the screen. The qualitative observations gathered during the data collection led us to carry out a small qualitative interview study on the children's solution strategies.

Qualitative observations of Agnes's strategies

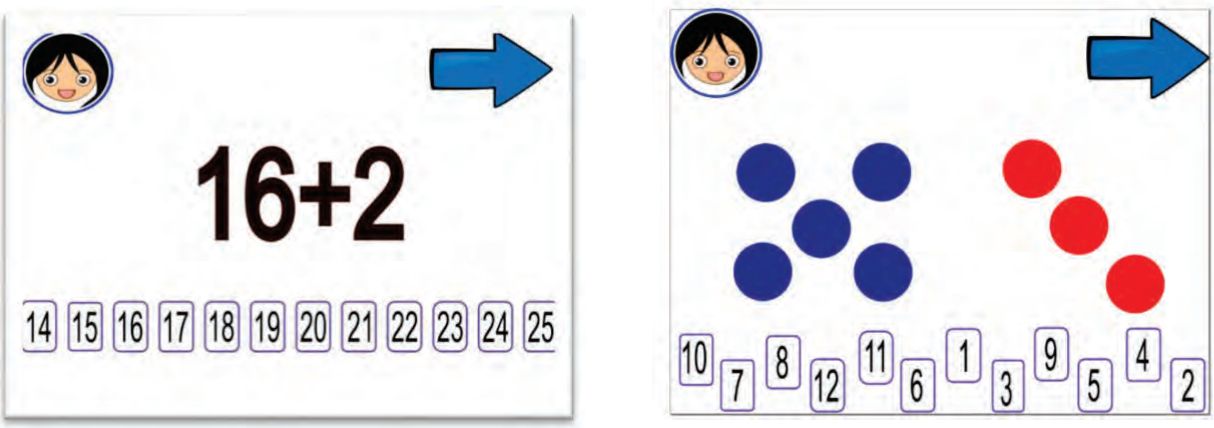

Figure 3: Sum items with systematic variation in the design elements

Left: item 10 with large answer, symbolic representations and ordered response buttons. Right: item 5 with small answer, pictorial representations, and unordered response buttons

In item 10, one of the children, Agnes, used the number alternatives on the screen to find the right answer, but she did not know what numeral she ended up with:

> Researcher: What is 16 and 2 altogether?
> (..)
> Agnes: It is... 16 and 2…
> (..)
> Agnes: Wait… and then we go 1-2.
> (Agnes points to 16 and makes two jumps with her finger on the numerals to the right)
> (..)
> Researcher: What are you thinking?
> Agnes: That one.
> (Points to 18)
> Researcher: Do you know what number that is?
> Agnes: 1-2-3-4-4-5-6-7-8-9-10-11-12-13-14-15-16-17-18. Eighteen!
> (Counting to 14 and then pointing to the numerals on the screen)

Agnes used the buttons to find the numeral that displayed the answer when she was unable to recollect the numerals after 14. In the design process, we did not expect the children to use the number alternatives in this way. These observations also emphasise the importance of investigating the available resources and how these could affect children's solution strategies.

To obtain a more fine-grained analysis of the role of ordered and unordered response numerals, we need to investigate an instrument in which items with ordered and unordered response buttons are designed with identical arithmetic problems.

Conclusions

To investigate the factors that influence the level of difficulty in digital assessment items for arithmetic, we have looked at the role of problem type, representations, numerical values and differently ordered response buttons. We have also considered how children may use the ordered response buttons to find the correct answer for an item.

The strongest determinant of item difficulty was the type of problem: difference items were more difficult than sum items, and compare items were more difficult than equalise items. The second strongest determinant of item difficulty was the numerical value of the item's answer. Whether the problem was presented in a symbolic or pictorial form did not affect item difficulty. Finally, although we could not conclusively determine the influence of ordered or unordered response buttons, our data indicates that ordered response buttons allow children who have not yet acquired mastery over large numerals to use these buttons as a number sequence that helps them solve the problem. Including both kinds of response buttons might help distinguish between the children's knowledge of large numerals and their reasoning regarding the number sequence or with a number line.

While digital technologies continue to influence the assessment of students' mathematical competence with its new possibilities, it is also important to consider the technical and methodological challenges involved in this development (Nortvedt & Buchholtz, 2018). There are many aspects to consider when investigating the various elements that affect children's solution processes when interacting with digital technologies. To ensure the validity of such assessments, it is important that future research looks more into how the various possibilities that digital technologies enable can both improve and hinder students' performance. One way forward could be to compare items that have different design elements but similar answers. Looking more directly at a greater variety of both word problems and symbolic items can allow us to determine how the different contents affects the difficulty of the items. With the use of digital technology, we could also look more closely into young children's competence for solving digital word problems. For instance, one could record the children's solution process while they are introduced to a variety of word problems with more elaborate instructions and pictorial representations. The use of different digital aids, with a larger degree of interactivity, could enable us to study in more detail how the children model and use different strategies to solve the problems.

Analysis of digital assessment in mathematics through the lens of connectivity

Mattias Winnberg

Stockholm University, Department of Mathematics and Science Education, Stockholm, Sweden
mattias.winnberg@mnd.su.se

The focus of this paper is to investigate the framework of connectivity in relation to analyses of summative digital assessment in mathematics. As an example, two digital items in mathematics are analyzed according to the framework of connectivity. The results imply that the framework, along with some instrumental adaptations, can be used to guide item analysis. In future, the framework could likely guide analyses of digital national tests in mathematics. A suggestion is to broaden the scope of this research to a macro level, which might focus on assessment platforms, and possible connections to other digital resources.

Keywords: Assessment, mathematics, connectivity, item analysis, technology.

Introduction

The growing use of technology in society and accordingly in schools (e.g. the use of e-textbooks[1]) can motivate digital assessment because technology is already present in students' learning processes and arguably assessment needs to keep up with this development (Beller, 2013; Bennett, 2002). Other arguments for digital assessment is the possibility to reduce teacher assessment related work-load and improve accessibility for students with special educational needs (Skolverket, 2021). Many researchers (see for example Beller, 2013; DePascale et al., 2016; Sireci & Zenisky, 2006) have motivated for digital assessment due to new opportunities for construct broadening which makes it possible to assess aspects which are not assessable in paper-based tests. For example, a spreadsheet program can be connected to a digital test item and thus assess knowledge and understanding in a more realistic way.

However, there are several issues regarding digital assessment, especially in mathematics. These challenges can be related to practical problems such as the transfer of information from screen to paper and vice versa, not having access to digital scribbling spaces and not being able to naturally navigate between items in a digital test (Russell et al., 2003). Problems can also be related to limitations in automatic assessment systems which may lead to artificial and non-authentic items in mathematics (Drijvers, 2018). Challenges of digital assessment can furthermore be related to validity and construct-irrelevant variance (Messick, 1989). In the context of mathematics and assessment this can refer to the risk of assessing computer skills instead of mathematics. These questions are especially relevant for high-stakes summative tests.

Background

In Sweden, such high-stakes summative tests are known as the national tests, because they are administered nationwide to specific year groups on an annual basis. The national tests are to be digital,

[1] Pepin et al. (2016) define an e-textbook as "an evolving structured set of digital resources, dedicated to teaching, initially designed by different types of authors, but open for re-design by teachers, both individually and collectively. (p.644)

or partly digital, in a few years' time. A decision has not yet been made as to whether the national tests in mathematics will be completely digital or performed as a combination of both computer and paper-based tests (Skolverket, 2021). Research is ongoing and during forthcoming field trials will study student responses to different digital item formats and digital items in an online assessment platform will be investigated. The PRIM[2] group at Stockholm University researches and develops the national tests in mathematics for primary school (grade 3, 6 and 9) and the first mathematics course at upper secondary school (grade 10) in Sweden. At the end of school year 9 the students sit a national test in mathematics, comprised of written parts (with multiple choice, shorter constructed response, and longer constructed response questions) and an oral part. The national test is assessed based upon scoring guidelines, and the results on the parts are aggregated to produce a score which corresponds to a grade. The students' result on the national test must then be given a special consideration, together with all other available results, in teacher's grading.

For the national tests in Sweden a systematic framework exists (Skolverket, 2017), the purpose of which is to ensure high quality national tests and high reliability regarding the use and consequences of the test results in relation to the purpose of the test, which is fair and equal grading. Importantly, the framework applies to the current paper-based national tests, and emphasizes that if relevant factors are changed, e.g. the mode of administration or the technology used to administer and assess items, evidence of validity must be reconsidered (Skolverket, 2017).

Consequently, in order to develop digital national tests of high quality, new analytical frameworks are needed. It is also reasonable that these frameworks should account for the increasing use of digital resources in education. The framework of connectivity developed by Gueudet et al. (2018) could meet such requirements. This framework has been developed for analysis of digital resources and is gaining recognition in the mathematics education research community. The concept of connectivity has been used to study how students use digital resources, such as online exercises and teaching materials (Sabra, 2019). With regards to assessment, I have not been able to find research applying the theoretical lens of connectivity. Despite this possible shortcoming, I argue that it is a suitable candidate for guiding analyses of digital assessments in mathematics, due to the incorporation of new learning theories that recognize modifications of learning processes in times of digitalization. However, the framework is developed for e-textbook analysis and in order to apply this framework to the context of digital assessment, some adaptations might be required. Therefore, the idea framing this paper is to investigate whether the framework of connectivity can be used in order to analyze digital items in mathematics. The ultimate goal, but beyond the scope of this paper, is to develop the framework to guide holistic examinations of digital national tests in mathematics. Thus, the paper is framed by the following research question:

How can the framework of connectivity be adapted in order to guide analyses of digital assessment in mathematics?

This question is highly relevant because digital assessment in mathematics (at least beyond the scope of multiple choice questions) is a relatively new phenomenon in educational systems. This new mode

[2] PRIM-group is a research and test developing unit, within the Department of Mathematics and Science Education at Stockholm University, where the author of this paper is affiliated.

of assessment calls for innovative analytical tools in order to develop and analyze the forthcoming digital national tests. The next section introduces the theoretical concept of connectivity by grounding the concept in modern theories about learning and understanding.

Theoretical framework

Since teaching, learning and assessment in many school systems is happening with and through digital resources (Drijvers, 2018), an analysis of these digital resources calls for new analytical frames (Gueudet et al., 2018). A traditional way of performing textbook analysis is to use quantitative measures. Researchers in mathematics education have also performed textbook analyses categorizing the content at macro and micro level[3]. An analysis at macro level may suggest a horizontal/holistic analysis with attention to general features of the textbook, whereas an analysis at micro level may propose a vertical analysis where specific mathematical content or competencies are considered.

Upon introducing the concept of connectivity Gueudet et al. (2018) ground the concept in Hiebert and Carpenters (1992) framework about understanding; that is, in order to understand and develop mathematical knowledge it is key to be able to make connections between structures of mental representations. The number and the strength of these connections is assumed to determine the level of understanding. This theory about understanding is thereafter connected to the epistemological position *connectivism*, introduced by Siemens (2005) as a new learning theory in which learning is not just seen as an internal activity, but also as actionable external knowledge, for example within a database or an organization. One argument presented in connectivism is that some learning theories (e.g. cognitivism, behaviorism, and constructivism) were developed at a time when learning was not affected by technology, and as such are unable to fully explain how learning takes place in a modern digital world. Within connectivism, learning is essentially about the connections which enable learning to take place. These connections can be understood practically as connections between people, as well cognitively as connections opened up by a digital resource.

This paradigm shift in how learning processes are viewed in a digital age is therefore motivating Gueudet et al. (2018) to study e-books looking

> for connections in, between, and across individuals' cognitive/learning tasks and activities, and how e-textbooks may support those (*micro* level)
>
> for "connected" learning between and across groups of individuals, teachers, or students (*macro* level) (p. 543)

The different ways of making connections within a digital resource is referred to as connectivity at micro level (internal) and the different ways of making connections from/to a digital resource is referred to as connectivity at macro level (external). The concept of connectivity of a digital mathematics resource is defined as the "connecting potential for a given user (student or teacher) both practically as well as cognitively." (Gueudet et al., 2018, p. 545)

[3] In Gueudet et al. (2018) the notion of textbook analysis at macro and micro level is explained in detail with examples of studies, and research questions when investigating textbook analysis at macro and micro level.

Relevant for this paper is the view that digital mathematics items presented in an assessment platform are digital resources for students. The framework of connectivity is developed for analysis of digital resources such as e-textbooks, and since an e-textbook in mathematics contains several items this view seems reasonable. Another reason for this is the possibility to integrate digital resources into an item (e.g. the spreadsheet in the item presented in Figure 1) which might offer students a connection between a software and a mathematical problem. Since this paper is focused on mathematics items presented in an assessment platform, only connectivity at the micro level is considered in the analysis.

The next section introduces two digital items in mathematics that were developed based upon curriculum descriptions of digital technology. The two items are thereafter analyzed through the theoretical lens of connectivity, at micro level. The adaptions needed in the framework of connectivity are subsequently presented in the results section.

Methodology

The items in this paper were developed in spring 2021 together with a year 9 test developer. The focus was content related to digital technology and the use of digital tools, according to the mathematics curriculum for years 7–9. For example, the curriculum states that “All pupils should be given the opportunity to develop their ability to use digital technology.” (Skolverket[4], 2018, p. 8)

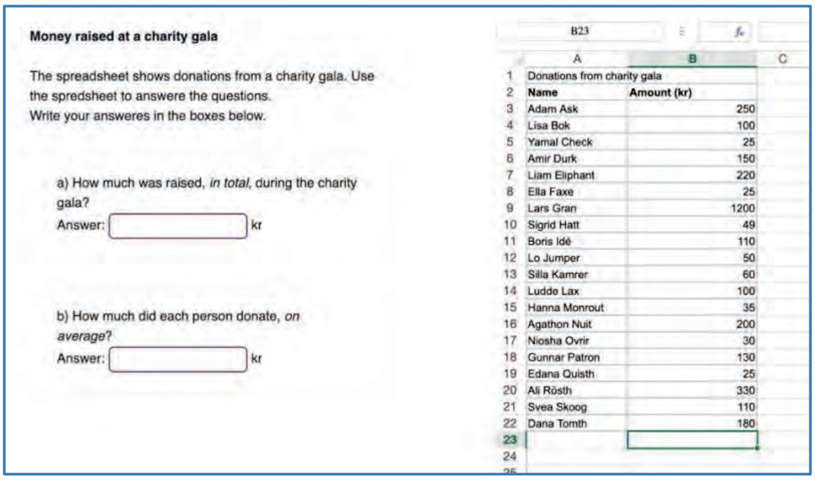

Figure 1: Money raised at a charity gala

The first item, Money raised at a charity gala (see Figure 1), has been translated from Swedish and presented in Figure 1 as it appears in the assessment platform used in Sweden. This item contains a spreadsheet showing donations at a charity gala. In the spreadsheet the students can interact with the spreadsheet, e.g. highlight cells; calculate the sum and mean. Students submit their responses by filling in the two boxes on the left of the screen.

[4] Skolverket is the Swedish National Agency for Education

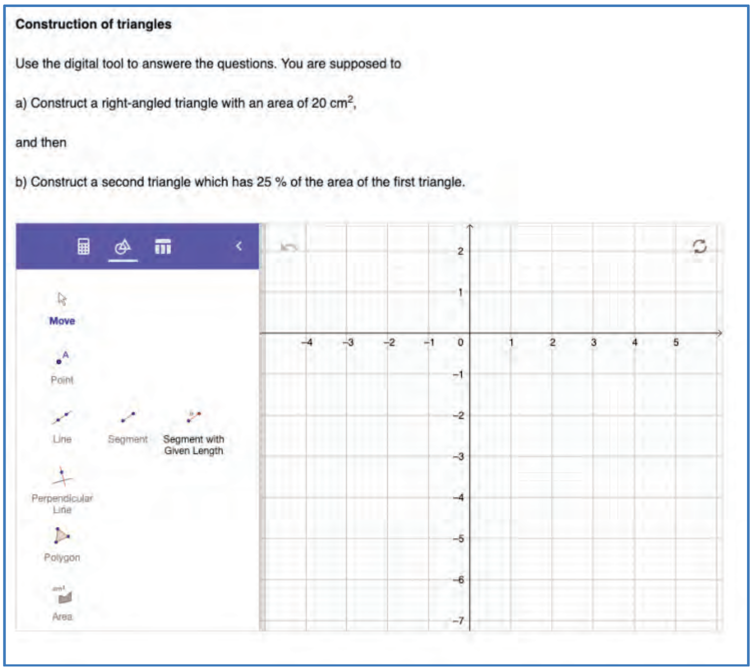

Figure 2: Construction of triangles

The second item, Construction of triangles (see Figure 2), contains a GeoGebra (Hohenwarter, 2021) component where the students can draw lines or line segments between points in a coordinate system, and calculate the area of a polygon. This item was developed based upon specifications in the curriculum about geometry and digital tools. Skolverket specifies in the core content for mathematics, years 7–9 that as part of teaching for geometry "Depiction and construction of geometrical objects, both with and without digital tools…" must be carried out in class, as well as "…Scales for reducing and increasing two and three dimensional objects." (2018, p. 59)

These two items were analyzed through the theoretical lens of connectivity at a micro level (Gueudet et al., 2018). The analysis was performed by examining the items using the micro level analysis grid presented in Gueudet et al. (2018, p. 548), see Table 1. The examination was carried out by searching for connections according to each of the aspects in the analysis grid. Since only two items were analyzed, a specific concept was not considered in the analysis, unlike how the analysis was performed in Gueudet et al. (2018).

Table 1: Micro level grid (for a given set of concepts)

Connections to/in terms of
Previous knowledge (learned in previous chapters in the same textbook)
Further knowledge (role of the chapter considered in further chapters)
Different concepts
Different moments of appropriation of the same concept
Different topic areas within mathematics
Authentic situations, real-life problems, problems referring to other disciplines
Different semiotic representations
Different software and calculator
Different strategies for the same exercise
Variations of the same exercise: same exercise with different values, different exercises around the same question etc.
Different students' needs: presence of exercises for high-achieving students, for students who have difficulties etc.
Assessment procedures and storage of results

Results

The analysis revealed that the following categories of connections in the micro level grid cannot be used: Previous knowledge, future knowledge, different moments of appropriation of the same concept, different topic areas within mathematics, variations of the same exercise, and assessment procedures and storage of results. These categories are not applicable due to differences in design and purpose of an e-textbook as opposed to a digital assessment in mathematics.

The item Money raised at a charity gala offers connections to different concepts, and to a real-life situation where software is used for a specific task. There are also connections between different methods to solve the item. The student can use a calculator tool to calculate the sum and the mean. Moreover, the integrated spreadsheet program will offer the possibility to highlight cells and read the sum and mean, or calculate the sum and mean with integrated functions in the calculating program.

The item Construction of triangles offers connections to a dynamic geometric representation. With the dynamic geometry program students are able to construct polygons and measure the area with the area tool, or calculate the area with the integrated calculator. The item also allows students to work with different methods, e.g. the area of a scaled object is equal to the squared scale factor.

The analysis further reveals that both these items are missing connections to the needs of different students. For instance it is not possible to listen to the text of the items, and there is no accompanying instruction video about how to use the digital tools included in the items. Thus the framework of connectivity helps by focusing on connecting potential, or the absence of connecting potential, when reviewing and developing items.

Discussion

These results illustrate that the framework of connectivity at micro level can be used in order to find connections. However, when analyzing the two items some adaptations of the framework were needed. Thus the lens of connectivity was not adapted in a theoretical way, rather the adaptations are related to the number of categories in the analytical tool (see results), and also to the method of analysis. Relating to method of analysis, when Gueudet et al. (2018) describe the analysis at micro level, they are searching for connections for a given mathematical concept (e.g. functions) between different parts of the e-textbook. These connections can also be related to how the concept is presented differently in different parts of the e-textbook, and can also be related to the progression of a concept. When analyzing isolated digital items in mathematics such comparisons are more limited due to the summative nature of testing, and in this case due to the fact that only two items (dealing with different mathematical concepts) were analyzed. In order to analyze the two presented items it was thus not possible to consider a single mathematical concept, and therefore some of the categories in the analytical tool were not applicable. Not being able to use the full range of the micro level tool is a limitation of the presented study and a recommendation for future research is to start with a large item-pool and choose items for a given concept or a mathematical theme, e.g. functions. In this way, it will likely be possible to look for connections to different moments of appropriation of the same concept, and also for variations of similar items connected to a specific concept. Another limitation of the presented study is the inability to contrast the results with other studies using the theoretical framework of connectivity within the scope of assessment.

A question for future consideration is how the framework could be used generally to analyze assessment in mathematics, and more specifically to guide analyses of digital national tests in mathematics. Such studies could also investigate the potential to consider a mathematical theme in the analysis, and furthermore to explore new categories that might be included in the analytical tool. A suggestion is to explore whether mathematical competencies (e.g. mathematical reasoning, problem solving) could guide these analyses along with a given mathematical theme. Another implication for future research is to analyze a digital resource (e.g. an assessment platform) through the lens of connectivity, at a macro level. Such an analysis may focus the potential of linking to and between users and resources/tools outside an assessment platform. This may include the potential to connect users with users (teachers, students), as well as users with designers (teachers, assessors, test developers, test designers) and the platform's interaction with other external resources, e.g. programs and teacher digital resource systems.

In the analytical framework of connectivity the possibility to make connections is seen as a critical feature of a digital resource, and important for learning and understanding (Gueudet et al., 2018). The importance to connect concepts is articulated in the syllabus (Skolverket, 2018) for the compulsory school, in the general aim for mathematics: "Teaching in mathematics should essentially give pupils the opportunities to develop their ability to: […] use and analyse mathematical concepts and their interrelationships" (p.56). The opportunities to develop mathematical abilities might be achieved through digital resources and the relationship between concepts might be described in terms of connectivity.

In an era of digitalization, connectivity also extends beyond digital resources and can be viewed as a critical feature of a teacher's working environment (Gueudet et al., 2018). Furthermore, this also relates to assessment. Since technology already is a part of learning processes in a digital age (Beller, 2013), it is fair that this technology, with its potential to make connections, also becomes a part of assessment. When digital resources play an even more important role in assessing knowledge and understanding, theoretical perspectives such as connectivism and theoretical frameworks such as connectivity can bring new insights and may offer novel possibilities to explore assessment beyond the narrow scope of this paper.

Keywords: curricular resources, task design, textbooks, curriculum implementation

Scope and focus of the working group

At the macro-level, teachers and students work with mathematics curriculum resources, both digital and traditional, inside and outside the classroom. Individually or collectively, teachers select, (re)design, modify, and interact with such resources for lesson preparation, student assessment, and the planning of their courses. These resources (e.g., educative curriculum materials) are the focus of professional development sessions, where mathematics teachers, often with educational researchers, design and transform curriculum resources, including blended materials, and in the process develop design capacity and valuable knowledge for teaching.

At the micro-level, curriculum resources contain mostly tasks derived from textbooks or other sources. The representation of these tasks in resources, their sequencing, and the teachers' actions during their enactment can limit or broaden the cognitive demand the tasks impose and affect students' views of the subject matter. Thus, they can influence the opportunities afforded to students to make mathematical connections, and to develop mathematical concepts, skills, or habits of mind. The literature indicates that tasks play a key role in effective teaching. There has been an upsurge in publications on various aspects of task design (e.g., task features that can help generate certain forms of mathematical activity); methods of task analysis (e.g., analyses of the learning affordances of certain kinds of tasks); and principles for task implementation in conventional and digital learning environments (e.g., factors affecting the fidelity of implementation of tasks in the classroom). Students can also be involved in task design activities to foster their reflections about what they know, understand, and do.

We summarize the papers presented at the conference according to the following predefined themes:

- Empirical research on teachers' and students' interactions with curriculum materials, resources, and tasks, related competencies (e.g., pedagogic design capacity), and influences on this interaction;
- Theoretical foundations and methodologies of task analysis helpful for task design and the design of curriculum resources;

- Studies on the use of carefully designed curriculum materials, resources, and tasks to support the implementation of particular learning goals and to enhance mathematical competence;
- Collaboration between teachers, between teachers and researchers, and possibly also students for designing tasks and resources and for analyzing their implementation;
- Affordances and constraints of digital and conventional tasks and resources.

Issues addressed during the sessions

An important issue in TWG22 was empirical research on teachers' and students' interactions with curriculum materials, resources, and tasks, related competencies (e.g., pedagogic design capacity), and a better understanding of how tasks and resources influence practice. At CERME12, three papers focused on students and their interactions with (digital) curriculum resources:

- Annalisa Cusi and Agnese Ilaria Telloni: Engaging students as designers of digital curriculum resources: Focus on their praxeologies and new awareness.
- Amal Kadan-Tabaja and Michal Yerushalmy: Online feedback designed to support self-reflection while solving fraction example-eliciting tasks.
- Carlos Quiroz, Saba Gerami, and Vilma Mesa: Student utilization schemes of questioning devices in undergraduate mathematics dynamic textbooks.

In these three papers, students assumed the roles of designers and users of digital curriculum resources in addition to those of learners. The papers reflected a combined focus on students with digital rather than traditional curriculum resources, mainly investigating the affordances of the former and how they are used or how they influence the learning process. All three papers related to attempts to foster students' reflection about the study content and learning process, which is regarded as an important aspect in learning.

Quiroz et al. investigated students' use of questioning devices — a new special feature of interactive textbooks, which seeks to engage students in thinking about the content and allows them to type responses to the questions in the textbooks. These answers are immediately shared with the teachers, who can use the information to adjust their teaching. Quiroz et al. identified three classes of situations, in which these questioning devices were used, and one utilization scheme for each situation. The findings reveal that students used the questioning devices for their intended purpose, but also for other purposes, exerting their agency in using curriculum resources for their needs. The term "questioning device" reflects the authors' and teachers' perspective and does not account for the students' perspective on this feature. For students, it is an answering rather than a questioning device. This leads to the question of how students' needs are considered in the design of digital curriculum resources. In an additional poster, Kanwar and Mesa introduced viewing patterns that were mapped to students' use of questioning devices.

Insight into how students think about the affordances of digital curriculum resources in mediating mathematical content was provided in the paper by Cusi and Telloni. Students were asked to design GeoGebra applets related to the content they had learned in a course supporting the transition from secondary school to university. Although students did not intend to become teachers or acquire pedagogical or didactic knowledge about the subject matter, they showed ability to reflect on the design principles they implemented in the design process and how this influenced their learning. Involving students in the design process of digital curriculum resources is a novel didactic approach afforded by digital resources. On the one hand, it has the potential to provide further insight into students' learning of mathematics. On the other, it seems to be a promising approach to deepening students' understanding of mathematical content. However, open questions remain regarding the timing and the framing of the design activities: Should students design while learning the content or after they have learned it? What happens with the designed resources? What is the goal of designing that is presented to the students? Should students design for other students, for themselves, or for the instructor?

Kadan-Tabaja and Yerushalmy presented an example of an interactive task with related feedback aimed at fostering students' self-reflection and meta-cognitive skills. The special design of the feedback, which combines automated evaluation of students' solutions with opportunities to reflect on the solutions, seems to be a promising approach for future feedback design.

Two papers theorized student interactions that could manifest through concrete design features of mathematical tasks, problem posing, and working backwards, and suggested finer definitions and characterizations for given student interactions:

- Ling Zhang, Andreas Stylianides, and Gabriel Stylianides: Problematizing the notion of problem posing expertise.
- Daniela Assmus and Torsten Fritzlar: Working backwards revisited: Some theoretical considerations.

Zhang et al. compared problem posing of master's and sixth grade students to demonstrate the challenge of characterizing expertise. Using a data-driven approach, they identified expert problem posers based on participants' problem posing characteristics, such as the number of problems posed, their complexity, and clarity. They found that performance was not aligned with the participants' previous mathematical experience or backgrounds. Their results suggest that defining an expert should be specific to the expertise assessed, considering additional aspects beyond mere mathematical background.

Assmus and Fritzlar demonstrated a range of tasks designed to promote the working backwards heuristic. Although this seems to be a single problem-solving strategy, the tasks analyzed revealed differences stemming from the design of the tasks. Focusing on characteristics such as operations and order, careful analysis shows that task design that incorporates different subsets of these characteristics requires distinct solving processes. These differences can considerably influence problem demands and students' problem-solving processes. In a related poster, Assmus and Forster demonstrated different designs of working backwards problems, showing that distinct solving processes were related to different proportions of elementary school students who had solved them correctly.

Two papers addressed contextual and cultural influences on teachers' and students' interactions with curriculum resources, and urged rethinking the conceptualizations of resources and textbooks:

- Dubravka Glasnović Gracin: Rethinking resource conceptualization in times of pandemic and earthquakes: What is important for (mathematics) education?
- Hendrik Van Steenbrugge: Rethinking the notion of textbooks as mediators between the official curriculum and classroom practice.

Glasnović Gracin analyzed how the relevance of resources varies depending on the context. Van Steenbrugge sought to identify how culture becomes apparent in curriculum resources beyond the influence of the curriculum, analyzing textbooks and teacher guides from different countries. Although different in their research object and methods: case study of two teachers (Glasnović Gracin) vs. document analysis of textbooks and teacher guides (Van Steenbrugge), both studies showed the interrelatedness of curriculum resources with the social and cultural context in which they are developed and used. This raises the issue of how to read and interpret studies about curriculum resources from different social and cultural contexts, and suggests that results from one context cannot easily be transferred to another.

An additional perspective on resources was apparent in papers that studied the affordances and constraints of digital vs. conventional tasks and resources. Three papers at CERME 12 revealed different research perspectives.

- Lisnet Mwadzaangati and Mercy Kazima: An examination of mathematical affordances available in grade 2 teachers' guide and learners' textbook on addition of whole numbers.
- Ayla Carvalho and Rúbia Amaral-Schio: Characterizing the presence of activities using GeoGebra in Brazil's mathematics textbooks.
- Malin Norberg: Students' expressions about working successfully with mathematics textbooks: Multimodality and socio-mathematical norms in early years.

Mwadzaangati and Kazima examined the learning affordances provided for a given learning goal. They analyzed the learning affordances of a teachers' guide for teachers in relation to the addition of whole numbers for grade two students relying on variation theory. The study examined the teacher guides used by teachers in Malawi to choose tasks for implementation in their classrooms. The paper adopted two perspectives, discursive and cognitive, by connecting mathematics discourse in instructional aspects with the cognitive ones of what is said and presented. The tasks in the textbooks were analyzed from a cognitive point of view, based on the additive structure of the tasks and their possible variations (Marton & Pang, 2006). The findings point to the low quality of Malawian mathematics textbooks on the addition of whole numbers suggesting that this might be one of the causes of persistent low performance of learners in mathematics (simple strategy). A general question is: How can the results presented influence textbook design or the classroom?

Carvalho and Amaral-Schio reviewed four printed collections of textbooks (16 textbooks from sixth to ninth grade) used in Brazil to characterize and count the textbook activities using GeoGebra, the main dynamic geometry system tool used in Brazil, and to bring to the fore their potential for exploration to engage students in mathematical discovery. The study shows that GeoGebra was used only for geometry activities in all textbooks. Few activities have been found, and even fewer with the potential of exploration. Yet the results do not represent the actual use of GeoGebra in classrooms, raising the question of the distance between the learning affordances of a task and effective learning.

Norberg reported on an ongoing study what was considered successful for 18 7-8-year-old students working with mathematics textbooks. The paper raised the question of socio-mathematical norms related to students' work, and what counts as mathematically sophisticated, accepted, different, efficient, given that norms regulate students' learning. The findings show a tension between using aids and being considered successful in mathematics, which could affect students' possibilities for mathematical learning. They raise questions about what is accepted vs. what is desirable. For instance, using mathematical symbols has been shown to be a way of appearing successful in math, whereas other modes of communication (fingers, gestures, images, diagrams, etc.) are not considered as successful, even if they are efficient. It may be important to consider learning goals in this study as well. And how is it possible to infer mathematical norms from observations? How is it possible to separate the effect of the didactic contract from norms when observing students? Methodologically, what was the influence of the researcher during data collection? In an additional poster, Tutuncu and Hodgen offered a method to analyze the potential of educative materials to offer productive formative assessment by combining analysis of formative assessment practices with the guidance provided to enact these techniques.

Two other issues of TWG22 concern the theoretical foundations and methodologies of task analysis for task and curriculum resource design, and collaboration between teachers, between teachers and researchers, and possibly also students for designing tasks and resources, and for analyzing their implementation. At CERME12, two papers focused on analysis of the selection and characterization of tasks by prospective teachers and teacher collaborative decision-making in task characterization.

- Cengiz Alacaci: Prospective elementary teachers' selection of mathematical tasks.
- Andreas Bergwall, Elisabet Mellroth, Torbjörn, and Johan Nordin: Teachers' characterizations of challenging introductory and enrichment tasks.

Alacaci's exploratory paper viewed mathematical tasks as powerful tools to develop mathematical ideas in the classroom and useful in teacher education. One assumption was that understanding task perceptions of prospective elementary teachers could help predict their eventual modification and appropriation for classroom use, which can affect teachers' practice. It also raised the issue of "good" mathematical tasks — good for what purpose? One of the consequences of the experiment was that prospective teachers were encouraged to think critically about tasks. Bergwall et al. investigated the collaborative characterization by eight teachers of tasks suitable for introduction or enrichment, and presented several dilemmas. Among the results was the observation that introductory tasks should have an easy entry level and not require pre-knowledge of the upcoming concept, while an enrichment task should require relatively deep conceptual pre-knowledge. Teachers' verbalization of task characteristics was one outcome, but not all tasks met all criteria. The teachers were involved in the writing of this paper.

Both papers raise some theoretical and some methodological issues about the choice of the theoretical framework, as well as the selection, characterization, and classification of tasks by teachers with regards to context, teachers' goals, and implicit characteristics, such as teachers' tacit knowledge (Herbst et al., 2011; Herbst & Chazan, 2011). This highlights the challenge in future attempts to generalize from these studies. In an additional poster, Gustafsson, van Bommel, and Liljekvist suggested pursuing the analysis of teachers' discussions in communities of practice to explore the various facets of mathematical knowledge for teaching that guide these discussions.

A central issue for TWG22 is the use of carefully designed curriculum materials, resources, and tasks to support the implementation of particular learning goals and to enhance mathematical competences. Thus, it is important to investigate how to design tasks and items to provide students with opportunities to make mathematical connections and develop mathematical concepts, skills, and habits of mind. The characteristics of task design can influence the processes that characterize students' interaction with the tasks or items themselves. Among these, reading processes can play an important role because they can direct and determine students' problem-solving processes. At CERME12, two papers focused on how the design of specific tasks and resources influences students' reading processes:

- Valentin Böswald and Stanislaw Schukajlow: Reading comprehension and modelling problems: Does it matter where the question is placed?
- Anneli Dyrvold and Ida Bergvall: The role of dynamic elements in digital teaching platforms: An investigation of students' reading behaviour

Both papers investigate the role played by specific factors in influencing students' reading processes. Böswald and Schukajlow presented a theoretical paper aimed at reflecting on the ways in which the position of the question within the text of a modeling problem can determine students' reading processes. They suggested that placing the question before the text in modelling problems can make the goal clearer for readers, supporting them in distinguishing between relevant and irrelevant information. Dyrvold and Bergvall investigated the influence of the choice of dynamic elements in digital items on students' reading behavior in a digital multimodal environment. Their analysis identified various types of challenges that students may face in working with dynamic elements. In particular, they stressed the potential of dynamic elements to evoke deep engagement in interaction and the risk of misunderstandings or omissions in relation to these elements.

The discussion of these two papers highlighted important aspects in the choice of a task design aimed at supporting students' reading processes. The two main aspects under discussion were: (a) the interrelation between enhancing efficient reading and enhancing students' comprehension and reasoning; (b) the role played by metacognitive processes in guiding students' reading processes when interacting with tasks with certain characteristics; and (c) the effect of students' age and of the focus on different mathematical contents on how the design of tasks and resources influence students' reading processes. Another common issue addressed by both papers was methodological: the use of eye-tracking technology to investigate students' reading processes when interacting with the designed tasks and resources. Some of the questions that arose concerned distinguishing the effects of task design on students' reading behaviors from the effects of other contextual or external factors, and the possible use of artificial intelligence in developing a categorization of reading behaviors.

In two additional posters, other design principles were suggested to achieve specific aims: Vytautas argued that problems that do not explicitly state the concepts needed to solve the problem can be defined as epistemologically potent. These tasks can still be approached by students, because the unknown concepts are not mentioned in the wording of the problem, leading to a meaningful learning process. Stenberg, Haavold, and Sriraman suggested employing pathologies to create uncertainty in order to catalyze creativity for mathematics students.

Another important issue for TWG22 was the design of various types of materials, tasks, and resources to be used in given learning environments. The choice of materials, the sequencing of tasks, and the actions performed by the teacher can affect students' learning processes. The role of the design of resources, materials, and learning environments was a common theme of the following papers:

- Henrik Stigberg: Digital Fabrication for Mathematics Education: A Critical Review of the Field
- Johanna Zöchbauer, Markus Hohenwarter, and Zsolt Lavicza: Improving the GeoGebra classroom tool to better accommodate online educational resource development based on the SAMR model
- Sofía Paz-Rodríguez, Armando Cuevas-Vallejo, and José Orozco-Santiago: A hypothetical learning trajectory for linear combination of vectors in R2

Stigberg proposed a critical review of digital fabrication for creating manipulatives in mathematics education research, stressing the role played by these technologies in enabling teachers to create context-sensitive manipulatives for teaching activities. Zöchbauer et al. investigated how the GeoGebra classroom tool can be improved to better accommodate a set of online educational resources to be used in combination with tangible tools. They used the case study approach to examine the implementation of these resources, highlighting the need for improvements, for example, making the sharing of resources with students easier and faster or enabling the teacher to have an overview of the number of students who answered the questions posed to them. The investigation presented by Paz-Rodríguez et al. enabled them to stress some limitations in the approach they adopted, which focused on the design of technology-mediated tasks, following a hypothetical learning trajectory aimed at supporting university students' conceptualization of linear combination. The analysis of the results of a teaching experiment in an online linear algebra class enabled the authors to identify elements that could support a redesign of this hypothetical learning trajectory.

Among the issues the discussion in these three papers raised, we mention the role played by frameworks and theoretical models to support both the design process (as in the papers by Zöchbauer et al. and Paz-Rodríguez et al.) and the research on this design (as documented in the paper by Stigberg). In particular, reference to the models guiding the design process is a common aspect in both the research presented by Zöchbauer et al., where the SAMR model (Puentedura, 2006) supported the design of an environment aimed at fostering the integration of digital media into the classroom, and the research presented by Paz-Rodríguez et al., where the C&P principles (Cuevas & Pluvinage, 2003) provided a set of criteria aimed at supporting the task design process.

The discussion on these papers also raised some reflections about another fundamental issue related to the design of learning environments, in particular when the focus of the design is also on the role of tangible tools or physical objects, considered as products of digital design (like in the paper by Stigberg) or as tools to be combined with digital ones (like in the paper by Zöchbauer). The paper by Stigberg raised the issue of teachers' learning when they make, share, and use manipulatives, suggesting the need to adopt communities of practice as a framework for understanding teachers' learning of digital fabrication for mathematics education. The paper by Zöchbauer et al. introduced initial reflections on the role played by the teacher's orchestration in combining the use of digital and tangible tools. They noted that teachers should make the connection between digital and tangible tools clearer if they want students to work effectively with a combination of these tools.

Possible directions for future research

TWG22 topics at CERME12 shared many research themes with CERME11 (e. g. different theoretical perspectives leading task design and analysis) and and also added novel themse as mentioned above. When discussing these studies TWG22 discussions often took the opportunity to discuss possible ways to enhance and deepen the topics studied in TWG22. The following directions for future research emerged from the discussions:

(a) Developments of means to communicate over curriculum materials and the wide perspective that takes into consideration different agents, open new opportunities to focus on the role of students in all stages stemming from task and curriculum design and implementation;

(b) The different theories employed in various studies underline the neeed for finer definitions and moving toward more precise and fine-grained analysis of processes and practices, which are theorized only in general forms;

(c) There is place for reports focusing on issues of scalability: many reports focused on a micro-process of design or implementation; large-scale studies or design considerations for scaling-up could contribute to a wider research perspective;

(d) While many conference research reports focus on short processes, long-term and longitudinal studies are needed for broader perspective. We acknowledge that long-term and longitudinal studies are probably challenging in the format of a conference research report; therefore intermediate stage reports are also welcome;

(e) More Research reports are needed to deepen the investigation of the teachers' role in their design and co-design interaction with resources and environments, in the context of professional development programs or research projects.

Prospective elementary teachers' selection of mathematical tasks

Cengiz Alacaci

University of Agder, Norway; cengiz.alacaci@uia.no

Mathematical tasks are powerful tools to develop mathematical ideas in classrooms and are useful in teacher education linking teacher decision-making, student work, and curricular themes. One of the core elements of teacher development is to be able to choose and use "good" mathematical tasks. Understanding task perceptions of prospective teachers can help predict their eventual modification and appropriation for classroom use. The current study investigated the features that prospective elementary teachers (PT) attend while selecting "good" mathematical tasks. Employing a modified repertory grid technique, we identified attributes of desirable tasks as viewed by PTs. We then present interpretation of findings for mathematical task design and for teacher education.

Keywords: Documentational approach to didactics, teacher education, mathematical tasks, task design.

Introduction

Due to recent reform efforts in mathematics education, many innovative mathematical tasks for classroom use have been available from commercial resources, professional organizations, or released public accountability tests such as NAEP (e.g., Mohr et al., 2019). This necessitated sharper skills for in-service and prospective teachers for selecting "good" mathematical tasks.

A mathematical task is a problem devoted to developing or assessing a particular mathematical idea (Stein et al., 1996). They are effective tools for communicating curricular visions of mathematics education. Therefore, designing, analyzing, appropriating tasks, and talking about leading classrooms to effectively implement them have become common practice in teacher education programs (Tekkumru-Kisa et al., 2020).

Given the potential role mathematical tasks can play in mathematics classrooms, considerable research has been done on the topic. Stein et al., for example, (1996) looked into the role of mathematical tasks in realizing curricular goals. They observed that mathematical tasks typically move through stages from *tasks as published* in the original curricular resources, to *tasks as set up* by the teacher, and to *tasks as implemented* in classrooms. It was possible to engage students with higher forms of mathematical thinking when assigned mathematical tasks with high cognitive demand but assigning students these tasks did not ensure their high levels of reasoning. Tasks often decline in elicited student thinking due to *inappropriateness* of the task or other factors such as prevalent norms in classrooms, issues of classroom management, or use of time (Stein et al., 1996; Tekkumru-Kisa et al., 2020). We believe that a core skill to be developed in teacher education should be to understand the factors that underlie a better match of tasks with student characteristics and develop the ability to modify the tasks to better match with the needs of students.

Theory

Taking a resource perspective, we consider mathematical tasks as a type of curriculum resource. Hence, we chose *documentational approach to didactics* (DAD) as a framework in this study

(Gueudet & Trouche, 2009). The framework provided a perspective to understand how teachers choose and interact with mathematical tasks. Pepin (2018) for example, proposed that looking into how teachers (and PTs) relate with mathematical tasks "as is" is not very informative, but we need to explore how they actually work with these tasks. The first step to use a task is to select them. By inference from the DAD framework, we think that PTs actively construct meanings and learn from choosing, transforming, and revising mathematical tasks. Further, as an extension of DAD perspective, the dialectic process of *instrumentation* (how a mathematical task influences a PTs didactic activity) and *instrumentalization* (how the PTs shape mathematical tasks for possible use in classroom) can capture the PTs' interaction with mathematical tasks (Gueudet & Trouche, 2009). Before instrumentation and instrumentalization take place, a PT needs to choose a mathematical task from among alternatives and consider using it in lesson planning. Then the question is, what attributes do PTs attend to choose a mathematical task from among alternatives? Answering this question is important to understand teacher-task interaction *vis-a-vis* mathematical tasks. Only the tasks that are selected or fall below the perceptual sieve can be modified and eventually used. It would be reasonable to expect that didactical affordances of a task (i.e., *instrumentation*) or modifications needed to be made on a task once it is selected (that is, *instrumentalization*) should be shaped by the PTs perception of the original task. So, we need to know more about how a (prospective) teacher think while selecting tasks before the teacher enters into a serious relationship with the task. DAD offers powerful insights into what happens after a task falls into the "basket" of use for a teacher. The goal of the present study is however to uncover what happens before it is selected. So, we hope that our findings will complement and further the insights offered by the DAD about teacher reasoning in the context of task use for instruction.

Methodology

To explore the task features PTs attend while they select tasks for classroom use, we employed a modified repertory grid technique for data collection. The technique is based on the assumption that a person's thinking is directed by the way in which s/he interprets events or objects through his/her personal constructs (Pope & Denicolo, 2016).

We compiled a set of six mathematical tasks organized into groups of two triads. The tasks in each triad were selected to address a common key concept at the same grade level. The tasks were selected from published sources (see Table 1) and they were adapted to the study.

To make the comparisons meaningful, we formed the task triads addressing the same key mathematical concept. However, we wanted to include tasks that represented variation in context; with abstract, illustrative, and applied contexts. This was to see whether PTs prefer tasks with certain contextual structures. However, we did not want to vary the tasks in cognitive demand level, as this may bias participant's selection towards tasks with higher cognitive level. So, all of our tasks had high cognitive demand (either "procedures with connections" or "doing mathematics") according to Smith and Stein's (1998) scheme. This was ensured by independent assessment of the tasks by two mathematics educators prior to the study.

The participants of the study were 14 PTs enrolled in a course "problem-based mathematics education" at master's level. Student teachers are given weekly problems to solve in small groups in

Table 1: Mathematical tasks used in data collection and their key mathematical concepts

Triad	Name of task	Key concept	Grade level	Source
	The pocket problem	Reading and		NCES (1993, p. 126)
1	The siblings problem	interpreting data	4	Small (2020, p. 186)
	The mystery graphs	from graphs		Zawojewski (1996, p. 376)
	The matchsticks pr.	Representing		Rivera & Becker (2008, p. 66)
2	The string task	linear functions	8	Posamentier & Krulik (2009, p. 79)
	The sumo wrestler			(Please see footnote below)[1]

this course that exemplify an inquiry vision of teaching and learning mathematics, analyze them for the curricular ideas and problem-solving strategies embedded, and offer and discuss classroom strategies for lessons centered around these problems. The course was offered in the fourth year of a combined 5-years teacher education program for elementary teachers at a Norwegian university.

In line with the repertory grid technique, data collection was completed in two steps. The first step required comparison of tasks in triads and the second involved individual surveys. The set of tasks were given in print to participants during class time. They were asked to discuss in small groups and solve the tasks. Then for each triad, the groups were invited to write any similarities or differences they could think of between the pairwise combinations of the three tasks (the constructs) from the perspective of their possible use in classroom. Once they complete writing the constructs, they were asked to indicate three tasks that "they like best for classroom use" from among the six. Following the session, the researcher prepared an all-inclusive but non-repeating list of the constructs elicited from the groups before the next class[2].

After the first data collection session, the researcher organized the constructs into rows of a table and the names of tasks into columns. In this session of data collection, individuals were given a print copy of the table (similar to table 3) and were asked if the constructs in the table were clear. The purpose was to make sure that all the constructs were understandable to participants. Then they were invited to rate each task for the constructs using a Likert-type scale from 1 to 5; 1 standing for "not true at all" and 5 "very true" and the values in between varying accordingly. Ratings were completed individually and took approximately 30 minutes.

---

[1] Link for this task: https://www.khanacademy.org/math/algebra/x2f8bb11595b61c86:forms-of-linear-equations/x2f8bb11595b61c86:writing-slope-intercept-equations/e/constructing-linear-functions-word-problems

[2] Repertory grid technique typically requires construct elicitation and ratings from individuals. Here, for the purpose of eliciting richer constructs, we asked the PTs to work in small groups to compare the tasks in step 1. But they rated the tasks in step 2 individually. Hence, we called our version of the data collection a "modified" repertory grid technique.

Results

Table 2 gives the tasks "liked" by the participants from among the given set and the number of participants who selected these tasks. The "string task" was liked by all PTs. The "matchsticks" and the "sibling" problems were the next two most popular tasks and were selected by nine and six participants respectively. The "mystery graphs" problem was least preferred with only 3 participants.

Table 2: The tasks liked by the participants

	Tasks	# of participants who selected the task
1.	The pocket problem	5
2.	The sibling problem	6
3.	The mystery graphs	3
4.	The matchsticks problem	9
5.	The string task	14
6.	The sumo wrestler	5

To understand the attributes that might have led the PTs choice of the tasks, list of constructs and the average ratings of the tasks for the 14 participants are computed and given below in table 3. For ease of comparison, ratings were given separately for the top three tasks based on PTs choices and the remaining three tasks. We present the constructs based on which the 6 tasks received high ($M > 3.5$) and low ($M < 2.5$) average ratings. High ratings are color coded in yellow, and low ratings are coded in brown for ease of seeing patterns in ratings. Because some constructs were worded negatively, we wanted to examine the tasks that received low and high average ratings so that we can identify both the negatively and positively viewed task features for the preferred tasks. Consequently, a yellow rating in table 3 does not always mean a desirable task attribute.

In our interpretation of findings, we give reference to constructs with construct-numbers presented in table 3. Below, we report by the common themes we think constructs are related to, for task attributes.

Use of visual elements

Using visual elements effectively seems to be a common feature among the favored tasks (see construct 1), with the most favored tasks having the highest rating based on this criterion.

Mathematical power

The task's potential to create a deep mathematical discussion in class (construct 3) and to require deep understanding and reflection (construct 18) were two factors that seemed to underlie favorable tasks. The only exception was the "sibling problem" to this observation. This task was assessed to

Table 3: Elicited constructs for comparison with average ratings of tasks

The constructs / task number in table 2	**5**	**4**	**2**	**1**	**6**	**3**

1	This task uses visual elements effectively.	4.6	4.2	3.9		3.3	1.7	3.1
2	The context is interesting in this task.	3.2	3.1	4.1		4.0	3.6	4.2
3	This task can create a deeper discussion in class.	4.5	4.2	3.8		3.9	3.5	3.9
4	This task requires developing a formula to solve it.	4.7	5.0	1.0		1.0	4.9	1.1
5	This task is structured in steps and is easier to follow.	4.3	2.3	3.3		3.2	2.4	2.3
6	This is an easy and clear task to do for pupils.	3.4	2.7	3.9		3.2	3.0	1.5
7	You need to interpret textual information to solve this task correctly.	4.1	2.6	3.3		4.8	4.5	5.0
8	This would be a good task to introduce a topic.	2.9	3.0	3.8		2.6	2.6	1.9
9	This task is more demanding in thinking and reasoning.	4.2	3.9	1.9		3.4	3.4	4.6
10	The story may be overwhelming for the kids in this task.	2.8	1.9	1.3		2.4	2.8	4.4
11	This task may be misinterpreted by the pupils.	2.5	2.7	2.0		3.5	3.4	4.4
12	This task may be difficult for individual pupils and hence better for a class discussion.	3.9	3.3	2.4		3.9	3.5	4.1
13	The wording is a bit difficult in this task.	2.2	1.9	1.6		2.0	2.2	4.5
14	This task requires just reading off information and is not a real problem-solving task.	1.6	1.4	4.8		2.4	2.4	1.9
15	There is too much text here.	1.6	1.1	1.3		1.5	1.8	4.4
16	This is more like a "pure mathematics" task.	3.2	4.4	3.4		2.5	3.9	2.1
17	This task is not very original, I have seen tasks like this one before.	2.8	3.4	4.2		2.4	3.1	1.9
18	This task requires deep understanding and reflection.	3.8	3.8	1.4		2.6	2.8	3.5
19	This task has a realistic and applied context.	2.6	3.2	4.3		4.1	3.9	4.1
20	There is a simplicity that I like in this task.	3.8	3.7	3.9		3.1	3.9	1.9

have the potential to create good mathematical discussion in class, but not requiring deep understanding or reflection by itself. PTs might have thought that a deep discussion opportunity can potentially be created by teachers while using this task.

Simplicity

Simplicity was another prominent attribute for preferred tasks (construct 20). Preferred tasks did not have too much text to read and interpret for solution (construct 15). The story of the task being overwhelming seemed also to be a distinct feature of the *least* preferred task (line 10) which may also lead to difficulty and misinterpretation in reading the text (constructs 11 and 13). Another aspect of complexity in textual information, namely a high level of need for interpretation (and hence requiring higher reading ability) was not seen favorably among PTs in mathematical tasks (construct 7).

Level of challenge

A high level of challenge and demand in mathematical reasoning seem to be important but not sufficient (and in one case, not even necessary) for the tasks to be seen favorably (constructs 9, 12 and 14). The highest cognitive challenge was seen in the "mystery graphs" task, but it did not receive high ratings for preference (for probably lack of simplicity). However, the two most favored tasks (the "string task" and the "matchsticks problem") had the next two highest ratings in demand for mathematical thinking and reasoning. Conversely, easiness of a task was not a common theme in the desired or not-so-desired tasks (construct 6). It looks like the *right level* of cognitive challenge (not too much, not too little) seems to be an attribute deemed desirable by PTs.

Other features of the tasks

Other features of tasks did not seem to be strongly associated with task preference. Among these are the features related to the context of tasks being interesting, applied or pure (constructs 2, 16 and 19), and tasks being structured in steps (construct 5).

Conclusions and discussion

In our view, the results paint a positive picture of prospective elementary teachers' ability to distinguish among tasks. In particular, PTs seem to have a sophisticated view of mathematical tasks. This may be due to prior course experiences on task design and analysis. However, this needs to be further investigated, perhaps with a bigger sample size. Effective use of visual elements was common to all highly rated tasks. Mathematical power embedded in the task that can support a good classroom discussion, nurture deep understanding of mathematical ideas, and provide opportunity for pupil reflection were also considered highly for their perception. However, high mathematical power did not necessarily mean complicated design, too many words, or a cluttered story line in their eyes. Hence, simplicity was another prominent feature of desirable tasks according to PTs. In other words, tasks should have not only the power, but also the economy and clarity and hence simplicity in set up, story line and wording. An optimum level of difficulty or challenge was considered highly for desirable tasks. A high level of difficulty or easiness by itself were not associated with "good" tasks. Selected tasks included both not so demanding as well as reasonably demanding tasks which pointed to an optimum level of challenge.

How do we interpret these findings from the DAD perspective? As PTs look for mathematical tasks for instructional planning, their *instrumentation* process could be guided by such powerful notions as mathematical power, visual elements, simplicity and level of challenge for pupils. These same notions can guide the *instrumentalization* (that is, task modification) for actual classroom use as well. When PTs are considering a task, they may be already thinking about how they will use it (see for example construct 8 in Table 3). Our study provides new insights into DAD and how teachers' perception of a task might be guiding task appropriation before use.

We also find it interesting that mathematical power and simplicity came out as prominent task features. In fact, their presence together reminded us Birkoff's (1956) model of aesthetics in mathematical products (as quoted in Dreyfus & Eisenberg, 1986). Birkoff offered a formulaic model of aesthetics; $M = O/C$, where M stands for *aesthetics*, O, a measure of *order* or mathematical structure, and C for *complexity*[3]. The formula suggests that aesthetic value of a mathematical object is a *proportion*, counterbalanced by two factors, *order* and *complexity*. In other words, aesthetics may be directly proportional to the mathematical structure embedded in it, while complexity being inversely proportional, and aesthetics may change with differing values of order and complexity. It looks like, even though the PTs did not use the term "aesthetics" in this study, their search for power and simplicity at the same time, might imply a desire for aesthetics in mathematical tasks. We thought this would connect with Sinclair and Crespo's (2006) point on aesthetics in a new light in mathematical task design.

Influences of text design on problem solving processes and results in working-backwards problems

Daniela Assmus[1] and Frank Förster[2]

[1]University of Halle-Wittenberg; daniela.assmus@paedagogik.uni-halle.de

[2]TU Braunschweig; f.foerster@tu-braunschweig.de

Keywords: working backwards, language in mathematics education

Working backwards is an essential problem-solving strategy that can be applied already at primary school age. For this, very specific tasks are often used with a missing initial value, given operations that are applied in a fixed order to this initial value, and a given final value in which the described process culminates (see P1 and P2 in figure 1).

Problem 1 (P1)	Problem 2 (P2)
Maja sells trading cards at the flea market. The first child buys half of the trading cards and then one more. The second child takes half of the rest and then two more cards. After that there are 6 cards left. How many cards did Maja have at the beginning?	Maja sells trading cards at the flea market. The first child buys half of the trading cards. The second child then buys one card. Then the third child takes half of the rest. The fourth child buys two more cards at the end. After that there are 6 cards left. How many cards did Maja have at the beginning?

Figure 1: Used problems

To solve problems like this by working backwards, it is necessary to reverse the operations described and to execute them in reverse order starting from the final value. Thus, reversible thinking skills are required. According to Krutetskii (1978), these are developed in germinal form at primary school age (in mathematically gifted children), but many children still show difficulties in processing such tasks. In particular, reversing the order of operations proves challenging, as has been shown in various studies with children in grades 2 to 6 with similar problems to P1 (Rott 2013, Aßmus 2010). It can be assumed that children at this age are not (yet) aware of the effects of different orders when linking additive and multiplicative operations.

However, another or further cause could lie in the textual design of problems like P1. Buying half and one (or two) additional card(s) is possibly interpreted as one action, especially because the operations in the text are related to the same recipient. Thus, the two sub-operations are not considered separately, making their order irrelevant to the students.

This aspect is investigated in the study of working backwards described here considering the following research questions: To what extent do third and fourth graders' solution rates differ when solving a problem with operations performed by different people (e.g. problem 2) versus a problem with linked operations performed by the same person (e.g. problem 1)? To what extent do the results differ with respect to consideration of the order of operations?

The study

Design: As part of a written entrance test for a university project for mathematically gifted primary school children, Problem 1 was used in 2013/14 and Problem 2 in 2015-18 (see figure 1). The test was administered under standardized conditions (individual work, comparable instructions, identical working time). Problem 1 was given to 156 children (grade 3: 120, grade 4: 36), Problem 2 to 283 children (grade 3: 200, grade 4: 83).

The mathematical model is identical for both problems: $((6 + 2) \cdot 2) + 1) \cdot 2 = 34$. In P1, however, two operations each are tied to one actor, whereas in P2 they are performed by different children and thus described as separate actions. As a further difference, in P2 each action is noted in a new line as well as the course of the process is made clear by supporting temporal adverbs.

The differences in the solution rates as well as the noted calculation steps are examined with a special focus on the correct use of the operation order. Based on qualitative content analysis, the answers were independently categorized several times and coded using MAXQDA.

Results: P2 was solved by a larger proportion than P1 (grade 3: P1: 5.8%, P2: 25.5%, grade 4: P1: 11.1%, P2: 34.9%). Furthermore, there were differences in procedures with correct reversal of operations but incorrect order (grade 3: P1: 14.2%, P2: 6.0%, grade 4: P1: 16.7%, P2: 9.6%). Here, problem 1 in grade 3 was usually handled by the calculation $(6 \cdot 2 + 2) \cdot 2 + 1 = 29$. This did not occur at all for problem 2. Also paired with other errors, the proportion of processes with incorrectly reversed order was reduced in grade 4 (grade 3: P1: 10.8%; P2: 9.0%, grade 4: P1: 13.9%, P2: 3.6%).

Overall, it can be stated: The text problem with an unknown initial state remains very challenging for the students of both grades. Basically, however, the study showed that the linguistic presentation of the task text and its modification has a clear influence on the problem-solving process and the children's success in solving the task. In particular, errors based on the use of an incorrect order of operations occurred in lower proportions.

Further studies: To narrow down which variables where causal for the higher solution rates, a third version was tested (Grade 3: N = 66, Grade 4: N = 39) in which two operations were presented in one line and one sentence, as in P1. Otherwise, the task corresponded to P2. Solution rates decreased only slightly in grade 3 (P3: 22,7%) compared to P2, and actually increased in grade 4 (P3: 43,6%). We therefore suspect that separating the operations was more important for the success i than consistently noting the individual actions line by line and sentence by sentence.

We are not interested in simplifying problems mathematically to the point of making a problem accessible to as many students as possible, since this often involves trivializing the problem. However, purely linguistic difficulties should be overcome with a formulation that allows as many as possible to adequately understand the problem in the first place. Qualitativ research will follow.

Working backwards revisited – some theoretical considerations

Daniela Assmus[1] and Torsten Fritzlar[2]

[1]University of Halle-Wittenberg, Germany; daniela.assmus@paedagogik.uni-halle.de

[2]University of Halle-Wittenberg, Germany; torsten.fritzlar@paedagogik.uni-halle.de

A look at scientific and pedagogical literature on mathematical problem solving reveals a wide range of different problems for which the use of the heuristic strategy of working backwards is considered useful by the respective authors. A comparison of these problems shows that the amount and type of information given, and thus the requirements and processes involved in working backwards, are quite different. This purely theoretical article proposes a systematization of the problems and processes that can provide a valuable basis for future studies and for design and revision of teaching materials. On the one hand, two different facets of working backwards and, on the other hand, three types of problems are distinguished and illustrated by examples.

Keywords: Problem solving, heuristics, working backwards.

On the importance of working backwards

Worldwide, problem solving is considered as an important process standard for school mathematics in all grades. This includes the goal of enabling students to acquire heuristic strategies and to apply or adapt them to new mathematical problems.

In mathematics, but also in "real life", working backwards is regarded as a particularly important heuristic strategy (e.g. Zimmermann, 2003). Pólya, who recommends it as a general approach to problem solving unless there is a specific reason to do otherwise (Pólya, 1981), describes working backwards as follows:

> … we assume what is required to be done as already done (what is sought as already found, what we have to prove as true). We inquire from what antecedent the desired result could be derived; then we inquire again what could be the antecedent of that antecedent, and so on, until passing from antecedent to antecedent, we come eventually upon something already known or admittedly true. (Pólya, 1971, p. 142)

Thus, working backwards is characterized by trying to get from the sought to the given (problems to find) or from the statement to prove to the assumptions (problems to prove). This temporarily changes the focus when working on the problem: starting from the unknown or unproven aim, the step-by-step construction of a previously unknown solution path occurs (phase of analysis), which afterwards should enable the problem solver to proceed in the reverse direction from the given to the sought (phase of synthesis). This view is widely shared. However, in many teaching materials, mathematics didactic textbooks, and research papers, problems or problem solutions are assigned to this strategy that do not fit this theoretical view. For example, Posamentier and Krulik (2015, p. 30) see the following as "a typical problem that lends itself nicely to the working-backwards strategy":

> *Problem 1:* David just came back from playing four games of baseball cards. He now has 45 cards in his package of cards. When I asked how he did, he told me he had lost one-half of his cards in

> the first game. After the second game, he had 12 times what he had before. In the third game he won 9 cards. The fourth game was a tie so no cards changed hands. How many cards did he start with? (cf. Posamentier & Krulik, 2015)

We agree with the authors insofar as the problem text describes a process whose final state is known (45 cards) and whose initial state is searched for. If one tries to determine this initial state by applying the reverse process steps in reverse order to the final state, however, one starts *from given data*. Thus, this approach contradicts Pólya's classical view of working backwards as *starting from the unknown*. Because this discrepancy is so widespread, it seems necessary to us to attempt a theoretical clarification of the working-backwards strategy in educational contexts. This could also contribute to a better understanding and evaluation of corresponding tasks and how students work on them.

We start our theoretical considerations with a more detailed analysis of two sample tasks and thereby elaborate processes that are commonly understood as working backwards. Based on this, we deduce two facets of working backwards: *working backwards in the classical sense* and *working backwards as reversing a process.* The article ends with a systematization of problem types for working backwards and a discussion of very specific cases and possible implications for further research or applicability in everyday school settings.

Two facets of working backwards

In order to elaborate different facets of working backwards, we compare two problems that are commonly associated with this heuristic strategy:

> *Problem 2:* Construct to a point outside a circle the tangents of the circle through this point.

This problem requires the execution of a construction. If the construction procedure is not known, it can be determined by working backwards as described by Pólya: One thinks of the tangents as already determined, thus the desired final state of the problem as already achieved. By analyzing it (possibly based on a sketch), conditions are determined backwards step by step, which must be fulfilled in order to be able to execute the construction forwards later on. The aim one starts from is what is sought in the problem.

Generalizing, it can be said that the final state of the problem (F), which forms the starting point of the working process, is (only) assumed to exist and to be constructible. Additionally, the individual operations from the initial (I) to the final state are not given. One has to investigate on one's own, which properties the assumed solution has and from which antecedent the desired aim or partial aim can be reached forward. This search process sometimes also includes aberrations or detours. To summarize: In problems of this type, *planning* starts from the aim which is the *unknown solution of the given problem*, working backwards *towards* the things "within one's power" (given data, assumptions, …).

> *Problem 3:* "A certain man entered a certain pleasure garden through 7 doors, and he took from there a number of apples; when he wished to leave he had to give the first doorkeeper half of all the apples and one more; to the second doorkeeper he gave half of the remaining apples and one more. He gave to the other 5 doorkeepers similarly, and there was one apple left for him. It is sought how many apples there were that he collected" (Fibonacci, 2002, p. 397)

In Problem 3, starting from an unknown initial value, a process as a chain of operations and the resulting final value are described. This process can be reversed to determine the searched initial value, here by applying the reversed operations in reverse order to the final value. One starts from the „aim" of the described process which, however, does not correspond to what is sought in the problem.

Generalizing again, unlike problems of the above type, the final state as starting point is concretely given here. Also concerning the knownness of the steps to be executed, differences become apparent because the problem text already contains all information about the operations to be executed from the initial to the final value. The "path" is thus given, for a solution it must be gone in reverse direction. Therefore, reversal processes play an essential role. If these are mastered, search processes are not necessary. To summarize: In problem of this type, *doing* starts from the aim which is the *given final state of the described process*, working backwards *using* the things "within one's power".

The approach described for Problem 2 fits with the traditional view of working backwards by Pólya and others as described above. Despite the outlined differences, tasks such as Problem 3 or Problem 1 are very often used to address working backwards in classroom situations. The two different approaches do not seem to be commonly distinguished or they are perceived as matching each other; possibly the approach to Problem 3 is assumed as preparatory to Problem 2. A possible explanation for the latter could be found in the didactic approach of complexity reduction in the introduction to the working-backwards strategy: The idea of working backwards should first be experienced as starting from a given final state with given operations, in the hope that students can later transfer this approach to problems with unknown final states and partial aims or operations to be found on one's own. Whether and to what extent such a transfer will be really attained, a corresponding heuristic program is really successful, has not been investigated so far, to our knowledge.
Due to the commonality of starting at an aim, we also understand both described approaches as working backwards. However, the differences that have been highlighted indicate that two different facets of working backwards should be distinguished, the first of which we would like to name *working backwards in the classical sense* and the second *working backwards as reversing a process*.

A review of mathematics didactic research and teaching literature reveals a large spectrum of different problems for working backwards, which can be assigned primarily to the second facet. In the following, a systematization is proposed with the aim to work out problem-type dependent requirements related to working backwards.

Problem types allowing working backwards

For a classification of different problem types for working backwards it can be distinguished on the one hand whether the initial state of a problem or a described process is determined by the problem itself, on the other hand whether the operations from the initial to the final state are given in the problem. In our view, three types of problems can be distinguished on the basis of the specification of the operations:

A. The operations and their order, and thus the entire process, are known / are described in the problem definition.

B. The types of operations are known; their respective number and order is not known.

C. The operations are not known.

Problems of types A fit to working backwards as reversing a process, problems of type C to working backwards in the classical sense. Problems of type B leave scope for interpretation.

Figure 1 gives an overview of the problem types we have identified that allow working backwards. It was obtained on the basis of an extensive review of research and teaching literature in German and English. Nevertheless, it does not claim to be exhaustive, which is indicated by the ellipsis points.

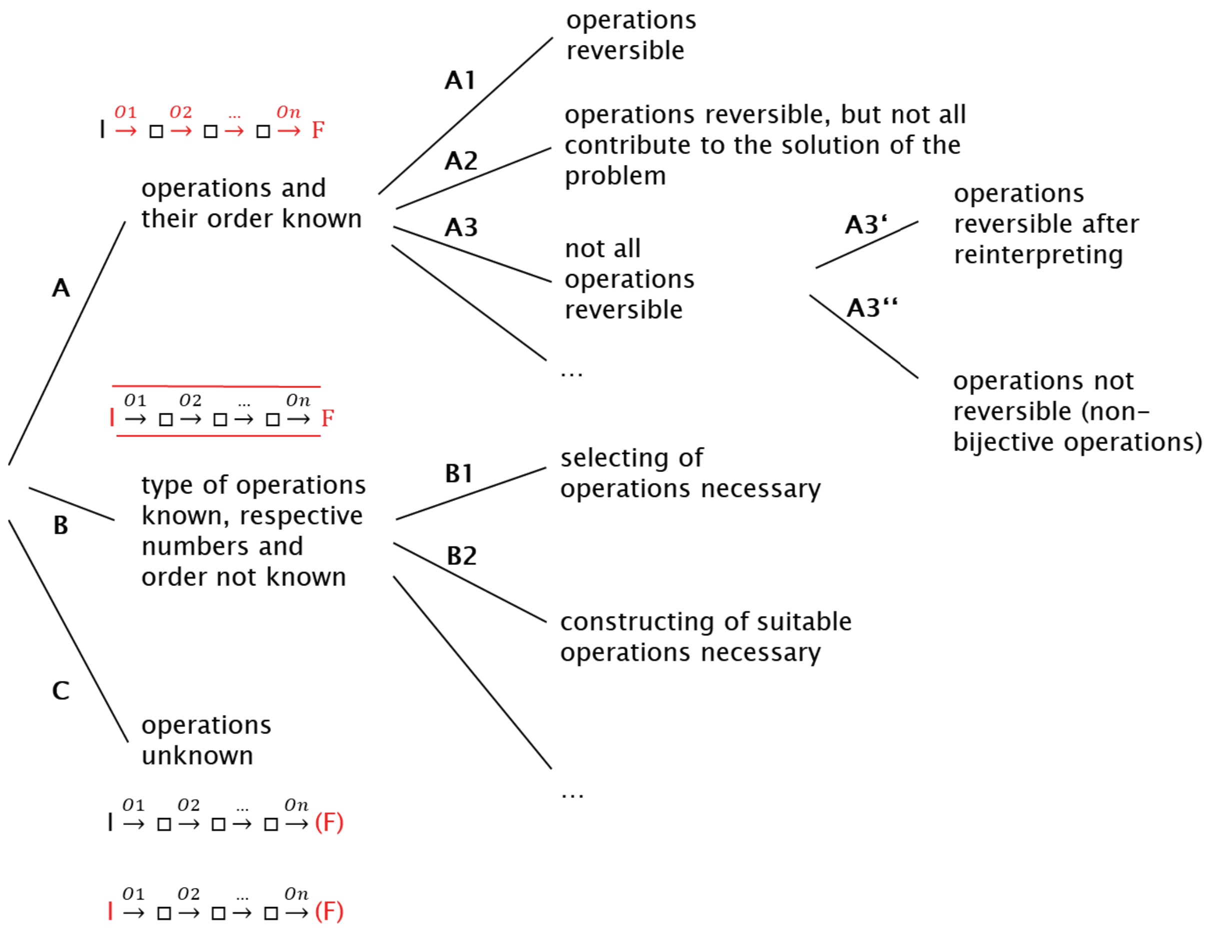

Figure 1: Problem types allowing working backwards

(Highlighted in red are the known elements of each problem type.)

Type A: This includes problems in which operations are applied to an initial value in order to achieve a final value. The initial value is unknown, the operations and the resulting final value are given (often in text form). The (number and) order of the operations is fixed by the problem. As a result, also the intermediate values arising when working backwards are determined. Problem 3 belongs to this problem type.

Subtypes of this problem type can be formed according to the reversibility of the operations: While subtype A1 includes those of the above problems where all operations are directly and uniquely reversible (Problem 3), this is not the case for problems of subtype A3 for at least one step. This occurs, for example, in the case of non-bijective operations (Problem 4), but also in problems as

Problem 5, where (at least) one change described in the text (taking away a third) involves the composition of several mathematical operations (determining the third and subtracting it from the previous number) which is why its direct inversion is not possible. It may be possible to generate a reversible operation (multiplying with 2/3) by reinterpreting the given one.

Problem 4: I think of a number, square the number, subtract 37, multiply the result by its successor, and get 156.

Problem 5: „Three tired and hungry men went to sleep with a bag of apples. One man woke up, ate 1/3 of the apples, then went back to sleep. Later a second man woke up and ate 1/3 of the remaining apples, then went back to sleep. Finally, the third man woke up and ate 1/3 of the remaining apples. When he was finished there were 8 apples left. How many apples were in the bag originally“? (Watson, 1988, p. 20)

In problems of subtype A2 given operations are uniquely reversible one by one, but not all values resulting in this way lead to the correct solution of the problem. Thus, not every reversed operation contributes to the solution of the problem. An example is the number machine (Problem 6): An inversion of the operation "minus 1" is always possible, however, starting from an odd number it delivers an even number as intermediate result, which would have to be halved on input into the number machine (and not decreased by 1). An unexamined reversal of all possible operations thus leads to partially incorrect results in this problem.

Problem 6: The number machine works according to the following rules: If you enter an even number, the number is halved. If you enter an odd number, the number is reduced by 1. Once you have converted a number, you can enter the new number back into the number machine. You can do this until you reach 0. For example, if you start with the number 6, you get the sequence $6 \rightarrow 3 \rightarrow 2 \rightarrow 1 \rightarrow 0$. Since you need four steps to reach 0 from 6, 6 is a "four-step number". Find all the four-/, five-/, six-step numbers. How many are there in each case? (cf. Fritzlar et al., 2006)

A special form A* of this type represents problems, with which the order of the operations is known, but the continuous adherence to this is not necessary for success or single operations can be ignored. The first is the case, for example, if several additive or several multiplicative operations follow one another, which are interchangeable due to commutativity. An example is Problem 7. The order in which the 15 and the 20 balls are removed is not relevant for the result as long as these are the last two operations. For working backwards, only the inversion of the operations is necessary here. Therefore, problem 7 can be assigned to subtype A3*.

Problem 7: "The Wolverines baseball team opened a new box of baseballs for today's game. They sent 1/3 of their baseballs to be rubbed with special mud to take the gloss off. They gave 15 baseballs to their star outfielder to autograph. The batboy took 20 baseballs for batting practice. They had only 15 baseballs left. How many baseballs were in the box at the start?" (Portnov-Neeman & Amit, 2016, p. 87)

In problem 1 in the introduction, the last game has no influence on the number of cards, so this step can be ignored. Therefore, it is a problem of type A1*.

Type B: In this problem type, the operations are not explicitly given, but only known in their nature. From a larger "range of operations" the target-leading reversible operations are to be selected (subtype B1) or e.g. by structure recognition to be constructed (subtype B2). The operations must be selected, for example, in the classical jug-pouring problems (Problem 8). The type of operations (filling the cans, decanting the water, possibly emptying the cans) is known, but the exact order and the number of steps must still be constructed in the problem-solving process. When working backwards, the concrete decanting actions have to be selected, which lead to possible intermediate aims (full can, empty can) when running through the sequence of actions forwards, until the initial state (all cans empty) is reached.

> *Problem 8:* „Lauren has an 11-liter can and a 5-liter can. How can she measure out exactly 7 liters of water?" (Posamentier & Krulik, 2015, p. 31)

The so-called NIM games can be assigned to problem type B2, as illustrated by Problem 9. Although possible operations are given in the problem (adding natural numbers that are smaller than 5), it is not possible to use the working-backwards strategy directly. Only by constructing of suitable operations, with which winning positions can be reached, working backwards becomes possible. In Problem 9, such winning positions are the numbers 15, 10, 5 and 0, which result starting from the target number 20 by stepwise subtraction of the sum of the smallest and largest possible number to add (1 and 4). Here, also the initial value (the number 0) is known in advance.

> *Problem 9:* Two players take turns adding numbers between 1 and 4 to the total reached so far. The player who reaches 20 wins.

Since in problem 8 operations are partly implicit and especially their reversibility has to be considered, from our point of view search rather than selection processes play an important role in working backwards. Therefore, we assign it to working backwards in the classical sense, just like problem 9, in which suitable operations have to be constructed.

Type C: In problems of this type, no explicit hints are given about the operations to be used. The path between initial and final state must therefore be found completely independently. This type includes problems which can be assigned to working backwards in the classical sense, especially proof or construction problems like Problem 2. The initial state can be known or unknown.

Some special cases

A classification of tasks is usually somewhat fuzzy. In the following, we will briefly discuss some special cases that are interesting from our perspective.

> *Problem 10:* After going to the store and buying milk for $2, Tony had $3 in his wallet. How much money Tony must have had before he bought the milk? (cf. Katz et al., 2016)

On the one hand, this task could be assigned to type A1 in purely formal terms. On the other hand, it can be objected that in the task only a single operation is described, which can be reversed immediately. However, if one understands working backwards as a heuristic strategy, this is a global (not local or even one-step) approach to a challenging problem (not to a simple task). Therefore, the second facet of working backwards occurs at most as a germ in this task.

Problem 11: A farmer wants to cross a river and take with him a wolf, a goat, and a cabbage. But the boat can only fit himself plus either the wolf, the goat, or the cabbage. If left unattended together, the goat would eat the cabbage, or the wolf would eat the goat. How can the farmer bring the wolf, the goat, and the cabbage across the river?

Katz et al. (2016) consider this problem, which has been known since the 9th century (Folkerts, 1978), to be particularly suitable for working backwards. However, there is no difference between the initial and final state of this transport problem (except the river bank) and all operations are uniquely reversible. Thus, working backward results in exactly the same requirements as working forward; the working-backwards strategy is not beneficial here.

This also addresses the question of when (beyond Pólya's general recommendation) working backwards is appropriate. According to Sewerin (1979), this is the case when the final state of the problem is clear, when operations are known that lead to or can be applied to the final state, and especially when the initial state does not allow or suggest a goal-directed approach. Indeed, in this case, working forward, if at all possible, would be associated with large uncertainties and the risk of "dead ends." Schreiber (2011) therefore considers working backwards as a heurism of reduction.

Problem 12: Four students in the class weighed themselves. Cobi was 15 kilograms lighter than Adi and Jenya was seven kilograms heavier than Gaby. They also noted, that Gaby was twice as heavy as Cobi. If Jenya weighed 71 kilograms what was Adi's weight? (cf. Portnov-Neeman & Amit, 2016)

Given relations can be arranged in a chain, which starts at the searched element and ends at a given element. In similar problems, such a chain of relations is sometimes already explicitly given. Starting from this, the problem can be (further) processed analogously to problems of type A. Because problems of this kind seem to us quite rare and artificial, we would like to include them as special cases in the presented classification. If, as in problem 12, a suitable chain of relation is not given, but can be generated by sorting given specifications, the problem seems to us to be located in the transition from problem type A to problem type B. If a chain is already explicitly given, it would be a special case of type A.

Possible consequences

All of the problems collected can be found in this or a very similar form in papers that aim to investigate or promote working backwards as a heuristic strategy. However, the differences identified here, which can have a considerable influence on problem demands and students' problem-solving processes, have not been addressed so far, which seems to us to be quite important for the validity of the studies and programs. In addition, we believe that it could be worthwhile to systematically investigate whether an intensive work on the second facet actually facilitates the acquisition of the classical working-backwards strategy. Of course, the elaborated theoretical foundation could also be used for mathematics didactic design research, specifically for the design and revision of problems for working backwards. The precise knowledge of the requirements of problems for working backwards are, of course, also important for the mathematics teaching in school and for supporting students in the acquisition of heuristic experiences and competencies.

Developing tasks for use in mixed-ability classrooms presents teachers with several dilemmas. By making one such dilemma an explicit object of inquiry, this study aims to capture characteristics for challenging tasks suitable for introduction or enrichment. It is based on eight teachers’ collaborative and retrospective analysis of challenging tasks developed in a combined research and school development project. Among the results are the observation that introductory tasks should have an easy entry level and not require pre-knowledge of the upcoming concept, while an enrichment task should require relatively deep conceptual pre-knowledge. It is suggested that attention to seemingly contradictory features of introductory and enrichment tasks can fuel collaborative learning processes so that they include several important aspects of tasks aimed at challenging all students. Teachers’ verbalization of task characteristics is one outcome of such a process.

Keywords: Task design, mathematical enrichment, mathematical introduction, upper secondary school.

Introduction

Mathematics tasks serve many purposes in mathematics classrooms. A suitably designed task has the potential to provide all students in a mixed-ability classroom – those with learning difficulties as well as those with high abilities – with opportunities to develop their conceptual knowledge. To do this, the task should challenge all students. It should offer them opportunities to struggle with important mathematical ideas (Hiebert & Grouws, 2007), require them to put effort into their work, and involve some level of confusion (Bobis et al., 2021). In the mixed-ability classroom, tasks with a “low floor” (i.e., an easy entry level), or with enabling prompts, can help engage students who otherwise have difficulties with challenging tasks. When the same task also has a “high ceiling”, an open end, or extending prompts, students with high ability in mathematics can also be challenged (Bobis et al., 2021). However, the guidance included in the task formulation must not turn into funneling – that is, leading the student around the difficulties and avoiding the struggle (Bauersfeld, 1998) – as this would place effective learning at risk. Tasks designed to let students create their own solutions lead to better conceptual learning, compared to when a task instructs students to apply ready-made methods (Russo et al., 2020; Sullivan et al., 2015).

In the professional development project that we report on in this paper, teachers have repeatedly decided whether a task is suitable for introduction or enrichment, whether it offers sufficient guidance without funneling, or whether it is specific enough while also offering opportunities for general reasoning (Mellroth et al., 2021). In this particular paper, we focus on the distinction between introductory and enrichment tasks. We argue that this distinction is beneficial when designing tasks for a mixed-ability classroom, and aim to capture some useful characteristics for these types of tasks and elaborate on teachers' notions of introductory and enrichment tasks. More precisely, we aim to answer the following research question: What characteristics do experienced upper secondary teachers attribute to challenging mathematics tasks suitable for introduction and enrichment, respectively?

Literature review and theoretical considerations

Teachers themselves emphasize that they need challenging tasks, especially when introducing a new concept and when they want to help students deepen their knowledge (Mellroth et al., 2021). However, textbooks tend to offer few such tasks (Jäder et al., 2020). Finding tasks that are appropriate is difficult and time-consuming (Mellroth, 2018) and involves a wide range of didactic considerations (Bergwall & Mellroth, 2021), as tasks often needs to be selected and (re)designed to fit discrepancies to learning goals (Jäder, 2019). But teachers who participate in long-term professional development on developing challenging tasks for all students become competent in differentiating tasks in order to provide each student with appropriate challenges (Mellroth, 2018; Mellroth et al., 2021)

Teachers' collaborative efforts to find, develop, or adapt challenging tasks for use in their classrooms can be conceptualized as a collaborative learning process (Mellroth et al., 2021) situated in an activity system (Engeström, 1987). In this perspective, tensions and contradictions within and between different elements of the activity system are what drive the learning processes. One way such contradictions can manifest is as dilemmas (Engeström & Sannino, 2011). In the context of differentiating mathematics instruction for a mixed-ability classroom, teachers are faced with the dilemma that, on the one hand, all students must be able to participate in joint classroom activities, and on the other that they need to be offered support and challenges tuned to their individual needs. This dilemma can take many different forms.

The classification of tasks as introductory or enrichment tasks was introduced by the project's teachers in response to such a dilemma. However, the teachers' criteria for those two task categories were not a priori made explicit, and it was not clear if they represented opposing ends on a continuous scale, a dichotomy, or just two properties that a task can have in any combination.

Method

We will answer the research question by reporting on findings from a combined research and school development project in which eight Swedish upper secondary mathematics teachers develop challenging tasks and two researchers study their collaborative learning processes. The focus will be on the teachers' retrospective analysis of tasks they have classified as either introductory or enrichment tasks. The paper has been co-written by the researchers and two of the teachers in the project.

The context and the school development project

Swedish upper secondary school encompasses Grades 10 to 12 (students aged 16–19 years). Students choose from a variety of theoretical and vocational programs. The project's teachers teach mathematics within a technology program, a theoretical program with a high density of mathematics, science, and technology, aimed to prepare students for tertiary education in STEM subjects. Five mathematics courses, building on each other, are offered within the program. For practical reasons, the teachers in the project formed two subgroups, one for those currently teaching the first two courses (here referred to as Group A) and one for those teaching the other three (Group B).

The school development project is a 2.5-year (Aug. 2019–Dec. 2021) project on collaborative learning in mathematics teaching. For collaborative learning to be successful, it is important that participants focus on developing some aspect of their practice that they themselves perceive as problematic. Early in the project the teachers decided to develop a collection of tasks, a problem bank. They felt that mathematics textbooks lacked tasks that can offer challenges to both students with difficulties and those who are highly able in mathematics (cf. Jäder et al., 2020). Their mutually agreed-upon aim for the problem bank was that it should include challenging tasks suitable for introducing new mathematical concepts (introductory tasks), and tasks that could be used to help students develop in-depth knowledge about one or several mathematical concepts (enrichment tasks). Thus, the decision was made early on to distinguish between introductory and enrichment tasks.

During the first two years of the project, the researchers and teachers read and discussed research-based literature on task design (e.g., Sheffield, 2003), differentiated instruction (e.g., Tomlinson, 2016), and high ability in mathematics (e.g., Szabo, 2017). Collaboratively, the teachers merged research findings with their own teaching experiences and developed (or adapted) 13 tasks for use in their own mixed-ability classrooms. The teachers adjusted the tasks to fulfil criteria of rich learning tasks (Sheffield, 2003), for example that (1) everyone should be able to start working with the task, (2) it should be possible to solve the task in several ways, (3) the task should be engaging, and (4) the task should offer an open end. They also tested a majority of the tasks (the COVID pandemic made classroom testing difficult), and then re-analyzed and revised some of them. Therefore, the teachers can be considered competent and experienced in task design as well as collaborative forms of educational development.

During the development and testing phase, the researchers took on the passive role of observers. To project meetings, the teachers brought tasks they found promising to develop to be challenging for all students. In the continued development process, the promising tasks were analyzed using a task analysis guide developed within the project. The criteria for rich learning tasks mentioned above formed part of the guide. Information was collected digitally, and was intended to be included in the problem bank as support for its future users. One item in the guide concerned whether a task was suitable for introduction or enrichment. Of the 13 developed tasks, one was classified as a pure introductory task, six as pure enrichment tasks, and three as both introductory and enrichment tasks. Three tasks were classified as neither introductory nor enrichment tasks, and are therefore out of the scope of this paper.

Data selection and analytic procedure

The results presented in this paper are based on the teachers' retrospective analysis of a subset of the tasks they classified as introductory or enrichment tasks (or both). This new task analysis was conducted during the last meeting of the project's second year. Prior to the meeting, the teachers voted on which tasks they found to be of most interest to analyze according to their suitability for introduction and enrichment, respectively. At the meeting, and based on the votes, the two groups singled out one task each from each category. Group A chose Colored Cube for introduction and The Ant's Walk for enrichment, while Group B chose Ferris Wheel for introduction and Disease Spread for enrichment. Of these four tasks, Ferris Wheel was the only one which had been classified as suitable for both introduction and enrichment. In the next step of the analysis the teachers focused on its use as an introductory task only. English translations of the four tasks are presented in Figures 1–3. Due to space limitations, the descriptions have been somewhat shortened.

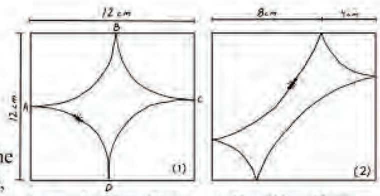
Colored cube

A 4x4x4 cube is colored on all sides.

How many small cubes…
- will have colored surfaces?
- will be completely uncolored?
- will have three colored surfaces?
- will have two colored surfaces?

- What are the solutions for a *nxnxn* cube?
- Are there any limitations?

The Ant's walk



Four circular arcs with the same radius have their middle points on the corners of a square, see (1). An ant walks along the arcs from A to B to C to D to A. How far has the ant walked?

The situation changes to (2) two circular arcs with radius 8 cm and two with radius 4. Show that the path has the same length as in (1).

The circular arcs can have many different radii in a square with the side 12 cm. Show that the length of the path is always the same.

What are the possible radii, if the ant is not allowed to cross a path it already has walked.

Figure 1: The two tasks chosen for retrospective analysis by Group A

Ferries Wheel

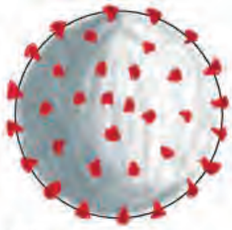
The diameter of a Ferries Wheel is 60m. Its center is placed 40m above the ground. One lap takes 4min. Assume that the wheel begins to rotate when a passenger is at the bottom.

1. Sketch a graph of the passenger's height above the ground at different times.
2. A mathematical model for the movement is given by $h = a + \cos(ct)$. Use the attached GeoGebra file and investigate how a, b and c affect the model. Determine a, b and c for your graph.
3. Sketch a graph for a passenger's position in the x-direction at different times. The movement in x can be described by $x = a + b\sin(ct)$. Determine a, b and c.
4. The movement in the x-direction can be described by $x = a + b\sin(ct)$. Determine a, b and c.
5. Describe the movement in part 2 with a sine function. You may need another constant.
6. Derive the equation of a circle by using the functions found in part 2 and 4.

Figure 2: The introductory task chosen for retrospective analysis by Group B

Disease Spread

Students are asked to implement the model and investigate how changing the constants in the model effects the spread of infection.



The population in a society is divided in three groups:

a) *Susceptible* (S): The proportion who have not yet been infected.

b) *Infected* (I): The proportion who are ill.

c) *Recovered* (R): The proportion who have recovered and become immune.

In this model, everyone who has recovered will be immune.

The SIR model for how the disease spreads can be described with the following differential equations:

$$\frac{dS}{dt} = -\beta IS \qquad \frac{dI}{dt} = -\beta IS - \gamma I \qquad \frac{dR}{dt} = \gamma I$$

β describes how contagious the disease is. γ describes the rate of recovery.

In this model the proportion of susceptible population decreases proportionally to the product of S and I. Those who leave Group S go to Group I. The proportion of those who leave Group I is proportional to I. Those who leave Group I go to Group R.

Examples of values for a disease are $\beta = 0.5$, $\gamma = 0.14$, $S(0) = 1$, $I(0) = 1 \cdot 10^{-6}$, $R(0) = 0$.

One way to compare different diseases is to find the *R*-number definded as $R = \frac{\beta}{\gamma}$.

Figure 3: The enrichment task chosen for retrospective analysis by Group B

All eight teachers, four from each group, participated in the analysis. We agreed on the following procedure: Each group would analyze their introductory task and enrichment task in parallel and answer two questions for each task. For the introductory task: a) What, above all, makes the task suitable as an introductory task? b) What, above all, makes it less suitable as an enrichment task? For the enrichment task: a) What, above all, makes the task suitable as an enrichment task? b) What, above all, makes it less suitable as an introductory task?

The time for analysis amounted to 45 minutes, approximately split as follows: 10 minutes for individual reflection, 20 minutes to compare and discuss individual reflections within the group and come to an agreement, 15 minutes to write a summary of the group's analysis. The discussions were audio-recorded for future reference, but the results presented below are based on the written summaries only.

From our perspective, those summaries are the results of the task analysis. However, for the presentation in the *Results* section, they have been translated to English and rearranged to have similar dispositions. This means that to some extent a content analysis has been conducted. All participating teachers have had opportunities to contribute to and influence the final formulations.

Results

First, as some tasks were categorized as neither introductory nor enrichment tasks, this categorization is not exhaustive. Neither is it a dichotomy, as some tasks were classified as suitable for both introduction and enrichment. Therefore, we conclude that from the teachers' point of view, a task can have both these properties in varying degree and in any combination. To cast further light on this, we now present the summaries of what it is that makes the four tasks suitable/not suitable as introductory and enrichment tasks, respectively. We start with Group A's analysis of Colored Cube and The Ant's Walk, and then Group B's analysis of Ferris Wheel and Disease Spread. Comparisons, similarities, and recurring themes are touched on in the *Discussion* section.

Group A considered Colored Cube to be primarily an introductory task. They found it suitable for this use because it is visual, has an easy start, and has a step-by-step increase in difficulty. It also offers opportunities for review later, and has a cliffhanger. Colored Cube satisfies the criteria for a rich learning task, and offers opportunities for the use of different solution strategies (here the group referred to Frank Lester). Group A found the task less suitable as an enrichment task because its first subtasks are too easy. They suggested that, for use as an enrichment task, the first four or five subtasks should be omitted, and the students should be asked to head directly for the general case.

The Ant's Walk was categorized as an enrichment task. Group A's main reason for this was that the task requires the student to produce a general, algebraic solution. The reason why they considered the task less suitable as an introductory task was that the step between providing a numerical solution and a general solution is too big.

Group B found Ferris Wheel to be a good introductory task because it refers to an everyday situation that students are familiar with, which helps turn the abstract theory into something concrete and tangible. Students can handle the problem even though they are unfamiliar with the underlying mathematical concepts/theory. In addition, they get a taste of what will be treated later within the trigonometry topic. The reason why Group B found this task less suitable as an enrichment task was that it would be too easy for someone who has understood the concepts/theory of trigonometry. Also, the second (and more difficult) part of the task is too similar to its first part.

Finally, Disease Spread was considered a suitable enrichment task because it requires considerable pre-knowledge about differential equations. Students need to understand that they cannot solve the system of nonlinear differential equations analytically but instead need to invoke digital tools. The task is relevant (in light of the COVID pandemic) and interesting, and lets the students see mathematics in a complex context. The results offer opportunities for interesting discussions, and the task can easily be modified and extended. The high demand on pre-knowledge, the inclusion of differential equations on a (for upper secondary school) high level, and the use of digital tools were also reasons why Group B found Disease Spread to be less suitable as an introductory task.

Discussion

In this paper we have asked what characterizes a challenging task that is suitable for introduction and enrichment, respectively. We have answered this question from the viewpoint of an experienced group of upper secondary teachers who have participated in a school development project and designed, analyzed, tested, and revised challenging tasks for use in mixed-ability mathematics classrooms. During their work, the teachers have in various ways encountered the dilemma that, on the one hand, every student must be able to work with the same task and, on the other, the task must offer challenges for all students. This dilemma can be conceptualized as a manifestation of a contradiction between agreed-upon aims of the tasks (Engeström & Sannino, 2011). As contradictions in an activity system fuel collaborative learning processes (Engeström & Sannino, 2011), such dilemmas should not be avoided but rather made visible and an explicit object of inquiry. The analysis of the four tasks presented in this paper is the result of such inquiry. The teachers' verbalization of the respective characteristics of introductory and enrichment tasks can be seen as an outcome of a collaborative learning process.

We therefore believe that our study and its results can contribute to mathematics teaching practice and educational research in different ways. Here, we highlight three. The first is that the results highlight characteristics for introductory and enrichment tasks that can guide teachers in designing, assessing, or selecting material for classroom enactment. Even though the results are hardly surprising, they point to important dimensions along which a task needs to be assessed in order to determine whether it is suitable for introduction or enrichment, with the two kinds of tasks often representing opposite ends of the scale. An introductory task should have an easy start and be visual and concrete, while an enrichment task should not have too easy a start and should aim for general solutions. In introductory tasks, the gap between subtasks must not be too big, and in enrichment tasks not too small. In introductory tasks one should not head for general, algebraic solutions too quickly, while in enrichment tasks one can go directly to general solutions. Introductory tasks must not require pre-knowledge, while enrichment tasks should do just that. One can be tempted to conclude that introductory tasks are those with a "low floor" or with enabling prompts, while enrichment tasks are those with a "high ceiling" or with extending prompts. However, for effective learning, all students should be offered opportunities to struggle with mathematical ideas (Hiebert & Grouws, 2007). To offer appropriate challenges to students with difficulties as well as those with high abilities in mathematics, both introductory and enrichment tasks should be designed to have both a "low floor" and a "high ceiling" (Bobis et al., 2021). We therefore suggest another interpretation: Introductory and enrichment tasks offer different kinds of learning challenges. These differences require that, when designing introductory tasks, extra focus should be placed on ensuring a "low floor", while the design of enrichment tasks requires greater focus on providing a "high ceiling".

A second contribution is that our results show how attending to the question of whether a task is an introductory or an enrichment task also can serve as a catalyst for discussions of other important aspects of task design for differentiated mathematics instruction. The act of designing tasks suitable for introduction and enrichment will present teachers with other dilemmas, such as whether a task provides enough guidance without funneling (Bauersfeld, 1998), and whether it is specific enough without depriving students of opportunities for general reasoning. Thus, for the collaborative learning process, attending to the question of whether a task is an introductory or an enrichment task might be more important than deciding on absolute criteria for such tasks.

A third, and methodological, contribution to the research community is the method used to clarify an outcome of a collaborative learning process: by conducting a retrospective analysis related to a previously discovered dilemma – in this case, the dilemma of designing introductory and enrichment tasks that are challenging for all students in the mixed-ability classroom.

Reading comprehension and modelling problems: Does it matter where the question is placed?

Valentin Böswald and Stanislaw Schukajlow

University of Münster, Department of Mathematics, Germany;

vboeswald@uni-muenster.de, schukajlow@uni-muenster.de

Text comprehension is a key aspect to consider when designing modelling problems. One important feature of mathematical problems is where the question is placed in the text. We present a theoretical background on text comprehension and modelling problems, and we discuss the pros and cons of placing the question before the text rather than placing it after the text. A review of the research revealed that placing the question before the text is more likely to result in improved comprehension. Further, we propose consequences for task design and future research.

Keywords: Reading comprehension, eye movements, modelling, mathematical materials.

Introduction

Prior research has indicated that mathematical problems are very important for learning mathematics. For example, in the TIMSS study, 80% of the time spent in mathematics classes was spent working on mathematical problems (Hiebert et al., 2003). Thus, in order to appropriately foster students' learning, thorough research must be conducted on task design. Niss et al. (2007) distinguished mathematical problems on the basis of their connection to reality, resulting in three different types of mathematical problems: modelling problems, word problems, and intramathematical problems. Whereas the third type have no connection to reality at all and can therefore be solved by applying heuristics and mathematical procedures, word problems are moderately connected to reality, meaning that the intended use of mathematics is embedded in an extramathematical context. Word problems differ from modelling problems in the strength of their connection to reality and in the cognitive processes necessary to solve the problem (Niss et al., 2007). Modelling problems require the problem solver to make assumptions about missing data and to structure and simplify the given context, whereas word problems are already prestructured and simplified. Usually, modelling problems are presented as texts. Thus, reading comprehension and the construction of an adequate mental representation of the real-world situation are essential for solving modelling problems. Based on this mental representation, the solution plan can be developed and carried out. As Leiss et al. (2019) showed, text comprehension was a significant predictor of students' performance in solving modelling problems. Thus, there is a need for research on text comprehension and task design in modelling. Initial attempts to conduct research on the design of modelling problems were carried out in the past by posing open modelling problems with missing information (e.g., Fermi problems) or by asking students to develop multiple solutions to the problem or to draw a picture that represents the situation (for an overview, see Schukajlow, Kaiser, and Stillman, 2021). However, to date, not much is known about how task design affects the reading comprehension and solving of modelling problems. One variation in task design involves so-called *question-placement effects* (Thevenot et al., 2007). The theory of question-placement effects suggests that comprehension should benefit from reading the question before reading the text of the mathematical problem. The aims of this theoretical paper are (1) to summarize and link theoretical and empirical findings from research in the areas of reading comprehension and modelling, (2) to ground the influence of questions and their placement on comprehension in mathematical modelling problems, and (3) to present consequences for research and task design.

Theoretical background

Text comprehension

Van Dijk and Kintsch (1983) distinguished between three levels of text comprehension that are built on each other but differ primarily in their complexity: the surface code, the text base, and the situation model. The surface code of a text consists of the exact wording and syntax of what is read, and thus, it is a pure representation of what has been read. In most cases, readers retain only the text surface of the last sentence or part of a sentence they read. Comprehension based on the surface code alone would be indicated through verbatim reproduction of the given text.

The text base reduces the text surface to the semantic content of the text – the wording and syntax are therefore no longer exactly the same as the surface code. However, the meaning of the text remains, represented in so-called *propositions* (van Dijk & Kintsch, 1983). This level illustrates a mental representation of the semantic content of the text via the process of building coherence locally, that is, the relationships between the subjects, objects, and so forth, and the predicates (e.g., traits or actions) given in the surface code in a sentence or between adjacent sentences. Successful comprehension on the level of the text base means the text base leads to an understanding of the basic features of the text, but deeper comprehension of the content of the text is not sufficient.

The highest level of comprehension is the situation model (van Dijk & Kintsch, 1983). It contains the content or context of the text and therefore no longer represents the explicit text but rather what the text is about. This mental model is constructed from the text base by drawing inferences and is augmented by prior knowledge and even external sources, such as the content of other texts or pictures. Building coherence across the entire text (i.e., global coherence) is crucial for constructing this mental model. The situation model may then be used to detect inconsistencies presented in external information and to evaluate the memory contents (Radvansky & Copeland, 2004). In the past, research on reading comprehension has been carried out by using different research approaches, including analyses of eye movements.

Eye movements during reading

The comprehension process is based on eye movements. Eye movements during reading can be classified into two different types: fixations and saccades. The former is “the state when the eye remains still over a period of time” (Holmqvist et al., 2011, p. 21). During reading, fixations occur when the eye temporarily stops moving on a specific word in order to process its meaning. Between two fixations (e.g., while switching from one word two another during reading), rapid eye movements occur, the so-called *saccades*. In reading research, a saccade that opposes the typical reading direction (e.g., *left to right* in Latin typeface) is called *regression*. Clifton et al. (2016) observed that the processes of word recognition and text comprehension (i.e., the construction of a situation model) are especially likely to have a strong influence on eye movements during reading.

Text comprehension in mathematical modelling

According to research by Reusser (1990) and Leiss et al. (2010), a situation model must be constructed to solve complex word problems and modelling problems. The real-world situation is represented in the so-called *situation model*, and it serves as the foundation for further steps in the solution processes. Blum and Leiß (2007) acknowledged this necessity and included the situation model in their modelling cycle, which has often been used to describe the process of solving modelling problems in the past. By comprehending the text, students construct an idiosyncratic mental representation of the real-world situation. This process can be described as a task-oriented structuring of individual knowledge. Importantly, the situation model contains more than just extramathematical knowledge (i.e., prior knowledge and prior experience). Rather, over the course of constructing a viable situation model of the problem, the student must identify a mathematically significant gap in the real-world situation in order to be able to complete the remaining steps in the modelling cycle on the basis of this situation model (Reusser, 1990). While constructing a situation model, the mathematically relevant information related to the question needs to be represented, and relevant information needs to be distinguished from irrelevant information regarding the modelling problem's question. On average, students spend around 40% of the time necessary to solve modelling problems on the comprehension process (Leiss et al., 2019). Therefore, there is a need to investigate how different task designs affect students' efficiency during this process. The process of comprehending the modelling problem is then followed by the process of structuring and simplifying the given information and thus constructing the so-called *real model*. Based on this deliberately structured mental model, mathematization is subsequently used to construct a mathematical model, which will allow the student to work mathematically within the mathematical model in order to generate mathematical results. These results then have to be interpreted on the basis of the real-world situation, followed by the deliberate validation of these results.

Hegarty et al. (1995) proposed two approaches used by successful and less successful word problem solvers: the direct-translation strategy and the problem model strategy. Problem solvers who utilize this first approach tend to base their solution plan on the selection of keywords and numbers given in the text of a problem. This rather superficial approach (for an overview, see Verschaffel et al., 2020) then leads to an incorrect solution more often when compared with the second approach the authors identified: the problem model strategy. Problem solvers who utilize this second approach deliberately construct a situation model of the situation described in the text and are therefore able to detect inconsistencies between their situation model and the given information by applying their solution process, a practice that is necessary for correctly validating the solution. In line with these results, Strohmaier et al. (2020) identified eye movements corresponding with these two approaches, plus a third approach that characterized readers who struggled while solving word problems. According to Strohmaier et al., utilizing the direct-translation strategy manifested in "a very linear and intense reading pattern with long mean fixation durations, short saccades and few regressions"(p. 10). On the other hand, the problem model strategy manifested in a shorter mean fixation duration and a high frequency of regressions. The third pattern Strohmaier et al. (2020) identified, which was linked to struggling readers, consisted of shorter saccades, higher fixation counts, as well as a higher regression count, resulting in overall longer reading times.

Effects of the placement of the question on comprehension in mathematical modelling problems

The reading goal is important for comprehension processes. In complex word problem solving, the reading goal is set by the question that accompanies the text of the task. While solving mathematical problems with relationships with the real world, the reading goal is to generate an accurate and deep understanding of the situation in order to answer the question. Usually, the question points to a mathematically relevant gap in the situation, which can be closed by using mathematics as a tool (Reusser, 1990), that is, by constructing a mathematical model and applying mathematical procedures. Because of the importance of questions for reading comprehension processes and for solving problems, the placement of the question needs to be evaluated critically with respect to task design. Depending on whether the question is placed before or after the text describing the real-world situation, comprehension processes can differ significantly. Placing the question before the text (i.e., reading the question first) should enhance the comprehension process because the reading goal is made more specific. Additionally, the question may serve as a tool for organizing and structuring the reading material, thus helping a student focus their attention on the relevant information. Therefore, decisions about the relevance of information given in the text should be made more precisely and quickly and, in conclusion, more efficiently. Furthermore, constructing coherence between the title and the question may enable initial inferences to be drawn and may therefore generate initial comprehension. The question and the title should facilitate the comprehension process, which should help a student solve a modelling problem similar to the ways a title facilitates a reader's understanding of a narrative text. This hypothesis was derived from numerous studies that have shown the effect of placing questions before the text on the retrieval of goal-relevant information (cf. Carpenter et al., 2018). As a result, the situation model should be more adequate (i.e., goal-related comprehension should be improved). The question could also be placed after the descriptive text. By placing the question after the descriptive text, the automated comprehension process would usually result in reading the text first and the question afterwards. Therefore, readers would have to construct hypotheses about the relevance of information for the superordinate reading goal, that is, solving the (at this point still unknown) problem. Placing the question after the text would result in the problem solver having to revisit the text after reading the question or adapting their situation model accordingly by shifting the relevance attributed to the information, ultimately leading the problem solver to learn from the text.

When discussing question-placement effects, some considerations have to be kept in mind. First, a question-placement effect on comprehension might only occur if the question cannot be inferred immediately and unambiguously from reading the text at hand. This is because, if the question is already clear to the reader, although they have not read it yet, the reading goal can be adjusted accordingly, thus organizing the process of distinguishing between goal-relevant and goal-irrelevant information. Second, the benefits of placing the question before the text are assumed to be specific to goal-relevant information (Carpenter et al., 2018). Therefore, the use of questions placed before the text might impair a student's ability to learn from the text. Third, the beneficial effects of the placement of the question in mathematical modelling problems should depend on the problem solver's mathematical competence. This is the case because the mathematically significant gap in the real-world situation needs to be identified, that is, the problem solver needs to construct a basic mathematical model that is based on the question in order to distinguish relevant from irrelevant information. The construction of the mathematical model requires adequate mathematical competence, and it was found to be affected by mathematical performance in the past (Schukajlow, Blomberg, et al., 2021).

Research on question-placement effects in mathematics education is scarce. Thevenot et al. (2007) showed that performance in solving arithmetic word problems was significantly better if the question was placed before the text. Their results opposed the results found by Arter and Clinton (1974), who did not find significant effects of placing the question before the text on error counts in a study on irrelevant information in arithmetic word problems. However, effects on the time needed to solve the problems were found, thus influencing the efficiency (the ratio of accuracy and time).

We would like to propose two prototypical comprehension processes regarding the two possible question placements in modelling problems by illustrating these induced effects with the sample problem called "Buddenturm" (Figure 1). We suggest that problems used for research in the field of question-placement effects should contain a title, a question, and a brief text that describes the situation. According to Thevenot et al. (2007), the descriptive text needs to be constructed in such a way that the problem's actual question cannot be inferred immediately and unambiguously. Otherwise, effects of question placement might be impaired as stated above. To do so, from our point of view, each problem should contain additional numerical information that is not relevant to answering the question. In the "Buddenturm" problem, the annual data, the length of the city wall, and the tower's former height are examples of irrelevant information.

Buddenturm

Question: How much area was refurbished in 2002?

The so-called "Buddenturm" is the only remaining fortified tower from the former city wall of Münster and was built in 1150. A few remaining rudiments of the 8-10-meter-high and 4-kilometer-long city wall can still be seen in two parts of the round tower. The Buddenturm is 30 meters high in total and has a 5-meter-high conical roof. In 2002, the outer wall of the 12.5-meter-wide tower was renovated along with the remains of the city wall by applying a new layer of limestone. This repair is only one of the few that the Buddenturm has experienced in its almost 900-year history; for example, it was still 40 meters high until 1945.

Figure 1: "Buddenturm" modelling problem with the question placed before the descriptive text

Assuming a linear reading pattern, the title of the problem is read first and does not depend on the placement of the question. By recognizing the name of the tower or by decoding the word *Turm* (in English: *tower*), readers can activate prior knowledge and integrate it into their initial situation model. After that, if the question is placed *before* the text (as is the case in Figure 1), readers will then read the question. By integrating the question and its content into the situation model, the reader may be able to draw inferences from it, such as that the tower is antique or at least in need of refurbishment. In conjunction with the information that the size of an area should be calculated to solve the problem, readers can enrich their situation model even further. After that, while reading the descriptive text, relevant and irrelevant information can be identified as such, simplifying the process of structuring the situation model for mathematization later on. In summary, the comprehension process initiated by placing the question before the text can be processed on a deeper level from the very beginning, rather than the problem solver focusing on generating a rough understanding of the situation. In turn, if the question is placed *after* the text, all information from the descriptive text needs to be integrated into the situation model initially, resulting in an understanding of the overall situation. To some extent, this is the result of the descriptive text being structured in such a way that the question (and thus, the reading goal) cannot be inferred unambiguously while solving modelling problems. Therefore, the ability to distinguish between relevant and irrelevant information during reading might be impaired. Although readers might anticipate a particular question, they cannot evaluate the relevance of information with certainty. This is because the actual question has not yet been integrated into the situation model. After reading the question and integrating it into the situation model, the situation model can be (re)structured and simplified for mathematization later on. Rereading the descriptive text might be necessary during this phase so that the problem solver can adequately represent all the relevant information.

These two prototypical comprehension processes might differ across the range of novices to experts as well as interindividually, as the processes depend strongly on prior knowledge. Experts in understanding modelling problems might structure their comprehension process in a specific way so that they read the title of the problem first but then immediately read the question, effectively simulating the question being placed before the text and thus possibly benefitting from the early integration of the question in their situation model.

Consequences for task design and future research

There are two possible conditions for the placement of the question, both already being used by teachers and textbooks: *before the text* and *after the text*. As described above, both conditions may have a positive influence on parts of students' cognition while also impairing other parts. The latter may challenge the problem solver by making it harder to initially comprehend the modelling problem, especially if prior knowledge is poor. But the reader will ultimately learn from the text, that is, the reader's ability to learn about the content of the text by solving the problem might be improved (e.g., learning that the tower's height in Figure 1 has changed across the centuries). The former may impair long-term learning about the content of the text but may in turn improve text comprehension, ultimately leading to an improved solution process, which in turn may result in improved modelling competence. However, both possible conditions and the extent of their influence have yet to be studied thoroughly. Thevenot et al. (2007) examined question-placement effects for arithmetic word problems, which were designed for fourth-graders. For modelling problems, research needs to be done on the influence of the placement of the question on text comprehension and the efficiency of text comprehension. Eye-tracking technology can be utilized productively to identify how the placement of the question influences students' comprehension of mathematical modelling problems and how students attempt to comprehend them. If a question-placement effect can be demonstrated through carefully designed studies, research on possible effects on modelling performance through effects on text comprehension may be conducted. However, the question-placement effect and its extent should furthermore depend on students' cognitive characteristics, such as working memory capacity, mathematical competence, and reading competence and on the problems' characteristics (e.g., the difficulty) (Thevenot et al., 2007) or the type of problem (e.g., "dressed up" word problems or intramathematical problems). As prior research was conducted on word problems, we can mostly speculate about how question placement might affect how students solve modelling problems.

Conclusion

In this theoretical paper, we discussed the theoretical background for question-placement effects in the reading comprehension of mathematical modelling problems and derived why placing the question before the text that describes the real-world situation should be beneficial for learners' comprehension processes, ultimately benefitting the solution processes. In short, placing the question before the text should help the reader better distinguish between relevant and irrelevant information by having a specified reading goal and constructing an adequate initial situation model just from the title and the question about the modelling problem.

Characterizing the presence of activities using GeoGebra in Brazil's mathematics textbooks

Ayla Carvalho[1] and Rúbia Amaral-Schio[2]

[1]University of Campinas, Brazil; a.mcarvalho1004@gmail.com

[2]São Paulo State University, Brazil; rubia.amaral@unesp.br

The Brazilian normative presents the obligation of using dynamic geometry software in the textbooks. However, each methodological approach allows many different applications. This paper aims to characterize the presence of activities using GeoGebra in Brazil's mathematics textbooks. To assemble these activities is essential to construct and explore visual aspects associated with experiments, as found in the literature. Analyzing four textbook collections of math for middle school, this paper found 36 activities. Through a methodological procedure created from the theoretical framework, the activities' characteristics show that textbooks must offer enhancing activities, not borderlines, and not use technologies as a pretext to be approved. So, there's space to change their approach in textbooks. Besides that, the proposed procedure altered perceiving an activity in a textbook, allowing future analyses.

Keywords: Dynamic geometry software, visualization, mathematical discovery.

Introduction

The textbook is one of the most used resources by teachers, which means it can influence an educator directly in a classroom, consequently, teaching and learning process. The importance of this resource is viewed through a Brazilian government program named National Textbook and Didactic Material Program – PNLD (Programa Nacional do Livro e do Material Didático), recognized as one of the most extensive national distribution textbooks programs in the world (Brasil, 2020a).

This program aims to offer didactic materials, including textbooks, for free, to every student studying in a public school. It is also important to highlight that the books are reused to assist the students for four years. In this period, it can only demand repositions or complementation (Brasil, 2020a). Only in 2020, more than 170 million textbooks were distributed, with an estimated total investment of BRL 1,4 billion, equivalent to approximately EUR 280 million, using the quotation in the given period (Brasil, 2020b).

All this process involving PNLD includes many stages, among which can be highlighted the writing of textbooks by the authors, the choosing of approved textbooks by the schools, the acquisition by the government of these books, the later production, and the distribution of the material having its final use inside the classroom. Thus, analyzing some of these PNLD textbooks allows us to understand Brazilian education, a relevant research field.

In this process, a crucial stage is the writing of textbooks by authors. Once, in this way, it is possible to observe the adopted approach of an object of knowledge by each one and the decision about how digital technologies will be used in their process. That's why textbooks are ingrained with the authors' conception about mathematics and the teaching and learning of math, explicitly or not (Borba & Villarreal, 2005).

As long as the contribution of the technology towards the changes in the social configuration is undeniable, which is also reflected in the learning space, it is necessary to think about integrating textbooks and digital technologies. For that reason, since 2014, the PNLD's public notice, dedicated to middle schools' textbooks[1], was the first of the Program that contemplated the inclusion of digital technologies.

Furthermore, PNLD 2020, bringing middle schools' textbooks written and published in 2018, was the first that had the main goal to contemplate the National Common Basic Curriculum – BNCC (Base Nacional Comum Curricular) (Brasil, 2018). It presents 11 of 121 math skills[2] addressing digital technologies, in which eight of them denote dynamic geometry software. Therefore, it is considered that it is clear the obligatoriness of the digital technologies' presence in textbooks available in Brazil currently.

However, these digital technologies in textbooks do not ensure that the authors present proposals using their potentialities or technologies just with a pretext to the same suggestions. So, an essential part is to think about this presence and these activities.

In light of the previous, this research considers it essential to reflect on: how the presence of activities using GeoGebra can be characterized in Brazil's mathematics textbooks? It opts here for this particular software, GeoGebra, because it is mentioned by three of four collections analyzed in this paper. All these collections present specific pages dedicated to a pedagogical task to be realized by students using this dynamic geometry software. Such studies will be called activities in this paper.

Theoretical framework

There is an essential differentiation between drawing and construction in the dynamic geometry paradigm, where movement is intrinsic to its processes. The first one is related to the non-resistance to the dragging proof; if a picture is dragged and doesn't keep its fundamental properties, the image is just a drawing (Laborde, 1998), as a picture of a geometrical object. The construction creates illustrations that permanently preserve its fundamental properties, even when one of its moving elements is dragged. Thus, the geometric figure resists the dragging proof (Borba et al., 2020).

Assuming this paradigm, it is understandable that the construction is essential to activities using GeoGebra to make scenarios that can enable mathematical investigation (Borba et al., 2020). Besides that, it may encourage the student to comprehend the properties that the geometric figures present

[1] Each year, this process occurs with a specific stage of school education: childhood education, primary school, middle school and high school. So, these textbooks are used during four years (before 2020, the period of use was three years).

[2] BNCC is a normative document that defines the set of essential learning that all students must develop throughout the stages of basic education. In Mathematics, there are 121 skills in total for the four years of middle school and every textbook has to follow it. If do not, they are not approved.

and the relations between the parties through visual feedback that the software provides (Laborde, 1998).

This idea of movement can be explored with the visualization since, based on the dynamism explored from the construction of geometric pictures, the possibility of manipulation opens up along with the visualization of objects. This means elaborating on a mathematics activity based in GeoGebra should explore the visual aspect once the software offers quick feedback. This feedback requires an interpretation by the students, and because of it, the visualization has a crucial role in dynamic geometry (Laborde, 1998).

Zimmermann and Cunningham (1991, p. 3) define mathematical visualization as "the process of forming images (mentally, or with pencil and paper, or with the aid of technology) and using such images effectively for mathematical discovery and understanding." Therefore, visualization is associated with understanding a problem as well as discovering something, as seen by the authors. At the same time, it requires an active role by whom is visualizing.

In this point of view, after constructing some geometric object, the activity must have a goal to visualize this construction. It can be raising a hypothesis, getting convinced of some conjecture, or confirming previously emerged ideas. This interaction with the constructed object is necessary, and this is possible because of the manipulation that GeoGebra offers.

Associated with the idea of visualization with discovery, it is the experiment. According to Borba and Villarreal (2005), an experiment is executed to discover something unknown, check the truth of a hypothesis with the view to accept or reject it or afford examples of known fact. These authors point out that the first idea of the experiment goal is discovering something new, which means it is related to mathematical discovery.

This idea is primordial on the production of mathematical senses, as Borba et al. (2020) point out. They express that discovering patterns or singularities between the representation of math objects (or components of these representations) propels the production of mathematical senses (Borba et al., 2020). Thus, there is an "empirical" dimension that involves both thinking and learning mathematics. In this process to the occurrence of mathematic learning, Borba et al. (2020) argue that the technological resources became leading figures for that predominant experimental and visual feature. Therefore, it can perceive the importance of experimental dimension gains in GeoGebra and the visual dimension already approached.

Therefore, it is relevant to note that Borba and Villarreal (2005) point out that an experimental approach in mathematics education, using technologies, provides:

"The possibility of testing a conjecture using a significant number of examples and the chance of repeating the experiments, due to quick feedback given by computers; the chance of getting different types of representations of a given situation more easily; a way of learning mathematics that is resonant with modeling as a pedagogical approach." (Borba & Villarreal, 2005, pp. 75–76)

So, it's relevant to seek comprehension for integrating visualization, exploration, and mathematics learning in activities using GeoGebra in textbooks. Whence, it is essential to characterize the activities through these approaches that could potentialize learning math.

Methodology

Four middle school math textbook collections were analyzed out of 11 approved in PNLD 2020 to perform this qualitative research. The collections will be named Collection A to D in this paper. Each of them consists of four books, from sixth to ninth grade (students here are between 11 and 15 years old), totalizing 16 textbooks analyzed. Of the more than 10 million math textbooks distributed in 2020 to Brazilian public schools, approximately 70% are from these four collections, highlighting them as representative collections for the analysis, as shown in Table 1. All these 16 books that were analyzed are teacher's books[3].

After choosing the collections, the most distributed books from different publishers, the researcher searched for activities using GeoGebra and identified the chapters where they were. These chapters were analyzed, purposing to identify how the activities using GeoGebra were distributed through the textbooks, according to grades and contents of geometry.

The theoretical framework's reading developed a methodological procedure to characterize the presence of activities using GeoGebra in mathematics textbooks, following Figure 1. Every task found was classified by it.

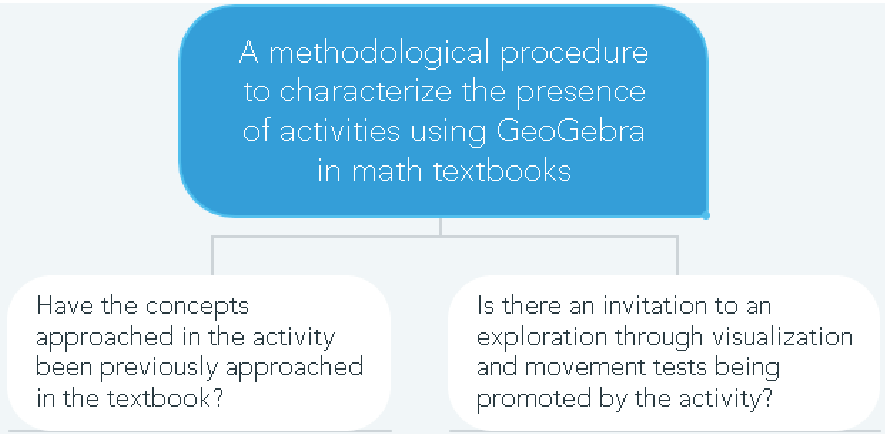

Figure 1: Methodological procedure developed by the researcher

To classify the activities by the methodological procedure, it was observed the following: 1) if the content worked in the activity was approached previously in the same textbook, or it is the first time that the author presented the content to students through GeoGebra; 2) after constructing a geometric object, if there is an invitation to drag something with a goal, it means, an exploration through visualization and movement or there is not this invitation and, so, the student construct a geometric object and does not have an exploration with it.

From two questions in Figure 1, therefore, it can be classifying the activities in four groups: activities that: 1) work concepts already approached in the textbooks and have an invitation to an exploration; 2) work concepts already approached in the textbooks and without an invitation to an exploration; 3)

[3] In Brazil, every public-school teacher receives a textbook containing student textbook and also some tips, instructions and answers for all activities of it (in another color, to do this differentiation, as Figure 2 shows in red).

work concepts are not approached in the textbooks previously and have an invitation to an exploration; 4) work concepts are not approached in the textbooks previously and without an invitation to exploration.

Giving attention to the third group, it is possible to see that activities from that have an approach promoting mathematical discovery. This assumption is based on the fact that in this case, the experimenters can discover something new that they did not know before, and test and visualize this result with quick feedback, following the theoretical framework.

Discussion of results

Analyzing the Collections A, B, C, and D, the results are shown in Table 1. Collection A, which represents almost half of textbooks coverage in Brazil, has just one activity using Geogebra per year, totalizing four activities.

Table 1: Data of 4 collections analyzed

Collection	Coverage in Brazil in 2020	Quantity of activities using GeoGebra
A	49,8%	4
B	10,1%	8
C	6,1%	15
D	3,4%	9
Total	**69,4%**	**36**

Focusing on those two questions presented in Figure 1, the results are shown in Table 2. It is possible to see that most activities have an invitation to exploration (first column); at the same time, works concepts are already approached (first line). Seven activities do not invite the student to explore, which shows they do not exploit the potentialities of GeoGebra of manipulation.

Table 2: 36 activities classified in four groups

	THERE IS AN INVITATION TO AN EXPLORATION	THERE IS NOT AN INVITATION TO AN EXPLORATION
CONCEPTS PRESENTED HAVE ALREADY BEEN APPROACHED	Collection A: 3 Collection B: 6 Collection C: 2 Collection D: 5 Total: 16 (44,4%)	Collection A: 0 Collection B: 1 Collection C: 1 Collection D: 3 Total: 5 (13,9%)
CONCEPTS PRESENTED HAVE NOT BEEN APPROACHED PREVIOUSLY	Collection A: 1 Collection B: 0 Collection C: 12 Collection D: 0 Total: 13 (36,1%).	Collection A: 0 Collection B: 1 Collection C: 0 Collection D: 1 Total: 2 (5,6%)

Also, there are five activities working concepts already approached in the textbook and having not an invitation to explore, as Figure 2 shows an example.

Previously, the chapter where this activity is localized has already approached the relations between angles in two parallel lines cut by a transversal. There is an activity on the same page with the same goal. The only difference is this first is to be done with pencil, paper, and a protractor. Furthermore, students are not invited to drag any constructed points to help convince them about corresponding or supplementary angles. So, this activity doesn't bring a potential use of GeoGebra, and a student could do this same task without any digital technology.

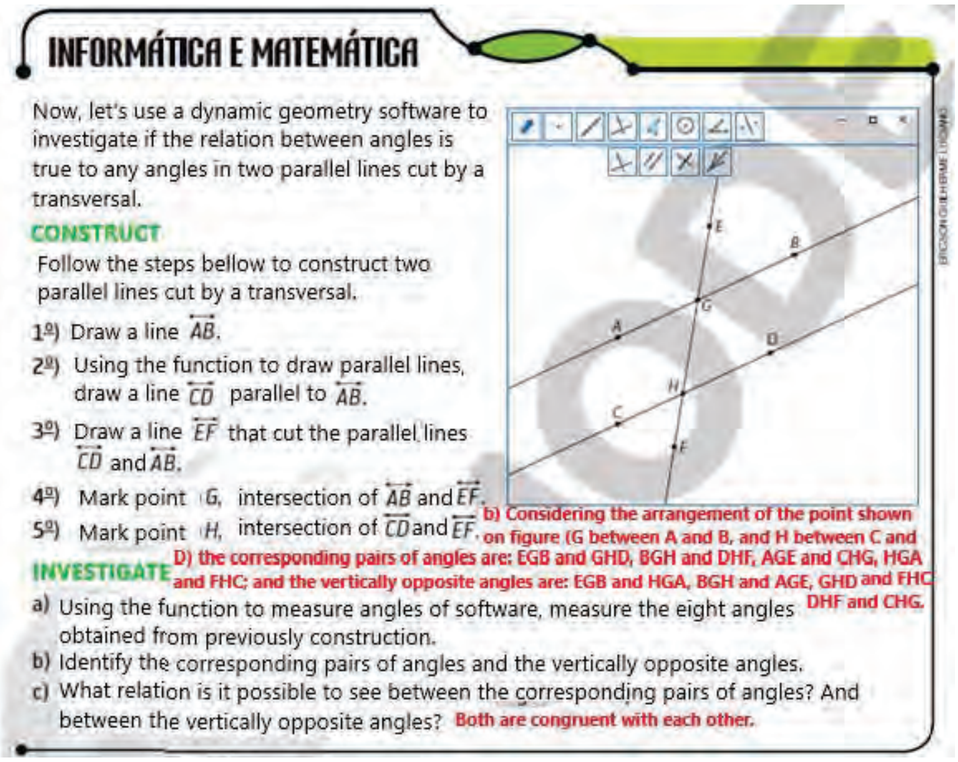

Figure 2: Activity using GeoGebra from Collection C – seventh grade

After this example of a borderline activity, backing to Table 2, in the third group, it is seen that Collections B and D do not present any activity promoting mathematical discovery. Otherwise, Collection C shows 12 out of 15 activities promoting mathematical discovery. For that reason, an example from this collection, in particular, will be explored.

The first activity from the sixth-grade textbook uses GeoGebra to represent parallel, concurrent, and perpendicular lines. It begins by requesting for the experimenter to construct parallel and perpendicular lines to be compared subsequently. For such, the student shall use three non-colinear points, constructing a ray and two segments, as Figure 3 shows. By measuring the angles and segments that appear in the image, the "investigate" part in the textbook shows up, as can be seen in the exact figure. This activity occurs at the end of the chapter so that the theory of all these points mentioned has already been approached. However, what is proposed is an investigation that has not been approached yet, that is, the conjecture that the shortest distance between a point and a straight line is the segment that unites them, forming 90°.

After the request to construct the parallel and concurrent lines in this activity, the student is requested to move the point E to equal AE to the measure of CD (letter b). For this, point E will have to be moved until CEA forms 90º. When continuing the activity (letter c), the student, from visualization and movement, using experimental procedures, is invited to elaborate the mathematical conjecture that the shortest distance between a point and a line corresponds to the measure of the segment that joins this point to the straight line forming a right angle (letter d).

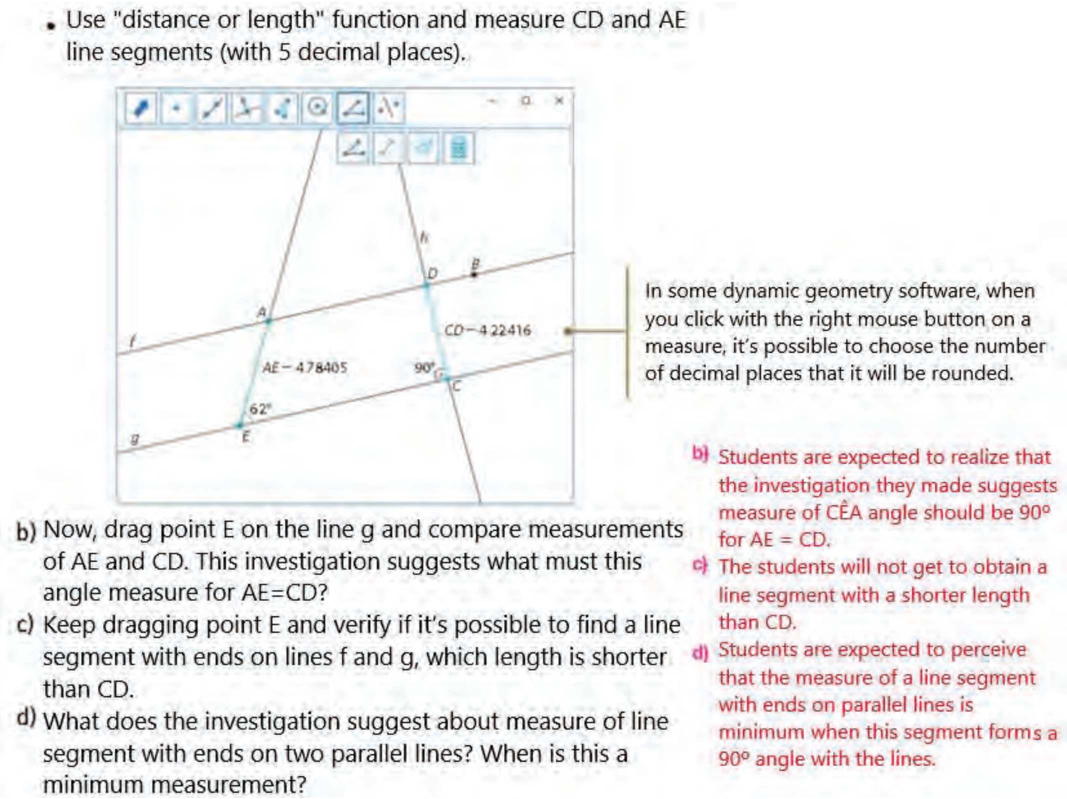

Figure 3: Final part of 1st activity from collection C promoting mathematical discovery – sixth grade

This way, it can define that the activity has a mathematical discovery approach (Borba & Villarreal, 2005). It happens because experimental procedures are used to generate a conjecture; there is the discovery of mathematical results previously unknown to the student and the possibility of several tests by dragging point E. It occurs while the students verify the measurement of the segment AE and the angle CEA compared to the DCE angle, which means they are invited to visualize and movement. This kind of activity can enhance students' mathematical learning once that it gives depth and meaning to understanding, as Hohenwarter et al. (2008) point out

"Instead of giving students an answer to a problem they didn't have in the first place, such explorations allow a more meaningful introduction of the abstract concept […] as a solution to a problem students experienced themselves." (Hohenwarter et al., 2008, p. 3)

Conclusion

Half of the Brazilian students, who use Collection A, can see one activity per year using this software, which is low. Giving focus on Collection C, which brings a more relevant number of activities using GeoGebra, it is the author's choices for an approach that has a goal to promote mathematical discovery, as can be seen from the methodological procedure (12 out of 15), what does not happen on Collection B and D once. This emphasizes the gap in the use of activities with dynamic geometry software in Brazil, making clear that there is space to introduce more activities using GeoGebra in the textbook and change their approach.

This paper was aimed to characterize the presence of activities using GeoGebra in Brazil's mathematics textbooks through two questions from the methodological procedure. From this, we could see how some activities (7 out of 36) don't invite students to explore and hence don't utilize the potentialities from GeoGebra and its dynamism. It's necessary that textbooks offer enhancing activities, not borderlines, and not use technologies as a pretext just to be approved by PNLD, for example.

We sustain that it is possible to potentialize the mathematics learning process through mathematical discovery once the students are invited to explore and search for their own results without a ready answer. That means they don't know where to arrive in the beginning. A textbook mustn't supply some answers before these activities using GeoGebra. In this way, students are more involved, as Borba and Villarreal (2005) observe, challenging them to discover something new by visualizing a problem and testing with quick feedback. And there is space to appropriate this approach better for making activities using GeoGebra in mathematics textbooks from Brazil, looking for promoting more meaningful math learning for students.

It is also noted that methodological procedure created from theoretical framework contributed to verify if an activity has an approach based on visualization and exploration and if it promotes mathematical discovery, changing to perceive an activity in a textbook, which shows us a fruitful field of development to future analyses.

In this paper we present the results of a pilot study focused on an educational programme aimed at involving upper secondary students in the design of digital curriculum resources (DCR) using the GeoGebra software. We analyse the reflections proposed by the students-designers during semi-structured interviews developed at the end of the educational programme. As a result of this analysis, we propose a characterization of students-designers' praxeologies in relation to the task of DCR-design. This characterization highlights their awareness both on the characteristics of the DCR that supports students' learning and on the role of the design process in fostering the designers' learning.

Keywords: Digital curriculum resources, students-designers, praxeologies, awareness.

Introduction

In the last decade an increasing interest in studying the role played by digital tools in supporting the process of task-design has emerged (see, for instance, Leung & Baccaglini-Frank, 2017). Here, we focus on digital curriculum resource-design to broaden the set of possible products of the design-process: not only tasks, but also revision guides for specific topics, digital materials to introduce new mathematical topics, interactive e-books. We refer to Pepin et al.'s (2017) definition of digital curriculum resources (DCR) as "organised systems of digital resources in electronic formats that articulate a scope and sequence of curricular content" (p.3).

Many studies in mathematics education have been focused on the effects of involving teachers in the process of task/resource-design on both their professional development and the effectiveness of the designed instructional materials (Jones & Pepin, 2016). Few studies have, instead, focused on students as co-designers (Diamantidis, Kynigos & Papadopoulos, 2019) or designers of digital tasks/resources (Alessio et al., 2021). Our research is set in this mainstream of studies. In this paper, we present the results from a pilot study aimed at involving upper secondary school students as designers of DCR.

Theoretical framework

The first component of our theoretical framework, the tetrahedron model (Albano, Faggiano & Rossi, 2018), is considered to interpret the dynamics that characterize the process of DCR-design. This model takes into account the relationships between the Teacher (T), the Student (S), the Mathematics (M) and the Designer (D) of digital materials, and considers technology as a mediatory sphere embedded in the tetrahedron with vertices T, S, M and D.

The second component of our theoretical framework is introduced to analyse how the process of DCR-design affect students' development of specific competencies and awareness about their learning. The design of DCR could be conceived, in fact, as a specific task for students. For this reason, a product of the process of DCR-design is the students' development of specific praxeologies associated to this task. The notion of praxeology has been introduced by Chevallard (1991). It could be structured in two main levels (García et al., 2006): the *know-how level*, which includes the task, or a family of tasks, and the techniques used to face the task; the *knowledge level*, which includes the "discourses" developed to justify or frame the techniques for the task. The discourses on the techniques, as stressed by Artigue (2002), could focus on both their *pragmatic* value, connected to their productive potential in terms of efficiency, costs, validity, and on their *epistemic* value, more difficult to be grasped, connected to the way in which the techniques could contribute to the understanding of the objects they involve.

Context of the study

The students involved in our study (7 upper secondary school students, grade 12) participated to an educational programme set up by the Department of Industrial Engineering and Mathematics of the University of Ancona. The programme, aimed at supporting the transition from secondary school to university, was articulated in 10 meetings (50 hours in total) during which participants have been guided in deepening their knowledge of specific mathematical topics through the use of GeoGebra as a tool for DCR-design. The first 2 meetings were devoted to introducing mathematical topics that participants had not faced at school, namely complex numbers and limits. The introduction of these topics was supported through the use and analysis of specific applets aiming at different goals (explanation, exploration, visualization, remediation, self-assessment). In this way, students experienced specific functionalities of the GeoGebra software, such as check boxes, input fields, sliders, drag and drop. In this initial phase, in order to make participants become familiar with the software, they were also guided in the creation of their first GeoGebra applet concerning the exploration of the function y=sin(x).

In the second phase (8 meetings), participants (in the following, SDs, acronym for students-designers) were asked to design and implement DCR through the creation of GeoGebra applets, choosing the mathematical topic on which they preferred to focus. SDs, who worked in small groups, were suggested to consider the difficulties students could face and to exploit the potentialities of the software to create DCR aimed at supporting them in overcoming these difficulties. This activity, which was the central one in the educational programme, was carried out in presence of tutors (university researchers), available to provide SDs with technical hints concerning software aspects, if necessary. Specific criteria for the DCR-design were not shared with SDs in order to enable them to identify their own criteria.

If we refer to the tetrahedron model to interpret SDs' activity within our educational programme, we can highlight specific new dynamics. In fact, while, usually, students are located in the S vertex of the tetrahedron and are mainly involved in the dynamics that characterize the S-M-T or S-M-D faces, in our programme students are located at the D vertex (as SDs) and the focus is on the D-M-T face. T represents the tutors, who has assigned to D the task of designing DCR, using digital tools to support the learning of the mathematical content M. Since the resource produced at the end of DCR-design will be, in turn, a task for other students, the meta-reflections developed by the students-designers enable them to become strongly involved also in the interactions that characterize the S-M-D face of the same tetrahedron (where S represents the hypothetical students for whom the DCR are designed).

Research aims and methodology

The main aims of this research are: (1) to characterize the praxeologies, developed by the SDs involved in our study, in relation to the task of DCR-design using the GeoGebra software; (2) to investigate how SDs interpret their experience of being both students and designers.

The data collected were: (a) the digital resources designed by SDs, (b) SDs' answers to a final written questionnaire on the process of DCR-design, and (c) a final audio-recorded semi-structured interview.

In this paper, we focus on the analysis of SDs' interviews. To characterize their praxeologies (first research aim), during the interviews, SDs were asked to describe the process of DCR-design (know-how level) and to justify the choices they made during this process (know-why level). In particular, they were asked to justify their choices by focusing on: the didactical objectives of their DCR (to review a topic, to assess students, to support recovering…); the potentialities and constraints of the GeoGebra software as a tool to support the design of their DCR (pragmatic value of the adopted techniques); the difficulties related to the mathematical content on which the DCR is focused and the ways in which the DCR-design could support the students' learning of this content (epistemic value of the adopted techniques). To investigate SDs' interpretation of their experience of being both students and designers, at the end of the interviews, they were also asked to assess their experience, by reflecting on its usefulness (or not).

The transcripts from the interviews were coded independently by the two authors, who identified specific excerpts useful to characterize both the know-how and know-why levels of SDs' praxeologies (research aim 1) and the ways in which SDs interpret their experience (research aim 2). Afterwards, codes were discussed in order to come to agreement.

Data Analysis

Characterization of students-designers' praxeologies related to DCR-design

Because of space limitations, we will focus on two SDs – Marco and Anna – and on their discourses about their design of a specific kind of DCR: a revision guide for a mathematical topic. We chose to compare the praxeologies of these two SDs because of their different previous experiences with GeoGebra and the different choices they made in relation to the mathematical topic on which to focus in the DCR-design. Anna had never used GeoGebra previously at school, while Marco attends to a school focused on digital technologies' use. Moreover, while Anna chose to focus on a mathematical content she already studied at school (goniometric inequalities), Marco chose a topic he studied for the first time within the educational programme (the comparison of infinities). During the interviews, Anna and Marco effectively re-construct their design, enabling us to characterize their praxeologies, related to the *common task* of designing DCR to support students in the revision of specific mathematical contents. Here we focus on common elements of these praxeologies.

In the excerpt of Anna's interview on which we focus here, she reconstructs the design of a DCR aimed at supporting students' revision of goniometric inequalities. In particular, the applet she created

(Figures 1A and 1B) is aimed at making students reflect on different possible representations of the solutions of the inequalities $cosx > a$ and $cosx < a$.

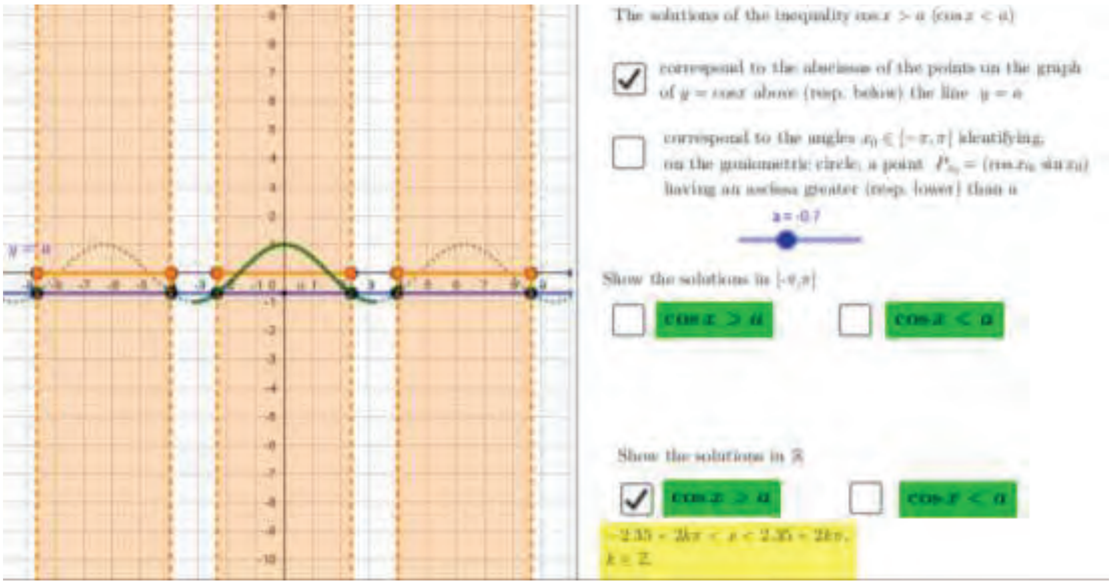

Figure 1A: The DCR on which Anna's interview is focused; the solutions of a goniometric inequality are represented as abscissas of points on the graph of the goniometric function $y = cos\ x$

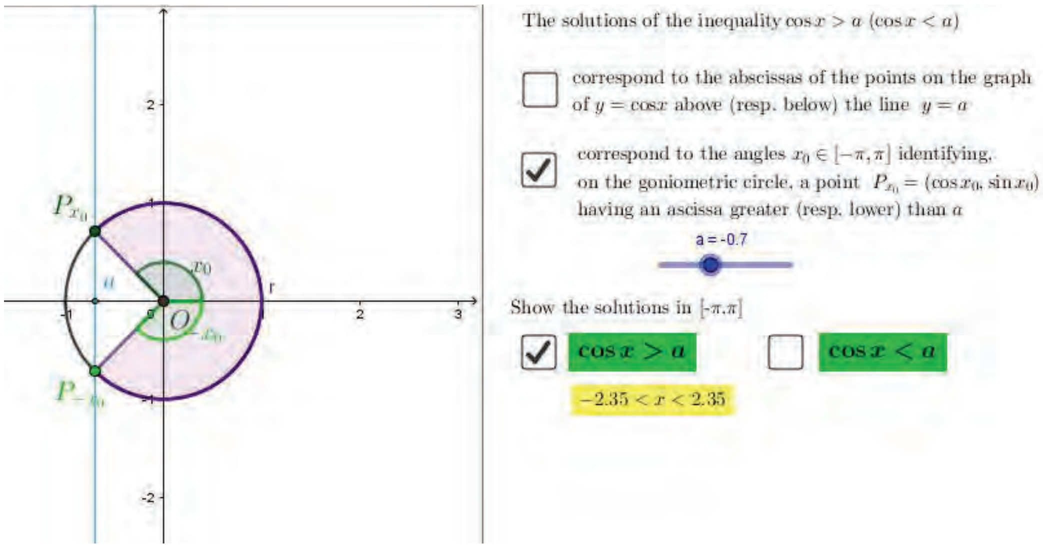

Figure 1B: The DCR on which Anna's interview is focused; the solutions of a goniometric inequality are represented as points on the goniometric circle corresponding to specific angles

In his interview, Marco focuses on his design of a DCR to support students' revision of the comparison of infinities in the study of limits. He created an applet (Figure 2) aimed at making students graphically compare the "ways" in which the functions $y = \log_a x$, $y = x^p$, $y = a^x$ and $y = x^x$ tend to infinity when the x variable tend to + infinity.

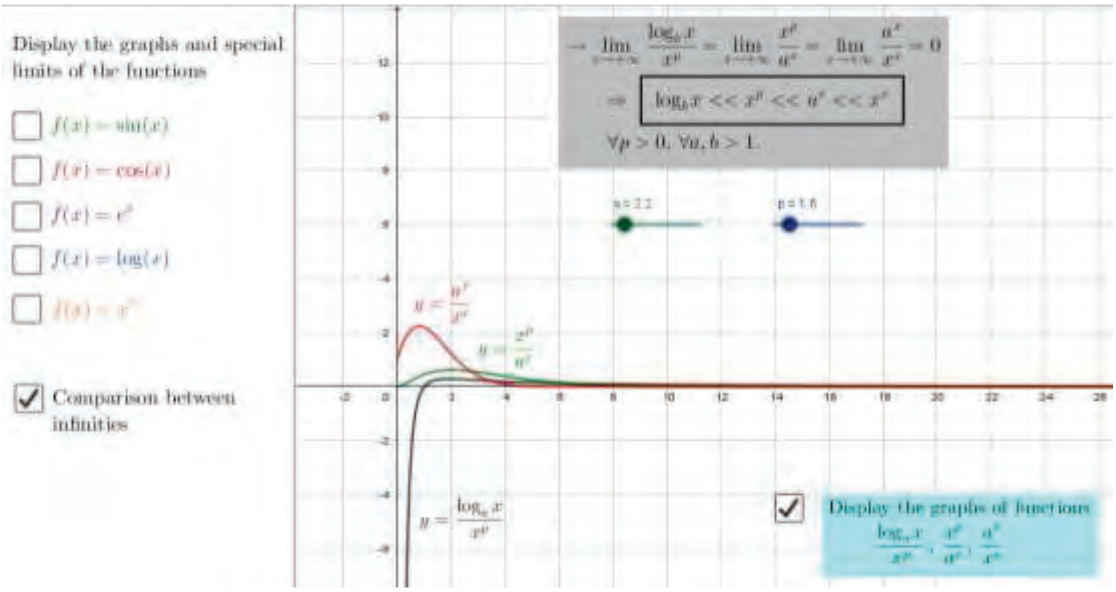

Figure 2: The DCR on which Marco's interview is focused

Even if they focused on different mathematical topics, the two students adopted similar *techniques* (*know-how level*) to face the task of creating revision guides. In their reflections, in fact, they stress on the importance of creating digital resources that enable students to: (a) choose the objects to display on their screens (different kinds of representations, graphs of specific functions, symbolic formulas…) and the order in which these objects are displayed; (b) see multiple representations at the same time and interact with them; (c) observe the effects of the variation and covarion of specific parameters using the sliders.

The use of these techniques is evident in both the DCR designed by Anna and Marco. Both students explicitly refer to these techniques in their interviews. For example, referring to *techniques (a) and (b)*, Anna declares that she has designed her DCR to enable students to choose the representation of the solutions of a goniometric inequality and also whether visualizing these solutions only in a range or across the whole set of real numbers (as in the Figures 1A and 1B). Marco refers to the same techniques when he stresses that, thanks to the design of his DCR, students can display different graphs at the same time and choose if visualizing the graphs of the functions $y = \log_a x$, $y = x^p$, $y = a^x$ and $y = x^x$ or the graphs of their ratios, that is of the functions $y = \frac{\log_a x}{x^p}$, $y = \frac{x^p}{a^x}$, $y = \frac{a^x}{x^x}$.

Both Anna and Marco inserted sliders in their DCR (*technique c*). Anna inserted a slider to enable students to explore different possible situations, according to the value of a within $cosx > a$ and $cosx < a$. Marco inserted two different sliders to enable students to visualize how the graphs of the functions dynamically vary according to the values of the parameters *a* and *p*.

When they justify these techniques (*knowledge level*), Anna and Marco focus both on the description of practical aspects connected to the DCR-design process (*pragmatic* aspects) and to the reflection on how these techniques could contribute in creating DCR that really support students in the learning process (*epistemic* aspects).

Both Anna and Marco stress that making students choose what to display (*technique a*) enables them to manage the information on which to focus. Anna, for example, focuses on pragmatic aspects when she declares:

> "[*this applet*] enables students to make graphs appear and disappear when they want, instead of visualizing them all together. In this way, there are not too many information, but only the information I require, so I can manage them".

In relation to the possibility of deciding the order in which to display information, she adds a reflection that shifts the focus on epistemic aspects, connecting the chosen technique to difficulties she experienced when studying goniometric inequalities:

> "It seems better to focus first on [*the solutions in*] an interval, so as to gradually introduce the periodicity. In the classroom, also, one of the main difficulties is to write the solutions with periodicity".

Marco also reflects on the epistemic value of technique *a*, when he explains how the teacher could use the DCR he created:

> "This exploits the potentialities of the software; [*the DCR*] has been designed for didactic purposes: [*the teacher*] shows the file and can show, for example, the cosine function first, then the parabola and this allows to give a further meaning to the concept of limit; the software allows you to show these things in the order you prefer and then allows you to explain".

Anna and Marco focus also on the potentialities related to making students work with multiple representations (*technique b*). Anna, for example, declares that her choice to adopt technique *b* in the design of her DCR was aimed "to give, to the users, the possibility to display all the representations of the solutions of goniometric inequalities". While Anna's reflection mainly refers to the pragmatic value of technique b, Marco focuses on the epistemic value of the same technique, by stressing that making students work with different representations enable them to give different meanings to mathematical concepts: "Give a new meaning, seeing limits, truly see them! It is something that this software enables to do."

When reflecting on *technique c*, Marco focuses on the role played by sliders as tools that support students' understanding, by enabling them to work with dynamical figures (pragmatic level) that represent classes of mathematical objects (epistemic level):

> "There are [*in my DCR*] classes of functions depending on sliders. This applet has been conceived with a didactical aim, so that a student who faces this topic for the first time, playing with sliders, can see how limits and classes of infinities change. It seems to me that it is like 'putting your hands in it', something more than seeing it in a 'sterile' way, within a textbook. This [*technique*] enables [*students*] to better understand what they see".

Anna justifies her choice of inserting a slider in her DCR by focusing on both pragmatic and epistemic aspects, since she observes that using sliders, differently from working with paper and pencil, enables students explore a wide range of possible situations (pragmatic level), interacting, at the same time, with different problems belonging to the same class of problems (epistemic level):

> "For the user, the sliders offer the opportunity to visualize and try different possibilities also in various points of the circumference and of the graph; if I had done it on a sheet [*paper and pencil*], I would have assigned a unique value to a [*the parameter in the inequality* $\cos x > a$], so there would have been less chance of comparison."

SDs' interpretation of their experience as both students and designers

When Anna and Marco are asked to assess their experience as designers of DCR, they both interpret the DCR-design as a particular problem-solving activity that enables the designer to reflect on aspects that usually are taken for granted. In this way, they highlight to be aware that the meta-reflections on the interactions that characterize the S-M-D face of the tetrahedron, which they developed thanks to the experience of DCR-design, have influenced their relationship, as students, with the mathematical content at stake. According to them, these meta-reflections gave to the designer the opportunity to autonomously discover, while facing the difficulties connected to the design process, key-aspects of knowledge construction. Marco, for example, declares:

> "It has been instructive, for me, to create tasks on these topics. In creating tasks, I learnt these topics. It has been a sort of problem solving where the problem is to create a problem. … At a didactical level, this work [*the DCR-design*] was very useful: putting your hands inside it, having to think about tasks … it seems to me that it is one of the best ways of learning a topic."

Thanks to their reflections on the dynamics characterizing the S-M-D face of the tetrahedron, Anna and Marco also have the opportunity to compare their experience as SDs with previous experiences as students. In particular, they contrast their learning through DCR-design, described as a "learning by discovery", with the learning realized through textbooks, described as a "pre-packaged learning", as testified by this reflection, proposed by Anna:

> "Creating resources from scratch was a completely new experience for me; I was used to textbooks, where exercises, and also theory, were ready-made. I found myself 'at the opposite side' with respect to those who study. It represented for me a new and more complete form of revising [*contents*]".

Final discussion

In this paper we have analysed the process of DCR-design in which a group of secondary school students have been involved during an educational programme carried out within a university context. The analysis we have performed, focusing on the reflections developed by SDs during the semi-structured interviews we carried out, has enabled us to reflect on the effects of DCR-design at two levels: (1) the level of students as designers; (2) the level of students as learners.

As regards level (1), the investigation of SDs' praxeologies has highlighted their capability of justifying their choice of adopting specific techniques in their DCR-design by clearly referring to both the efficiency of these techniques with respect to those adopted within a paper and pencil environment (*pragmatic value*) and the learning that each technique could support (*epistemic value*).

As regards level (2), the semi-structured interviews we have conducted have boosted SDs' reflections on the ways in which acting as designers could support the designers' learning itself, showing the effectiveness of activities aimed at fostering students' reflections on the dynamics that characterize the S-M-D face of the tetrahedron.

As a further development of this research, we are deepening our investigation of SDs' praxeologies related to DCR-design by combining the analysis of a-posteriori interviews with the audio and video-recording of the DCR-design process. We are also working on the re-design of the teaching methodology that characterized the educational programme to promote opportunities for SDs to share their reflections about their double role of designers and learners with their school mates, involving also their teachers in this process.

The role of dynamic elements in digital teaching platforms - an investigation of students’ reading behaviour

Anneli Dyrvold[1] and Ida Bergvall[1]

[1]Uppsala university, Department of Education, Uppsala, Sweden; anneli.dyrvold@edu.uu.se; ida.bergvall@edu.uu.se

The use of digital teaching materials in mathematics education has gained ground since the first introductions of various hard- and software. A distinguishing feature for digital teaching materials is the possibility to offer interactive and dynamic elements. In this study, eye-tracking is used to explore students’ reading behaviour when working with mathematics items in a digital environment. In particular, the focus is laid on how students read depending on the extent to which the items offer dynamic elements. Analysis of data from the eye-tracking in combination with students’ responses in the interviews provide a broad picture of different types of challenges that students may face in working with dynamic elements. The results also reveal that commonly used dynamic elements as films or feedback on given answers are valuable because users emphasize them as useful and informative.

Keywords: Mathematics, eye tracking, feedback, stimulated recall.

Introduction

New ways to visualise and opportunities to interact with mathematics provide learning opportunities that have proven valuable, for example in digital books that incorporate dynamic geometry applets (Radović et al., 2020) and in tasks with the ability to give feedback (Stevenson, 2017). In this study we use eye tracking to analyse students’ reading behaviour when working with mathematics items with five types of dynamic functions. Increased knowledge about what dynamic functions means for a student working with mathematics is valuable in relation to not only digital teaching platforms, but also other types of digital teaching materials.

Background

Dynamic functions in digital teaching material provide opportunities for learning not possible when printed materials are used. For example, Pohl and Schacht (2019) stresses the need for further research about new digital textbook elements. They contribute an empirical study of student use of textbook elements for the learning of mathematics, highlighting that these elements provoke new types of activities indicating that mathematical hypotheses may also be generated in new ways. In the contemporary rush to digitize there is also a need for awareness of potential shortcomings of digital materials. For example, writing mathematical equations may be harder than on paper and there is a risk of extended use of multiple-choice questions, something that can limit the readers opportunities to actively construct their understanding. Analyses of students’ interaction with digital teaching materials have revealed that digital materials contribute in determining how students engage in problem solving by reinforcing iterative strategies such as trial and error behaviours (Lantz-Andersson et al., 2009). Such strategies may impede learning if used instead of problem solving based on analyses of the task, which means that the manner in which students interact with digital materials is important. Digital teaching materials are for example argued for based on an intention to let students experience dynamic functions and to benefit from automatic feedback from the material. The possibilities to interact with dynamic media, enables an enhanced expressivity and the possibility that the technology functions as a collaborator rather than merely a tool or mediator, which means the mathematical activities become more participatory (Moreno-Armella et al., 2008). The expanded space of interaction in digital resources in contrast to printed (Pepin et al., 2017) implies a potential to play an important role in students' learning. Research also reveals increased learning when digital materials are used to achieve knowledge acquisition through active learning, for example in an interactive response system (Wang, 2020) or using a computerized training method to learn mathematics (Taleb & Hassanzadeh, 2015). An investigation of the effect of various types of feedback offered in digital textbooks revealed a low effectivity of the feedback regarding whether a correct solution was given after receiving the feedback (Rezat, 2019). The feedback did not lead to the desired results even if it was given stepwise in relation to further trials, and the author suggests further development of feedback in digital textbooks.

These previous studies give rise to the question about how students experience work with dynamic mathematics items and receive different types of feedback. In this study we make a contribution by using eye tracking to investigate students' encounters with digital items offering different types of feedback.

Eye tracking, theory and practice

A fundamental assumption when using eye tracking methodology is the eye-mind hypothesis; what you pay attention to and think about is associated with where you place your gaze (see Hoffman, 1998). This assumption has been questioned, and results also reveal that the gaze and the attentional focus sometimes diverge (Schindler et al., 2016). There are however convincing results about the correlation between the gaze and thought (Andrá et al., 2015). What is possible to measure is the students' gaze and how much, how often and for how long the gaze lingers on different elements in the text. Because a prerequisite for decoding and comprehension, the two components of reading according to Gough and Tunmer (1986), is to place the gaze on the text, the data is considered to reflect parts of the reading process. Based on the eye-mind hypothesis, the gaze is here interpreted as reading the multimodal and dynamic text elements in the analysed items.

In mathematics education research, eye tracking has proved to be particularly beneficial for studying processes, not outcome, and for research including aspects of visualisation and mental representation (Strohmaier et al., 2020) and because these descriptions hold for the current study the method choice is reasonable. The current study takes its starting point from a previous study revealing a limited use of dynamic and interactive elements in digital teaching platforms in mathe-matics (Dyrvold, submitted) which raised a question whether such elements should be used more. In the current study, eye tracking enables a comparison of reading behaviour depending on the offered dynamic and interactivity in mathematics items. Heat maps (visualising fixations) offers snapshots of students' reading that are easy to interpret, and therefore valuable in stimulated recall interviews.

Aim

The aim of the study is to achieve an in-depth understanding of reading behaviour in a digital multimodal environment: teaching platforms in mathematics. To enable analyses of which role variations in interactivity and dynamics plays for reading behaviour, mathematics items with elements that differ in those aspects were designed. These different element types are described in the Method section. Two research questions are posed; i) what do different element types mean for how a text is read?, and ii) how do students experience reading digital materials with different element types?.

Method

Three grade nine students (15 years old) with much gaming experience have participated in this study. The students were selected using a convenience sampling and were familiar with the interviewer. The students' previous mathematical achievements were unknown. Each student worked with five items in a digital environment, each containing one mathematics task, and their work was monitored using eye-tracking equipment. The items were designed to touch on areas of mathematics that are new to the students. The apt difficulty of the items was outlined based on a review of Swedish grade nine textbooks. At a later stage tentative items were further discussed and adjusted in cooperation with two teachers who are also experienced textbooks authors. All items had the same structure, consisting of three parts, an introductory text, a question and some essential theoretical content (hereafter called Theory), each part constituting an area of interest (AOI). The eye-tracking analysis was built on how the student's gaze moved between these AOIs (visualised as the four grey areas in Figure 1).

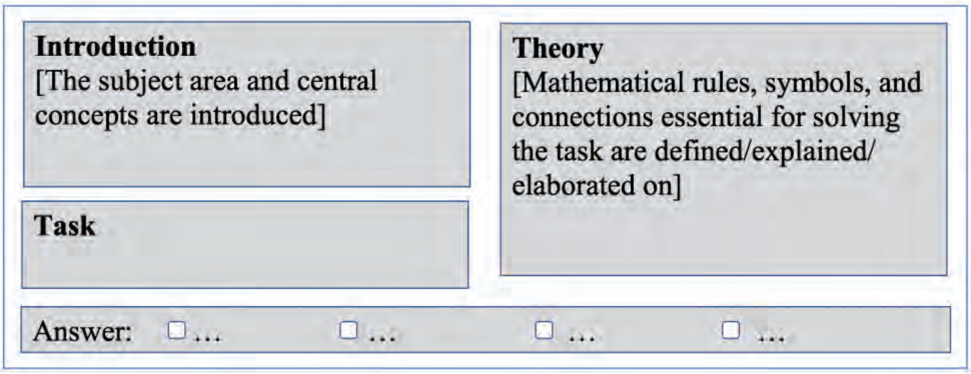

Figure 1: Basic design of the items and visualization of areas of interest (AOIs)

The intention was that the task should not be able to solve based only on the introduction; rather the Theory would be needed. The Theory is essential in the analysis because the type of elements (i.e. how dynamic and interactive) utilized in this section is altered between the items. With access to the information in the Theory, the intention was that the tasks could be solved without using paper and pencil. The Theory in each item was designed with a dynamic function, from one of five element types (ET) (Dyrvold, submitted). The element types with their characteristics are as follows: ET1, static presence: static content, e.g. similar to typed text in print; ET2, opted presence: static content opened by a click, e.g. a definition; ET3, dynamic presence: continuously dynamic but not interactive, e.g. film; ET4, dynamic feedback: dynamic and (instantly) interactive, e.g. to choose in a list and receive feedback; ET5, continuous dynamic feedback: continuously dynamic and interactive, e.g. by providing feedback when dragging.

The students were interviewed with stimulated recall directly after working with the items following a semi structured and pre-formulated interview guide, based on three main themes. The first theme took its point of departure in the question “What did you think about the items in general?” in order to capture the students’ general impression of the items and the various dynamic functions. The second theme concerned the question “Is there anything special that you thought of when you worked with the different types of Theory?” (Interviewer exemplifies if needed). After that, heat maps from the students’ work were shown to the students (visualizing main fixation points) and they were asked questions on their reading of the items and the five element types for example: “How did you think when you worked with this item”, “You looked at X for a long time/several times, do you remember how you thought or why you looked at just that?”, “When you see how you read the Theory, do you remember anything special?”, and finally “What are your thoughts about the various dynamic functions in the items?”. The interview leader was well known to the students, the interviews were recorded and transcribed verbatim, and then summarized using short notes. Analysing these two kinds of data together contribute to fulfil the aim of the study because the different data nuance and enrich each other.

Eye tracking analysis

The students’ readings were analysed based on the following analysis questions: (1) How appealing do the students perceive the different element types? (TFF – time to first fixation on the ET); (2) How do the students use the different element types? (Fixation duration (FD) on ET and total number of fixations (TNF) on the ET); (3) How do the students read the explanations in the Theory due to element types? (Fixation duration on introduction and on task in relation to ET ((I+T)/ET)

Time data from the eye tracking and short notes from the interviews with each of the three students were compiled and qualitatively analysed to gain insight into the relation between reading behaviour and experience of reading the text. The current study is to be followed by a larger quantitative study and results in relation to the current study will also be used to refine the method in the larger study.

Result

The results reveal both differences and similarities in how students perceive and read mathematics offered using different element types. There are not very distinct differences between how students interact with the five element types but if the element types are clustered according to level of interactivity and dynamics, some patterns occur. The results reveal both differences and similarities in how students perceive and read mathematics offered using different element types. There are not very distinct differences between how students interact with the five element types but if the element types are clustered according to level of interactivity and dynamics, some patterns occur.

Table 1: Overview of collected data about the element types for each participant

	Item 1:ET1			Item 2:ET 2			Item 3:ET 3			Item 4:ET 4			Item 5:ET 5		
	S1	S2	S3	S1	S2	S3	S1	S2	S3	S1	S2	S3	S1	S2	S3

Measures are given in seconds except TNF, which is given in number of counts

Results in relation to the two research questions about how the items are read and how students experience the reading are presented in themes, where each theme relates to both research questions.

Theme 1. There is a pronounced difference in how the students read an item with only static content (ET1) in contrast to items with dynamic and interactive content (ET2-5).

Less fixations and less time is spent on the Theory that is purely static. One student (S1) refers to the heat maps with ET1 saying “I read it [Theory] several times” and “The concepts were difficult and therefore I looked at the image [introduction] several times” indicating an experience of having engaged deeply with the text. Eye tracking data reveal that items with ET2-5 do generally reveal more fixations and totally longer summarized fixation time on the AOIs. The students’ experience from reading these items and reflections on the heat maps reveal several explanations to this pattern. Most prominent is utterances about joy and usefulness: “I liked the opportunity to drag” (S2) (see Figure 2), ”I thought it [receiving feedback] was good … because it shows that you understand” (S3).

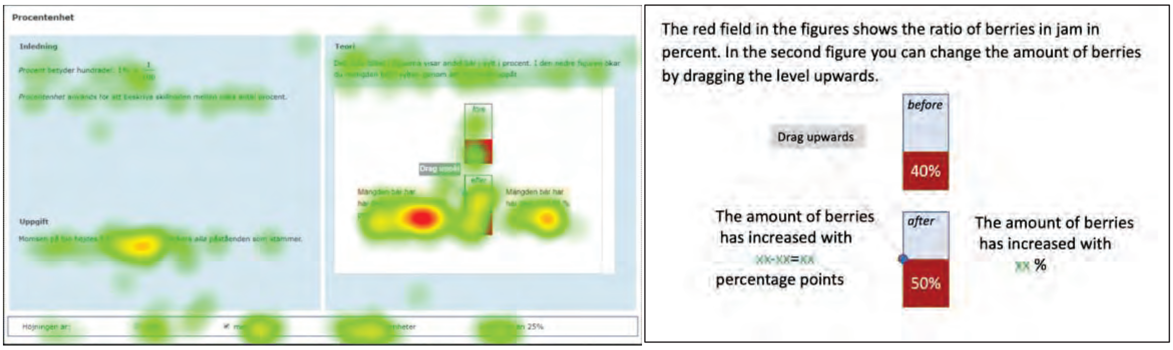

Figure 2: Heat map showing S2 dragging in ET5 and translated Theory part.

In the dynamic element (Figure 2) the green values on both sides on the rectangle changes dynamically when the level is dragged upwards. The translation of the introduction and task reads as follows: Per cent means hundredth 1%=1/100. Percentage points is used to describe differences between different numbers of per centage. Task: The VAT on cinema tickets increased from 6% to 25%. Tick all correct alternatives (19%; more than 50%; 19 percentage points; less than 25%).

Theme 2. Dynamic elements have a potential to evoke deep engagement in interaction, but there is also a risk of misunderstandings or omission in relation to the elements.

The eye tracking data reveal that the students fixate their gaze on Theory as a static page (ET1) or film (ET3) immediately (almost in every case within two seconds). In the Swedish context, these element types are something the students are familiar with. In the item with ET2, on the other hand, one student (S1) left the Theory unread for quite a time because the student did not realize that more content was offered behind a click. Another student (S2) referred to the same content as clearly presented and “fun” to be able to open. In the item with ET5 the invitation to interact with the material is by one student perceived as part of the task to solve, not Theory, “Because it was possible to drag, it made me think that it was part of the task” (S1), something that made the student a bit confused.

Theme 3. Some element types demand investment in time from the reader, but time spent on the element does not assure that the reader is engaged in a learning situation.

The eye-tracking data do rather clearly show that the students engage the most with the Theory presented as a film (ET3) or a continuously dynamic activity (ET5). If the reader does what is requested these elements have an inherent demand of persistence. A film may not make sense if not watched to the end, and a dynamic activity may leave questions lingering if not completed. In this study the participants invested the required time, and when that is the case, the content offered has a large potential to provide a fruitful learning situation. On the other hand, if for example a film is omitted, this learning situation is lost. The student with most fixations on the film (S2) watched the film twice and explained clearly the benefits with a film “It is easier to understand when someone is reading. Then you get help with symbols that are read”.

In addition to these results there were some differences between the participants’ reading and reflections about the items that call for attention because they highlight that there is no such thing as the best teaching material. The usefulness is to a large extent dependent on who the reader is and if a sound base material is offered, it provides a good fundament for a learning situation. The teacher is essential and discussions and other activities can contribute further to the individual use of digital teaching platforms. For example, one student (S3) explains that he missed the information “drag” when he read the item with ET5. He experienced the item as too difficult and did mainly struggle to get a grip on what was requested in the item. In this particular case, a discussion with a peer or a teacher could have clarified the intention with the item.

Discussion

This study is designed as a response to the current development of digital teaching materials. The current study contributes to this issue with insights about how dynamic and interactive elements can be used to boost students’ gain from interaction with digital materials. The results highlight students’ engagement with items that are dynamic and interactive but also some potential challenges. The analysis reveals both enthusiasm and engagement in the dynamic ETs, also for a minor addition of questions which return ‘correct/false’ directly, in the Theory (ET4). The positive result in relation to ET4 was not expected, since it is such a trivial addition to a static text. However, the same element type caused some quandaries because the questions signal to the students that this is the task to solve, not a part of an explanation.

Previous studies highlight that what students choose to engage with and how, in digital materials, is a factor worth taking into account when evaluating such materials (Lantz-Andersson et al., 2009; Bartelet et al., 2016), and the attraction to element types that offer interaction is notably on this issue. The students in the current study invested in the dynamic element types, also when the student “didn’t understand anything”, and such engagement must enhance the chance of learning. The persistence with which the students engaged with ET3 and ET5 was also surprising. The participating students are used to rapid activities in a digital milieu, which may cause restlessness, something that did not seem to affect the reading negatively. A lingering hypothesis is that previous rich digital experience may have fostered an ability to skim and to use split vision in a fruitful way. Such an ability could explain that students with many fixations and a high fixation duration on the ET also had high values for the AOI on introduction and on the task. The question remains to investigate further.

In this study the combination of eye tracking data and students' reflections on their reading behaviour constitute rich data useful for in-depth analyses. The number of quantitative measures may falsely signal an intention to generalise about relations between reading behaviour and particular element types, which is not our aim. These measures are, in the current study, meaningful in relation to the interview data, because reading behaviour differs between readers and also depending on the intention with the reading. It is also important to be aware of the difference between the five items, both regarding representations and mathematical complexity. This means the reading experience may differ more regarding other aspects than the ETs between the items, and accordingly comparisons between the reading of ET1-5 must here be done very carefully. A limitation in the current study is also that the items are designed to suit the set up with quantitative analyses using eye tracking equipment and therefore the dynamics and interactivity is only found in the Theory.

Visualisations such as heat maps are often criticised for being just 'eye candy' but when used to replace read aloud protocols this kind of data is very useful because it aids the students in recalling their solution process. The interviewed students were, aided by the heat maps, able to give rich descriptions of how they experienced the items depending on element type in the Theory. A refinement of the interview guide will however be made in relation to the heat maps because the students were very prone to describe what they saw, not their thoughts when they read or reasons behind the reading pattern. The results are applicable not only in relation to digital teaching platforms but for all types of digital teaching materials in relation to the extent they incorporate dynamic and interactive elements and functions.

Rethinking resource conceptualization in times of pandemic and earthquakes: What is important for (mathematics) education?

Dubravka Glasnović Gracin

University of Zagreb, Faculty of Teacher Education, Zagreb, Croatia; dubravka.glasnovic@ufzg.hr

The conceptualization of resources provided by Professor Jill Adler distinguishes between basic resources, human, material, and social and cultural resources. In 2020, a year of the COVID-19 pandemic and lockdowns, Croatia dealt with another huge challenge: several big earthquakes struck the Zagreb area and its surroundings. These catastrophes had an effect on education in general as well as within mathematics education. The study presented in this paper refers to a teachers' view on the stabilities and changes in basic, material and non-material resources in a period of time marked by the pandemic and earthquakes. The participants highlighted internet connection and physical interaction as important resources for (mathematics) education. The study results indicate the dynamic nature of the resources within the resource systematization; their significance changes under different circumstances.

Keywords: Resources, mathematics education, pandemic, earthquake.

Introduction

Resources surely play an important role in mathematics education. Teachers and students use and adapt a wide range of resources for teaching and learning mathematics. Although the research was focused to a large extent on material resources such as textbooks (Fan et al., 2013), non-material resources such as human resources also proved to be important in learning and implementing innovations (Black & Atkin, 1996). These various types of resources, material and non-material, raised the need for their conceptualization within mathematics education (Adler, 2000).

The research on resources has so far encompassed different cases from different countries (Trouche et al., 2019). In this paper, the focus is on the issue of how the resources for (mathematics) education change in times of natural catastrophes. The context that gave rise to this issue lies in the circumstances of the pandemic in 2020 and the several big earthquakes that struck Croatia in the same year. According to the United Nations report (United Nations, 2020), the COVID-19 pandemic "has created the largest disruption of education systems in history" (p. 2), encompassing closures of schools and other learning institutions. On 16 March 2020, the Croatian government mandated the closure of schools and introduced remote teaching with provided solutions for the use of various ICT tools (Ministry of Science and Education, 2020). These solutions ranged from television schooling to online chat groups and virtual classroom platforms (Ristić Dedić & Jokić, 2020).

Soon after this first lockdown, on 22 March 2020, Zagreb was struck by a 5.5 magnitude earthquake which damaged many buildings in the Croatian capital, including schools and faculties. It was followed by numerous after-shocks, and then on 29 December 2020 an earthquake with a magnitude of 6.6 struck Petrinja, 45 km from Zagreb, causing thousands to lose their homes and the destruction of many buildings, including schools. These circumstances meant additional changes had to be made to educational practices in Croatia, including the use of resources important for teaching and learning mathematics. For example, the school building itself is considered as a basic resource (Adler, 2000). But what if the school is destroyed or the students and teachers cannot enter it because of restrictions due to the pandemic? In these circumstances the school building loses its significance as a basic resource and is replaced by other resources, such as internet connection and computer.

The abovementioned catastrophes from 2020 raised issues on how they affected the use of resources for teaching and learning mathematics in compulsory education. The study presented in this paper therefore raises the following question: What material and non-material resources for mathematics education were used or highlighted as important by teachers in times of pandemic and earthquakes? How were they used?

Theoretical framework

Adler (2000) conceptualized resources as an important issue for mathematics teacher education, indicating that resources refer to anything likely to re-source the practice of mathematics teachers. The author categorized resources as basic, human, material, and social and cultural (Adler, 2000). Basic resources are "necessary for the maintenance of schooling" (p. 209), such as buildings, water, electricity, but also to basic teacher qualifications. Human resources refer to teachers and their knowledge-base, parents, colleagues and collegiality. Material resources include school mathematics materials (textbooks, educative software, etc.), technologies (e.g., computers, chalkboards and tablets), mathematical objects (e.g., proofs, lumber lines) and everyday objects (e.g., money, newspapers). Social and cultural resources refer to language (e.g., verbalisation, communication) and time (e.g., timetable).

This classification, which encompasses a wide spectrum of resources, from basic, to material and social, raises the question of their stability in different circumstances. Adler (2000) claims that "the effectiveness of resources for mathematical learning lies in their use, that is, in the classroom teaching and learning context" (p. 205). In this study, the aim was to find out what different kinds of resources the participating teachers used and considered important for teaching mathematics during 2020, and in what way.

Methodology

In order to examine how the use of resources for mathematics education change in times of natural catastrophes, a qualitative approach was chosen. The case study focused on compulsory education (grades 1-8) in the Zagreb area. The study involved two teachers from two schools in Zagreb, one of primary grades (in this text named as Teacher Zg1) and one of middle grades (named as Teacher Zg2). These teachers were chosen because both their schools were damaged in the Zagreb earthquake in March 2020 and they both have 25 years of teaching experience and therefore they can express and compare the phenomena of schooling before and during the new circumstances. Primary grade teachers in Croatia teach six different subjects to their class in grades 1-4, one of the subjects is mathematics (4 lessons per week). In middle school (grades 5-8), mathematics is also taught 4 lessons per week. The study encompassed a qualitative approach, using semi-structured interviews. The intention was to get a better in-depth insight into the participants' views and teaching experiences in 2020. The interview questions and outlines follow the participants' use of resources during 2020 regarding Adler's (2000) conceptualization of resources: Explain how (mathematics) education was organized in 2020 in your school. Did it undergo any changes after the earthquake? The semi-structured interview further contained outlines on basic resources (What resources were crucial for teaching in 2020, i.e. resources without which schooling wouldn't be possible); human resources (What knowledge and competencies did you need to have? What was the role of parents? What about the collegiality of teachers – did this change in any way? What about the collegiality of students?); material resources (Describe the technology issues for mathematics teaching in 2020. How did you use textbooks and other school materials?), and social and cultural resources (Describe the educational issues connected to language and communication in mathematics education in 2020. How does time management in 2020 compare to the previous period?)

The interviews were conducted during 2021. The interview transcriptions were analysed according to the qualitative content analysis methodology, using codes that are in line with Adler's categories.

Results

The findings showed different resources important for mathematics education in 2020. In this section, the results are organized according to the categories provided in the methodology section.

Basic resources

Both teachers highlighted internet connection and computers (or tablet, laptop, cell phone) as basic resources for teaching and learning in 2020. Still, there was a problem with these resources because these were not equally available to each student.

> Teacher Zg1: They (students) had to have a computer and internet at home. (...) I said, if it is possible, somehow, not to use a mobile phone, because it was difficult for them. It was no good, they couldn't see well on Zoom.
>
> Teacher Zg2: They all got tablets, this generation got them within the curricular reform process. (...) Internet... That's another story, many of them really did not have internet access so they used SIM cards provided with the tablets, which needed to be loaded. But the parents did not know how to do it ... it was difficult.

These results imply that the new circumstances may lead to changes in basic resources, showing their dynamic and changeable nature. As seen in the interview excerpts given above, the school building was no longer considered a basic resource; the key basic resources in 2020 were internet access and computers.

Human resources

Human resources (teacher, parents, cooperation with colleagues) are also found to be important educational resources in these new circumstances. Still, teachers had to possess the additional competencies necessary for remote teaching. Besides digital competencies, participants highlighted adaptability and resourcefulness.

> Teacher Zg1: Well ... digital competencies, I mean, IT literacy, resourcefulness. (It required) a different, I mean really different, approach.
>
> Teacher Zg2: I thought I'd manage it, because we mathematicians can usually handle the technology a bit better than other teachers, especially primary teachers. (...) In fact, we handled it on our own.

Both participants found support in cooperation with their colleagues, particularly in the first weeks of the lockdown.

> Teacher Zg1: When we got the announcement about online schooling, we had a meeting in school. Our IT teacher asked if anyone wanted to create a class web page. We all (colleagues) looked at each other, and she showed us how it should look. (...) We were given support (by the IT teacher) and really we managed the technical issues together at first. After that, we managed at home on our own.

Also, teachers' informal groups were helpful, such as Facebook or WhatsApp target groups.

> Teacher Zg1: I must say that we were on Facebook, I was in the teachers group (...) teachers were giving video lectures on how to work. These were teachers who had already had experience with some projects. But that was own-initiative, not connected to the Ministry. (...) About the Ministry, here, I can't say that we got any support.
>
> Teacher Zg2: Besides being left school-less, we also didn't have anywhere we could actually meet, and that was not ideal. But the solution was our joint WhatsApp group... where we asked each other things...

Assistance from human resources could be therefore divided into two parts by both participants: the first approximately two weeks, when they strongly relied on colleagues and IT teachers, and the period after that, when the participants mainly used their own resources and learned on their own. In the first time period, both participants used non-simultaneous teaching, using videos and other materials that they had prepared or found. After that, both participants realized that lessons in real time with students were a better solution. These findings highlight the dynamic nature of the resources used over time.

Parents are also important human resources in the process of education, and the cooperation of parents, teachers and students is found to be crucial in these new circumstances.

> Teacher Zg1: Yes, (this cooperation) was more intensive in the first one to two weeks, until the parents figured it out. They were very upset. (...) Until we overcame the technical issues, we were in touch really a couple times a day.

Unlike the primary teacher, the middle school participant complained that the remote teaching decreased the quality of communication with parents.

> Teacher Zg2: Parents' engagement was surely greater (than before the lockdown) ... but for me the bigger problem was that the online teaching significantly decreased the quality of communication with parents. (...) I found that really hard, and it continued into the next school year. Well, I didn't see the parents for such a long time, we talked over the phone, but that was not good. Everything was so distant...

The results on human resources presented in the study highlighted not only the dynamic nature of resources over time (the use of different resources before and after the lockdown), but also the dynamics across the resources. For example, the change in basic resources (internet access and computers in remote teaching) led to changes in human resources (e.g., the need for digital competence in teachers and parents, and different types of communication between teachers, students and parents).

Material resources

Material resources, as perhaps the most visible type of resource for teaching and learning mathematics, also underwent changes. As computers and internet access became basic resources, school mathematics materials mainly turned to ICT, making the importance of teachers' digital competence even more apparent. The results given within human resources showed that in the first two weeks the participants tried to provide teaching which is not given in real time. In this period, different material resources were used (videos, educational web pages with various educational links and texts). In the second phase, the participants realized that e-teaching in real time was better for them and for their students.

Teacher Zg2: During the first days I was personally preparing materials which were sent to pupils. These were textual materials, mostly with links to various videos ... I did not make videos. I know that many of my colleagues did, but I thought that there was no need to because there are so many existing materials. (...) But, afterwards, with time, I moved on to live meetings... I have a laptop with a touch screen (...) From that moment it was like I was reborn.

Teacher Zg1: Firstly, I used to record (videos) until 1 or 2 in the morning... recording my voice with the presentation simultaneously. But then I realized that it's better to make a presentation, long division and mathematical content that they find difficult ... to make a presentation with animations and then to go through it together with the pupils.

During the second phase, the participants also used e-textbooks, presentation tools, quiz applications and other educational software.

Teacher Zg1: And Wordwall... every day I gave them a task at the end of the lesson, a quiz. (...) We also used Matific, it's great, and it proved to be very good for us. We promptly had access to the results and the ranking list.

Teacher Zg2: Platforms provided by Profil (the publisher), online textbook, GeoGebra of course, because there is a lot of material provided in GeoGebra ... (...) Online textbooks helped a lot.

These two phases highlight both of the aspects of the dynamic nature of resources: over time and across the resource types (different phases required different human and material resources).

Even in these new circumstances, it can be said that the participants tried to conduct online lessons which are structurally similar to their lessons before the lockdown. Zoom lessons in real time encompassed following the teacher's actions via the screen, and the students had to use their tangible textbooks, notebooks and pencils, as they would do in the classroom. Also, they used everyday objects for learning mathematics.

Teacher Zg1: They (students) always readily had all materials, manipulatives, textbooks, as well as notebooks. (...) Children had to prepare for mathematics lessons, we set that up, some candies or pencils, so that they can do division. In that way, we started from concrete objects and did a lesson motivation. We improvised and tried to make them to come to new knowledge through discovery.

Teacher Zg2: They used their notebooks a lot. (...) They had their textbooks available, and I would open the online textbook, and I sketched on it if necessary, some illustrations, some drawings, especially if we were doing geometry.

The Ministry of Science and Education provided TV-school every day on national TV and on two other TV stations. In this way, the lessons for each subject and each grade 1-12 were covered. These lessons were recorded and could be watched at any time on the Ministry website. Nevertheless, the two participants in this study did not utilise them in their teaching.

Teacher Zg1: But mainly the mathematics (provided by TV lessons) did not correspond to my plan and programme. Therefore, in fact, I did everything myself.

The other participant did not mention TV schooling at all.

Social and cultural resources

Remote teaching also brought modifications in the usage and importance of some non-material resources for teaching and learning mathematics, such as time or verbalization and communication. When it comes to communication, remote teaching made clear the difference between uni-directional and bi-directional communication with students. Uni-directional communication was shown through the web pages on which participants put links and materials for their students. Bi-directional communication with students was conducted through WhatsApp groups, MS Teams or Zoom live meetings. Both participants highlighted the role of bi-directional communication as an important resource for learning. They stressed calling on students to answer a question or make a response as being particularly important in mathematics education.

> Teacher Zg1: So that each pupil participates somehow, so that I can call on each of them, even if I only saw them on the screen.
>
> Teacher Zg2: So, in this way (with Zoom meetings) actually, I think, we "saved" the school year. I would ask a student to tell me what I should write down (on the touch screen).

Remote teaching implies students separated from their teachers, in recent times mainly using computers. Still, the participants highlighted direct student-teacher contact as the non-material resource which they missed the most. For them, it was important for social, psychological and pedagogical reasons, particularly in the early grades.

> Teacher Zg1: Absolutely I missed it (direct contact). Touch as well, teamwork ... all that interaction was somehow lost in the digital environment. (...) Exactly, the contact with children. Well, education is a live process. (...) Nothing can compare with live contact teaching, no way. In other subjects, too, but in mathematics especially. Because that contact with children ... to see in their eyes if they understand or not, discovery learning, I think that it can't be realized that much through Zoom on the screen. And somehow, they can't concentrate so well in that way.

Language is also an important resource for mathematics education. Teacher Zg2 claimed that in particular textual tasks were neglected in her remote teaching in 2020.

> Teacher Zg2: In online education, I could not include many textual tasks, because the students did not manage to master even the simple routine tasks. Because everything was different, slow... a lot of waiting for a connection (...) everything was slower.

This quote brings us to another important non-material resource: time. The participants complained that remote teaching takes a lot of time, both for preparing lessons and during lessons.

> Teacher Zg1: Since we (teachers) were not skilled, we always needed more time. I would, for example, record a video lesson 20 times, and I still wasn't satisfied with it. (...) It took a lot of time, and I think it was not as effective as the live teaching.
>
> Teacher Zg2: Still, searching for a suitable video or illustration took a lot of time. So, in the first days I was sitting in front of the computer from the morning until the evening...
>
> Teacher Zg1: Everything (during the lesson) was so slow, the tempo was much slower. (...) The students did not manage to do the tasks. Exercises, revisions – these parts we missed the most. We needed more time because everything was so much slower.

These quotes also reveal the dynamics and interconnectedness of the different types of resources: as the basic and material resources switched to ICT, and teachers, parents and students were "not skilled" (human resources), the whole process of education needed more time (socio-cultural resource).

Interestingly, it seems that the study highlighted another important non-material resource in remote teaching – pedagogic intentions during the lesson. Pedagogic intentions (such as discovery learning, teamwork, calling someone out to the board) were a challenge in remote teaching.

> Teacher Zg1: We couldn't manage the teamwork. (...) And so, it was not comparable with contact teaching when everyone has it on their desks ... when I see them all and have complete control, I can lead them through their discovery learning.

Discussion and conclusions

The study presented in this paper showed the dynamic nature of the resources within their systematization (Adler, 2000), because their significance changed under different circumstances, particularly in terms of remote teaching. The school building was no longer considered to be a basic resource; the most important resources for the maintenance of schooling in 2020 were internet access and computers. Teachers' knowledge-base (human resource), including new digital skills and resourcefulness, were highlighted as very important by both participants. Material resources were mainly leaning on IT (internet mathematics materials, videos, e-textbooks, educational software, Zoom lessons in real-time, etc.). Social and cultural resources highlighted by the participants were bi-directional communication and time. The two teachers most missed some important pedagogical intentions, such as discovery learning and teamwork.

Although recent research has focused on the teachers' experiences from contact to remote teaching (e.g., Azari & Fajiri, 2021; Mullen et al., 2021), the study presented in this paper considers this transfer from the standpoint of resources as the focus. Such a view revealed that the dynamic nature of resources was manifested in two aspects: dynamics over time, and dynamics across the different types of resources. Dynamics over time refers to the use of different resources before and during remote teaching, within the categories introduced by Adler (2000). Dynamics across the resource types refers to how the changes necessitated in the basic resources brought about changes in the other resources, i.e. the human, material and socio-cultural resources. Adler (2000) highlights that "mathematics teacher education needs to focus more attention on resources, on what they are and how they work as an extension of the teacher in school mathematics practice" (p. 205). This study may bring new insights into the individual teachers' experiences with resources in times of pandemic and earthquakes.

The findings showed that the participants tried to align remote teaching to their "old habits" in teaching, trying to keep the teaching structure and resources as they were before the lockdown. This result indicates that the transition from face-to-face contact to effective remote teaching is a sensitive process that requires more attention and teacher education. Mullen et al. (2021) highlight "that this process does not always respect the transformational nature of the transition, and that the recontextualized use of essentially unaltered traditional pedagogies might not be the best response" (p. 4). It particularly stresses mathematics teaching because it requires corrective feedback, multi-modality, and specific devices suitable for writing mathematics (Mullen et al., 2021). On this issue, general and specific support from authorities is very important because "teachers need competence in managing learning that is different from before the COVID-19 pandemic" (Azhari & Fajiri, 2021, p. 13).

The study presented in this paper is a qualitative study, which had no intention of generalizations. However, future research may encompass a larger quantitative study with more participants from the Zagreb area. The comparison of findings in Zagreb and other regions or countries may contribute to isolating the issues related particularly to using resources in times of earthquakes, unrelated to the pandemic. Further, Adler's (2000) conceptualization of resources refers to the perspective of mathematics teacher education. It would be interesting to look at the students' perspective in using resources as well (Glasnović Gracin & Jukić Matić, 2021).

Investigating curriculum resources and mathematics knowledge for teaching in teacher planning discussions

Marcus Gustafsson[1], Jorryt van Bommel[2] and Yvonne Liljekvist[3]

Keywords: Mathematics teachers, curriculum resources, MKT.

The research topic

This poster reports on the design of a study that will be conducted in the fall of 2021, with the aim to create more knowledge on in-service mathematics teachers' use of curriculum resources. Our research questions are: what types of resources are used, in what way, and for what reasons? The data in the study consist of audio-recorded collaborative teacher planning discussions in Sweden where, just like in other countries, new teaching resources (digital and analogue) have made their way into practice the last decade. It is of interest to explore how these resources are used together with existing resources, particularly as the Swedish curriculum offers and leaves teachers with large freedom in choosing their teaching resources.

The Design Capacity for Enactment (DCE) framework (Brown, 2009) describing resources use and Mathematics Knowledge for Teaching (MKT) (Ball et al., 2008) will tentatively be the frameworks used for analyzing these discussions.

Theoretical background

Teachers participate in several different communities of practice (Lave & Wenger, 1991). One such community can be collaborative planning, where teachers together discuss matters of teaching in-between enacting lessons, either casually or more organized with specific common goals.

While planning lessons (individually or collaboratively) teachers draw upon different curriculum resources as well as their experience. When it comes to teachers' use of these resources in the practice of planning for and enacting teaching, Brown (2009) has proposed the DCE framework that connects curriculum and teacher resources, as well as different types of use, such as offloading, adapting, or improvising.

Brown's model emphasizes different types of resources. Each resource can incorporate different aspects relevant for teaching mathematics. These aspects can be labeled using the teacher knowledge domains in the MKT framework (Ball et al., 2008): *Common Content Knowledge (CCK), Specialized Content Knowledge (SCK), Horizon Knowledge (HK), Knowledge of Content and Students (KCS), Knowledge of Content and Teaching (KCT)* and *Knowledge of Content and Curriculum (KCC).*

In short, CCK can be described as the mathematical knowledge needed to teach, for example correct mathematical concepts and language, or to know if a calculation or statement is correct or not. SCK helps to connect, deepen and analyze different mathematical concepts, used in teaching. KCS relates to students through, for example, knowledge on common mistakes or thinking in relation to a mathematical content. KCS can help identify student thinking from spotting a mistake, and KCT in its turn, helps in choosing a suitable response to the student, or to guide the teaching of that content in general. HK is about knowledge on how mathematical concepts are related and connected. Parts of HK are closely intertwined with KCC, which corresponds to knowledge about the conditions for teaching mathematics in school, such as how the curriculum defines the mathematical progression through its sequencing, or the subjects' connections to other subjects.

Method

A previous project examining mathematics teachers' communities of practice, has generated recorded data from upper-secondary school mathematics teacher discussions. Around ten of these discussions from three different teacher groups with about five teachers in each, ranging upwards 60 minutes in length each, concern the planning of lessons covering a variance of upper-secondary school mathematical content. These planning discussions will be transcribed and analyzed through content analysis, with a deductive approach. The analysis of the discussions aims to describe the practice of teachers in terms of types of knowledge used within this planning context, using the domains of the MKT framework (Ball et al., 2008) for the description of types of knowledge and aspects of Browns' DCE framework (Brown, 2009) for the types of resource used.

Possible results and implications

Based on a preliminary analysis, an asymmetry regarding what domains of the MKT framework that are being visited during these planning discussions, is expected to be found. Further, an asymmetry is expected to be found in the types of curriculum resources that are being used. There is also a possibility to investigate whether certain types of resources associates with certain domains of MKT. This can help to create new knowledge on what kind of support teachers need from curriculum resources, both in content and style. The poster will set out the design for the study and following the analysis conducted during the fall 2021, some of the results will be possible to include at the CERME12 conference.

Online feedback designed to support self-reflection while solving fraction example-eliciting tasks

Amal Kadan-Tabaja[1] and Michal Yerushalmy[2]

[1]University of Haifa, Faculty of Education, Israel; math33444@gmail.com

[2]University of Haifa, Faculty of Education, Israel; michalyr@edu.haifa.ac.il

Feedback as a personal metacognitive tool can be effective only if learners respond to it by self-reflection on their learning process. A central challenge of the online assessment platforms is to develop ways that guide students to self-reflection. We report on a study involving a dedicated design pattern of a pair of complementary example-eliciting tasks designed based on the logic-of-yes and the logic-of-not principles. Each task, presented as an interactive diagram, requires constructing examples of fractions and classifying them using a given set of characteristics. The set was given to students in a personalized report and used to automatically analyze their work. We explored whether and how the design supports 5th-grade students' learning the topic of fractions using online resources. We analyzed task-based protocols of one pair of tasks, aiming to identify connections between the design patterns and students' self-reflection, performance, and metacognitive skills.

Keywords: Feedback, self-reflection, example-eliciting tasks, metacognitive, task design.

Introduction and theoretical background

Feedback is considered as one of the most powerful ways of supporting learning processes (Hattie & Timperley, 2007) and developing metacognitive skills, but it should not an effective tool if students fail to consider it or do not engage with the information they receive. Shute (2008) pointed out that elaborated feedback, which addresses the topic, response, particular errors, and examples, and provides guidance toward a correct answer, appears to enhance students' learning more than other types of feedback. Shute's review indicated that presenting too much information may result in superficial learning and invoke cognitive overload. Even a comprehensive design of assessment and how it is being reported cannot support the learner or lead to self-assessment unless metacognitive reflection skills of planning, monitoring, and evaluating follow (Ruchniewicz & Barzel, 2019). In this study, we distinguish between two meanings of feedback. Feedback as an object, which refers to the contents of feedback itself (the information), and the feedback process, which describes the student's interactions with the task and the feedback information.

Ruchniewicz and Barzel (2019) investigated feedback as part of autonomous learning and explained how it turns into a process, in which learners make sense of information about their work to improve learning strategies, metacognitive skills, and future performance. Following their study, we designed tasks that require constructing examples with an interactive diagram and characterizing the construction using a given set of statements that the student is asked to reflect upon as part of solving the task with feedback. In our study, the feedback was automatic, and the set of statements used to automatically analyze the submitted constructions appeared in the personalized reports given to students. Arzarello and Sabena (2011) proposed two types of inquiry logics to be considered when designing tasks to help students in inquiry-based knowledge acquisition: the "logic of yes" (LoY), which leads students to empirically test their examples, and the "logic of not" (LoN), guiding students to an indirect validation of an example by attempting to argue the impossibility to find a counterexample. These designs should lead students to explore, observe facts, and ask and answer questions to discover connections between them (Arzarello & Sabena, 2011). Following these inquiry logics, students in our study were requested to reflect on their examples before submitting them.

Fractions are a central topic in the mathematical curriculum. Learning the concept of fractions poses a significant challenge to students and has been for a long time a focus of research of the mathematics education community. Arnon, Nesher, and Nirenburg (2001) studied and reported on fifth graders who learned with the Shemesh software, which was designed to promote conceptual learning of equivalent fractions, offering concrete representations of the fraction and the operations performed on it. The current study, based on a similar representation, uses the Seeing the Entire Picture (STEP) platform. STEP is a formative assessment environment that involves the student with automatic information analysis of rich example-eliciting tasks (EETs). EETs require students to formulate an example and present it by submitting one or several constructions based on an interactive diagram.

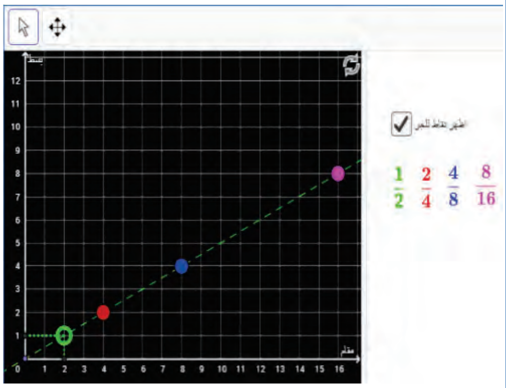
Recently, online platforms have been offering ways to obtain rich and varied evidence that enriches learning assessment. Traditionally, automatic assessment provided judgmental reaction, verified the correctness of information, and often suggested tasks for students to perform to achieve better results (Scalise & Gifford, 2006). With STEP, the automatic analysis generates information about the correctness of the task, but its main objective is to analyze the work according to other mathematical and pedagogical characteristics, which were defined when the task was designed and were individualized to report back to the student. These include methods of work, misconceptions or common mistakes, and the diversity of the example space (Olsher, Yerushalmy, & Chazan, 2016). The platform automatically points out whether or not the characteristics are present in the student's submissions. We refer to the interactions of the student with the activity – the task requirements and the automatic report – as the "online personalized feedback" process. The novelty of this study lies in the interaction of the online personalized feedback process with the task design to lead students to self-reflection and examine their performance in three areas: (a) the correctness of the answer, indicating whether the example meets task requirements and conditions; (b) the metacognitive skills: planning problem-solving goals, strategies, and allocating resources; monitoring what has been achieved to set goals of comprehension and performance; and evaluating the assessment of given problems or understanding of mathematical concepts, for example, through self-reflection (Ruchniewicz & Barzel, 2019); and (c) the richness of the personal example space, as the collection of examples to which an individual has access at any moment (Liz, Dreyfus, Mason, Tsamir, Watson, & Zaslavsky, 2006, p. 133).

We ask whether the interaction of the online personalized feedback process with the task design results in self-reflection and better performance on the part of the students. We studied the potential of task design that explicitly requires students to conduct a reflection on their work. This reflection should be made explicit by analyzing (a) student`s checking and marking all the useful listed characteristics that they have encountered already in the previous automatic report; and (b) student`s submitting of answers that meet as many (logic-of-yes) or as few (logic-of-not) possible characteristics while working on two consecutive EETs on the topic of fractions. Our research question was: Is the special design of a complementary pair of EETs reflected in the students' self-reflection, performance, and metacognitive skills, and if yes how?

Methodology

Research setting. To explore the effect of task design on student performance, we designed tasks for which the feedback process is part of student self-reflection, and conducted an empirical study of the way students engage with such tasks. Two students, aged 12 years, participated in this study. They shared one computer while solving the tasks. In the instructions we provided to student before they start working on the tasks, we encouraged conversation and a think-aloud process. We transcribed the students' segments of discussion and analyzed them qualitatively to find evidence of connection between the engagement with the task design principles and the students' self-reflection, performance, and metacognitive skills. The students had learned fractions according to the national curriculum in a regular classroom. They were presented with a sequence activity of four tasks and given 45 minutes to complete these tasks delivered on STEP. Following each task, five sets of mathematical characteristics were used to automatically analyze the work, and the feedback was given to the students as automatic report. For the second and third tasks, students were asked to characterize their example using this set of characteristics.

Construction part



Automatic report

The requirement of the task

1.The fractions that you chose are equivalent X

The characteristics of the submission

2.The visual representation line crosses all points at the same time

3.You chose a fraction that is less than one

4.One fraction is an expansion or reduction of the green fraction

5. The numerator and the denominator of one fraction are larger additively by the same number than the numerator and the denominator of the other fractions

Figure 1: Diagram for the first task **Figure 2: Automatic report for the example on the left**

Diagnostic and summative tasks. The interactive diagram (Figure 1) that the student used to solve each task displayed points in the coordinate system representing a fraction. The numerator was represented by the number that appears on the vertical axis, and the denominator by the number that appears on the horizontal axis. Students were asked to choose a fraction by dragging first the green point, then the other three points to represent equivalent fractions to the one chosen. The requirement was to construct three examples as different as possible of equivalent fractions. The criteria of difference between the submissions were based on a comparison of the characteristics of each. When all fractions were equivalent to the fraction that the student chose, a line demonstrating the "equivalent fractions" appeared automatically. The diagnostic task (Task 1) and the summative task (Task 4) were identical and were assigned to evaluate the effect of the personal report and the work on Tasks 2 and 3. Both were intended to assess the characteristics of the students' submissions when they created equivalent fractions. The criteria for assessing changes between the diagnostic and summative tasks were based on a comparison of the automatically assessed characteristics, assuming that the change in the example space indicates changes in the students' concept of equivalent fractions.

Online personal feedback process refers to the interactions of the student with the task requirements and the automatic report. The report was automatically generated in response to submissions. It included five characteristics (Figure 2), one corrective characteristic (characteristic 1) and four characteristics of the submission labeled 2-5: characteristic 2 had the potential to explain the visual representation of the examples; characteristic 3 had the potential to explain the mathematical characteristic of the example; characteristic 4 had the potential to explain the method for finding equivalent fractions; and characteristic 5 had the potential to explain misconceptions or common mistakes in the course of finding equivalent fractions. Figure 2 shows the analysis of a correct submission (characteristic 1) which indicated whether the student's submission was answering the requirement of the task (green checkmark) or not (red X sign), three mathematical characteristics that were identified by STEP in the students' submission, these were automatically highlighted in yellow (characteristic 2, 3, 4) and one that was not present in the example (characteristic 5). These characteristics were designed to reflect the curricular foci of the task and the basis for the student's engagement and self-reflection process in the LoY and the LoN tasks.

LoY and LoN intermediate tasks (Figure 3). To help students self-assess their performance while reflecting on and regulating their learning, the task was designed to include a construction and a reflection part. The construction part required students to choose two equivalent fractions by dragging two points. The reflection part required students to characterize the construction using a given set of characteristics. This set had been used to automatically analyze the work and was given to the student as a personalized report. STEP enables students to compare their self-reflection with the automatic report. Each task placed different constraints on the statements that should be reflected in the construction, indicating either a LoY or a LoN. The LoY (Task 2) was formulated as follows: "Choose two equivalent fractions by dragging the red and the green points. To the right of the interactive diagram, five statements can help you characterize the two fractions you have created. Check each characteristic that is present in your example before submitting it. Try to submit two fractions in a way that your submission should comply with as many statements as possible. Submit three such examples, as different as possible from each other." The maximum number of characteristics that the students could check was four because characteristics 3 and 5 were mutually exclusive. In the LoN task (Task 3), the students were asked to submit examples that comply with as few statements as possible, the minimum number of characteristics being two (characteristics 1 and 2). In these tasks the representation line did not appear automatically. It was a tool that students could choose to use or not, when the fractions were not equivalent there would appear two distinct lines- green and red, the lines were united when the fractions were equivalent. The using of the representation line could help students connected it with the correctness of their answers.

Data sources and analysis. The data needed to answer the research question were based on the automatic information analysis by STEP, observations of students working together on the tasks, their initial submission, the processing of the automatic feedback, and their final submission. Their discussion was video recorded. We analyzed the students' interactions while working on the tasks and their response to the online personalized feedback process. After the discussion was transcribed, we analyzed the segments and correlated the analysis with the STEP data to find an indication of the principles of task design being reflected in their work and meta-cognitive skills.

Results and preliminary remarks

Construction part	Reflection part	Automatic report
$\frac{6}{6}$ $\frac{4}{4}$ 		**The requirement of the task**
	☑ 1. The fractions that you chose are equivalent	1.The fractions that you chose are equivalent ✓
		The characteristics of the submission

	☐ 3. You chose a fraction that is less than one	3.You chose a fraction that is less than one
	☑ 4. One fraction is an expansion or reduction of the green fraction	4.One fraction is an expansion or reduction of the green fraction
	☑ 5. The numerator and the denominator of one fraction are larger additively by the same number than the numerator and the denominator of the other fraction	5. The numerator and the denominator of one fraction are larger additively by the same number than the numerator and the denominator of the other fraction

Figure 3: Construction, reflection and report for the example 4/4=6/6

Below we present empirical evidence of the students' self-reflection process as they were working on the tasks. Limar and Sana worked on the first task. Limar chose fractions that are equal to one (2/2=3/3=4/4=5/5), (9/9=8/8=7/7=6/6), (6/6=8/8=9/9=10/10). Limar noticed that the presentation line that appeared indicated that their answers were correct. For each example, the STEP automatic report indicated characteristics 1, 2, and 5. The students were interested only in the correctness of their submissions (especially Limar, who led the working on this task. The pair quickly moved to the LoY task. Limar chose the fractions: (2/2=4/4), (4/4=8/8), (4/4=6/6), and checkmarked statements 1, 2, 4, and 5 for the first submission (2/2=4/4) after reading every statement. The students chose the same characteristics for the second and the third submissions, without reading the statements. They evidently thought that having chosen fractions that were all equal to one, the submissions should have the same characteristics. After receiving the report, they examined the statements they had checkmarked.

26	Sana:	We chose all fractions equal to one. Why in this submission (means 4/4=6/6, Figure 3) statement 4 [which they had checkmarked] is not highlighted [by the online feedback]? [Reading statement 4] OK, fractions should be an expansion or reduction of one of the other; in this submission there is no integer that we multiply by 4 and we get 6. We shouldn't have checked this statement.

The students compared their checkmarked statements in the reflection part of the LoY task with the highlighted statements in the online feedback because they noticed that the online feedback did not match their self-reflection, which made them check their answer again and changed their mind about the answers. Because they were interested only in the correctness as indicated in the feedback and skipped the other characteristics, they did not notice that the statements in the online feedback were the same statements that they had received for the LoY task, otherwise they may have been more specific while checking their statements. Figure 3 shows an example of the students vs. submission and the corresponding online feedback.

When the students started to work on the LoN task, Limar chose the fraction (3/3=6/6). Segment 29-34 shows their working on the LoN task.

29	Sana:	But if we do as we did in the previous task [she drags the points to 10/10=7/7], this will give us three characteristics, and we want as few statements as possible. Here, there is no expansion or reduction, there is no integer that we multiply by 7 and we get 10. [Checkmarks statements 1, 2, and 5 and submits]. The question is, can we choose an example that has fewer than three? [Meaning checkmarked statements]. [Drags the green point and chooses 1/2] This is half, this is less than one [points to statement 3], it's not good.
30	Limar:	Yes, it’s not good. Try to do 2/1 [dragging the green point]. This is equal to the number 2. But how can we find a fraction that is not an expansion or reduction to this fraction? Usually, when the fraction is not equal to one, I do expansion to find the equivalent fraction.
31	Sana:	Wait [writes in the notebook] 2/1 expanding by 2 is equal to 4/2, if we expand again by 2, we get 8/4. No, it’ll always be an expansion because when we expand by 2 we get an even number. Maybe we should expand by an odd number, 3 or 5 for example?
32	Limar:	[Writes in her notebook (2x3)/(1x3)=6/3 and (2x5)/(1x5)=10/5)].
33	Sana:	[Points at the fraction that she wrote in the notebook and the fractions that Limar wrote] Yes, here are two fractions 6/3=4/2. There is no integer number that we multiply by 4 and get 6. The same with 4 and 10.
34	Limar:	Let’s take 6/3=4/2 [They check the presentation line that the two points are there]. Great! We have only two checkmarked characteristics.

The students tried to have as few characteristics as possible, the fewest being two, characteristics 1 and 2. They had to check the statements and to find examples that met the requirements of the LoN task. It was clear to them that they should *not* choose a fraction that was less than one. They used the expansion to find equivalent fractions, and used even and odd numbers to find fractions that are not expansions or reductions. They succeed in finding such fractions, although their explanation was not entirely correct. For every example the students used the representation line to check whether it crossed the points because it indicated for them the correctness of the answer. The students then went on to the last task, and Limar chose (12/12=13/13=16/16=19/19) (segment 36-37).

36	Sana:	Let’s choose also fractions that are not equal to one. [Drags the green point to 1/2, expanding by 2, 3, and 4 in her notebook and dragging the points to 1/2=2/4=3/6=4/8, then she submits].
37	Limar:	[Laughing] I want to choose easy fractions. Here we shouldn’t checkmark any statements, for me, the main thing is the correctness of the answer [drags and chooses 20/20=21/21=23/23=25/25 and submits].

Sana tried to create a new type of fraction that they did not have in previous submissions. This fraction related to statement 3, which they were sure not to checkmark in the LoN task. Despite Sana’s suggestion to choose fractions that are not equal to one, Limar chose to submit fractions that equal precisely one, as she did in the first and second tasks. She justified her choice by having to meet the demands of the task. She decided to choose easy correct answers, especially given that the task did not require checkmarking any statements, as she stated. Thus, the statements in the LoY and the LoN tasks served as a tool for self-reflection, otherwise the mathematical discourse about the tasks concerned only the correctness of the submissions. For Limar, 20/20=21/21=23/23=25/25 and 12/12=13/13=16/16=19/19 were correct answers, and she may have seen them as different examples although both are equal to one.

Discussion

In this study, we designed a pair of complementary example-eliciting tasks following the LoY and LoN principles. Each task was given as an interactive diagram and required constructing examples of fractions and characterizing the construction using a given set of characteristics. The set was used to automatically analyze the work and was given to the student as a personalized feedback. We explored whether and how the tasks design elicited the students' metacognitive skills and led to learning the topic of fractions.

The empirical results show aspects of work on these specially designed tasks and suggest that self-reflection has occurred in response to these designed features. Three skills of metacognition were apparent in the work on the tasks and on the online feedback: *planning*, *monitoring*, and *evaluating.* **Planning**. The students planned their chosen type of fraction in response to the requirements of the LoY and LoN tasks, which motivated the student think not only about the correctness (as they did in the first task), but also about other mathematical characteristics in their examples, or to identify characteristics that should not be present in their submissions. The students chose fractions that were "not easy" for them to choose, and generated more varied examples in their submissions than they did in the first task (unlike in the last task where they paid little attention to the feedback because they were sure that they could answer correctly). Thus, task design helped students enrich their example space. To solve the LoN task, the students discovered a new strategy for finding two fractions that were not expansions and shared their previous knowledge about the concept of even and odd numbers regarding statement 5 in the task. **Monitoring.** The students used the online feedback of the platform to compare their self-reflection in the LoY and the LoN tasks. The option of making comparison part of the task design enabled students to identify features that characterized their answers, and they tried to understand the meaning of every characteristic and the relation between them. One of the relations was the connection between the correctness and the representation line; the students chose their examples, then checked their correctness based on the representation line. All this led them to **evaluate** their learning process, rethink their choices and concept image, and change them. The task design also led the students to modify and adjust their learning process.

The findings are consistent with the literature that found a large potential for task design that combines feedback with the students' metacognitive reflection and self-assessment in advancing their performance and metacognitive skills (Ruchniewicz & Barzel, 2019, p. 55; Carless, Bridges, Chan, & Glofcheski, 2017). This is especially true for designs based on LoY and LoN principles (Arzarello & Sabena, 2011): LoY activates the students' inductive approach by finding an example that supports the statements, whereas LoN energizes students' thoughts as they seek a counterexample to the statements (Soldano, 2017). We combined the two logic principles with statements from an automatic feedback that students received in response to their submissions. This task design developed students' metacognitive skills, and enabled them to engage with the online personalized feedback process and compare their self-reflection with automatic feedback, leading to a change in their performance. These findings may serve as a basis for further research in the field of task design and self-reflection. The study was limited by the small number of participants and should be reproduced with larger groups.

Mapping student real-time viewing of dynamic textbooks to their utilization schemes of questioning devices

Palash Kanwar[1] Vilma Mesa[2]

[1]University of Amsterdam, The Netherlands; palash.kanwar@student.uva.nl

[2]University of Michigan, United States; vmesa@umich.edu

Keywords: Real-time textbook viewing data, questioning devices in textbooks, utilization schemes, undergraduate students, knowledge graphs, mathematics textbooks.

We seek to map real-time viewing data of dynamic textbooks with student utilization schemes of questioning devices, an interactive feature that collects student responses to questions that promote reflection. An instrumental approach (Rabardel, 2021) suggests that knowledge of students' utilization schemes can provide useful information to textbook designers and authors (Quiroz et al., 2021). This information supports instructors' reflection on how students utilize textbook features designed to engage them with the content, so that they can adapt instruction. However, identifying utilization schemes requires intensive qualitative analysis of data collected via observations, interviews, or students' self-reports. As these analyses are time consuming, finding alternative ways of reliably identifying utilization schemes in a short period of time when many students are using a particular feature is beneficial. We present exploratory work that uses real-time viewing data of features in dynamic textbooks to identify viewing patterns that could be reliably mapped to student utilization schemes, possibly automatically. The textbooks we study are written in PreTeXt (https://pretextbook.org/) a markup language that precisely identifies every element in a textbook; when opened in a browser, it is possible to collect student responses to questioning devices and information about when individual users view specific textbook elements and for how long. These textbooks allowed us to gather large amounts of data from many students (over 400) who used the same textbooks across many states. The textbooks are used in calculus, linear algebra, or abstract algebra courses.

We provide here only a brief description of how we used knowledge graphs (Hamilton, et al., 2017) with tracking data (date and time of viewing, the sections that were viewed, and the total time in minutes spent viewing the section) to map viewing patterns of questioning devices to their utilization schemes using about 4,000 viewings of questioning devices collected over five semesters from 492 consenting students from 27 teachers in the U.S. Knowledge graphs are graphical representations of information that capture interactions between individuals and entities. The viewing data are represented in a network of nodes and edges to establish the occurrence of consistent and repetitive viewing behavior across the same student or several unique students. Each node contains the name of the section viewed and the amount of time spent in minutes viewing that section. Directed edges denote a jump to the next section, undirected edges denote possible concurrent viewing sections within a minute of viewing during the viewing period. Each knowledge graph is unique to each day of viewing for a particular student. An algorithm created to automate this process generates combinations of nodes and edges to create unique knowledge graphs facilitating the identification of common patterns that occur while viewing the textbook. The evidence needed to support our study is hypothesized to be of three types (1) Knowledge graphs for different students following the same utilization scheme should be consistent; (2) Knowledge graphs for the same student following the same utilization scheme should be consistent; and (3) Each utilization scheme should lead to a network of knowledge graphs representative of a community of unique students with similar viewing patterns. We used the three utilization schemes identified by Quiroz et al. (2022): Familiarizing with Content Before Class (US1), Studying by Practicing and Doing Homework (US2), and Self-Evaluating and Understanding of Content (US3). With this technique we were able to identify three types of knowledge graphs with unique features that map them to each utilization scheme. We show a case, the first network of knowledge graphs represented in Figure 1, which always follows a linear viewing trajectory. The student views the sections in the textbook in the order they appear. This type of knowledge graph was mapped to the first utilization scheme, familiarizing with content. The other two networks of knowledge graphs were mapped to the other two utilization schemes (not shown for space reasons). The accuracy of the algorithm is high, 91%,86%, and 89% for US1, US2 and US3 respectively.

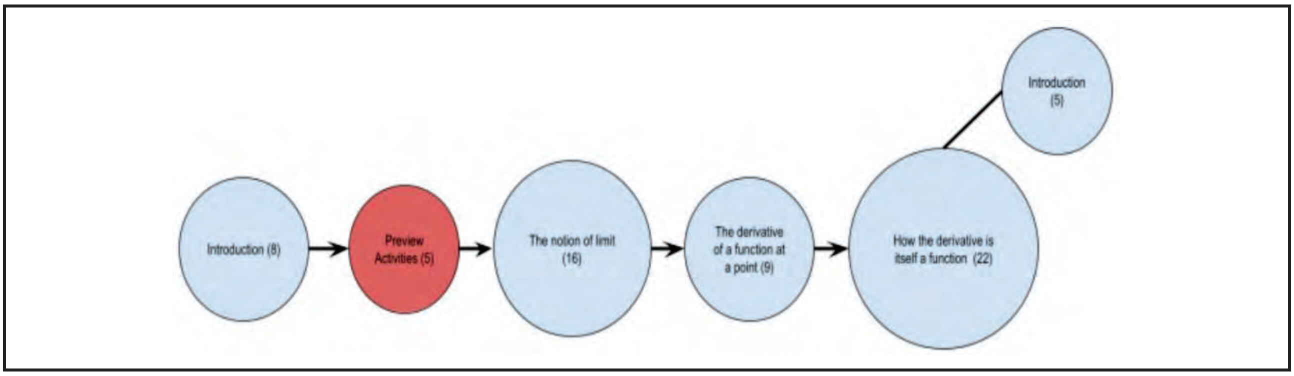

Figure 1: Representative knowledge graphs for viewing data mapped to US1: Calculus student 50 (Teacher 35); 29% of students, 91% accuracy

We will study the nature of the networks for the 18% of unmapped viewings, to see what they reveal about use of questioning devices. This problem mostly occurs when students view the textbook multiple times on the same day, deploying different utilization schemes each time, and thus the algorithm has difficulty making the classification.

Towards a coherent mathematical story: epistemologically potent problems

Vytautas Miežys[1]

[1]Vilnius University, Faculty of mathematics and informatics, Vilnius, Lithuania; vytautas.miezys@mif.vu.lt

Keywords: Mathematical story, coherence.

Research topic

Instructional coherence has been identified as a significant factor that can improve students' conceptual understanding of mathematics (Hiebert et al., 2003; Chen and Li, 2010). It allows students to make connections among the ideas that are presented, see causal and logical linksbetween them and sustain interest and engagement in a topic (Chen and Li, 2010; Richman et al., 2019; Dietiker et al., 2020).The concept of instructional coherence has been linked to literary stories by noting that good lessons of mathematics should possess features of good stories (Chen and Li, 2010). Dietiker and her colleagues have identified that if mathematics teaching is interpreted as a literary story, coherence of the story does contribute to the perceived interestingness of it and engagement with it (Richman et al., 2019; Dietiker et al., 2020).

However, little is known about how to purposefully construct coherent stories of mathematics. Hence the research question of this poster is: *given a set of mathematical concepts, what are the first steps one can take in order to create a coherent mathematical story that would introduce the chosen concepts?*

Theoretical framework

Dietiker (2015) has developed a theoretical framework to view a mathematical text as a story. In the framework, the notion of mathematical plot plays a central role. In order to study mathematical plot, one has to consider what questions are present in the reader's mind at a given point in a story. Some questions are quickly answered by the story, while others may be open for a long time. Having questions that are kept open for a long time is a key property for a story to be coherent (Richman et al., 2019).

The coherence of the story is defined as "the extent to which the events and mathematical ideas of the mathematical story (...) are connected to each other for a reader" (Richman et al., 2019, p. 4) and a way to test if a mathematical story is coherent is to look for overarching questions that are engaged throughout the length of the story and frequent progress on these questions is being made. If such a question exists and the rest of the questions considered in the story allow for progress to be made on the main question, then one can expect that the mathematical story is coherent.

Epistemologically potent problems: a backbone for a coherent mathematical story

Consider the following problem: "Alice has 2/3 of a baguette. If she eats 3/5 of that, how much of the whole baguette would that be?" Notice that in the wording of the problem, the concept of fraction multiplication is not mentioned, yet the conventional way to solve such a problem is to multiply 2/3 by 3/5. So this problem has an interesting property – it does not mention fraction multiplication, yet it requires this concept to be solved.

Problems with this property have the potential to show to students why mathematical concepts (fraction multiplication in this case) are needed, from what problems they arise. Hence I call such problems epistemologically potent (Harel, 2013). Such problems cannot be easily solved by students as they have not been exposed to the concepts that are needed to solve the problem, yet can be approached by them, because the unknown concepts are not mentioned in the problem's wording.

If a teacher were to construct a lesson or a series of lessons built on the analysis of an epistemologically potent problem, then due to the fact that the solution to the problem requires a mathematical concept that is currently not known to the students, many questions will need to be considered and answered before solving the initial problem. Since all the questions would arise from considering the same initial problem, they would all be related. Hence the instruction based on the analysis and consideration of an epistemologically potent problem is likely to be coherent.

Implications

Epistemologically potent problems can serve as a good starting point when considering how to construct a coherent mathematical story, since such problems are, by definition, accessible to students, yet require the use of concepts that are yet to be discovered by the same students, hence allowing for a continued exploration and progression on the problem.

An examination of mathematical affordances available in grade 2 teachers' guide and learners' textbook on addition of whole numbers

Lisnet Mwadzaangati[1] and Mercy Kazima[2]

[1]University of Malawi, Zomba, Malawi; lmwadzaangati@cc.ac.mw

[2]University of Malawi, Zomba, Malawi; mkazima@cc.ac.mw

This paper present findings from a textbook analysis which examined the structure and patterns of variation of addition examples presented in a grade 2 mathematics teachers' guide (TG) and learners' textbook (LT). Classification scheme for addition problems was used to analyse the structure of the examples, and Mathematics Discourse in Instruction framework for Textbooks was used to analyse their patterns of variation. The findings revealed that the example sets in the TG and LT afford development of additive reasoning as they contain different patterns of variation that might lead to higher levels of generality if teachers focus learners' attention to these. The examples however constrain development of additive reasoning as they comprise of only one structure with both addends given and require calculating the result. To decide a better professional development for teachers, it is necessary to study how teachers use these resources to plan and deliver mathematics lessons.

Keywords: Examples, mathematics teachers' guide, mathematics leaners' textbook.

Background

Malawian learners, on average, have been performing poorly in mathematics in both national and regional assessments (Ravishankar et. al., 2016). Despite Malawi's overall improvement on national primary school examination pass rates, performance in mathematics is still very low (Ministry of Education Science and Technology [MoEST], 2020). At international level, the Southern African Consortium for Monitoring Education Quality (SACMEQ) results show that Malawian learners perform extremely low on number and operation in mathematics (Milner et al., 2011). This is very worrisome considering that number concept and operations define numeracy, which is an indicator of educational quality (Ravishankar et al., 2016). The problem of learners' low performance in mathematics in Malawi has persisted even after government's implementation of several educational reforms to improve education quality. Some of these reforms include revising of primary education curriculum and curriculum materials such as teacher guides (TG) and learners' textbooks (LT) for all subjects. Despite the crucial role that mathematics TGs and LTs play in the planning, teaching and learning of mathematics in developing countries (Leshota, 2020), little research has been conducted to examine how the content of the revised TGs and LTs afford or constrain learners understanding of mathematics. In mathematics education, "mathematics textbooks play a particularly prominent role in guiding teachers on specific materials to teach (Chang & Salalahi, 2017, p. 236). Thus many mathematics teachers use textbooks such as TGs and LTs to decide the type of tasks to implement in their classrooms and how to engage students in such tasks (Leshota, 2020; Stylianides, 2014).

The findings presented in this paper are part of an ongoing study which aims at examining the mathematical affordances presented in Malawian primary mathematics textbooks. In this paper, we pursue the following research question; what mathematical opportunities are made available in addition of whole number examples presented in mathematics grade 2 TG and LT? For every primary education subject in each grade in Malawi, there in one TG and one LT. The TG contain instructions for teachers in terms of the tasks, examples, and resources to be used for teaching while the LT contains learners worked and exercise examples. In most cases, these two books are the only curriculum resources used by Malawian primary school teachers to plan and teach their lessons. Therefore this study is useful in informing policy during revision of the books as well as informing educators on necessary professional development needs for primary school mathematics teachers not only in Malawi but also in other countries. As noted in literature, mathematics textbooks such as TGs are the mostly used resource in mathematics teaching and learning not only in developing countries but in developed countries (Stylianides, 2014). We specifically focus on the quality of addition examples by examining their structure as we agree with Olteanu (2018) that mathematics teaching and learning is mainly done using examples. Suggesting that the quality of mathematical examples presented in textbooks determine the quality of mathematics teaching in the classroom (Leshota, 2020; Ronda & Adler, 2016).

Analytical frameworks

Two frameworks were used to analyse the examples in the TG and LT: the classification scheme for addition problems developed by Carpenter, Fennema, Franke, Levi and Empson (2015), and the Mathematics Discourse in Instructional framework for Textbook analysis (MDITx) developed by Ronda and Adler (2016). Carpenter et al. (2015) describe 2 classes of addition problems (which are called examples in MDITx) according to the kinds of action or relationships described in the problems; join and part-part-whole problems. “Join problems involve a direct or implied action in which a set is increased by a particular amount and part-part-whole problems involve adding or subtracting 2 disjoint subsets” (Carpenter et al., 2015, p. 8). These two types of addition problems can contain different structures in which either the result/whole is unknown but the start or change/parts are known, or one start/change/part is unknown, but the result/whole is known. When children engage with addition problems that require them to find the result/whole, they use a joining all basic counting strategies. In joining all (counting all) strategy, children use objects to first count each addend separately (numbers of object being added), put the objects together and counting them all again to find the sum (Carpenter et al., 2015). For children to use complicated counting strategies like joining to and trial and error, they need to be given either a join problem in which the start or change is unknown or a part-part-whole addition problems in which either the first or second part is unknown (Carpenter, et al., 2015). In joining to counting strategy, children do not count each start/change/part, but they start counting on from a predetermined number like either the given start/change/part (Carpenter, et al., 2015). As such joining to counting strategy is complex counting strategy and it enhances conceptual understanding and additive reasoning. Carpenter et al. (2015) therefore suggest that to increase number sense when learning addition of numbers, children should be given a variety of addition problems that offer them opportunities to use both simple and complicated counting strategies. We therefore used this classification scheme to examine the addition examples in the TG and LT to find out if they are varied in a way that promote learners’ number sense.

The MDITx framework describes the quality of mathematics made available to learn in a textbook (Ronda & Adler, 2016). MDITx comprises of five key elements aimed and achieving generality and structure; object of learning, examples, tasks, naming/word use and legitimations. The object of learning is what learners need to know and be able to do at the end of the lesson, as such, it is the goal of the lesson. Opportunities for learning mathematics are either afforded or constrained by the way author(s) use examples, tasks, words and legitimations (Ronda & Adler, 2016). Due to space limitations, we only give a brief description of what examples entail in MDITx as these are in focus in this paper. Examples are a particular case of a larger class used for drawing reasoning and generalisations (Ronda & Adler, 2016). They are what teachers and learners mainly work on during mathematics instruction. Carpenter et al. (2015) refer to examples as problems. MDITx draws from key principles of Variation Theory which emphasize on paying attention to variation amidst invariance when selecting examples (Marton & Pang, 2006). This means that textbooks must contain examples which are deliberately sequenced to enable learners to understand a particular object of learning in a coherent manner through noticing aspects that remain the same and those that change. Ronda and Adler (2016) therefore suggests that to analyse and determine variation in an example set, three categories of variation must be used. These are; contrast (C) (when differences are noticed), generalization (G) when similarity is noticed and fusion (F) (when at least 2 different objects of learning are in focus). Thus they describe a set of three progressive indicators for analysing and coding example spaces in a textbook lesson as follows: Level 1, if only one pattern of variation is used throughout the textbook lesson, Level 2, if two different patterns of variation are used in the textbook lesson, and Level 3, if all three patterns of variation are used. A fourth code called NONE is used to code example spaces in which no pattern of variation is detected. We used these descriptions to code the example sets during data analysis.

Methodology

Analysis of the structure of addition problems in grade 2 mathematics TG and LT (Kachisa, Mphando, Mwale, Soko, & Toto, 2012a; 2012b) involved examining what is given and what is required to be calculated in each problem using Carpenter et al.'s (2015) classification scheme. Thus, we examined whether a problem contained both addend and required calculating the sum, or whether it contained the sum and one addend and required calculating the other addend. To examine the variation in the examples, we regarded examples under each activity in both the TG and the LT as an example space and examined the type of variation available using MDITx framework by Ronda and Adler (2016). Where one type of variation was used throughout, we coded the example space as level 1. If two types of variation were used, we coded the example space as Level 2, and Level 3 if all three types of variation were used.

Results

The findings show that Unit 2 of both the TG and LT contain three main activities with specific object of learning for each activity. In the TG, each activity has several tasks and each task is accompanied with a set of examples. We begin by presenting findings on the nature of the structure of addition examples/problems, followed by findings on the nature of variation afforded by the examples using Figures 1, 2 and 3.

The structure of the addition problems

As it can be seen in Figures 1, 2 and 3, both the TG and LT have provided addition problems containing both addends and requiring finding of sums. Only activity 1 of the TG contain word problems as well as non-word problems, but the other activities only contain word problems. All LT activities do not contain word problems. The word problems in activity 1 of the TG belong to two types of addition problems. Problem 2a *Chifundo has 2 mangoes and Paul gives her 3 mangoes, how many mangoes does Chifundo have altogether?* is a join problem because as it implies action of giving mangoes, hence causing an increase in Chifundo's total number of mangoes. The problem has initial number of mangoes that Chifundo had (2 mangoes) and then the change or increase she is given by Paul (3 mangoes), and the requirement is to find resulting amount (altogether). This problem can be represented as $2 + 3 = \square$. Addition problems 2b and 4 are part-part-whole problems because they do not imply action but require finding the sum of two disjoint sets of objects like sweets, sticks and stones. For example, problem 2b *Mphatso has 9 sweets and Tamanda has 4 sweets, how many sweets do they have altogether?* The structure of this part-part-whole problem is similar to that of problem 2a and can also be presented as $9 + 4 = \square$. As such learners might count the two sets of sweets separately and then count the total by starting from first set and continuing with the other set. The same structure of providing two addends that require finding sum is also observed in problem 4 and the other non-word problems in activity in all activities in both the TG and LT. This implies that both the TG and the LT do not contain addition problems with a structure that contains the sum but require finding of one of the addends like $9 + \square = 13$ or $\square + 4 = 13$.

Variation afforded by the examples

The examples under each task were regarded as an example set while all examples under each activity were regarded as an example space for a particular object of learning. Each activity in the LT mainly contains one task with several examples under each activity and these were also regarded as an example space. Table 1 presents a summary of the findings on the nature of variation afforded by the example set under each task.

Table 1: Nature of variation of examples

Activity 1 : Adding numbers horizontally	**Activity 2: Adding numbers vertically**	**Activity 3:Mastering addition facts**
Example set 1 (TG): Level 1 (C).	Example Set 1 (TG): Level 0	Example set 1 (TG):Level 3 (G, C, F)
Example set 2 (TG): Level 1 (C)	Example Set 2 (TG): Level 2 (C)	Example space from LT: Level 3 (G, C, F)
Example Set 3 (TG): Level 0	Example space from LT: Level 3 (G, C, F)	

Example Set 4 (TG): Level 1 (C)		
Example Set 5 (TG): Level 1 (C)		
Example space from LT: Level 3 (G, C, F)		

As Table 1 shows, in Activities 1 and 2 in the TG, one example set is in level 0 because it only had one example so it was not possible to generate pattern of variation. The other example sets in Activity 1 and 2 of the TG are in level 1 as they only enhance contrasting pattern of variation. Only examples of activity 3 in the TG enhance all patterns of variation. The LT examples for all activities enhance all patterns of variation. I clarify these findings using Figures 1 and 2.

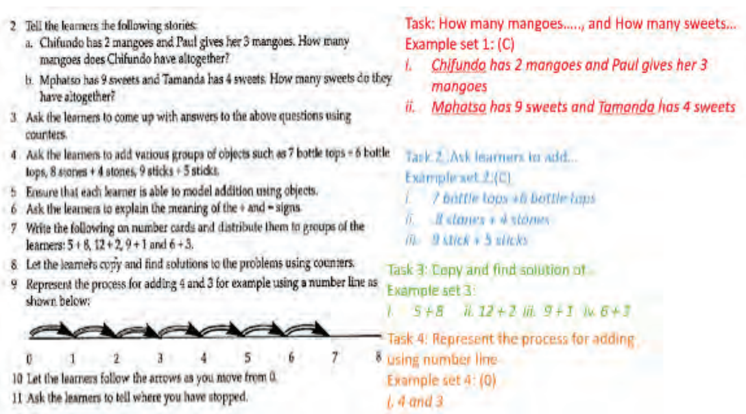

Figure 1: Activity 1 from TG (Kachisa et al., 2012a, 13)

Figure 2: Activity 1 from LT (Kachisa et al., 2012b, 23)

As it can be noticed in Figures 1, 2, the number of addends and the position of the = sign remain the same (invariant) in all examples, what changes are the values of the addends. As shown in Figure 1, the examples from each example set contain different addends that generate different sums. We therefore coded each example set as contrast (C) as at it might enable generalising that different sets of addends generate different sums, hence level 1 of generalisation. In the LT, the example space under activity 1 is in Level 3 of generalisation because it contains examples which enhance all patterns of variation as shown in Figure 2. Several examples can be combined from the example space in Figure 2 to form example sets that might enhance generalisation through noticing different patterns of variation. Examples 1-2, 2-4, and 16-18 can be used to generalise that different sets of addends can generate similar sums. As such we coded these example sets as G. Since these examples also enhance development of number facts, we also coded them as F. Similar patterns of variation and fusion can also be drawn through combination of examples 9, 11 and 14, as well as examples 10, 12 and 15. However, if the learners solve the examples in a manner that is presented in the LT, then examples 6-15 would enhance generalisation through contrast (C) pattern of variation as they addends and sums are different. As such we coded this part of example space as C. Since the example space contain examples which might help understanding of two objects of learning such as adding numbers and number bases, then we also coded it F.

Discussion of the results

In this paper, we examined the mathematical opportunities made available in grade 2 TG and LT by analysing the structure and nature of variation of examples/problems on addition. As the findings have revealed, the TG has provided more Level 1 example sets that enhance noticing of only one pattern of variation than Level 2 and Level 3 example sets that enhance noticing more than one pattern of variation. All level 1 example sets in the TG are enhanced contrast pattern of variation, meaning that the TG has provided more opportunities for only noticing how different set of addends can generate different sums, but not to notice how the different sets of addends can generate similar sums. Contrast is a first step or low level type of generalisation and is supposed to be followed by similarity to enable children to move into deeper levels of generalization and understanding through identification of more patterns and justifications (Watson & Mason, 2006). This suggests that to enhance development of additive reasoning, the TG is supposed to deliberately contain examples that afford them opportunities to recognise aspects that change within aspects that do not change (Ronda & Adler, 2016; Watson & Mason, 2006). Provision of example sets that help learners to see not only contrast but also similarity signals a move to higher level of generality (Ronda & Adler, 2016) and it can engage learners with understanding of mathematical structure (Watson & Mason, 2006). The findings however show that the examples in the TG activity of number bases might enhance learners' understanding of the commutative property that the change in the order of the addends does not lead to change in the sum of the addends (Carpenter et al., 2015; Hunter, 2010). Understanding of the commutative principle helps learners to develop generalisations that help develop algebraic reasoning which is the difficult part of later mathematics (Hunter, 2010). Activity 3 of the TG and other example sets in the LT might also enhance learners' development of additive reasoning through enhancing understanding of number facts (Carpenter et al., 2015). Although the LT contains example sets that enhance noticing of both similarity and contrast patterns of generalisation, the instructions from the TG only require the teacher to ask the learners to do the tasks but not to focus on noticing any pattern of variation. This implies that depending on their knowledge, some teachers may help the learners to pay attention to these patterns of variation while others may not. As Brown (2009) noted, teacher knowledge greatly influences how teachers adapt textbook content.

As the findings reveal, the TG and LT have only provided joint and part-part-whole addition problems which contain two addends and require leaners to find the sum, but they do not provide problems requiring finding an addend. According to Carpenter et al. (2015), when children are given join problems to find the result, and part-part-whole problems to find the whole, they only use simple counting strategies like joining all modelling strategy and counting on modelling strategy. Thus children need to be given problems whose either start, change, or part are unknown in order for them to use more sophisticated modelling and counting strategies like joining to, separating from, separating to, counting on to and counting (Carpenter et al., 2015). Providing different unknowns in addition problems enable children enhance their additive reasoning through promotion of use of different counting strategies (Carpenter et al., (2015). The findings imply that both the TG and LT place more demand on the teacher especially during planning of lessons for delivering the curriculum (Brown, 2009). Thus implying that learners' full development of additive reasoning relies on teachers' ability to notice the shortfalls of the examples in both the TG and LT and deciding how to adapt them to increase their level of generalization and enhancement of development of additive reasoning. One of the factors that influence teachers' ability to recognise what the textbook affords and constraints is teacher knowledge (Brown, 2009; Leshota, 2020). Considering that like most Sub-Saharan countries, teacher knowledge is one of the challenges constraining Malawi from achieving the SDG 4 of improving education quality (MoEST, 2020), then it is unlikely that most Malawian teachers might notice the gaps in these mathematics textbooks. These findings confirm Milner et al.'s (2011) suggestion that the low quality of Malawian mathematics textbook content might be one of the causes of persistence of learners' low performance in mathematics. We concur with Leshota (2020) that countries with high textbook compliance policies need to ensure that they develop high quality textbooks and train their teachers on how to use these materials when planning lessons for delivering curriculum.

Conclusion

This study investigated mathematical opportunities available in addition examples/problems for addition topic in Malawian TG and LT of grade 2. The findings revealed that both the TG and LT contain addition examples comprising of only one structure whereby both addends are given and a sum is to be calculated, hence limiting learners' development of additive reasoning through use of complex counting strategies that develop when learners practice calculating an addend when given sum and one of the addends. Regarding variation of examples, the findings revealed that the TG has more example sets that can enhance achieving low levels of generality and few example sets that can enable achieving higher levels of generality. The LT contains more example sets that can enhance noticing of more than one pattern of variation, hence capable of enabling learners to move to higher level of generality of addition. However, the teacher might not focus learners' attention to notice the different variations because the TG which is the main resource that the teacher uses to plan lessons does not contain any instruction about noticing similarity or difference. Thus the structure and patterns of variation of the addition examples available in the TG and LT place much demand on the teacher as they require much adaptation to enhance additive reasoning through changing of structure and variation. This might be possible if teachers have adequate content knowledge to adapt these materials. These findings suggest that there is a need for professional development of teachers on how they can use these resources as suggested by other researchers. However, for an effective professional development of teachers, it is necessary to investigate how teachers use these resources to plan and teach mathematics lessons to find out if they do notice the gaps in the examples and make necessary adaptations.

Students' expressions about working successfully with mathematics textbooks

– multimodality and sociomathematical norms in early years

Malin Norberg

Mid Sweden University, Faculty of Education, Sweden; malin.norberg@miun.se

This paper reports on an ongoing study about students' expressions about mathematics and what is considered successful when working with mathematics textbooks. 18 Year 1 students (7–8 years) working with mathematics textbooks were analysed according to how they used different communication resources, or modes, and sociomathematical norms. The results showed sociomathematical norms about (1) aids that are supportive for solving the exercises in the textbooks, (2) clues that are given in the task design and (3) aspects considered successful by the students. It is stated that there is a tension between using aids and being considered successful in mathematics, which could affect students' possibilities for mathematical learning.

Keywords: Early years, mathematics textbooks, multimodality, sociomathematical norms.

Introduction

Mathematics is for everyone. Therefore, mathematics teaching should be designed so that students' different ways of expressing mathematics are utilized. Mathematics is multimodal (O'Halloran, 2005), which means that different resources for communications, or modes (Kress, 2010), is essential in doing and expressing mathematics. All students' mathematics learning is supported by focusing on the multimodal nature of mathematics and the possibility of expressing mathematics in many ways, with different modes such as images, gestures, speech, and writing. However, if one communication resource, mathematical symbols, already in year 1 has a unique position (Norberg, 2020), students, if possible, choose to avoid other forms of modes, mathematics teaching risks suiting only the students who are already confident with the mathematical symbols.

Students' possibilities to express mathematics in mathematics teaching are affected by the norms in the classroom, what is considered accepted and what is considered desirable. Mathematics textbooks are common learning tools used by more than 75% of students in compulsory schools worldwide (Mullis et al., 2012). The use of textbooks means activities with mutual participation between textbooks and students (Rezat & Sträßer, 2012). In a theory-oriented paper using a socio-didactical tetrahedron Rezat and Sträßer (2012) stated that social and sociomathematical norms are considered essential in students work with mathematics textbooks. Students use textbooks differently (see, for instance, Norberg, 2020; Rezat, 2013). Ewing (2006) stated that students who find working with mathematics textbooks hard are "blamed for their inability to learn" (p. 14). Also, students' individual work with mathematics textbooks is an unexplored research field (e.g., Österholm & Bergqvist, 2013) Therefore, studying sociomathematical norms, normative aspects specific to mathematical activities when students work with mathematics textbooks can create essential knowledge about mathematical learning. Multimodality entails an approach in which all communication resources are utilized, which further strengthens the study's relevance.

This paper presents preliminary results from an ongoing study built on a reanalysis of data from my PhD project (Norberg, 2020) about students' meaning making when working with mathematics textbooks in Year 1 (7–8 years). The study builds further on students' expressions on what is considered successful or not when working with mathematics textbooks. The study is also a pre-study for a proposed research project. The paper aims to deepen the understanding of students' meaning making when working with mathematics textbooks regarding sociomathematical norms and the use of different modes, clarified by following research questions: *What modes are used in the students' meaning making?* And *What sociomathematical norms related to the use of different modes are conveyed by the students?* I will share my findings so far, and I hope this will be a starting point for discussions that can increase my knowledge of sociomathematical norms linked to students' work with mathematics textbooks. In the long run, a study in this area could provide essential knowledge about what shapes conditions for young students' mathematical learning.

Background

The study reported in this paper derives from the research field of mathematics education and students' experience of working with mathematics textbooks emphasising two different areas, mathematics as a multimodal subject and sociomathematical norms. Besides that, there is also a particular focus on younger students' experiences.

In an introduction of the papers presented in TWG22 at CERME10 and CERME11 (Pepin et al., 2019), the authors stated that one of the directions for future research discussed was to understand better what impact tasks have on students. That is focused on in this paper. Knowing what sociomathematical norms exist when students work with their textbook's better conditions for students' mathematical learning can be created. Another possible direction for further research discussed was to include students, and their learning experiences when designing tasks. The results from this study could contribute to such knowledge.

The subject of mathematics has a long history of using several different modes to create mathematical representations. O'Halloran (2005) describes mathematics as multisemiotic and argues that the strength of the subject of mathematics lies in the fact that the different modes together give more information than the sum of what each mode can contribute. Yackel and Cobb (1996) found in a visit to a classroom for year 2 (7–8 years) that it was central that the students discovered that mathematics could be expressed in different ways. Although mathematics is a multimodal subject, a former study showed that mathematical symbols have a special position and that it is the desirable mode to use to represent mathematics (Norberg, 2020). A conclusion drawn was that striving not to use the images can lead to the students' meaning making not being directed towards the mathematics content that the exercise is designed to offer (Norberg, 2020). This motivates the multimodal approach used in the study reported in this paper.

Sociomathematical norms are related to students' work with mathematics and concern what counts as mathematically sophisticated, accepted, different, efficient, and not (Yackel & Cobb, 1996). Many students find mathematics difficult and have poor self-confidence regarding their mathematical knowledge, also at earlier stages (Larkin & Jorgensen, 2016). This relates to sociomathematical norms (Yackel & Cobb, 1996) which form conditions for both students and teachers and regulate students' learning. This is supported by Rezat and Sträßer (2012) who concluded that students and teachers act accordingly to their norms in mathematics teaching. In a study of year 1 students (6–7 years) and teachers with data from videotaped lessons during a school year, Perry et al. (2011) concluded that students at this early stage can be engaged successfully in learning mathematics and that teachers play a big part in this. Students are thereby socialized into mathematics teaching culture. Wester et al. (2015) found differences between the students' and the teacher's views of norms and the students participating (14–15 years) expressed that manipulatives should be used when you need to learn something new but that it is better not to use manipulatives for your calculation. All in all, research on students working with textbooks is sparse, sociomathematical norms are important for students meaning making, and a multimodal approach provides a tool for studying all modes used in the communication between student and textbook.

Theoretical approaches

Sociomathematical norms are defined as "normative aspects of mathematical discussions that are specific to students' mathematical activity" (Yackel & Cobb, 1996, p. 458) and derive from a constructive perspective, like multimodal social semiotics. Sociomathematical norms differs from social norms which are general norms about being a student. *Multimodal social semiotics* (see, e.g., Kress, 2010) assumes that all communication is made through various communication resources, or modes. Yackel and Cobb (1996) distinguish between sociomathematical norms that are considered mathematically sophisticated and those considered accepted. The perspective provides tools that can be used both to support researchers to make rational descriptions of mathematical representations, and help structure interpretations of representative functions (Morgan, 2006). Sociomathematical norms contribute with tools to detect which norms are constructed in the classroom. Multimodal social semiotics enables the possibility to analyse all communication in the classrooms, in all modes used.

Central to the project is the student's *meaning making* activities. Students' working with mathematics textbooks is understood as meaning making and focuses on meaning making as a multimodal activity (Kress, 2010). Meaning making is defined as an activity where the individual tries to understand the world around her and happens continuously, everywhere (Kress, 2010). Meaning making takes place in a social, cultural, and historical context and describes the individual's focus. *Multimodality* refers to the perspective's assumption that all communication occurs in different resources for communication, *modes* (Kress, 2010), such as images, gestures, speech, and writing. In multimodality, meaning is attributed to all modes. All modes carry different potentials for meaning making (Jewitt et al., 2016; Kress, 2010), which means that you cannot give the exact same information in, for instance, writing mode and image mode. *Modes* are culturally and socially shaped resources for meaning making and are used in communication and representation (Kress, 2010).

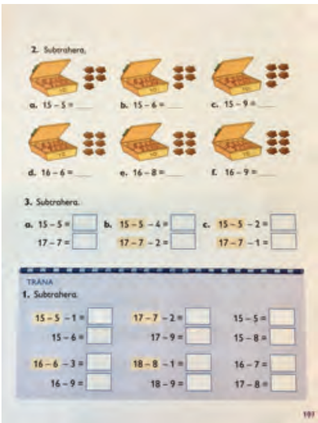
Methodology

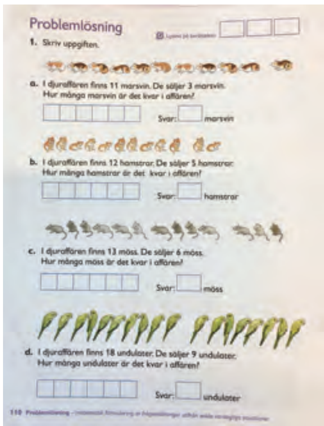
Different data types were collected: textbook pages, video transcripts of students working individually with these pages, and the students' solutions to the exercises. Video transcripts and representations from 18 Year 1 (ages 7–8) students were collected. The school is located in a medium-large city in the centre of Sweden and chosen from a convenience sample. All students in the class whose caregivers had both completed the consent form participated in the study. Before the data collection, I spent a week with the class to get to know the students so that the video recordings would not feel uncomfortable to them. Here, my former work as a compulsory-school teacher was valuable.

The aim was to study the students' work in an as realistic situation as possible. Of course, the most natural situation would have been studying the students in the classroom during mathematics lessons; but, since much of the work with the mathematics textbook consists of working alone in silence, that approach would not yield much insight into the students' meaning making. Therefore, I studied the meaning making of one student at a time in a room adjacent to the classroom, which made it possible to ask questions to the students during and especially directly after their work.

The video material consists of 450 minutes of film – approximately 25 minutes per student with a tablet in May 2017. The student and I sat at a table, with the tablet placed obliquely above us. In order to influence as little as possible, the student started working on the exercise by herself (or himself). Then, I asked questions to understand how the student was making meaning from the exercise, such as, "Can you tell me how you did this?", or "I saw that you did something with this image here, can you tell me about that?".

The textbook series used in this study is widely used in Sweden: *Favorit matematik* (Favourite Mathematics) (Ristola et al., 2012a, 2012b). The pages were chosen based on the results of a quantitative study (Norberg, 2021) using the following criteria: the exercises had to address subtraction as an arithmetic operation, be commonly used in the textbooks, and show breadth based on the different modes were used. The pages were copied in colour and given one at a time. Examples are shown below, with the publisher's permission (see Figures 1–2). *Exercise* is defined as tasks of the same kind. For example, three exercises are pictured in Figure 1.





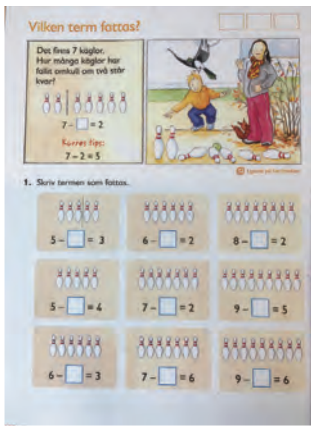


Figure 1: Exercise 1, Ristola et al. (2012b). p. 107. Illustrator: Rajamäki, M.

Figure 2: Exercise 2, Ristola et al. (2012b). p. 110. Illustrator: Rajamäki, M.

Figure 3: Exercise 3, Ristola et al. (2012a). p. 150. Illustrator: Rajamäki, M.

Framework for Analysis

The analysis stems from the research questions and, the categories developed inductively. Due to the multimodal approach, the video transcripts were first transcribed under three separate columns following different modes: speech, images, and body language. This answers to the first research question. In the image column, the students' use of images was documented and instances of a student drawing a picture to support her calculation. The body language column communication made with the body was documented, such as pointing, using finger-counting, shaking the head, e.g. The textbook pages and the students' solutions to the exercises were used as support for the analysis, for instance, for discovering which task the student focused on or how she/he represented the answer on the paper. In the next step, I was looking for expressions for how the student used the mathematics textbook, both things emphasised as good working methods (considered mathematically sophisticated, Yackel & Cobb, 1996) and those emphasised as less good (considered acceptable, Yackel & Cobb, 1996). This was understood as sociomathematical norms regarding the use of the mathematics book. After that, the transcripts were coded by reading through the material several times and highlighted using a colour code. Then condensed meanings were summarised in a matrix, from which various categories emerged. This answers to the second research question.

Preliminary results

Students expressed norms about *Aids supporting the calculation*, *Clues in the task designs supporting the calculation* and *What is considered as successful when working with mathematics textbooks* when working with the textbooks. The multimodal assumption is noticeable in the results as communication in all modes (for instance, images, gestures, mathematical symbols) are made visible.

Aids supporting the calculation

The norms that emerged in terms of aids supporting the calculation was:

(1) use *finger-counting,* which showed in two different ways in the data. One way was to hide the fingers under the table, which indicate that the student should preferably not use the fingers. However, another way was to do the finger calculation above the table, in front of us, indicating that other students did not have the understanding that finger-counting should be made without showing. This could indicate that there might be different norms according to different students in the classroom, this must be studied further.

(2) *draw an image,* which was used for support even though there were images in the exercises.

The student draws an image in order to support her calculation (Figure 1).
Me: Is it possible to use the images in the exercise to do the calculations?
Student: Yes, I think so, but I didn't see how to.

(3) *ask the teacher or a friend,* some students suggested one of these options, and some suggested both options connected to how to work with the mathematics textbook. This could refer to social norms instead of sociomathematical norms and needs to be studied more deeply to know whether this norm is connected to mathematics teaching or teaching in general. There can be differences between subjects when it comes to asking for support.

(4) to use a *number line*, which refers to a number line that the students place before them during mathematics teaching.

Clues in the task designs supporting the calculation

Norms about clues in the task-design that hold information about how to solve the tasks was expressed in the data. The students expressed clues from:

(1) *to read the instruction and/or guide boxes,* one expression was that you only read as far as you need to understand.

> "I read to here (points at the middle of the sentence instruction the exercise), and then I understood what to do."

This category could also refer to social norms and needs to be studied more to know whether this is connected to mathematics teaching or teaching in general, due to differences between subjects.

(2) the number of empty pre-drawn boxes indicate how long the answer should be

> The student solves the task with the guinea pigs (Figure 2) but frowns when he realises that one of the boxes in the answer remains empty. He then erases what he had written.
>
> Me: Why did you erase? Do you think it was wrong?
>
> Student: No but, it shouldn't be like that. It shouldn't be empty boxes… (He thinks for a while). Ahh, one number in *each* box, *now* I know.
>
> So, when he wrote "11" not in one box but in two separate boxes, the written calculation used all the boxes, and the student was satisfied.

(3) *dashed numbers* indicate that they should be filled in.

(4) *not all tasks in an exercise can have the same answer*

> A student is figuring out the answer of a task in an exercise (Figure 3). The first answers were the same, and the student says: It cannot always be two so I think it is eight this time.

(5) *tasks at the beginning of an exercise are easier than the rest.* Students expressed that the first tasks are easier to solve and that it gets harder further down in the exercise.

What is considered successful when working with mathematics textbooks

The data also reveals norms for how a successful student working with the mathematics textbook acts, norms considered mathematically sophisticated, which are:

(1) *Solving all tasks on the page without skipping some of them*. This was expressed when some of the students questioned when I told them to solve some of the tasks and not the whole page.

(2) *Quickly understand how to solve the exercises*. It was expressed as good if the student understood what to do with the exercise immediately, perhaps without reading the instructions. So, working fast is something that is considered successful.

(3) *Solving the tasks with mental calculation* is something that is expressed as good. This is often followed by answering in mathematical symbols on an empty line.

(4) *Not using the images*. Students expressed that it is desirable to solve the tasks without using the images for support.

> Me: Can you use the image to do the calculation?

Student: Yes, but you don't need that if you are good at math.

This approach was also shown in action when some students used the image to solve the exercise. When they worked with the exercise, I saw them using the images, but when I asked how they went along with the exercise, they did not mention the image. First, when they were specifically asked if they used the image, the students said they did.

Concluding remarks

The results showed norms about aids and clues in the task designs that support students' calculation, and norms about what is considered successful when working with mathematics textbooks. The aids mentioned were finger-counting, drawing an image, to ask a friend or the teacher or to use a number line. These are all considered resources and modes supporting the calculation. The clues given in the task design were to read the instruction and/or guide boxes, that the number of empty pre-drawn boxes indicate how long the answer should be, dashed numbers, that not all tasks in an exercise can have the same answer and that tasks at the beginning of an exercise are more accessible than the rest. Things considered as successful when working with mathematics textbooks were to solve all tasks on the page without skipping some of them, quickly understand how to solve the exercises, solve the tasks with mental calculation and not to use the images. This approach was considered mathematically sophisticated (Yackel & Cobb, 1996) by the students.

In further research, it would be interesting to study sociomathematical norms linked to digital textbooks. Partly because there is potential for more modes to be used and partly because students can interact with the textbook. Also, it is sometimes possible to manipulate the tasks during the work with the digital textbook and get feedback during or after the work. More knowledge about this could provide essential knowledge supportive for students' learning in mathematics.

[1]Cinvestav - IPN, Mexico; sofia.paz@cinvestav.mx, ccuevas@cinvestav.mx

[2]Universidad Autónoma de Coahuila, Mexico; jose.orozco@uadec.edu.mx

This paper presents the results of the first cycle of an ongoing design research. A Hypothetical Learning Trajectory (HLT) is proposed to introduce the concept of linear combination in a first linear algebra course. To evaluate the HLT, we conducted a teaching experiment with engineering students in a Mexican public university. In the analysis phase, the HLT was compared with the Real Learning Trajectory (RLT) to evaluate how university students' understanding progresses when they work with tasks designed under the practical action projects. We use emergent modelling as a theoretical framework for describing students' level of understanding achieved. Results showed some limitations of the HLT to achieve a formal level of understanding.

Keywords: Design research, emergent modelling, hypothetical learning trajectory, linear combination, university mathematics.

Introduction

Linear algebra is one of the fundamental and required courses for many science and engineering students. However, several researchers have reported that linear algebra remains a difficult course for students (Dorier et al., 2000; Stewart & Andrews-Larson, 2018). For example, Dorier et al. (2000) point out that students' difficulties with linear algebra are a consequence of abstraction, the abundance of new words, symbols, definitions, theorems, and the lack of connection with previous knowledge.

Consequently, since the late 1980s, several studies have been carried out on teaching and learning linear algebra concepts. Trigueros and Wawro (2019) report that linear algebra topics most frequently studied are span, linear independence, linear transformations, eigenvectors, and eigenvalues. In particular, the existing documentation on the concept of linear combination is scarce. Nevertheless, some researchers (Cárcamo et al., 2021; Stewart & Thomas, 2007) point out the importance of its learning to construct and understand other linear algebra concepts such as linear dependence, linear independence, spanning set and span.

Concerning studies on the linear combination, Parraguez and Uzuriaga (2014) present a genetic decomposition of the concept under the APOS (Action, Process, Object and Schema) theory. Mutambara and Bansilal (2021) examined the errors and misconceptions that mathematics teachers have when solving problems based on the linear combination and found that the most frequent errors are the foundational type, relating to misinterpretations of solutions to systems of equations. Furthermore, other studies present teaching and learning proposals, such as the one conducted by Wawro et al. (2012), who propose an instructional sequence known as The Magic Carpet Ride based on the Realistic Mathematics Education (RME) theory to study span and linear independence. This sequence begins with a problem that introduces the formal notation and language of scalar multiplication, linear combinations, and systems of equations. In general, the results found in the literature served as the basis for the design of our HLT tasks.

Theoretical framework

In this study, we use the work of Simon (1995) to construct a HLT with tasks based on the practical action projects principles (Cuevas & Pluvinage, 2003). *Hypothetical learning trajectories* are a structure that describes the process by which the teacher develops a classroom activity plan. A HLT is made up of three components: learning goals, learning activities, and the hypothetical learning or hypothesis of students' learning process. This last component is hypothetical because the students' RLT is unknown (Simon, 1995) . RLT is defined by Leikin and Dinur (2003) as the learning trajectory carried out in the classroom, including real events and procedure.

Although the HLT constitutes the starting point for task design, it does not indicate how a task should be designed. In this sense, we use the principles proposed by Cuevas and Pluvinage (2003), or C&P, as principles for designing the tasks presented in this study. These principles are decomposition into partial operations or mathematical concept analysis, prior to the design, to determine concepts necessary to achieve understanding; the action or the need to include dosed problems that promote student's active participation; starting a task with a problem in context; implementation of inverse operations; articulation of representation registers if the concept allows it.

On the other hand, emergent modelling is one of the three RME instructional design heuristics which describes how a series of models may support the mathematical advancement of students. Instead of telling students how to interpret a given model, an incremental process is sought in which models are constructed (Gravemeijer, 2020). The students are expected to develop formal mathematics through their informal mathematical activities. This heuristic is compatible with our approach to designing tasks for learning the concept of linear combination. In this respect, after a teaching experiment, we use Gravemeijer's (1999) levels of emergent modelling as an analytic framework to assess students' levels of understanding achieved with HLT. Gravemeijer distinguishes four levels of activity:

1. *Situational level (activity in the task setting).* At this level, interpretations and solutions depend on understanding of how to act in the setting (often out of school settings).
2. *Referential level*. In this level, models-of refer to activity in the setting described in the task. Consequently, models are grounded in students' understanding of real settings and are integral to explanations in which students describe how they interpreted and solved tasks centering on the starting point settings.
3. *General level*. This level begins to emerge when students reason about the mathematical relations involved. Therefore, it emerges as students' reasoning loses its dependency on situation-specific imagery. In this sense, models-for serve more as a means of mathematical reasoning than as a way of symbolizing mathematical activity based on environments.
4. *Formal mathematical level.* This level will often coincide with the use of formal notations. It is achieved when students no longer need the support of models for mathematical activity.

This study is guided by the following research question: How do technology-mediated tasks organized in a HLT support the conceptualization of linear combination in university students? This paper presents a HLT for linear combination and aims to examine how university students' understanding of the concept of linear combination progresses when working with tasks mediated by digital technology and designed under C&P principles.

Methodology

The study presented in this paper was developed under the Design-Based Research (DBR) methodology consisting of the following phases: preparation and design, teaching experiment, and retrospective analysis (Bakker & van Eerde, 2015).

Preparation and design phase

In this phase, a first HLT for the concept of linear combination in $\mathbb{R}^2$ was designed and developed (see Table 1). This HLT consists of four tasks that start with a problem in context about a carnival game we call "*Atrapa el Oso*" (Catch the bear), in which students must manipulate two robotic arms to grab a teddy bear. For each task, virtual interactive didactic scenarios (VIDS) were developed, accompanied by exploration and guided learning sheets (EGLS). These VIDS simulate the game: a board on which are placed a teddy bear and two robotic arms (green and red) whose movement depends on the vectors $\mathbf{k_1u}$ and $\mathbf{k_2v}$, respectively, as shown in Figure 1. The tools of the VIDS are four buttons (A, B, C, and D) that change the bear's position on the board, two sliders (k_1 and k_2) which are scalars that multiply vectors **u** and **v** to control the movement of the robotic arms ($\mathbf{k_1u}$ and $\mathbf{k_2v}$) and two buttons to grab or release the teddy bear. In task 4, the sliders or scalars values are hidden to be found by the students.

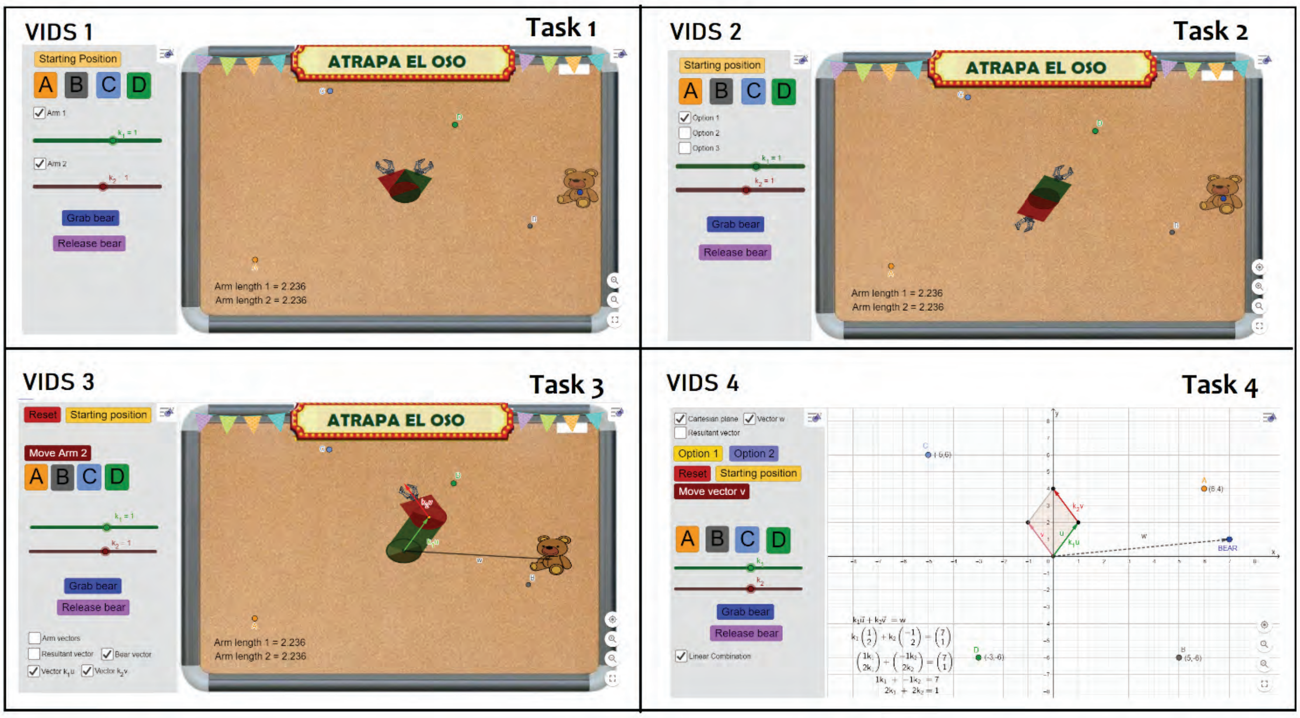

Figure 1: VIDS used in each HLT task

Table 1: HLT for the linear combination of vectors in $\mathbb{R}^2$

Learning goals	Learning activities	Hypothetical learning process
Task 1: Investigate which positions on the board it is possible to grab the bear with the robotic arms. Goal: Identify the motion limitations of robotic arms by analyzing the length and rotation of the links (magnitude and direction of vectors).	Students interact with VIDS 1. They change the bear's position and manipulate the sliders (k_1 and k_2) to identify in which of the four positions it is possible to grab the bear with each proposed robotic arm: a green robotic arm (k_1u with $\mathbf{u} = \binom{1}{2}$) and a red robotic arm (k_2v with $\mathbf{v} = \binom{-1}{2}$).	Students will identify arms' characteristics such as lengths and directions of movement: the green arm moves in a northeasterly and southwesterly and the red arm in a northwesterly and southeasterly direction. Therefore, it is possible to grab the bear in D with the green arm and C with the red arm.
Task 2: Investigate whether it is possible to grab the bear in position A by combining the movements of the robotic arms. Goal: Identify the need to bring the robotic arms together to grab the bear at any position on the board (addition of non-collinear vectors).	Students interact with VIDS 2. They identify the robotic arms characteristics in three options: $\mathbf{u} = \binom{1}{2}$ and $\mathbf{v} = \binom{-1}{-2}$; $\mathbf{u} = \binom{1}{-2}$ and $\mathbf{v} = \binom{-1}{2}$; and $\mathbf{u} = \binom{1}{2}$ and $\mathbf{v} = \binom{-1}{2}$. Then, they discuss whether it is possible to grab the bear in position A by combining the movement of the robotic arms.	Students develop a vector addition representation, i.e., they recognize that combining the movements of the arms consists of placing the red arm's origin at the green arm end. This representation makes it possible to identify that it's possible to grab the bear in position A only with option 3.
Task 3: Investigate if it is possible to grab the bear in positions A, B, C, and D with two degrees of freedom (2 DOF) robotic arm. Goal: Development of vector addition and identification of k_1 and k_2 as scalars.	Students interact with VIDS 3. They can link the robotic arms to form a 2 DOF robotic arm to identify the positions in which this new arm can grab the bear. Finally, they discuss the function of the sliders relating the k_1 and k_2 values to the magnitude and direction of vectors $\mathbf{k_1u}$ and $\mathbf{k_2v}$.	Students deduce that the 2 DOF arm can be modeled as a vector addition represented graphically as arrows. They also identify the movement of the arms as a scalar multiplication where k_1 and k_2 are the scalars.
Task 4: Model the problem of grabbing the bear in different positions on the board. What values must k_1 and k_2 have to grab the bear? Goal: Construct the linear combination expression modeling the bear grabbing problem.	Students interact with VIDS 4. They identify an expression that models the bear grabbing problem, at positions A, B, C, and D, with robotic arms (first with non-collinear vectors and then with collinear vectors). Finally, students solve systems of two equations to find k_1 and k_2.	Students model the bear grabbing problem with the equation $k_1\mathbf{u}+k_2\mathbf{v}=\mathbf{w}$ and identify the change produced by the sliders as scalar multiplication of vectors. They can also define whether $\mathbf{w}$ is a linear combination of $\mathbf{u}$ and $\mathbf{v}$.

Teaching experiment

This study reports the results of the first cycle of design research on understanding the concept of linear combination as part of an ongoing doctoral study. A teaching experiment was performed during the SARS-Cov-2 pandemic using the Zoom platform in a linear algebra class to investigate how the HLT helped students learn the concept of linear combination. Participants were 38 second-year engineering students at a Mexican public university who had already learned the concepts of linear equations, matrices, vectors, scalar multiplication, and vector addition. Participants had not previously studied the concept of linear combination. The experiment consisted of 4 sessions in which students worked in 10 groups of three or four students and two whole-class discussion sessions. Students were presented with the HLT tasks via links to access EGLS and VIDS. During the group interaction, each group performed the following activities: sharing the computer screen with the VIDS, reading the EGLS, discussing tasks, and recording the computer screen interaction. One of the authors was the class teacher. The data collected consisted of student EGLS, video recordings of group interactions, and whole-class discussions.

Analysis and results

The students' EGLS were analyzed in the retrospective analysis phase, and video recordings of each working group were transcribed. Subsequently, the research group met to examine the students' RLT, identify their actual learning and define the level of understanding achieved on each task. The following sections will show an approximation of the level achieved by a group (students S1, S2, S3, and S4). This group was chosen for the richness of their discussion and interpretation of tasks.

Task 1 results

The RLT shows that students achieved the situational level in task 1. Initially, the students acted in the task setting to identify the positions in which they could grab the bear with the given robotic arms. To do this, they used the sliders to determine the movement characteristics of each arm. Although S1 used the terms 'magnitude' and 'direction' (an informal way of talking about the properties of vectors) during the group discussion, he used them to describe the movement of the robotic arms.

S1: Is it possible to grab the bear in position D with arm 1?
S3: There, it will be possible (S3 answers before interacting with VIDS 1).
S4: If you could place the bear in any position on the board, at what position on the board, could you place the bear to grab it with this arm? And why?
S1: Well, it would be in position D, wouldn't it? Because the direction cannot be moved in the arm, only the magnitude can be extended.

Task 2 results

The RLT shows that students achieved the referential level in task 2. Students began to reason about the mathematical relationships involved in the starting setting when they discussed the following question: *If you could combine the movement of these arms, might you grab the bear in position A?* From the group discussion, it was revealed that the idea of combining the movement had led students to the concept of vector addition.

S1: I believe it is possible. If we take the vector k_1 and then add it to k_2 but in a smaller magnitude, then yes, it would be possible, wouldn't it?
S3: Only by addition, correct?

S1: Aha! That is if we leave k_1 like that and decrease the magnitude of k_2. Then, it would be possible if we put k_1 at the end to k_2.

S4: But can't we change the origin?

S1: Umm, no, but we can do like the addition, that is, they must keep their direction, but we can do like vector addition because it says: If you could combine the movement of these arms? I mean, I imagine that by combining, I want to think that we can put k_2 at the end of k_1.

S3: Something like what I am going to write down, that at the end of k_1, you put k_2, and here you have the vector, right? (S3 uses the zoom tools to draw an arrow representing the vector addition as shown in Figure 2).

Figure 2: S3 drawing of vector addition

Task 3 results

The RLT shows that students remained at the referential level when solving task 3. The students used the sliders to identify the positions in which they could grab the bear with a 2-DOF robotic arm, and they recognized this model as vector addition. However, the focus of the discussion remained on the starting setting. Although students were expected to identify the movement of each arm as the scalar multiplication of vectors, they didn't achieve this objective. The students knew that the sliders controlled the movement of the robotic arms, but they could not relate the observed changes to the scalar multiplication where k_1 and k_2 values are scalars.

Task 4 results

The RLT shows that students achieved the general level in task 4 without getting the formal level. This task set the stage to introduce the definition of linear combination as follows: 'A linear combination of vectors is the sum of two or more vectors multiplied by a scalar'. Students' reasoning lost dependence on situation-specific imagery. The focus of discussions shifted from evaluating ways to grab the bear whit the robotic arms to determining whether a vector could be expressed as a linear combination of vectors. This reasoning can be observed when students discuss the following question: *Suppose the bear is in the position denoted by the vector* $\mathbf{w} = \begin{pmatrix} -5 \\ 6 \end{pmatrix}$. *Is it possible to express* **w** *as a linear combination of the vectors* $\mathbf{u} = \begin{pmatrix} 1 \\ 2 \end{pmatrix}$ and $\mathbf{v} = \begin{pmatrix} -1 \\ 2 \end{pmatrix}$*?*

S1: Let's say v is from here to here, right? And then this would be from here to here. Can it be a linear combination w? (E1 draws the blue arrows shown in Figure 3).

S4: No, I don't think so.

S1: I don't think so, too, because if we do a vector addition, this one could be pointing this way (E1 draws another arrow as shown in Figure 4), and if we narrow it down, it would also be pointing this way, but, no, wait! I think this one can be.

S3: I think it could be because of the vector you put.
S1: The v, right? Can you put it in the negative?
S3: Yes!
S1: And then add up, yes, yes, it is true.
S3: If we make this vector multiply by a negative scalar, like here, maybe it will work.

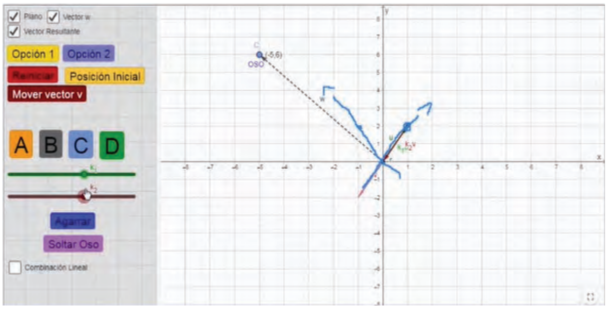

Figure 3: S1 drawing of vectors u and v

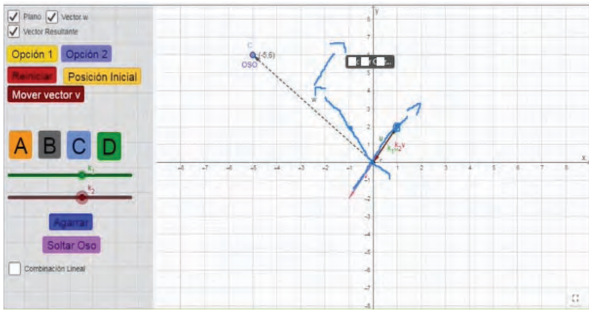

Figure 4: S1 drawing of linear combination

Preliminary conclusions

This paper presented the results of the first cycle of an ongoing design research, in which a HLT for the concept of linear combination was developed. Tasks were designed under the C&P principles and digital technology. Emergent modelling was used as an analytic framework to identify the levels of understanding students achieved with the proposed HLT. The results of the teaching experiment show that tasks based on the context of the game "Catch the bear" supported students in developing the concept of linear combination at the situational, referential, and general levels of understanding. However, they did not help in developing the formal level. In general, we observed that the interaction with the VIDS promotes dependence on models in the mathematical activity concerning the linear combination of vectors. Therefore, in the second cycle of design research, we should incorporate tasks that promote the development of formal mathematics. Since we present the case of four students, this is a first approximation, and an analysis of all groups is necessary.

On the other hand, to develop a formal level of understanding, there must be a balance between the conceptual and procedural. In this respect, results also showed that students have problems solving systems of equations, which are essential to developing the procedural part of linear combination. Therefore, we agree with Mutambara and Bansilal (2021) about promoting access to technological resources to reduce the time spent doing many computations by hand and to spend more time in developing conceptual understanding.

Student utilization schemes of questioning devices in undergraduate mathematics dynamic textbooks

Carlos Quiroz[1], Saba Gerami[2] and Vilma Mesa[3]

[1]University of Michigan, United States; cquirozs@umich.edu

[2]University of Michigan, United States; sgerami@umich.edu

[3]University of Michigan, United States; vmesa@umich.edu

We describe how students utilize questioning devices, an interactive feature designed into university textbooks to invite them to read the textbook before the class in which the content will be discussed. This feature has been added to three open-source and open-access dynamic textbooks intended for calculus, linear algebra, and abstract algebra. Using self-reports from 392 students in 23 courses and an instrumental approach, we identified three classes of situations in which the feature was used and three corresponding utilization schemes: Familiarizing with Content Before Class, Studying by Practicing and Doing Homework, and Self-Evaluating Understanding of Content. We suggest further areas of inquiry.

Keywords: Questioning devices in textbooks, instrumental approach, undergraduate students, mathematics textbooks, utilization scheme.

Mathematics digital textbooks offer opportunities for students to engage with mathematics in ways that go beyond the mere act of reading the textbook. In this paper, we focus on what we refer to as dynamic textbooks—a special type of digital textbooks that are open-source and open-access and have embedded interactive features. Because textbook features shape students' opportunities to engage with mathematics, how they are designed to engage students matters (e.g., level of interactivity, presentation, and order of features). In writing these textbooks, authors need to make many design decisions with students in mind as the main textbook users; as such they may not fully anticipate all the ways in which students will use textbooks features or the conditions that motivate their use. In the absence of this understanding, author-designers may add features that in the end might not be as useful for the students. In this study, we contribute by investigating student use of questioning devices that were added to three undergraduate dynamic mathematics textbooks in linear algebra, abstract algebra, and calculus. Specifically, we answer the following research question: What are the students' utilization schemes of these questioning devices?

We build on prior work (Mesa et al., 2021) in which we defined questioning devices as a form of questioning embedded in textbooks that seek to engage students in thinking about the content on their own before class. Differently from questions used in classrooms or asked in exercises, this other form of questioning in textbooks seeks to establish a personal relationship between the reader, the author, and the mathematics (Weinberg & Wiesner, 2011). In the textbooks used in this study readers can type responses to those questions directly into their textbooks, immediately sharing their thoughts with their teacher prior to a lesson. Teachers then become aware of how students might be thinking about the material and adjust their lessons accordingly. In Mesa et al. (2021), we found instructors' utilization schemes of these questioning devices. Because instructors' schemes can be related to students' utilization schemes, in this paper we complement our investigation by turning our attention to students. Because we have reviewed the literature on questioning devices in detail in Mesa et al. (2021), in this paper we provide an overview of the literature that focuses on students' use of digital and interactive textbooks.

Literature Review

Instructors indicate that reading the textbook is a very important skill relevant not only for mathematics majors (Mesa & Griffiths, 2012) but for all students because it supports mathematics learning. Judging from the extant research on student reading practices in university mathematics (e.g., Wiesner et al., 2020), knowing whether and how students read their textbooks is a key question for teachers and researchers. Research on university student use of digital textbooks are typically case studies at single universities or classrooms and describe use of interactive components (e.g., Johnston & Ferguson, 2020); relation between student grades and time spent reading (e.g., Allred & Murphy, 2019); skills, emotion, and participation and interaction (e.g., Bikowski & Casal, 2018); differences in student motivation and perceptions of learning when using interactive textbooks (Kondratieva, 2018); or use of digital resources in connection to rules of didactical contract (Gueudet & Pepin, 2018). These researchers indicate that undergraduate students see digital textbooks as resources that motivate and facilitate learning and have documented different levels of reading, different uses of features, and different expectations regarding the utility of interactive features. The differences seem to be related to students' prior knowledge and to personal goals regarding their courses (e.g., passing a course). While these studies suggest that students might not use their textbooks as intended, they do not indicate how students interact with specific interactive features.

Theoretical Framing

In Rabardel's instrumental approach (Rabardel, 2002) an instrument is "a whole incorporating an artifact (a human-made or a physical object) and one or more utilization schemes" (p. 65). A utilization scheme encompasses stable and structured manners that a user has for operating an artifact that includes observable behaviors and non-observable goals and rationales. Following Vergnaud (1998) we define schemes as the "invariant organization of behavior for a certain class of situations" (p. 229). This organization includes goals and expectations; rules of action (which can be seen as the "generative part of the schemes"); operational invariants (propositions that are held to be true by the subject when they act, that are used "to infer, from the available and relevant information, appropriate goals and rules); and possibilities of inferences (p. 229). Vergnaud views "situations and schemes [as] essential in the development of knowledge" (p. 237). Instrumental genesis s the process through which a user transforms an artifact into an instrument by creating utilization schemes associated with that artifact. Because pre-existing artifacts are instrumentalized by a user, different subjects can produce different instruments for the same artifact. Instrument production, carried out by the subject, encompasses two subprocesses, instrumentalization (the "emergence and evolution" of the artifact component of the instrument) and instrumentation ("the emergence and evolution of utilization schemes and instrument-mediated action: their constitution, their functioning, their evolution by adaptation, combination coordination, inclusion and reciprocal assimilation, the assimilation of new artifacts to already constituted schemes, etc." Rabardel, 2002, p. 103). The notion of utilization schemes is central to instrumentation. To document student instrumentation of an artifact—

questioning devices in dynamic textbooks—we identified the utilization schemes students reported when using questioning devices available in three textbooks designed to increase their interaction with the content.

Methods

This research is part of a larger mixed-method study that seeks to understand how teachers and students in undergraduate levels utilize three open-access open-source dynamic textbooks: *Active Calculus* (hereafter AC, Boelkins, 2019), *First Course in Linear Algebra* (hereafter FCLA, Beezer, 2019), and *Abstract Algebra: Theory and Applications* (hereafter AATA, Judson, 2019). The three textbooks are written in PreTeXt (https://pretextbook.org/), a markup language that allows the textbooks to be rendered in various formats (e.g., HTML, PDF, Braille, bounded). With PreTeXt, authors can infuse the textbook with interactive features, such as live computation cells with Python (Sage cells), immediate solution feedback, and collection of student responses to questioning devices for instructor use. The three textbooks were chosen to represent different student audiences. In the United States, calculus is a course that is taken by most students seeking an undergraduate degree in science, technology, engineering, mathematics, business, economics, and health. Linear algebra is a gateway course for mathematics and computing related majors, and in some cases for biology. Abstract algebra is a course usually taken only by mathematics majors (which include future secondary teachers). The questioning devices are called Preview Activities in the calculus textbook and Reading Questions in the linear algebra and abstract algebra textbooks. For this study, we analyzed data from 392 consenting students from 23 teachers across the United States who participated for a semester from Spring 2019 to Spring 2021 (187 used AC, 145 used FCLA, and 60 used AATA). Students (147 female, 142 male, 3 non-binary or trans, 100 no information) had an average age of 20 years, an average GPA of 3.43, and obtained an average grade of 82.58 in their respective courses.

We used data from five student logs (biweekly surveys with 8 to 19 closed- and open-ended questions about student textbook use). We used responses to two questions (see Table 1) intended to identify why and how students used the questioning devices (Q9, and Q5 are open-ended)[1].

Table 1: Log questions used in this study and number of responses by textbook

Question	FCLA	AATA	AC	Total
Log 1 Q9: Your textbooks include Reading Questions/Preview Activities in some sections. How have you used these?	130	41	145	316
Log 2 Q5: What are your priorities (objectives, goals) while using Preview Activities/Reading Questions? Explain how you use them.	86	32	125	243

Analysis

We used a constant comparative analysis with the answers to the two open-ended questions (Q9 and Q5) to identify classes of situations, goals, and rules of actions. The analysis proceeded in four steps.

[1] Across all the textbooks less than 10% of the students stated that they never used these features, indicating high use across the sample.

First, we identified three classes of situations in which students reported using questioning devices: *Before Class Preparation, Study,* and *Self-Evaluation. Before Class Preparation* included situations in which students expressed, they used questioning devices to get ready for an incoming class. *Study* included situations in which the students expressed using questioning devices for practicing, doing homework, and studying for exams. *Self-Evaluation* included situations in which students said they used the questioning devices for testing their own understanding of the content. Using these categories, we classified each of the 559 responses (316, Log 1 Q9 + 243, Log 2 Q5) under one of these situations or as "No Class" if the response did not convey enough information to identify a situation (e.g., "yes"). In the second step, we inspected responses within each class to identify goals. We identified and coded eight goals that students associated with the classes of situations: three related to *Before Class Preparation*, four with *Study*, and one with *Self-Evaluation*. In the third step, with the responses organized by class of situation, we identified 10 rules of action. In the fourth step, the first and second author identified the operational invariants, looking for explanations for why students were using the questioning devices. The most frequent reason was that students used the questioning devices because they were required by their teacher (61 out of 511). Other operational invariants appeared but were less frequent.

The first authors coded all the responses; the other two authors independently coded classes of situations, goals, and rules of actions for 10% of the responses. The average Cohen's Kappa for coding for situation, goals, and actions were 0.78, 0.71, and 0.63. These three values are within the range of [0.61 - 0.80], which correspond with a substantial agreement.

Findings: Students' Instrumentation of Questioning Devices

We identified three utilization schemes of the questioning devices, one per class of situations, *Familiarizing with Content Before Class, Studying by Practicing and Doing Homework,* and *Self-Evaluating Understanding of Content* (see Figure 1). While we characterized the utilization schemes separately to make sense of students' use of the questions devices, students often mentioned multiple goals, rules of actions, and operational invariants. Moreover, although we identified all three utilization schemes across students using the three textbooks in calculus, abstract algebra, and linear algebra, not all goals were mentioned across these groups of students.

In the first utilization scheme, familiarizing with content before class, students said they use questioning devices to get acquainted with the upcoming material in the course:

> They have been assigned to us before classes. I look over (*rule of action: skimming*) the preview questions [questioning device], try to solve the activity (*rule of action: answering*) and it gives me an idea of what we will be working on in class that day (*goal*). (30.07, Spring19, AC)[2]

In this excerpt, a clear goal is stated: to get "an idea" of what will be taught in class. We identified two more goals under this class of situations in the corpus: to better prepare for class and to connect

[2] We identify quotes of a student using the convention "XX.YY, term, textbook" where XX refers to the instructor and YY to the student of that instructor.

previous material with new content. To accomplish these goals, four actions were mentioned: skimming and answering the questioning devices, reading the chapter associated with the questioning devices, and writing down questions they could ask in class. To justify these actions, students collectively offered four reasons: the questioning devices were assigned (e.g., “My professor has it mandatory to answer the reading questions for each section,” 36.20, Fall20, FCLA), the questioning devices addressed important content (e.g., “I usually remember the material in a reading question as what is most important for me to know,” 46.05, Spring21, FCLA), the questioning devices helped them with understanding the new material (e.g., “These are very helpful in introducing the concepts of the section,” 35.70, Fall20, AC), or because their instructors used the questioning devices to teach in class (e.g., “We have used these in our class to give our initial answers to the reading, and then our professor gives us feedback on our responses,” 23.20, Fall20, AATA).

Utilization scheme 1: Familiarizing with content before class		
Goals	Rules of Action	Operational Invariants (rationale)
1. To prepare for class 2. To connect previous materials with new ones 3. To find out what will be taught	- Skimming questioning devices - Answering questioning devices - Reading the chapter associated to questioning devices - Preparing questions for the class	- I answer the questioning devices because my teacher told me to - I noticed that the questioning devices address important content - I noticed that the questioning devices help me understand the new material - My teacher uses them in class to teach
Utilization scheme 2: Studying		
4. To practice 5. To do homework 6. To prepare for assessments 7. To find out what is important in the chapter/section	- Skimming questioning devices - Answering questioning devices - Checking their answers to the questioning devices - Taking notes of parts of the questioning devices and their solutions	- I answer the questioning devices because my teacher told me to - The questions devices help me learn - I noticed that the assessments have very similar problems and questions as in the questioning devices - I noticed that the questioning devices address important content
Utilization scheme 3: Self-evaluating		
8. To check own understanding of the content	- Attempting the questioning devices before reading the chapter - Attempting the questioning devices after reading the chapter - Re-reading the chapter if unable to answer the questioning devices - Comparing answers to the questioning devices with answers provided by textbook, classmates, teacher, or other resources	- It is important to me to make sure that what I know is correct

Figure 1: Students’ utilization schemes of questioning devices

In the second utilization scheme, students said they use questioning devices to study after the material was introduced in class:

> When I have a similar homework problem to work out, I will use the Reading Questions (*rule of action: answering*) for extra practice and to gain better understand[ing] (*goal: practice*; *operation invariant: because I learn by answering questioning devices*). (45.15, Spring21, FCLA)

This student indicates using the questioning devices as “extra practice” when doing homework because doing so will help gain a “better understanding” of the material. We identified four goals associated with this scheme: to practice (when questioning devices are not assigned as homework), to do homework (when questioning devices are assigned as homework), to prepare for assessments (e.g., “Used them as reference to how class questions on exams and quizzes will look like,” 45.53, Spring21, FCLA), and to find out what is important to study in the chapter or section associated with the questioning devices (e.g., “If these are not assigned as homework, I use these questions as reinforcement of the main/big ideas from the chapter,” 33.13, Spring20, AATA). We identified four student actions: skimming and answering questioning devices, checking answers to the questioning devices, and taking notes on the questioning devices and their solutions. We identified four operational invariants that students reported as justifying these actions: Students were required by their instructors to work on the questioning devices during class or at home (e.g., “We use them in class and as homework,” 30.23, Spring20, AC); using the questioning devices benefited their own learning of the material (e.g., “I take advantage of this completely in order to be successful. i [*sic*] enjoy how you can reflect and absorb the material this way,” 44.03, Spring21, FCLA), problems on their examinations were similar to those in the questioning devices (e.g., “I complete the preview activities for a grade but I think that they help a lot in the initial learning process because it lets students know what questions on a test might look like,” 35.57, Fall20, AC), and ideas showcased in the questioning devices were important ideas in the chapter or section (e.g., “I find them [reading questions] helpful because they make sure I understand important parts of the section,” 44.06, Spring21, FCLA).

In the third utilization scheme students said they use the questioning devices for self-evaluation of their understanding of the material:

> I mostly use this to check for my understanding of the chapter. If i [*sic*] get to the reading questions and do not understand them I know I have to reread the chapter again. (37.08, Fall19, FCLA)

This quote represents the essence of the scheme, that students take the questioning devices as a kind of arbiter of the content of the chapter; not knowing the answers triggers a process of reading other parts of the textbook. Three rules of action were associated with this scheme: attempting the questioning devices to evaluate their understanding before reading a chapter (e.g., “Do them to see where my baseline is for this chapter,” 35.65, Fall20, AC); attempting the questioning devices after reading the chapter to check ability to answer them; when unable, students re-read the chapter; and compare their answers to the questioning devices to other resources, such as the solutions provided by their textbook, their classmates, or their instructors (e.g., “Do them and then go over them with classmates," 35.81, Fall20, AC). The operational invariant is inferred as the need to know that their knowledge is correct; this is done either by contrasting responses with the content of the reading questions or with external resources, such as peers or the instructor.

Discussion and Conclusion

These findings are important for textbook designers, as well as instructors using the textbooks, because they confirm that the questioning devices are being used for their intended purpose and more. The three utilization schemes help us understand what motivates students to use questioning devices and how they use them. For two schemes, (*Familiarizing with Content Before Class*, *Studying by Practicing and Doing Homework*) one main motivator was that teachers assigned the questioning devices to the students. This highlights the important role that teachers have in influencing student use of textbooks, supporting prior findings that indicate that when asked, students will use the textbooks as teachers suggest (Mali & Mesa, 2018). However, that was not the only motivator for students to use the questioning devices; students, by *motu proprio* used the questioning devices for familiarizing themselves with the content, studying by practicing, and more interestingly for evaluating their own understanding of the material. Because the third scheme does not seem to be motivated by the teacher assigning the questioning devices, we wonder whether this particular scheme would emerge without exposure to the questioning devices initiated by the teachers.

The findings show that although designer-authors and instructors may have specific ideas of how a feature should be used, students find ways to exert their agency and decide how to use them. In the case of questioning devices, these features were designed to be completed before a lesson; therefore, they may not be the best fit for students when it comes to studying and self-assessment. Although we encourage students to use their textbooks for their needs, we believe that by learning about the intended purposes and embedded opportunities of textbooks' features students can make better use of their textbooks tailored for specific situations. For example, the WeBWorK exercises embedded within the AC textbook provide immediate feedback to students while questioning devices do not; thus, we expect that these features are better suited for self-assessment than questioning devices.

This study was done to complement our prior work on teacher utilization schemes of questioning devices identified in Mesa et al. (2021), namely (1) *Instructors complete the questioning devices for lesson pre-planning,* (2) *Instructors require students to do the questioning devices for the purpose of lesson planning,* (3) *Instructors use the questioning devices for the purpose of instruction,* and (4) *Instructors require students to complete the questioning devices for the purpose of assessment.* We anticipate that the four teacher utilization schemes are related to the student utilization schemes of the questioning devices we found here. As a next phase in our work, we will determine the connection between these utilization schemes and investigate differences by textbook.

Uncertainty as catalyst for creativity in students' mathematical problem-solving process

Eirin Stenberg[1], Per Haavold[2] and Bharath Sriraman[3]

[1,2] UiT- The Arctic University of Norway, Faculty of humanities, social sciences and teacher education, Tromso, Norway; eirin.stenberg@uit.no; per.oystein.haavold@uit.no

[3]University of Montana, Department of Mathematical Sciences, Missoula, USA; sriramab@mso.umt.edu

Keywords: Creativity, uncertainty, mathematical pathologies.

The role of creativity in mathematical competence and problem-solving

Among the fundamentals of mathematical competence is problem-solving abilities, which in the context of school mathematics often is related to mathematical creativity. Sriraman (2005) defines mathematical creativity as novel or insightful solutions to a problem, as well as the formulation of new questions which allows "old" problems being viewed differently, where the use of imagination is a key element. A certain level of mathematical ability is necessary for creative mathematical thinking to manifest, but mathematical ability can also lead to fixations and hinder creativity (Sriraman & Haavold, 2017). Contrasting fixations, cognitive flexibility is often viewed as essential for gaining creative insight (Haavold & Sriraman, 2021). Thus, creativity seems to play an essential role in mathematical competence and problem-solving, and therefore an important question to be answered is how creativity can be catalysed in mathematics education. The focus of this research proposal is to give an outline to an investigation of whether and how uncertainty can catalyse creativity in mathematics students' problem-solving process.

Uncertainty and its relation to creativity in mathematical problem-solving

Sriraman (2021) defines uncertainty as a state of ambiguity and curiosity, as well as the sense of being in doubt, also labeled "creative doubt". Sriraman (2005) argues that creativity requires exposure to uncertainty and experience with the struggle of creating mathematics and solving problems. Creative problem-solving is further associated with cognitive flexibility, which involves the ability to switch between mental sets and strategies when dealing with uncertainty (Haavold & Sriraman, 2021). Sriraman (2021) found that uncertainty plays an important role as a catalyst for mathematical creativity in the work of professional mathematicians, but uncertainty is otherwise a little researched concept in the field of mathematics. Therefore, an interesting perspective would be to investigate whether the relation between uncertainty and creativity which Sriraman (2021) suggests, also exists in the work of students of mathematics. In the following paragraphs, pathologies as a potential task design for the purpose of catalysation is explained.

Mathematical pathologies as a facilitator of uncertainty and creativity

Sriraman and Dickman (2017) argues that mathematical pathologies can foster creativity through addressing misconceptions and false beliefs. The authors define pathologies as "[…] examples that are specifically designed to violate properties that are perceived as valid. The term 'pathological' is also specifically used in mathematics to refer to objects "cooked up" to provide interesting examples of counterintuitive behavior" (Sriraman & Dickman, 2017, p. 137). Examples that are directed at violating valid properties create a space where domain limiting barriers must be overcome and this is where creativity plays an important role. A pathology can take form as a counterexample, but it's not a necessity. Further, a pathology is not the same as a misconception because the intention of pathologies is not to point out the wrong- or rightness of a mathematical concept. The intention is to foster creativity in the face of uncertainty. Lastly, a pathology is a task-design, while a misconception is something within the mind of a student (Sriraman & Dickman, 2017). In the following methodology of the research proposal, pathologies are proposed as generators of uncertainty in the process of catalysing creativity in students' mathematical problem-solving.

Methodology

To investigate whether and how uncertainty can catalyse creativity for mathematics students, we tend to employ pathologies in task-based interviews with students. An example of a task that can be given is presented in Figure 1. This task addresses incorrect fraction cancelation which by chance still leads to the correct answer. Students can be asked to investigate if there exist other fractions with this property. While solving the tasks, the students should think aloud so that insight to their problem-solving process can be accessed and analyzed. The focus of the analyzes will be mapping of how fixations occur and what leads to creative, flexible ways of viewing the problem when dealing with uncertainty generated by pathologies**.** Both video and sound, in addition to collecting their written answers, are useful data collection tools. The results can indicate whether and how uncertainty provided by mathematical pathologies can catalyse creative solutions to a problem in the work of mathematics students. The hypothesis is that pathologies as task design can catalyse creativity by generating uncertainty, also for students of mathematics.

$$\frac{19}{95} = \frac{1\cancel{9}}{\cancel{9}5} = \frac{1}{5} \qquad \frac{26}{65} = \frac{2\cancel{6}}{\cancel{6}5} = \frac{2}{5}$$

Figure 1: Two- digit anomalous fractions (Sriraman & Dickman, 2017, p. 140)

Digital Fabrication for Mathematics Education: A Critical Review of the Field

Henrik Stigberg

Østfold University College, Faculty of Teacher Education and Languages, Norway; henrik.stigberg@hiof.no

This article presents a critical review on digital fabrication for creating manipulatives in mathematics education research. It provides an overview of the research field from two perspectives: 1) explored digital fabrication technologies and reified mathematical concepts, and 2) applied pedagogical theories and research methodologies. Results show that 3D printing is the most common technology for creating manipulatives reifying mathematical concepts within geometry, algebra, and functions, as well as fractions. In the typical research project, a qualitative paradigm is chosen, and learning is investigated from a constructionistic perspective. The review reveals a small but trending research community and concludes with two specific opportunities for consolidating research on digital fabrication for mathematics education.

Keywords: Critical review, digital fabrication, manipulatives, mathematics education.

Introduction

This article presents a critical review of previous research on digital fabrication for mathematics education. Digital fabrication (DF) is “the process of translating a digital design developed on a computer into a physical object” (Berry et al., 2010, p. 168). DF technologies such as 3D-printers, laser cutters or vinyl cutters, have become affordable and can be found at Makerspaces and FabLabs[1] around the world. These tools enable people to create professionally looking items rapidly and at a relatively low cost. Blickstein (2013) argues that DF and making can play a major role in education, “bringing powerful ideas, literacies, and expressive tools to children” (p. 2). DF technologies might support mathematics teachers through the creation of manipulatives. Manipulatives or concrete material are physical objects that are used to reify abstract concepts in mathematics education. Previous research highlights, that students benefit from long-term use of manipulatives in mathematics education. Both students’ achievements in and motivation for mathematics increase when manipulatives are used (Pires et al., 2019). However, manipulatives are not self-explanatory and to draw maximum benefit from students’ use of manipulatives, teachers must continuously situate their activities and the physical objects based on students’ previous experiences, as well as their teaching context (Thompson, 1992). Stylianou (2010) has found that teachers have knowledge gaps of how different representations, such as manipulatives, are translated into mathematical concepts. DF technologies could enable teachers to create context-sensitive manipulatives for teaching activities, situated in the classroom and enhance teachers’ knowledge on manipulatives to improve their teaching. There is prior research (Ford & Minshall, 2019; Hielscher & Smith, 2014; Papavlasopoulou et al., 2017) reviewing DF education in general. To my knowledge, there does not exist a review focusing on mathematics education and how DF can be used to create manipulatives,

[1] https://fabfoundation.org/global-community/

which is the objective in this article. I performed a critical review of previous research in the field to answer the following research question: *What characterizes research on digital fabrication for creating manipulatives in mathematics education?*

Method

The aim of this review is to explore how DF has been used in mathematics education research so far, focusing on DF technologies as well as mathematical concepts and manipulatives on one hand and used theories and research methodologies on the other. I applied a three-step iterative critical analysis (Çorlu et al., 2017; Stigberg, 2017): finding appropriate papers including selection of databases and search terms; eliminating irrelevant papers based on a set of exclusion criteria; analyzing appropriate papers based on key terms answering the research questions. Grant and Booth (2009) describe that "a critical review goes beyond mere description of identified articles and includes a degree of analysis and conceptual innovation" (p. 93). In this review, I will analyze identified articles, highlight research gaps and provide opportunities for further research in DF for mathematics education.

Step 1: Retrieving Publications

The database used as primary source for finding literature is Ebsco, including Education Source, Education Research Complete, Academic Search Primier, ERIC, CINAHL, MathSCINet via EBSCOhost and MEDLINE. To broaden the search and ensure to include as many relevant publications as possible, I chose to perform a search on Google Scholar as well.

From the research topic and research questions, I derived the following keywords: "digital fabrication", "3D-printing" or "laser-cutting", in combination with "mathematics education" and "manipulatives" or "concrete materials". 3D-printing and laser-cutting are popular DF technologies and often used as representatives or synonyms of DF and therefore highly relevant as keywords. A search for vinyl-cutter, another DF technologies gave no hits and was excluded from the final search query. In mathematics curricula, both terms manipulatives and concrete material are used to describe physical objects that reify a mathematical concept and were included in the search. Finally, I used '*' special character in the search query to allow different forms of all keywords. I did not define a timeframe since I was interested in finding all relevant literature. The final queries used in the search can be found at: shorturl.at/eqxP4. The search queries were used for a full text search in both Ebsco and Google Scholar. The literature search resulted in 73 hits from Ebsco and 277 hits from Google Scholar. After removing duplicates, the total number of found articles is 254.

Step 2: Appropriate papers

In this step, the papers that were not appropriate for the review were eliminated based on the following exclusion criteria: not peer-reviewed (36), non-English work (10), not empirical (purely theoretical papers or review articles) (66), do not concern mathematics education or manipulatives not investigated (159), studies on STEM projects not specifically highlight mathematics education or creating manipulatives (81), or 3D-pen as technology (5). Several publications corresponded to more than one exclusion criteria. For a complete list of inclusion/exclusion criteria, see link: shorturl.at/aioyU. The elimination process resulted in a final list of 17 papers to be included in the analysis. The included literature can be found in **Table *1***.

Step 3: Analyzing the papers

Quantitative and qualitative data was extracted from the articles and gathered in a database. The analysis of each paper included general bibliographic information, as well as type of DF technologies, reified mathematical concepts, applied theories, research design and methodology.

Results

There is limited research on DF technologies for creating manipulatives in mathematics education (17). Most of the initially found publications (254) present research on STEM (81) or do not focus mathematical content or manipulatives (159). Often research presents interdisciplinary projects to facilitate students design thinking and innovation skills. Furthermore, searching on Google Scholar gave several articles that were not peer reviewed (36) such as teaching material or blog entries. Research on 3D pens was excluded based on the definition of DF as computer-controlled tools (Gershenfeld, 2012). Most of the research on DF technologies included in this review is published 2018 or later (14) indicating a growing interest in DF technologies for education. Furthermore, the research community around DF in mathematics education is limited to a small number of research groups. For example, Greenstein published 7 out of the 17 articles (F, H, I, J, K, M, O). A major research project on DF technologies in mathematics education is a project concerning pre-service teachers called: Prospective Teachers Making for Mathematical Learning (F, I, K). In the following, I have analysed the 17 articles from two perspectives: Firstly, focusing on DF technologies and created artefacts reifying mathematical concepts. Secondly, focusing on applied theories, research design and methodologies.

Digital fabrication technologies

3D printers are the most used DF technology for creating manipulatives (15). Two articles, based on the same project, explore the use of a die cutter as DF technology (G, Q). Four articles provide a rationale for their choice of DF technology. 3D printers are starting to become cheap and accessible (A, B), enable teachers and students to create artifacts with little effort and in reasonable time (C, P) and the possibility to reproduce existing artefacts (P). The reviewed articles present different software choices for modelling 3D objects: TinkerCad (C, J, N), OpenScad (C, P), SketchUp (E) and AutoDesk 123D Design (L). FabLab Model Maker was used to design 3D models for the die cutter technology (G, Q). Nine articles do not provide information about a specific 3D modelling software. Wan and

Ivy (2019) mention Thingiverse[2], an online platform where makers can share their work, as one possible resource for finding 3D models for mathematics education.

Artifacts reifying mathematical concepts

The reviewed articles present three core mathematical concepts: geometry, algebra and functions, and fractions. Geometrical objects such as rectangular prisms and cubes (C, D, G, Q), cones (J, N), prisms representing triangles (M), tessellation with pattern blocks (D), general geometric properties (L) and 3D printed geoboards for representing area and volume (E). Created objects reifying concepts of algebra and functions such as: coordinate system (J), 3D printed representations of graphs of functions with one variable (P) and two variables where students investigate contours, partial derivates, gradient vector field, and restrictions to the curve (A), and models of the integral as area under a graph (J). Mohamed et al. (2020) presents different 3D printed triangular prism to investigate students' reasoning about quadratic changes. 3D printed objects reifying fraction as value (F, I) and fraction of time using circle segments (K, O).

Opportunity 1: Exploring alternative technologies, added mathematical concepts, and resources for creating and sharing manipulatives

The results expose that previous research on DF in mathematics education is sparse. There is a need to explore different DF technologies, alternative manipulatives reifying more mathematical concepts, and investigating the use of available online resources. Most of the research has been done using 3D printers, limiting the type of manipulatives that can be created through additive manufacturing. Laser cutter or vinyl cutter enable subtractive manufacturing and open a new design space for manipulatives. So far, laser cutter technologies are expensive, but one could argue that they will become more commonplace in schools like 3D printers today. Manipulatives are created for geometry, algebra, and functions, as well as fractions. One interesting research path is investigating how manipulatives can reify other concepts such as arithmetic, decimal system, combinatorics, or probability, all are part of the mathematics curriculum. Research has focused on how students and teachers can use software to create 3D models that can be printed. There are plenty of online resources available for teachers to choose from e.g., Thingiverse. Understanding how manipulatives can be shared by teachers, taking part in the maker culture is missing. From prior professional development projects, I often met teachers requested pre-made material or lesson plans they can adopt to their own teaching. They express a lack of time to develop their own material on the one hand, but they prefer to be creative and develop their own teaching materials on the other hand.

Applied theories

Three theoretical characteristics have emerged: 1) constructivism and constructionism as theoretical underpinnings, 2) design theories for creating a learning context, and 3) theories for analysing teachers' and students' knowledge. Firstly, many of the reviewed articles refer to constructivism and constructionism as rationale when creating manipulatives (9). Papert's constructionism (Papert & Harel, 1991) is based on Piaget's constructivism (Piaget, 2013), but emphasizes that learning is

[2] https://thingiverse.com

happening when we create sharable things (Ackermann, 2001). Secondly, the research group around Greenstein frames the process of creating manipulatives as learning by design (H,I,K). The approach presented by Koehler and Mishra (2005) provides an "opportunity to consider the interplay between the evolving artifact and the application of teacher knowledge domains in the artifact's development" (Greenstein et al., 2019, p. 1152). Thirdly, teachers' technological, pedagogical, and content knowledge (TPACK) is explored in three articles (B,H,K). Dilling and Witzke (2020) apply theory of subjective domain of experience when analysing students' knowledge. According to this theoretical framework, students experience is linked to the specific learning context and their knowledge needs to be described according to their situational link, including previous experiences. Greenstein et al. (2020) is an article that investigates learning from a sociocultural perspective, using theory of commognition (Sfard, 2007) to analyse students' changes in discourses. In their article, they specifically analyse, students' narratives about; mathematical objects, participants of the discourse, learning about mathematics, and design decisions. An overview can be found at: shorturl.at/mnsN3.

Research methodologies

The included articles present different cases how DF was used in a teaching context. Most commonly, researchers report on their own teaching experiences in higher education (10), on interventions applying manipulatives in a classroom setting for K-12 students (5), or from a workshop or course for in-service teachers (2). Most articles (14) use purely qualitative methods in their research design based on observation, video recordings, interviews, and hand-ins. Three articles (B,H,L) use mixed methods to collect data including surveys, and pre- and post-tests. Research on teaching experiences in higher education analyse cases based on selected students and their work (D,F,I,J,K,M,O), data from students' self-reports (B,H), or description of the course and used manipulatives (A,N). Research projects involving K-12 students investigate interventions with manipulatives developed by researchers in a classroom setting (E,L), and students' learning outcomes when creating manipulatives (G,P,Q). Ulbrich et al. (2020) report on their experiences from a workshop series with 200 in-service teachers. They conclude that it is essential to learn more "about a teacher's needs and expectations using technologies" (Ulbrich et al. 2020, p. 303). Greenstein & Olmanson, (2017) provide a case of a DF course for in-service teachers including examples of created artefacts. Seven articles did not use a framework for analysing their results.

Opportunity 2: Adopting communities of practice as a framework for understanding in-service teachers learning of digital fabrication for mathematics education

The typical research project investigates DF for pre-service teachers applying constructionism (Papert & Harel, 1991) as theoretically underpinning describing learning from an individual perspective. Constructionism provides an acknowledged framework for understanding learning when creating and sharing manipulatives. However, for professional development projects with in-service teachers, a sociocultural perspective on learning is preferable, because it offers a "more effective means to, understand and implement an educational partnership for work-place learning" (Spouse, 2001, p. 512). The review found two research projects exploring how in-service teachers could use DF to create their own manipulatives and only one research project applies a sociocultural perspective. To consolidate research on DF for mathematics education both perspectives (individual and sociocultural) need to be investigated appropriately for both pre-and in-service teachers.

Communities of practice (CoP) deploys a situated learning perspective with sociocultural elements and is widely accepted in education research and work-place learning (Hammersley, 2005). CoP could provide a theoretical lens on how learning emerges when pre- and in-service teachers engage in authentic learning experiences, such as making, sharing, and using available manipulatives to develop their professional identity in their community (Wenger, 1999). CoP has been proposed as a suitable research paradigm for the mixed methods approach, which has been found in three articles included in this review (Denscombe, 2008).

Conclusion

This paper presents a critical review of 17 research articles on DF for creating manipulatives in mathematics education. Previous research is concentrated at stray research clusters. The typical DF research project explores manipulatives for reified mathematical concepts in geometry, algebra and functions, and fractions, using 3D printing and is published 2018 or later. Qualitative methods or mixed methods are predominant for data collection. The review reveals three main theoretical perspectives. Firstly, constructionism, with roots in constructivism (Papert & Harel, 1991), as underpinning theories. Secondly, design theories, such as Learning by Design (Koehler & Mishra, 2005), and thirdly, theories for analysing teachers' and students' knowledge. Finally, the paper provides two specific opportunities for consolidating research on DF for mathematics education: 1) Exploring alternative technologies, added mathematical concepts, and resources for creating and sharing manipulatives, and 2) Adopting communities of practice as a framework for understanding in-service teachers learning of DF for mathematics education.

An Analysis of Educative Curriculum Materials for Formative Assessment

Sumeyra Tutuncu[1] and Jeremy Hodgen[1]

[1]UCL Institute of Education, United Kingdom; s.tutuncu@ucl.ac.uk; jeremy.hodgen@ucl.ac.uk

Keywords: Formative assessment, educative curriculum materials.

Background

Black and Wiliam's comprehensive review (1998) that includes more than 250 studies worldwide suggests the close relationship between achieving learning outcomes and teaching practices associated with formative assessment. However, despite considerable research and development work, the implementation of formative assessment remains a problem. A key issue is that variety has been observed among the definitions and exemplars of formative assessment. Although these definitions and exemplars do not contradict each other, they highlight different elements. Formative assessment includes the elements such as identifying learning intentions, monitoring students' learning, regulating learning, identifying the actors of learning, and using appropriate teaching strategies and tools. All these elements should be considered holistically for productive practices. Moreover, it should be noted that the features of these elements can vary from discipline to discipline (and sometimes even between topics within the same discipline). Teachers need exemplars in order to understand the principles of formative assessment authentically and enact them in practice. Well-designed educative curriculum materials can be used to communicate these principles to teachers. That is to say, educative curriculum materials aim to improve teachers' learning alongside students' learning (Davis & Krajcik, 2005). In this research, the aims are to identify educative exemplars that can communicate the aspects of formative assessment to teachers and suggest principles that can guide future design. Using multiplicative reasoning as a critical case, the existing curriculum materials are analysed to achieve these research aims.

Theoretical Framework

Two frameworks guide the material analysis. First, formative assessment strategies suggested by Wiliam and Thompson (2007) are used in order to identify formative assessment techniques. These strategies include five aspects: understanding and sharing learning intentions, eliciting students' learning, feedback, using students for each others' learning and self-regulation. This framework is grounded in the idea that the function of formative assessment is to regulate learning. This regulation is examined in three ways: proactive regulation (before the lesson), interactive regulation (during the lesson) and retroactive regulation (making the decision for the next lessons or different contexts). Second, the educative features of the materials are analysed in terms of including the guidance to enact these techniques and the rationale of these techniques (Quebec-Fuentes & Ma, 2018).

Methods

The materials to be analysed were selected purposively from curriculum materials designed for early secondary mathematics teaching. First, these materials are chosen based on whether they include topics relevant to multiplicative reasoning such as ratio, proportion and geometric similarity. Second, the materials that include a separate teacher guide are chosen. Third, the materials that include formative assessment features explicitly or implicitly are chosen. When sampling the materials, whether the materials include formative assessment explicitly or implicitly has been decided according to how the designers advertise these materials. As a result, five groups of multiplicative reasoning lessons are chosen from the projects Mathematics Assessment Project (MAP), Increasing Competence and Confidence in Algebra and Multiplicative Structures (ICCAMS), CornerStone Maths, Mathematics Formative Assessment Systems (MFAS) and from a commercial resource widely used by teachers in England, White Rose Maths. While MAP, ICCAMS and MFAS lessons are advertised as formative assessment resources, CornerStone Maths and White Rose Maths involve formative assessment as one element of teaching. The main reason to choose a variety of resources is to access rich formative assessment techniques and educative features. It is not aimed to compare the materials from different resources and rank their overall quality. Instead, the educative features in the data will be analysed to inform future design. In order to achieve research aims, reflexive thematic analysis is conducted (Braun and Clarke, 2006).

Progress after CERME 12 conference

At the CERME 12 conference, the poster that outlines the methodological decisions of this research was presented. Following the discussions at the conference, the data was revisited and the suggested initial themes in the poster were revised. As a result, in terms of educative support, five themes are identified: learning goals, students' thinking and misconceptions, students' participation, differentiation and assessment norms. These five themes are found as a result of a largely semantic coding that mainly explored explicit educative support in the materials. In the next step of the data analysis, we prefer a more latent coding orientation in order to reveal implicit educative support hidden in the materials regarding these five themes.

Rethinking the notion of textbooks as mediators between the official curriculum and classroom practice

Hendrik Van Steenbrugge

Stockholm University, Department of Teaching and Learning, Sweden;
hendrik.van-steenbrugge@su.se

Textbooks are frequently understood to mediate between the official curriculum and the classroom from an alignment perspective. Such an understanding of textbooks has advanced our knowledge of the multifaced nature of curriculum implementation, though it runs short on explaining the origins of aspects in textbooks that aren't typically covered in the official curriculum. As an alternative, I propose to understand textbooks as a locally constituted hybrid. Such a position does not a priori approach textbooks from their alignment with the official curriculum and classroom practice, but might take a network of social practices in relation to textbooks into consideration. I believe that this helps to inquire about the origins of the social aspects of teaching and learning mathematics typically covered in textbooks, but usually not covered in great detail in official curricula. I also believe that such an understanding helps to foreground textbook studies as a full-fledged research field.

Keywords: Mathematics textbooks, culture, social relations.

Introduction

Mathematics textbooks are commonly situated in between the official curriculum and the actual classroom practice, often with an assumption that content and values travel from the official curriculum through the textbook into the classroom (e.g., Pepin, Gueudet, & Trouche, 2013; Valverde, Bianchi, Wolfe, Schmidt, & Houang, 2002). Although the specific labeling differs between studies and frameworks, our field of study differentiates between the official curriculum (standards, national or regional frameworks, and sometimes even high-stake tests), written curriculum (the textbooks), teacher-intended curriculum (teachers' ideas for instruction), enacted curriculum (as instruction unfolds in the classroom), and attained curriculum (students' outcomes) (e.g., Remillard & Heck, 2014; Valverde et al., 2002). Underlying this conceptualization is an idea of alignment: an alignment between the official curriculum and the textbooks, the textbooks and the teachers' ideas, the teacher ideas for instruction and the actual instruction, and the actual instruction and students' outcomes. Such an understanding of curriculum and of textbooks has helped to advance the field's understanding of how curriculum possibly impacts student learning, and of the multifaced nature of curriculum implementation.

The curriculum implementation process is primarily framed from a content-related perspective. Yet, as much as teaching and learning mathematics is about mathematical content, it is a social activity, making it relevant to also inquire about the nature of the social relations between the teacher, students, resources, and mathematical content (Love & Pimm, 1996; Pepin & Haggarty, 2001; Rezat & Sträßer, 2012). Whereas official curricula typically don't contain much detail about the configuration of these social relations (Boesen et al., 2014; Valverde et al., 2002), mathematics textbooks do. Thus, the idea of alignment between the official and written curriculum runs short in understanding where the configurations of social relations in textbooks come from. To advance the field's related understanding, I propose to change a predominant understanding of how textbooks are culture. In this paper's remainder, I will first exemplify the predominant view of alignment in influential curriculum studies. I will then describe two views of culture in mathematics education, arguing that one particular view has dominated the field, and to understand textbooks as a locally constituted hybrid. Next, I will apply such an understanding to interpret an example textbook study of configured social relations and present a network alternative to the predominant alignment view.

An alignment view in influential curriculum frameworks and studies

In this section, I attempt to illustrate how an alignment view in thinking about curriculum has dominated the field. I do so in relation to the highly influential framework adopted in the TIMSS textbook studies and in relation to a group of cross-contextual studies that explicitly aimed to uncover part of the cultural dimension of teaching and learning mathematics.

The TIMSS textbook studies

The TIMSS studies center on a model of educational opportunities in which textbooks play a mediating role between systemic intentions and classroom instruction. The grounding of the model of educational opportunities, Valverde and colleagues (2002) describe, is a tripartite model of curriculum: the intended curriculum (the curriculum as system goals), the implemented curriculum (the curriculum as instruction), and the attained curriculum (the curriculum as student achievement). Stressing the mediating role of textbooks, Valverde and colleagues (2002) position the textbook as the potentially implemented curriculum between the intended and implemented curriculum. The language underlying the TIMSS textbook studies reflects a view that understands content and values to travel from the intended (or official) curriculum, through the textbook, into the classroom:

> The model envisions content standards, frameworks, programs of study and the like as primary defining elements of potential educational experiences. […] Even so, another characterization is essential for the model. This is a portrayal of the most important instruments intended to translate these goals into prescriptions or suggestions for specific opportunities to be created in classrooms. Thus, an additional important component of the TIMSS measurement strategy included a look at how textbooks provide templates for student actions in the classroom. […] How textbooks are related to the intended curriculum and the particular vision that they promote regarding what students are expected to learn are among the fundamental features of educational systems. […] The ability to link these features to other outcomes – such as instructional practices and student achievement is another strength of this approach. (Valverde et al., 2002, pp. 8–9)

The abovementioned description stresses the primary role of the intended or official curriculum, the role of textbooks as translators of the official curriculum, and the linking of textbooks to classroom practice and student achievement. In fact, the title of this study "According to the book. Using TIMSS to investigate the translation of policy into practice through the world of textbooks" (Valverde et al., 2002) stresses exactly this idea of linearity.

Other TIMSS textbook studies (Schmidt et al., 2001; Schmidt, McKnight, Valverde, Houang, & Wiley, 1997) have added empirical grounds to such a linear notion of alignment. Reflecting the textbook research field's focus on mathematical content (Fan, Zhu, & Miao, 2013; Herbel-Eisenmann, 2007), these two studies prioritized the content over the social dimension of teaching and learning mathematics. Also, building further on the TIMSS framework, Remillard and Heck (2014) have further specified the official curriculum. Underlying their model is also the notion of alignment from the official to the operational curriculum, partially mediated by textbooks. Remillard and Heck also draw an arrow from the operational to the official curriculum, yet this is one of the few arrows that don't get concretized or explained in great detail.

Cross-cultural textbook studies

Pepin and colleagues have studied French, German, English, and Norwegian textbooks in terms of their cultural underpinnings (Pepin et al., 2013; Pepin & Haggarty, 2001). This influential body of cross-cultural work found that the textbooks differed in terms of the particular mathematical focus and the sequencing of activities. French textbooks, for instance, were clearly sequenced according to a learning trajectory consisting of small investigations, essential content, and practice whereas Norwegian textbooks contained a mix of practical activities followed by exercises. These scholars understood the observed differences in terms of underlying beliefs about rationality (as part of encyclopaedism) in France and doing math in Norway. Traces of these underlying beliefs were also observed in official curriculum documents and teachers' actual teaching, which led Pepin et al. (2013) to conclude that these underlying ideas travel from the official curriculum, through the textbooks, to the classroom practice. Interestingly, Pepin et al. (2013) also mention that the French and Norwegian textbooks under study were designed by teachers and teacher educators, which calls to complicate the idea that underlying ideas travel from the official curriculum, through the textbooks, to the classroom practice. Teachers and teacher educators represent classroom and teacher education practice, each bringing in their particular interest (e.g., Apple, 1992). The design of textbooks by teachers and teacher educators is a frequent practice in multiple educational systems across the globe. It seems that multiple paths toward the textbook, or even a network is at stake. Therefore, I propose to reconsider textbooks as culture. That is at focus in the following section.

Two views of culture

Reflecting on research on instructional practices to support equitable learning opportunities in mathematics classrooms, Hodge and Cobb (2016) come to identify two views of culture in relation to teaching and learning mathematics. The vast majority of studies, Hodge and Cobb argue, is to be situated in the Cultural Alignment Orientation. Related studies understand culture as a network of relatively stable practices of a bounded community. Research then departs in students' out of school practices to work toward aligned classroom practices that offer meaningful opportunities to learn. The Classroom Participation Orientation, on the other hand, considers culture as a network of local hybrid practices that people jointly constitute. In this orientation, research tends to originate in classroom practices that offer meaningful opportunities and considers adjustments and supports to ensure participation of all groups of students. Hodge and Cobb argue that the latter orientation considers cultural alignment as one of the several resources for more equitable learning opportunities, but not as the default option as is the case for the first orientation, and hence as more promising in terms of providing instructional guidance.

Relating Hodge and Cobb's identified views of culture to textbook analysis, I believe it is fair to say that most of the (cross-cultural) textbook studies are to be situated in a cultural alignment orientation.

As illustrated in the previous section, influential studies point to the alignment of textbooks with the official curriculum and with classroom practices (Pepin et al., 2013; Pepin & Haggarty, 2001; Schmidt et al., 2001; Schmidt et al., 1997; Valverde et al., 2002). Instead, I propose to understand textbooks and the culture in textbooks as a locally constituted hybrid. Such a perspective does not a priori focus on textbooks in terms of their alignment toward the classroom and the official curriculum, but tries to better understand how textbooks embody culture and how actors representing multiple social practices – hence the hybrid – are engaged in jointly constituting – hence the local – textbooks as cultural artefacts. As Apple wrote about textbooks about 30 years ago, "[Textbooks] are the simultaneous results of political, economic, and cultural activities, battles, and compromises. They are conceived, designed, and authored by real people with real interests" (Apple, 1992, p. 4). In the following section, I will describe an example textbook study that focuses on the social dimension of teaching and learning mathematics – for which the cultural alignment orientation falls short in explaining where the observed configurations of social relations come from. I will then try to illustrate how the notion of textbooks as a locally constituted hybrid one might help to inquire in a more powerful way about the origins of these configurations.

The textbook as a locally constituted hybrid

Intended configurations of social relations in textbooks from Sweden, USA, and Flanders

In a related study, I have analyzed textbooks from Sweden, the USA, and Flanders (Van Steenbrugge & Remillard, in preparation). We focused on lesson guides, or the section where textbook authors explicitly communicate with teachers about the author-intended lessons. Bezemer and Kress (2015) describe that writing is no longer the main mode of communication to facilitate students' engagement with textbooks, and we soon experienced that the same applies to the sections that talk explicitly to teachers. The selected textbooks from all three educational contexts appeared to communicate consistently through written text, layout, and images, which helped to identify particular configurations of social relations between the teacher, students, the central artefacts at stake, and the mathematical content (See Table 1).

We started from Rezat and Sträßer's (2012) tetrahedron model to visualize the social relations between teacher, students, and artefact, and their position relative to the mathematical content, but further specified the model in three ways. We differentiated between the social relations during lesson enactment (blue lines) and lesson preparation (green lines) because lesson guides both communicate about the intended lessons and are usually read by teachers during lesson preparation. We also specified the central artefacts at stake: student textbook and/or chalkboard during lesson enactment, and lesson guide during lesson preparation. Finally, we characterized the relations in terms of agency, intimacy, and prominence. Arrows signal who has agency over whom. In some cases, agency was shared between two nodes, which we indicated by means of a double-sided arrow. In other cases, none of the nodes seemed to have authority over one another, which we indicated by means of a line without arrows. Variations of distance between nodes is used to indicate that some social relations between nodes were more intimate compared to other nodes. We marked more prominent relations from less prominent ones by means of thicker lines. The figures appear to be quite consistent within each context, but differ considerably across the three contexts.

Table 1: Configured social relations in elementary mathematics textbooks from Flanders, USA, and Sweden (from Van Steenbrugge & Remillard, in preparation)

<table>
<tr><th>Flanders</th><th>USA</th><th>Sweden</th></tr>
<tr><td>Kompas (KP)
</td><td>Math in Focus (MiF)
</td><td>Matte Direkt (MD)
</td></tr>
<tr><td>Nieuwe Tal-rijk (NT)
</td><td>Everyday Mathematics (EM)
</td><td>Matte Eldorado (ME)
</td></tr>
</table>

These representations of the particular privileging of configured social relations relate to particular ideas about what it means to be a student learning and a teacher teaching mathematics. These ideas seem to differ primarily from context to context, with some more within-context variation in the USA, where multiple groups advocate for certain views in relation to teaching and learning mathematics. In Flanders, for instance, student access to mathematics seems to be mediated by the teacher and the chalkboard. During class, the teacher, ultimately, is the authority of what counts as mathematical correctness. This stands in sharp contrast to the particular configuration of social relations in EM, from which it seems that mathematical authority is a shared responsibility. One of the aspects that differentiates the Swedish textbooks from the others is their configuration of the teacher-related relations. The blue lines without arrows between teacher and student, and teacher and textbook indicate that the teacher has a responsive, rather than an active role during the lesson. The important message here is that the configurations of social relations in textbooks, and the underlying particular ideas of what it means to be a mathematics student and teacher, seem to differ across contexts. This points at context-specific culturally valued norms as to what it means to teach and learn mathematics. That is the starting point for the next section.

Where does the configuration of social relations come from?

The previous section suggests that textbooks from different educational contexts privilige particular configurations of social relations, which have roots in underlying meanings of being a student and teacher. These differences call to nuance a linear conception as to how culture finds it ways into the classroom and the assumed transmissive role of textbooks in this matter (e.g., Pepin et al., 2013; Valverde et al., 2002). Official curricula do not contain such detailed descriptions of social relations as the ones represented in Table 1 (Boesen et al., 2014; Valverde et al., 2002). So where do these configurations of social relations in textbooks come from? Even if it is likely that the enacted lessons differ from the pictures that come out of our analysis (Stein, Remillard, & Smith, 2007), it is worth thinking about where the observed cross-cultural differences come from. In discussing that particular question, I propose to consider textbooks as a locally constituted practice. Thus, rather than primarily understanding textbooks in function of the official curriculum and classroom practice, it is worth focusing on the social practice of textbook design in trying to better understand how cultures of mathematics teaching and learning are constituted in textbooks.

From a locally constituted hybrid perspective on textbooks, the observed privileging of configurations of social relations represent mathematics education culture amongst the actors involved in textbook production. In many cases, textbook authoring includes participation among teachers, teacher educators, researchers, and other stakeholders such as the inspectorates. Each brings in a specific interest, even if not explicitly named. The textbooks under study are published by commercial publishers, which also brings an economic aspect into the picture. Also, families or other influential communities such as the labor market practices influence textbook production and adoption (e.g., Apple, 1992). The view of textbooks as a locally constituted hybrid helps to uncover potential sources other than the official curriculum. Explicitly studying this hybrid and locally constituted nature of textbooks therefore seems to have the potential of adding to our understanding of the cultural and political significance of textbooks.

How could an alternative to the predominant view of alignment look like?

I think that Valero’s (2010) conceptualization of mathematics education as a network of social practices is helpful in this regard. Such a conceptualization stresses that the social practices outside of the classroom, such as the textbook design practice, are as significant practices of mathematics education as the actual classroom practices. Figure 1 is an attempt to capture some of the relevant social practices in relation to textbooks and textbook design. There are connections with the official curriculum and classroom, but this is not the main flow. There are also connections to other social practices such as teacher education, teaching, high stakes testing, mathematics education research, and digitalization. These social practices are also connected to one another. High stakes testing, for instance, has connections to the official curriculum and the classroom. Digitalization has connections to the mathematics education research field, the classroom, and families. As indicated by the dark blue lines in Figure 1, the configurations of the social relations, then, can come from a negotiation (locally constituted) between teacher educators, teachers, and researchers involved in the design of textbooks, where each draws on her/his particular background (the hybrid). Nowadays, and especially with the COVID-19 pandemic as a catalysator, digital textbooks and platforms are increasingly present in the learning and teaching of mathematics, which also potentially impacts the configurations of social relations (e.g., Ruthven, 2018). Furthermore, the constitution of the network and the prominence of social practices and connections between these practices can accommodate to the particular educational context. In Sweden and the USA, for instance, significant curriculum interpretation resides at the individual teacher level and in high stakes testing, respectively (Van

Steenbrugge et al., 2019). This makes the official curriculum – teachers – classroom connections particular prominent in the Swedish network compared to the official curriculum – high stakes testing – classroom connections in the USA (See the orange and red lines in Figure 1).

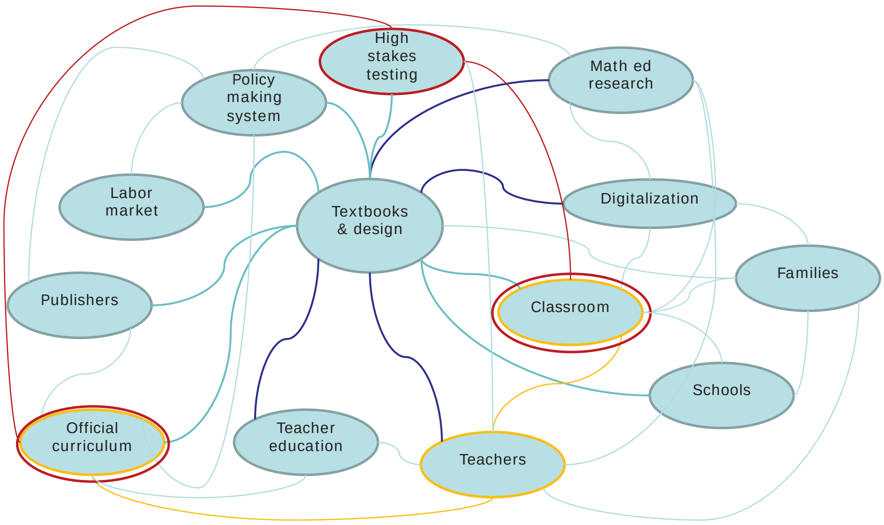

Figure 1: Textbooks in a network of social practices

As one can see in Figure 1, the network allows to take distance from one primary form of alignment. Rather than considering other factors as potentially influencing alignment, it understands these factors as constitutive elements of the network of social practices that relate to textbook design. It also points towards understanding textbook studies as a research field on its own, not just as auxiliary to studying classroom practices and student performance.

Problematizing the notion of problem posing expertise

Ling Zhang[1, 2], Andreas J. Stylianides[2] and Gabriel J. Stylianides[3]

Problem posing, which we view as a form of task design performed by the learner, is an important mathematical activity. Several studies have investigated differences between expert and novice problem posers, but no clear definition of problem posing expertise has generally been agreed upon. In a study involving 66 masters and 60 sixth-grade students we identified expert problem posers based on their performance on problem posing tasks (with or without numbers/context) rather than as in prior research presupposing who expert problem posers were based on their mathematical experience or backgrounds. The results showed that masters students had a significantly lower proportion of the Top-level (expert) problem posers and a significantly higher proportion of the Bottom-level (novice) problem posers than sixth graders, demonstrating that presupposing problem posing expertise based on mathematical experience or backgrounds would have been misleading.

Keywords: Mathematical problem posing, experts, novices, task design.

Introduction

Problem posing has recently attracted much attention among researchers and educators, including curriculum standards (e.g., NCTM, 2000). As a form of a curricular opportunity (embedded in curriculum resources) in which teachers and students can engage, problem posing is an important mathematical activity like the well-known problem solving. Several types of problem posing tasks have been used in research and teaching practice (Lee, 2021). The aim of having problem posing tasks in curriculum resources could be not only for assessing students' mathematical understanding or mathematical learning, but also for supporting students to become competent problem posers and problem solvers (Cai et al., 2015). One research strand in this area views problem posing as a goal of mathematics instruction and focuses on how one develops problem posing capacity (Cai & Leikin, 2020), showing that students and teachers are capable to pose problems (Cai et al., 2015) and that training to problem pose is feasible (Cai et al., 2015; Koichu & Kontorovich, 2013). However, little attention has been paid thus far to the meaning of problem posing expertise. This is problematic because without a good understanding of what constitutes an expert problem poser, efforts to develop problem posing capacity among students and teachers are lacking important conceptual foundation.

In this study, we aimed to identify expert problem posers by examining our participants' performance on problem posing tasks rather than as in prior research presupposing who expert and novice problem posers were based on their mathematical experience or backgrounds. Specifically, we addressed the following research question: *How can we distinguish between expert and novice problem posers based on their performance on problem posing tasks, and how do the resulting groups of expert and novice problem posers compare with how these groups would normally be defined based on participants' mathematical experience or backgrounds?*

Theoretical Considerations

Experts in Mathematical Problem Posing

Several researchers explored differences between expert and novice problem posers by assuming that problem posing expertise was connected to a particular attribute of participants' mathematical experience or backgrounds – such as their problem solving experience (Pelczer & Gamboa, 2009), teaching experience (Voica & Pelczer, 2009), or mathematical maturity (Zhang et al, under review) – but the results showed that their "expert" problem posers were not always performing better than the "novices." For example, Voica and Pelczer (2009) compared problems posed by pre-service and in-service teachers, considering the former group to be novices in problem posing and the latter group to be experts. They found that their perceived expert group did not perform better than their perceived novice group, presumably because in-service teachers' pedagogical knowledge and classroom experience constrained their views of the problems that could be posed. Also, our prior research (Zhang et al, under review) had examined problem posing by comparing mathematically more mature students (masters students majoring in pure mathematics or mathematics education) and mathematically less mature students (sixth-grade students). The surprising finding that the more mature participants did not outperform the less mature participants in problem posing further prompted us to problematize the notion of problem posing expertise and its presumed association with participants' prior mathematical experience or backgrounds.

Kontorovich and his colleagues conducted a series of studies to explore the possible characteristics of the problem posers for mathematical competitions, arguing that those who systematically create problems for high-level mathematical competitions may be considered as expert problem posers (Kontorovich, 2020). While this notion of expertise is still linked to participants' mathematical backgrounds, problem posers for mathematical competitions may be less controversial as an expert group than in-service teachers or masters students due to mathematical competitions often being reputed as treasures of "elegant," "intriguing," and "surprising" problems that reach the students after thorough committee discussions (Koichu & Andzans, 2019).

To conclude, no clear definition has generally been agreed upon for who problem-posing experts are though prior studies have provided some useful insights into possible characteristics of these experts. The participants of those studies identified as expert problem posers were presupposed to be experts based on their prior mathematical experience or backgrounds. Yet this approach to identifying experts yielded some surprising findings such as novice problem posers outperforming presumed experts.

Criteria for Identifying Expert Problem Posers

Most of the research on problem posing has involved the assessment of the types, quality, and quantity of the posed problems, often inferring from these the participants' problem posing ability. Silver and Cai (2005) proposed three criteria that might be selectively applied to most problem-posing tasks when used in assessment settings: quantity, originality, and complexity. Several researchers have adapted these criteria to assess participants' problem posing ability (Cai et al., 2020). In what follows, we discuss four common criteria used in prior studies for assessing the problems been posed. In the study we report herein, we used these criteria to operationally measure problem posing performance and thus as criteria for identifying expert problem posers.

The first criterion is *the number of mathematical problems posed* (Leung & Silver, 1997; Silver & Cai, 2005). Silver and Cai (1996) found that nearly 30% of the problems posed by middle school students were either nonmathematical problems or simply nonproblem statements (even though the directions clearly asked for mathematical problems). Crespo and Sinclair (2008) hypothesized that students' difficulties generating mathematical problems might relate to a lack of opportunity to explore a problem situation adequately before and during the posing process. Therefore, the number of mathematical problems been posed might reflect how adequately the posers explore the problem situation. The number of problems posed was also used as a measure of fluency in studies that assessed creativity using problem-posing as a test tool (Bicer et al., 2020). The more mathematical problems being posed, the more adequately posers might have explored the problem situation and the higher their anticipated level of mathematical fluency.

The second criterion is *the number of posed problems that are solvable* (Cai et al., 2015; Leung & Silver, 1997; Zhang et al., under review). Even though students and teachers were found to be able to pose mathematical problems, the posed problems were not always solvable or relevant (Silver & Cai, 1996), which suggests that the participants might not have selected enough elements or organized adaptive relations to construct the problems. The more solvable mathematical problems being posed, the more adaptive elements and relationships posers might have selected to formulate the problems or the better their understanding of the problem-posing tasks.

The third criterion is *the complexity of the posed problems*. Some research measured this criterion by the number of steps for solving the posed problem (Cai et al., 2020; Leung & Silver, 1997). According to the concept of problem space proposed by Milinkovic (2015), any problem can be described in terms of its context, elements, and the relationships between elements. Zhang et al. (under review) considered the sum of relationships and elements in the constructed problem space to reflect the complexity of the posed problems. The larger the sum of relationships and elements constructed in the problem, the more complicated a problem space has been formulated by the poser.

The fourth criterion is *the clarity of the posed problems*. According to NCTM (2000), using mathematical vocabulary, notation, and structure to clearly represent ideas, describe relationships, and model situations are important for students' ability to communicate mathematically. Zhang et al. (under review) found that nearly a third of the problems posed by students were expressed unclearly or partially clearly. The greater the clarity of the posed problem, the better the ability of the poser to communicate in problem posing.

Methodology

Participants

The participants were 66 masters students and 60 sixth-graders from 11 classes of a primary school, all in China. The masters students were recruited via an advertisement that we posed to call for volunteers among masters students majoring in pure mathematics or mathematics education in a university among the top 100 Chinese universities. Regarding the sixth-graders, 5 or 6 students from each class of the selected school, which was affiliated with the aforementioned university (ranked in the top 10 of the local city), volunteered to participate in this study. Each participant signed an informed agreement letter prior to the study. The sample was appropriate for our study because, according to the conventional way of defining problem posing expertise based on participants' experience or backgrounds, the former group would be the experts and the latter the novices. Whether these expert/novice groups would be confirmed empirically was the subject of the research.

Data Collection

The study was conducted in a soundproof and uniform light laboratory with a voice recording. The participants were given a description of the research procedure along with brief instructions that they were expected to think aloud while completing the Problem-Posing Tasks (PPTs). Then they underwent a training phase to get familiar with problem posing via two simple tasks. Two kinds of test combination (1A-2B-3A-4B and 1B-2A-3B-4A) were provided on a daily rotating cycle. The participants chose their available time to get one of the test combinations, described in Table 1, and were tested individually. We considered two types of tasks (with/without number; with/without context) since several researchers (English, 1998; Leung & Silver,1997) have predicted that task format affects subjects' problem posing performance. The target tasks were chosen from the PPT-number test comprising translated versions of tasks used by Leung and Silver (1997), which included the task situations of House Purchase and Pool Maintenance, and the PPT-context test comprising modified versions of tasks used by Cai et al. (2020), which included the task situations of Driving Home and Sporting Goods. No time limits were set on participants' work with the tasks.

Table 1: Test items and distribution of participants

		PPT-number				PPT-context			
		House Purchase		**Pool Maintenance**		**Driving Home**		**Sporting Goods**	
		1A[1]	1B	2A	2B	3A	3B	4A	4B
Masters Students	P_1=30	✓			✓	✓			✓
	P_2=36		✓	✓			✓	✓	
Sixth Graders	N_1=30	✓			✓	✓			✓
	N_2=30		✓	✓			✓	✓	

[1]*Format A in the PPT-number test is the task with numbers, Format B in the PPT-number test is the task without numbers; Format A in the PPT-context test is the task with context, Format B in the PPT-context is the task without context.*

Data Analysis

We re-analyzed the data in our prior research (Zhang et al., under review), guided by our new research question. The responses of the 126 participants who completed the PPTs were recorded and coded with respect to six criteria as shown in Table 3. These included the four main criteria for identifying expert problem posers that we discussed earlier and two further sub-criteria in which "the complexity of the posed problems" was divided into "the largest sum of relations" and "the largest sum of elements."

Principal Components Analysis (PCA) was conducted according to the four main criteria to select the Top 15% (19 participants, experts) and the Bottom 15% (19 participants, novices) from the overall sample of 126. We chose 15% so as to be selective but also to have enough students in each group to conduct meaningful statistical analyses. For the correlation assumption test, the correlation between each index (criterion) ranged from 0.507 to 0.975 (>0.30), which meant that there was a linear correlation between each index; the KMO (Kaiser- Meyer- Olkin) value of 0.773 indicated that the sampling was adequate (a value between 0.7 and 0.8 was taken to be "middling"); the Bartlett's test of sphericity with an associated p value of <.001 indicated that we could proceed to use PCA to analyze our data. The result of total variance explained showed that only the first component had eigenvalues over 1.00 (that is, 3.267) and that together they explained 81.669% of the total variability in the data. This led us to the conclusion that one factor solution was adequate.

Results

Top 15% and Bottom 15% participants' distribution

We sorted the participants according to the main factor extracted by PCA, and we selected the top 15% (19/126) participants and the bottom 15% participants (19/126). The general information of both groups is shown in Table 2. Surprisingly, in the Top 15% group nearly 80% of the participants (N=15) were sixth graders; only 4 participants were masters students. A Z-Test showed that there is a significant difference (at 95% confidence interval) between masters students and sixth graders in the Top 15% group. In the Bottom 15% group, nearly 70% of the participants (N=13) were masters students; only 6 participants were sixth graders. There is a significant difference (at 80% confidence interval) between masters students and sixth graders in the Bottom 15% group. Table 2 also shows the distribution of participants in the two categories of tests.

Table 2: Top 15% and Bottom 15% participants' distribution

	Categories of students			**Categories of tests**[2]	
	Master students	Six graders	Z-Test [1]	1A-2B-3A-4B	1B-2A-3B-4A
Top 15% (total=**19**)	4	15	2.234(95%)	9	10
Bottom 15% (total=**19**)	13	6	1.492(80%)	13	6

[1]95% (80%) refers to significant difference at 95% (80%) confidence interval (2-tailed). [2]Specific information about the categories of tests was shown in Table 1.

Top 15% and Bottom 15% participants' performance in each of the problem posing criteria

We selected the top-level and bottom-level students by ranking the *combined score* on the main factor, which was extracted by PCA. However, the top-level students' performance in *each criterion* was not necessarily better than the bottom-level students' performance. This made meaningful the comparison of the two groups across each criterion separately, which we present in Table 3.

Regardless of the task format (with or without context/numbers), the results of a multi-factor analysis of variance indicated that the mean performance of the Top 15% participants was higher than that of the Bottom 15% participants on all criteria. In Table 3 we present the findings for the two PPT-context tasks; the findings for the two PPT-number tasks were similar but are not reported here due to space constraints. Specifically, for the Driving Home task, the Top 15% participants posed more mathematical problems (F=83.97***,η_p^2=.712), posed more solvable problems (F=102.4***,η_p^2=.751), posed problems with a larger sum of relationships and elements (more complicated problems) (F=63.36***,η_p^2=.651), and posed more clearly-expressed problems (F=90.28***,η_p^2=.726).

Table 3: Top 15% and Bottom 15% participants' *performance* on the PPT format with/without *context*

Criteria		**Driving Home**			**Sporting Goods**		
		With context	Without context	*Group effect*	With context	Without context	*Group effect*
Number of math problems posed	Top 15%	7.67(2.9)	5.30(1.7)	F=83.97***	7.70(4.9)	3.11(1.1)	*F=23.74****
	Bottom 15%	1.77(0.7)	0.50(0.5)	η_p^2=.712	2.00(0.9)	0.31(0.5)	η_p^2=.411
	Task format effect	*F=9.70**; η_p^2=.222*			*F=12.95**; η_p^2=.276*		
Number of solvable problems posed	Top 15%	7.33(2.4)	5.20(1.8)	F=102.4***	5.30(2.3)	3.11(1.1)	*F=55.97****
	Bottom 15%	1.69(0.8)	0.17(0.4)	η_p^2=.751	1.33(0.8)	0.23(0.4)	η_p^2=.622
	Task format effect	*F=12.03**; η_p^2=.261*			*F=12.93**; η_p^2=.276*		
Complexity of the posed problems	Top 15%	10.33(1.3)	7.00(0.0)	*F=63.36****	10.00(2.4)	7.00(0.0)	*F=37.18****
	Bottom 15%	5.23(2.7)	1.17(2.9)	η_p^2=.651	4.83(3.4)	1.62(3.1)	η_p^2=.522
	Task format effect	*F=28.99***; η_p^2=.460*			*F=12.91**; η_p^2=.275*		
- The largest sum of relationships	Top 15%	3.78(0.4)	2.00(0.0)	*F=52.53****	3.00(0.8)	2.00(0.0)	*F=37.35****

*[1] According to Cohen (1988)'s partial eta squared, 0.01 is considered a small effect, 0.06 is considered a medium effect, and 0.14 is considered a large effect. [2] ***p < .001, **p < .01, *p < .05.*

Discussion

Prior research tended to presuppose problem posing expertise based on participants' mathematical experience or backgrounds (Koichu & Kontorovich, 2013; Kontorovich, 2020; Pelczer & Gamboa, 2009; Voica & Pelczer, 2000). In this paper, we problematized whether this way of identifying expert problem posers is indeed valid. Specifically, we followed a data driven approach to identify expert problem posers based on participants' problem posing performance rather than presupposing who the expert problem posers were based on participants' prior mathematical experience or backgrounds. Had we followed prior practice, we would have considered the masters students to be the experts and the sixth graders to be the novices in problem posing. However, our PCA showed that the masters students had a significantly lower proportion of Top-level problem posers and a significantly higher proportion of Bottom-level problem posers than the sixth graders. This result indicated that it was reasonable to identify expert problem posers by their problem posing performance rather than by their mathematical experience or backgrounds. Also, we compared the Top-level and Bottom-level groups across each of the four criteria used in prior studies for assessing problem posing performance; in PCA the 126 participants were ranked by an extracted main factor with a combined score. The fact that experts outperformed novices in each theory-driven criterion complements the PCA findings in suggesting that the identification of problem posing expertise by the data driven approach as used in this study was indeed appropriate.

From interviews with masters students in our prior study (Zhang et al., under review), we can get some insights as to why the masters students as a group did not do as well as one might have expected in the problem posing tasks. When asked about what their biggest challenge was when posing the problems, the masters students indicated that the cues motivating them to construct new problems were those they had seen in their primary school textbook or relevant reading materials. They did not attempt to use higher level mathematical knowledge. Also, the masters students were more used to working on problem solving tasks rather than problem posing tasks. Conversely, over the last decades primary school students have had increasing opportunities to pose problems in their classes. This is supported by Cai et al.'s (2017) investigation of the problem posing tasks in Chinese textbooks from the 1990s to the 2010s, which found that the number of problem posing tasks significantly increased over the years. The aforementioned indicates that participants' problem posing performance is influenced by many factors, and so it is not reasonable to assume in advance that one group of participants will be the expert group simply from their level of mathematical knowledge/backgrounds.

Improving the GeoGebra Classroom tool to better accommodate online educational resource development based on the SAMR model

Johanna Zöchbauer, Markus Hohenwarter, Zsolt Lavicza

Johannes Kepler University, Austria;
johanna.zoechbauer_1@jku.at, markus.hohenwarter@jku.at, zsolt.lavicza@jku.at

This paper describes an exploratory case study within a project aiming to develop a novel connected classroom technology (CCT) for offering new possibilities for teaching with technologies. It outlines a lesson in which three-dimensional coordinates were taught through an online resource created based on the SAMR (Substitution, Augmentation, Modification, Redefinition) model and the GeoGebra Classroom tool. Moreover, this paper presents findings of our study focusing on the interconnections of tangible and digital tools as well as on tasks that offer whole-class activities and student interactions. Findings of our study indicate that creating online resources based on the SAMR model, collaborative work between developers of tools and task designers could be valuable. In addition, when creating online resources offering advanced teaching possibilities, developers of these tools and task designers must collaborate and interact with teachers who are using them.

Keywords: Class Activities, connected classroom technology, digital tools, tangible tools, educational resources.

Introduction

This research project aims to develop a new, mathematically suited, tool offering novel opportunities for mathematics teaching to support teachers as well as to assist students' learning. Our objective is to develop a tool that allows a variety of possible applications in teaching and supporting learning. The idea is to use powerful mathematics software and further develop an existing online tool into a connected classroom technology (CCT) by implementing new features and functionalities (see Zöchbauer & Hohenwarter, 2020; Zöchbauer et al., 2021). The technology, in this case, is GeoGebra Classroom, an online tool for teachers' and students' devices that are connected online and can be used for teachers and students to interact with each other. GeoGebra Classroom can be used for interactive teaching approaches in various settings and can be applied to all levels of education. Moreover, we have great opportunities to work with developers to adapt this tool based on our research findings.

"Connected classroom technology refers to a networked system of personal computers or handheld devices specifically designed to be used in a classroom for interactive teaching and learning" (Irving, 2006, p. 16). This technology offers a broad range of innovative features such as facilitating communication between teachers and students, displaying student responses in real-time, and allowing rapid aggregation of student work by teachers (Irving, 2006; Shirley et al., 2011; Wright et al., 2018). Furthermore, CCT enables most students to contribute directly to interactive activities and to play a more active role in classroom discussions (Shirley et al., 2011; Wright et al., 2018). GeoGebra Classroom could be also used in the classroom for formative assessment enabling teachers to utilize a wide variety of teaching methods. According to the Organisation for Economic Co-operation and Development OECD (2005), "formative assessment refers to frequent, interactive assessments of student progress and understanding. Teachers are then able to adjust teaching approaches to better meet identified learning needs” (OECD, 2005, p. 13).

Within this project, we conduct studies in various STEM lessons for evaluating potential uses of GeoGebra Classroom for mathematics teaching and learning. This paper describes our most recent research, where the first author was using tangible and digital tools in a lesson by conducting an exploratory case study with a mixed-methods approach. Moreover, the first author created online resources that offer a unique experience thanks to new technology. For creating such online resources the SAMR (Substitution, Augmentation, Modification, Redefinition) model of Puentedura (2006) was used.

Regarding the combination of tangible and digital tools for the learning and teaching of mathematics, there has been a growing interest, which is also due to a slow evolution of teachers’ practices in integrating digital tools in mathematics teaching (Soury-Lavergne, 2021). Nemirovsky and Sinclair (2020) “distinguish digital tools as being computer-screen centred and tangible tools as being for holding, grabbing, and manual transport” (Nemirovsky & Sinclair, 2020, p. 107). By using digital tools as well as tangible tools there is a high potential for bodily engagement (Nemirovsky & Sinclair, 2020).

In this case study, the first author used online resources with GeoGebra Classroom as the digital tool (see Figure 2) and some Dick System Maths Cubes together with a handmade 3D coordinate system (see Figure 1) as tangible tools. For working with the digital resource, all students used an iPad.

This case study is part of a larger project, where the GeoGebra Classroom tool is evaluated with mixed methods, where we utilized the combination of educational research with usability and user experience methodologies. In this case study, we focus on the usage of the online resource, which is adapted according to the SAMR model. Moreover, we explore the potential of GeoGebra Classroom for whole-class activities and collaboration as well as for group discussions. This case study shows an intermediate step in the development of the online tool and how to improve it. Consequently, the research question for this case study is: How can the GeoGebra Classroom tool be improved to better accommodate online educational resources developed based on the SAMR model?

Theoretical Framework

For creating online resources, we looked at different models and chose Puentedura's SAMR model (Puentedura, 2006). This model provides a tool for integrating digital media into the classroom. Moreover, it describes how teaching and learning are transformed using technology and explains how the design and processing of tasks in the classroom can be improved (bildung.digital, 2021). The four technological levels of use of the SAMR model are *Substitution*, *Augmentation*, *Modification*, and *Redefinition*.

At the lowest level, *Substitution*, there is only a transfer of analog worksheets to digital worksheets happening without functional improvement. An enhancement or a simple functional improvement of the tasks happens in the second level, *Augmentation*. The first two levels are considered *Enhancement* steps, whereas a *Transformation* takes place in the last two levels. In level *Modification*, the tasks will be rephrased in a way, so that digital support is essential for solving the tasks and where the advantages of the technology will be made explicit. In the top-level *Redefinition*, the tasks will be created in a way that solving them without technology is not possible (bildung.digital, 2021; Puentedura, 2006).

Setting and Task Design

The case study involved a class of 7th-grade secondary school students (age 12-13), learning about the coordinates in a 3D cartesian coordinate system. We have chosen this group of students as they used GeoGebra Classroom and GeoGebra resources before and therefore we do not have to focus on learning the system but could focus on the usage. In a classroom setting, all students received the Dick System Maths Cubes together with a handmade 3D coordinate system (see Figure 1) as tangible tools and an iPad for working with the digital resource (see Figure 2). The students received the devices at the beginning of the lesson from the school equipment. In the class, 21 students participated in the lesson, but only two-thirds of them filled in the questionnaires afterward.

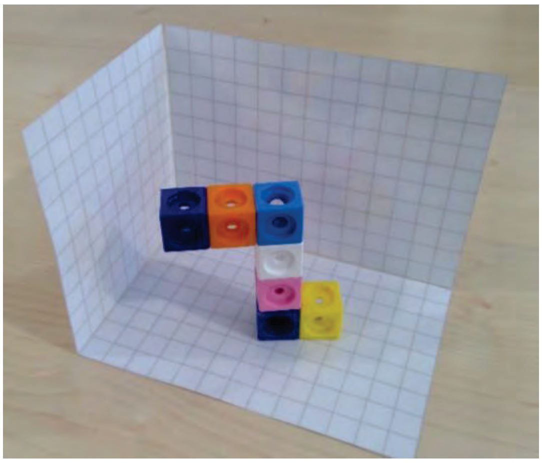

Figure 1: Dick System Maths Cubes

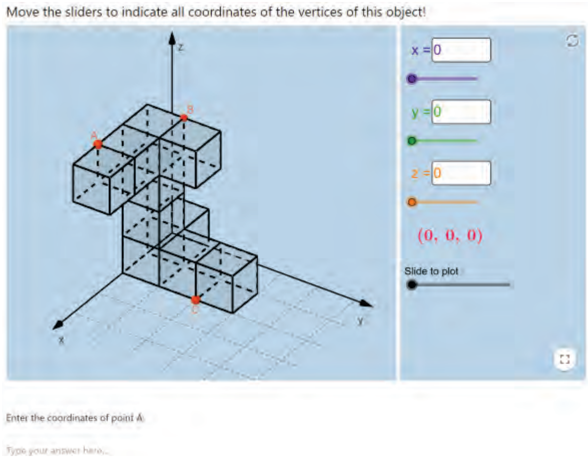

Figure 2: Online Resource

The resource was created by the first author, and the tasks were formulated according to the SAMR model. When creating the tasks, we tried to follow the steps of the SAMR model until we reached the top-level *Redefinition*. For the students, the resource was created in German, a translation can be found here: https://www.geogebra.org/m/tuzwbwez.

Firstly, texts were inserted into the online resource as they would have been on a paper and pencil worksheet (level *Substitution*). Secondly, questions were inserted in the online resource as multiple-choice questions (MCQ) or open questions (level *Augmentation*). Then, the 3D object was not inserted as an image, but as an object in the GeoGebra 3D applet, where additional features are possible. Students can move or rotate the object so that they can observe it from different perspectives. Moreover, some sliders are added, where students can move them to show and move a point in the coordinate system (level *Modification*).

As *Redefinition*, a whole-class activity was inserted as the last activity in the online resource. For this activity, the teacher collected all responses of students reasonably quickly and used them for further questions. As a first task, students entered coordinates of a point that was located a) inside the object, b) outside the object, or c) on the surface of the object. Afterward, the teacher selects one of the answers, reads it aloud and the other students had to choose where this point was located by selecting the correct answer of the MCQ. Before the teacher was choosing another example, all students selected “New”. This activity is considered a redefinition because, within seconds, the teacher can select random students’ examples and observe students' responses to these new tasks by using the MCQ feature. This way the teacher generates a lot of new tasks and can assess students’ understanding quickly and conveniently.

Methods

To answer the research question, we have selected an exploratory case study. In a case study, a temporary phenomenon is being investigated in-depth and in a specific real-world context (Yin, 2014). In this research, the first author used the current version of the GeoGebra Classroom tool together with some tangible tools in a lesson sequence and collected different kinds of data. A mixed-methods approach was used, and qualitative and quantitative data were analyzed with different instruments.

The whole lesson sequence was video- and audio-recorded with cameras and the teacher’s device was screen recorded. Moreover, we automatically collected student products in GeoGebra Classroom and additionally the teacher’s reflective notes that were made after the lesson. After the lesson sequence, students received an online questionnaire, which consisted of some information about the students, a German translation of the System Usability Scale (SUS) by Brooke (1996), some open questions about their experience with GeoGebra Classroom, and the German version of the User Experience Questionnaire (UEQ) by Laugwitz et al. (2008). The SUS is a simple usability scale giving a global view of subjective assessments of usability (Brooke, 1996), whereas the main goal of the UEQ is a fast and direct measurement of user experience (Laugwitz et al., 2008).

In this case study, the Content Structuring Analysis (Mayring, 2014, 2020) was used, where, as a first step, the categories were defined. According to Mayring (2020), the qualitative content analysis approach is category-based, where the categories refer to aspects within the text and the content analysis procedure is research question oriented. Therefore, concerning the research question, we defined the categories regarding the four technological levels of use: *Substitution, Augmentation, Modification,* and *Redefinition*. Content structuring in particular means to “filter out from the material specific content dimensions and to summarize this material for each content dimension” (Mayring, 2014, p. 104), and this was accomplished in the next step. Then, we extracted all coded material for each category and summarized it according to Mayring (2014). In each category, all issues are considered, where the usage of GeoGebra Classroom with the resource did not work as expected or where obstacles or interruptions happened during the lesson. Moreover, we collected all issues, where an improvement, either from the teacher or the online resource could be made.

Results

In the first category *(1) Substitution,* all issues are summarized that are referring to the transfer of analog worksheets to online resources only. In the beginning, students needed some minutes to access the online resource and asked three times in total for the link, although it was presented with the QR code on the projector screen above the board in the classroom. Even if the teacher saves time for printing and copying the worksheets in advance, during the lesson, it took nearly five minutes of the 30 minutes lesson sequence to hand out all the other things like iPad, cubes, and coordinate systems.

One thing that was mentioned by students in the questionnaire three times and also seven times during the lesson, was that there were some lags during the lesson caused by the usage of the GeoGebra Classroom tool. Additionally, in the recorded video and teachers' reflective notes, it was shown that not all students used tangible tools for solving the given tasks. Some of them only worked with digital tools and not with tangible ones.

Category *(2) Augmentation* summarizes all issues, where a functional improvement was visible. The teacher could observe in real-time all responses of the students and check several times on the dashboard if the students finished the task on the online resource before discussing it. But during the work with the MCQ, some issues occurred. When discussing the results of the MCQ, the teacher never knew if all students answered this question when opening the chart with all students' responses. Although the teacher could observe in real-time all changes of the selected answers, and see which one has selected which option, there was no information if every student had already answered the question. In the first attempt, the teacher counts all numbers that were shown, but if one student selected two possible solutions, then this method did not work. One thing that worked well was that the teacher showed the different notations of the coordinates (see Figure 3) and explained to them the correct mathematical notation of coordinates.

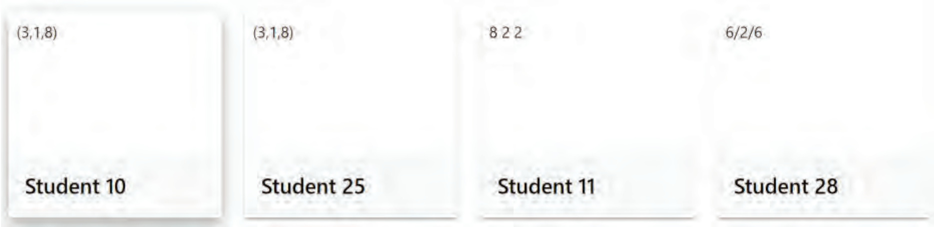

Figure 3: Example of Student Responses regarding Coordinates Notation

All issues regarding the inserted GeoGebra 3D applet (tasks with a significant redesign) are collected in the category *(3) Modification*. The online resource that was used in this lesson, was initially created to be used on a computer with the mouse, but, during the lesson, the students worked with iPads. Therefore, additional hints of using the GeoGebra 3D applet without a mouse would have been helpful. For example, in some cases, the object rotated all the time and students did not know how to stop it. The teacher was interrupted several times to help the kids with this problem. Another issue that occurred was that students could accidentally drag some of the cubes' edges in the 3D applet and therefore change the object dramatically. It was not possible to reset the object to the original one, as the reset button was not available for the 3D view, and refreshing the page did not help either. In this case, these students had to leave GeoGebra Classroom and the online resource and rejoin as new users. Although their work was saved on the teacher dashboard, the students could not access their previous work anymore.

The last category *(4) Redefinition* shows all issues regarding the whole-class activity, a previously inconceivable task. Nevertheless, for the work with the whole-class activity, where several rounds were played, the teacher requested in the reflective notes to just reset all the MCQ solutions instead of choosing the fourth answer "NEW" and to get a notification, when or if all students answered the MCQ. Because during this short whole-class activity it always took some time, until all students switched from their answer to "NEW" to start with the new example. Moreover, during orchestrating the discussion, the teacher was interrupted two times to help students with technical issues.

The results of the SUS and UEQ will be compared within this project and evaluated in the next phase of the project. Furthermore, the analysis of the relation between the SUS and UEQ data, and the qualitative lesson observation is still in progress and will be presented later.

Discussion

Sinclair and Robutti (2020) describe that the use of digital technology has the two main functions supporting organizing students' work and supporting new ways of doing and representing mathematics. In our study, it was shown that the GeoGebra Classroom tool has the potential to be seen as supporting both functions, whereas in both cases an improvement is necessary.

This case study aimed at investigating how the GeoGebra Classroom tool can be used for online education resources based on the SAMR model of Puentedura (2006). As it was presented in the results section, there are currently several issues that need to be addressed. To answer the research question, we came up with ample amounts of suggestions on how the GeoGebra Classroom tool can be improved to better accommodate online educational resources developed with the SAMR model.

First, sharing the resource with the students should be made easier and faster. The lags which were also mentioned in the questionnaire by the students should be fixed. Nevertheless, it is not clear whether this problem is caused by the GeoGebra Classroom tool itself, the WI-FI connection in the school, or the devices that the students used.

As it was mentioned by Shirley et al. (2011) and Wright et al. (2018), students play a more active role in classroom discussions and the technology enables most students to contribute directly to these interactive activities, such phenomena were also shown during the lesson. Students worked with the online resource and participated actively in the last activity, the whole-class activity. However, when working with the MCQ, it would be great to have an overview of how many students just answered an MCQ instead of always going back to the overview page or counting them. If this was made possible, the teacher could foster students to play even a more active role in the whole-class activity and could easily assess students' understanding quickly. Moreover, a reset button for the MCQ would be helpful when asking a lot of similar questions with the same answer options. Furthermore, in some cases, the option to only allow one possible choice of the MCQ would be helpful.

Besides, there occurred even more issues during the lesson sequence, that are not due to the new tool, but to the creation of the online resource. Thus, before further evaluating the tool, the online resource needs to be enhanced as well. Regarding the 3D applet, editors must always ascertain that all objects are fixed and cannot be dragged by students accidentally. Moreover, a reset button for every view in the GeoGebra applet should be inserted or activated. Furthermore, teachers need to tell students in advance how various features work, such as the rotating feature, and how the students can stop the rotation. Therefore, maybe some additional hints of using the 3D applet would have been helpful for the students and to avoid interruptions. Hence, it was shown that the *Transformation* levels *Modification* and *Redefinition* were not completely fulfilled in this online resource. Some students could not benefit from the 3D object, as there occurred several problems and therefore the 3D applet with the sliders was useless and the resource did not reach the *Modification* level. To have an online resource, where all stages of the SAMR model are fulfilled, the resource and the system need to be further developed. Moreover, teachers as well need some guidance to work with similar classroom activity tasks.

Additionally, if teachers want students to work with a combination of digital and tangible tools, they should make that connection clearer. Only handing out tangible tools and just giving oral tasks is not enough. Teachers could present this assignment as the first task on the online resources to advise them to build the given object by themselves or verbally repeat this several times and check again if really all students use these tangible tools. Another idea could be to use the *Pause* button of GeoGebra Classroom to interrupt the work of students. When activating the *Pause* feature, students cannot continue working on their tasks and the teacher can get the students' attention and give them important information or additional explanations.

This case study is part of a bigger project and the results of the SUS and UEQ will be compared within this project and evaluated. Once the tool is further developed, the research will be repeated with another case study in a similar setting, but with an enhanced tool and online resource. As the preliminary findings already show, the user experience of the tool is also dependent on the creation and the design of the tasks in online resources.

To sum up, tasks designers, developers, and teachers should be aware of several issues related to educational online resources that are in the *Transformation* level as well as in the *Enhancement* level of the SAMR model of Puentedura (2006). As we can learn from this case study, when creating online resources according to the SAMR model, there are more collaborators than the teacher involved. To have online resources that could offer new possibilities of teaching, developers of new tools and task designers need to work together and with the help of teachers, who are in the classrooms every day and can observe and confirm if the developments are successful.

TWG23: Implementation of research findings in mathematics education

Introduction to the papers of TWG23: implementation of research findings in mathematics education

Mario Sánchez Aguilar[1], Linda Marie Ahl[2], Boris Koichu[3] and Morten Misfeldt[4]

This introduction offers an overview of the eighteen contributions (15 papers and three posters) to the TWG23 at CERME12. The three thematic discussions that took place in this Thematic Working Group are addressed, namely: the role of change, matters of scaling, and the conception of stakeholders.

Keywords: Implementation research in mathematics education, change, scale, stakeholders.

Introduction

The 12th Congress of the European Society for Research in Mathematics Education (CERME12) was first postponed and then held virtually, in February 2-5 2022, due to the COVID-19 pandemic. Before the conference, a virtual pre-conference event was organized in February 2021. This event included two discussion sessions dedicated to Thematic Working Group activities, and particularly to planning the activity of the Thematic Working Group 23 (TWG23) "Implementation of research findings in mathematics education". This introductory report gives an overview of the TWG23 at CERME12.

Contributions to the TWG23 at CERME12

The TWG23 at CERME12 was led by Mario Sánchez Aguilar, Boris Koichu and Morten Misfeldt, along with Rikke Maagaard Gregersen (until August 2021) and Linda Marie Ahl (from September 2021). The TWG23 received 18 contributions consisting of 15 papers and three posters. The authors of the contributions came from Austria, Denmark, Finland, Greece, Israel, Italy, Luxembourg, Mexico, Norway, Sweden, and the UK. The contributions were organized into thematic categories:

- Implementation of problem-solving and problem-posing approaches
- Implementation of teaching models and teachers' perspectives on implementation
- Conditions for sustainable implementations
- Diagnostics tasks, instructional sequences, and curriculum design
- Implementation of programming, computational thinking, and other digital technologies

Due to the overarching nature of the poster by Konrad Krainer, it was selected to be the first contribution to be presented in the TWG23. This poster presentation served to set the scene in the group by means of providing the TWG23 participants with conceptual categories (technical rationality, reflective rationality, and societal rationality) that were then often referred to during the conference for identifying and contrasting different approaches to the implementation of innovations and implementability of research.

The first thematic category "Implementation of problem-solving and problem-posing approaches" included contributions providing methodological and theoretical tools for the implementation of mathematical problem-solving and problem-posing approaches. The paper by Nafsika Patsiala and Ioannis Papadopoulos presented an instrument to record and examine whether students develop — through their experiences with problem-posing — the habit of mind named "seeking and using structure". The paper by Jason Cooper and Boris Koichu introduced the notion of "problem-solving implementation chain" for analyzing the evolution of a problem-solving activity as it passes from the proponents to teachers and finally to students.

The second thematic category grouped two types of contributions. One type of contribution consisted of the studies that addressed the implementation of specific teaching approaches. This was the case of the research by Morten Blomhøj and collaborators, who introduced a three-phased didactical model to facilitate the implementation of an inquiry-based approach to mathematics teaching. Another research in this group of contributions was presented by Ola Helenius, who offered a theoretical discussion on large-scale implementation of a research-based teaching model for elementary school arithmetic. The other type of contributions within this category included studies focusing on teachers' actions and perspectives on implementation processes. This focus was evident in the study by Maria Kirstine Østergaard and Uffe Thomas Jankvist, who used theoretical constructs from implementation research (IR) to identify elements of a mathematics teacher's practice and thereby identified factors that seemed to influence the implementation of teaching units aimed at fostering students' reflections on the nature of mathematics as a discipline. Other papers included in this category were by Åsmund Lillevik Gjære, who examined one Norwegian teacher's enactment of an innovative system for mathematics teaching called developmental education in mathematics; and by Alessandra Boscolo, who reported the perspective of teachers about the implementation of active, bodily experienced mathematics learning activities.

The contributions grouped in the third thematic category brought to the fore the discussion of the sustainability of the implementation of innovations. The paper by Johan Prytz and colleagues paid particular attention to the issue of sustainability of an innovation in mathematics education, and the potential role of textbooks in sustaining the innovation. Another contribution within this category was the work presented by Mario Sánchez Aguilar and Apolo Castaneda, who pointed out the importance of distinguishing between politics of enactment and implementation as the first step in integrating the analysis of political sustainability into IR.

In the fourth category, a group of contributions addressed issues of the implementation of diagnostics tasks, instructional sequences, and curriculum design. One contribution included in this category was the work presented by Morten Elkjær and Jeremy Hodgen. These scholars formulated an implementation process model for designing and implementing tasks for formative feedback in an online learning environment. Another contribution in this category was the literature review developed by Linda Marie Ahl and colleagues. This review dealt with the implementation of instructional sequences aimed to enhance students' learning of mathematical concepts or competencies. The review identified which competencies are targeted in the chosen sample of studies and what characterizes the implementation of the instructional sequences. Also included in this category was the contribution of Ellen Jameson and collaborators, who pointed out challenges to implementing mathematics education research through the processes and products of curriculum design. The work reported by Tuula Koljonen and colleagues examined the feasibility of using the Documentational Approach to Didactics to gauge the fidelity and characteristics of teachers' implementation of scripted teaching sequences for the teaching of arithmetic in primary school.

The fifth category included contributions focused on the implementation of digital technologies, mainly those related to computer programming. One case is the work by Raimundo Elicer and collaborators, who addressed the role of educational task design in implementation research. In collaboration with a 4th grade school teacher, the authors designed a geometric task from a hypothetical learning trajectory that required students to draw on their knowledge of mathematics and Programming and Computational Thinking (PCT). Another presentation was based on the paper by Andreas Lindenskov Tamborg and colleagues, who reported on the development of a survey tool to investigate how PCT is implemented in Denmark, Sweden, and England. Within this category was also the poster called "Comparing the implementation of programming and computational thinking in Denmark, Sweden and England" by Morten Misfeldt and collaborators (this poster was one of three winners of the first ever ERME Poster Award). Finally, another poster included in this category was by Ben Pierre Haas and collaborators, where they gave an overview of how technologies such as augmented reality, 3D printing, and tutoring systems could be employed by different users for teaching and learning STEAM-based educational ecosystems.

Thematic discussions

The TWG23 program included three thematic discussions. The themes were selected on the basis of previous discussions that had emerged as central for IR. Namely, they had been identified based on the papers published in the special issue on IR of ZDM – Mathematics Education (Koichu et al., 2021) as well as based on the papers published in the first two issues of Implementation and Replication Studies in Mathematics Education (IRME).

The role of change

The first theme was "intended change". The background for this theme was that it has proved difficult to measure the success of implementing innovations. For instance, are we reaching the intended change in a given implementation? And how can this question be addressed? The question for the first thematic discussion was:

> How can we work with articulating and evaluating intended change? What are the pros and cons in relation to constructions such as program theory (theory of change) and realistic evaluation?

Matters of scaling

Large-scale implementations are complex endeavors, often intending to reach a large number of classrooms. If an idea is proven to work well in a certain setting, we are interested in disseminating it into other settings. As phrased by Artigue (2021, p. 22): "...implementation research, even if it can take advantage of studies of limited scope, must be able to meet, as a genre, the scaling-up challenge". The question guiding the second thematic discussion was:

> What are the possible roles of small-scale vs. large-scale studies in implementation research? For example, in relation to different phases such as planning, testing, enacting, and evaluating.

The conception of stakeholders

No large-scale implementation can be successful without the scaffolding of stakeholders at different levels. Krainer (2021, p. 1175) asked: "Who are the relevant stakeholders whose voices should be heard when discussing implementation? What is the role of policymakers, administration experts, researchers, and practitioners with regard to defining and solving problems that occur in practice?" With insight into the absolute necessity of having a strategy for working with stakeholders, the theme for the third thematic discussion was:

> How do we work with stakeholders? This includes conceptualizing their roles, designing/framing their participation, and evaluating the impact of their involvement in relation to three levels: administration/policymakers, researchers, and practitioners.

Concluding remarks

Concerning "change", the TWG23 participants agreed that the tension between intended change and achieved change in an implementation project is a delicate question of interest for our research field. As for "scale" and scaling, the participants agreed on the need for both small-scale and large-scale studies in mathematics education IR. Moreover, it was clear that there is a need for further discussions on the conception and definition of "stakeholders". The overall outcome of the TWG23 thematic discussions was that none of the three themes addressed can be fully explored in isolation from the others.

Future research directions emerging from the TWG23 discussions at CERME12 are the following: we need to discuss how a theory of change can be used to design, understand and evaluate implementations. It is necessary to further explore how small-scale and large-scale studies can provide the relevant information for different parts of an implementation process. There is a need for progressing our knowledge on how the concept of stakeholders can be used to refine different types of analysis of implementation projects. These discussions will continue at CERME13 in Budapest in 2023, and also on the pages of IRME.

Political challenges for the implementation of research knowledge as part of educational reforms and mathematics textbooks

Mario Sánchez Aguilar and Apolo Castaneda

Instituto Politécnico Nacional, CICATA Legaria, Mexico; mosanchez@ipn.mx; acastane@ipn.mx

This paper reports an exploratory study of political factors that may influence the implementation of research knowledge in the formulation of educational reforms and mathematics textbooks in Mexico. The study is based on the analysis of an in-depth interview with a key informant, who has extensive experience as a textbook author and as an advisor in the Ministry of Education of Mexico. Two instances are identified in which there is an effort to implement research knowledge from the field of mathematics education in the study programs or the mathematics textbooks. The factors that appear to have hindered the implementation of such research knowledge are also identified.

Keywords: Implementation research, educational policy, mathematics textbook research.

Introduction

The implementation of any educational innovation is shaped by political factors. There are studies in the field of mathematics education that illustrate aspects of the interaction between policy and the implementation of innovations in mathematics instruction (Krainer, 2021; Prytz, 2021). These studies highlight the importance of having a better understanding of the political factors that influence the implementation of innovations in mathematics education. Lester (2018) notes that politics is centrally important to implementation for at least two reasons: First, it creates the legal authority, funding, and other capacities that are needed to implement a program effectively. Second, politics does not stop when a law has been enacted. It continues throughout the implementation process.

The importance of recognizing the political in implementation research has been pointed out by some educational researchers. McDonnell and Weatherford (2016) mention that there is little evidence in educational research about the political dynamics of implementation. However, it is also acknowledged that a problem with this empirical focus is that much of the political action takes place far from the public eye, making its analysis complicated. Thus, the study of the political factors that may shape the implementation of educational innovations tends to be elusive.

This paper reports on an exploratory study that focuses on identifying political factors that have the potential to shape the content of educational reforms, in particular the content of mathematics textbooks that are officially authorized for use in the lower secondary education system in Mexico. This study is based on the analysis of an interview with an experienced mathematics education researcher, who has extensive experience as a mathematics textbook author but also has an academic advisor to the Ministry of Education of Mexico (in the following called the ministry).

Background and study aim

One of the main concerns of the TWG23 has been: how can we bring into practice the accumulated research knowledge produced within the field of mathematics education? (Jankvist et al., 2017). Addressing this concern implies acknowledging the existence of factors that influence the enactment of any educational innovation, but it also entails recognizing that some of these factors may be political in nature. The studies by Krainer (2021) and Prytz (2021) illustrate aspects of the intricate interrelationship between the implementation of innovations and policy.

Krainer (2021) refers to the IMST (Innovations in Mathematics and Science Teaching), which is a project triggered by Austria's modest performance in the TIMSS advanced mathematics and physics achievement test of 1995, and with the aim of fostering innovations and improving teaching and learning at secondary schools in Austria. Through the analysis of this project Krainer asserts that in the implementation of large initiatives such as the IMST project "*policy*, *research*, and *practice* need to be regarded as influential and closely interrelated communities regarding implementation." (2021, p. 1185, emphasis in the original). In turn, Prytz's (2021) historical investigation provides evidence on how the role of researchers and the procedures that they followed for preparing three Swedish major development projects in mathematics education—the New Math project (1960–1975), the PUMP project (1970–1980), and the Boost for Mathematics project in (2012–2016)—, co-varied with the shift from centralization to decentralization that happened gradually in school governance policy from the mid-1970s to the 2010s.

The study reported in this paper addresses TWG23's expressed concern: 'how can we bring into practice the accumulated research knowledge produced within the field of mathematics education?', but placing special emphasis on the political factors that may influence the implementation of such research knowledge. Thus, the aim of this research study is *to identify possible political factors that influence the implementation of research knowledge produced within the field of mathematics education, as manifested in educational reforms and mathematics textbooks in Mexico*.

The empirical data for this study consists of an in-depth interview with a mathematics education researcher with a history of collaboration with the ministry as a textbook author and advisor. To make sense of the information contained in the informant's narration, some notions related to the politics of implementation were used. These notions are introduced in the following section.

Conceptual framework

The Oxford Advanced Learner's Dictionary define *politics* as "the activities involved in getting and using power in public life, and being able to influence decisions that affect a country or a society". This definition conforms to the conception of 'politics' used in this study. However, we are aware of the existence of early efforts to formulate a notion of 'implementation politics':

> Implementation politics is, I believe, a special kind of politics. It is a form of politics in which the very existence of an already defined policy mandate, legally and legitimately authorized in some prior political process, affects the strategy and tactics of the struggle. (Bardach, 1977, p. 37)

Political scientists such as the previously cited Eugene Bardach (1977) and Pressman and Wildavsky (1973) are pioneers in the study of implementation as part of policy processes. In the field of educational research, McDonnell and Weatherford (2016) take these early works as a reference to argue that politics permeates the implementation process, but they also warn about the importance of distinguishing between the politics of enactment and the politics of implementation, as a first step in integrating the analysis of political sustainability into implementation research.

The *politics of enactment* refer to politics that come into play during the process in which a policy or reform is configured and becomes official. The *politics of implementation* refer to the process of translating a policy or reform into educational practice. McDonnell and Weatherford (2016) pinpoint three cross-sectional characteristics to identify political factors "that influence whether a policy option gets on decision makers' agendas and is eventually enacted" (p. 235), namely: (1) the time frames and (2) the decision venues for policy design and enactment as compared with those for implementation; and (3) the interest-based coalitions active during each phase. Table 1 shows a comparison of how these three characteristics can be manifested in the politics of enactment and in the politics of implementation.

Table 1: Comparison of how the time frame, decision venues and interest-based coalitions can be manifested in the politics of enactment and in the politics of implementation. Taken from McDonnell and Weatherford (2016, p. 235)

Comparing the Politics of Enactment With the Politics of Implementation

	Enactment	Implementation
Time frame	• Episodic; proposals on and off the policy agenda, sometimes over long periods • Proposals modified as policy problems and political coalitions change • Once on a decision agenda, proposal passed or rejected quickly	• Continuous process, typically over several years or longer • Variation comes from different interpretations, not changes in formal provisions • Long time frame for implementation may be bad politics
Decision venues	• Contained within one or two venues, with clearly defined decision rules • May be visible only to policy elites • Information available from a limited number of well-known sources	• Multiple venues, with considerable variation • Many small decisions by implementers aggregate to become agency policy • Information typically diffuse and anecdotal • Localized, varied, and unpredictable policy feedback
Interest-based coalitions	• National interest groups dominate the process • Enactment coalitions and resulting policy create incentives for whether winners and losers remain mobilized postenactment	• State and local affiliates and grassroots groups often have incentive to mobilize • Groups active during enactment may modify issue position • Interests may support or oppose the policy by attaching other policies and political issues to it

The notions contained in this section were used to give meaning and structure to the narration provided by the key informant who participated in this exploratory study. The characteristics of this key informant and other components of the research method are discussed in more detail in the next section.

Method

The exploratory research reported in this manuscript uses as source of information an in-depth interview with a key informant with extensive experience as an author of mathematics textbooks and as an educational advisor. In the following sections we provide details about this key informant and the interview conducted.

The key informant

Key informant refers to the person with whom an interview about a particular organization, social program, problem, or interest group is conducted. According to Fetterman (2008), key informants "are individuals who are articulate and knowledgeable about their community. They are often cultural brokers straddling two cultures" (p. 477). The importance of brokers in the development of national mathematics curricula has been acknowledged, as they are individuals who "act as conduits for introducing elements of one practice [research] into another [mathematics teaching]" (Potari et al., 2019). They are insiders that typically provide information through in-depth interviews and informal conversation, and their experience is important to assess their quality as a source of information.

The key informant participating in this study is a broker. He is an experienced mathematics education researcher who has 20 years of experience as a mathematics textbook author. He has also been part of disciplinary commissions invited by the ministry, which provide advice on the disciplinary content that should be included in the national educational reforms and the study programs. For 36 years he has held a researcher position in a mathematics education research department in Mexico City. The key informant was emphatic in clarifying that he knows first-hand most of the information provided in the interview, however, he also acknowledges that there is part of the information that he knows second-hand through third parties directly involved in the process.

The interview and its analysis

As mentioned before, an in-depth interview was used as a research instrument for this study. It was carried out on September 3, 2021 via Zoom, and lasted 1 hour and 10 minutes. The two authors of this paper participated in the interview. There was no script for the interview, but rather an informal chat between the three people involved. Before starting the interview, an attempt was made to communicate to the informant the purpose and meaning of the research study. The interview was recorded for later analysis.

A tape-based analysis (Onwuegbuzie et al., 2009) was applied to the interview recording. Here the researchers first became familiar with the data—by listening to the interview repeatedly—in order to identify the parts of the interview that provide information about the political factors that may influence the implementation of research knowledge produced within the field of mathematics education in mathematics textbooks. This procedure was applied independently by each of the authors of the study. Subsequently, a meeting was organized between the researchers to exchange their views on which moments of the interview provided relevant information for the study. These key moments of the interview were identified and agreed upon through a discussion among the researchers. The results of this analysis are presented in the next section.

Results

The interview with the key informant was rich in information. Through the analysis of his account, it was possible to identify a structure that interrelates different political actors involved in the design of the study programs for primary and lower secondary education in Mexico, which are official documents from which the mathematics textbooks are derived. The analysis of the interview also allowed us to identify two instances in which there is an effort to implement research knowledge from the field of mathematics education in the study programs or the mathematics textbooks. The factors that appear to have hindered the implementation of such research knowledge were also identified.

Next, the structure that interrelates different political actors involved in the design of the study programs for secondary education in Mexico is presented, which will be used as a reference to illustrate the two instances in which there is an unsuccessful effort to implement research knowledge from the field of mathematics education.

The political structure underlying the development and establishment of study programs

When planning an educational reform, the ministry is in charge of producing the *study programs* for secondary education. Study programs are guiding documents aimed mainly at teachers from all over Mexico, which contain the topics that must be covered for each discipline—including mathematics—, as well as the teaching approaches that must be used to communicate them. These study programs are the foundation for developing the textbooks. For the ministry to approve the national use of a mathematics textbook, it must adhere to the contents and procedures expressed in the mathematics study program.

According to the key informant, there are different groups of stakeholders involved in the configuration of the study programs. There are *disciplinary commissions*, which are groups of specialists from different areas of knowledge who act as counselors to the ministry about the contents and approaches that should be reflected in the study programs. There are also the *teachers' associations*, who through workshops and consultation forums obtain previews of the potential contents of the study programs, and express their opinions to the ministry about them. In turn, the ministry considers these opinions to define the study programs.

When the study programs are approved they are published and made available to the public[1]. It is then that *textbook writers*—sponsored by publishing houses—can read, interpret and translate the ideas of the study programs into their textbooks. These textbooks must be evaluated and approved by *expert evaluators*, which are scholars hired by the ministry to verify that the textbooks adhere to the authorized study programs.

Unsuccessful efforts to implement research knowledge—and hindering factors

The analysis of the interview led to the identification of two instances where there are unsuccessful efforts to implement research knowledge from the field of mathematics education. These instances are named: (1) it is important to include probability as part of the mathematics education of primary school students, and (2) it is necessary to distinguish between a 'problem' and an 'exercise' when adopting a problem-solving approach. The following sections illustrate what each of these instances consisted of, and what are the factors that seem to hinder their materialization.

(1) *It is important to include probability as part of the mathematical education of primary school students*. The informant recalls an educational reform in 2009, in which the ministry decided to remove the teaching of probability from the study program for primary education—indeed, the 2009

[1] The current study programs are available at https://www.planyprogramasdestudio.sep.gob.mx (information in Spanish).

study program for primary education in Mexico does not include the teaching of probability (see Secretaría de Educación Publica, 2009). However, research suggest an intuitive approach to the teaching of probability where children start from their intuitive ideas related to chance and probability. There are also recommendations related to understanding and applying basic concepts of probability for children in Grades 3–5 (see Batanero et al., 2016). Our key informant—at that time a member of the disciplinary commission for mathematics—was part of the opposition to this measure. He considered it inappropriate and in opposition to world trends in probability teaching.

Informant: When I was participating [in the disciplinary commission] I said that this could not be, that this was an issue that did not correspond to what all countries did. Rather, all countries incorporate probability from the beginning of primary school, and we did not have probability throughout primary school! […] In fact, I invited Carmen Batanero to give some talks there at the ministry and I had discussed this issue with her. And she mentioned that it did not seem like a good idea that probability was not in elementary school.

Despite the opposition, the teaching of probability was not included into the study programs. The informant identifies teacher associations as a possible obstacle in the incorporation of probability teaching in primary school. According to the informant, the teaching of probability was postponed to the middle school level on the argument that primary school teachers have many difficulties in understanding probability and therefore were not well prepared to teach the topic.

Informant: What was the justification for this? X told me [he mentions a ministry official] that it is because the teachers did not understand probability. They had complained that they did not know what to do, and that is why it was removed. I think that was a very strong decision that it was due to the teachers' complaints in the different workshops.

Instance (1) serves as an illustration of the politics of enactment that can take place during the configuration of a study program or curriculum. It illustrates how decision venues are reduced—only some selected individuals have access to the configuration of the study program—, but it also shows the existence of interest-based coalitions (such as mathematics teachers and their associations) that can hinder the enactment and implementation of research knowledge due to various reasons, such as the lack of adequate mathematical knowledge for the teaching of certain topics.

(2) *It is necessary to distinguish between a 'problem' and an 'exercise' when adopting a problem-solving approach*. In the educational reform of 2011, the study program for lower secondary education indicated a problem-solving approach to the teaching of mathematics. The analysis of the interview suggests that the lack of clear guidelines on what it means to adopt a problem-solving approach in a mathematics textbook, is a factor that seems to minimize the fidelity and homogeneity of implementation of a problem-solving approach to mathematics textbooks.

According to the informant, the study program contains only general guidelines on how instruction should be, and these guidelines are primarily aimed at teachers. The lack of clear and specific guidelines for the preparation of textbooks opens a space for different interpretations of the study program. Writers should interpret the study program and translate it into a textbook, hoping that their interpretation matches that of the expert evaluators (for their book to be approved by the ministry) and that of the mathematics teachers (for them to purchase the book).

An illustration of this is our informant's interest in having his textbooks clearly distinguish between an 'exercise' and a 'problem', as suggested by the fundamentals of problem-solving in mathematics education (e.g., Schoenfeld, 1985). However, implementing this distinction in his textbooks may have negative consequences. For instance, the informant thinks that his textbooks are not popular among mathematics teachers, precisely because they include actual problems and not exercises, which makes his textbooks more difficult for teachers and students to use.

Informant:	I, for example, think that my textbooks are difficult for students and teachers […] Because I try to pass on mathematical messages like the ones that are promoted... For instance problem solving. I try to make the problems actual problems in the sense that research says, that is, they are situations that the student will not know how to solve from the start, and that they may have to make an effort to solve it. Well, just that idea makes the textbook that I write different from other textbooks where for them [the other authors] a problem is an exercise.
Interviewer:	It is easier for the teacher to use this second kind of book than yours.
Informant:	Exactly, exactly.

Instance (2) illustrates aspects of the politics of implementation as experienced by a textbook author when trying to implement research ideas as part of the contents of a mathematics textbook. The textbook author who participated in this study claimed to receive diffuse and non-explicit information about the specific contents of the textbooks, which requires interpretation. However, the author's interpretation of the specific contents may be in opposition to the interpretation of the expert evaluators who have an influential opinion on which books are authorized by the ministry.

Conclusion

We have tried to illustrate the potential of the concepts of "politics of enactment" and "politics of implementation" to illuminate the intricate relationships between the implementation of innovations in mathematics education and politics. These theoretical notions bring to the fore the issue of political sustainability into implementation research. In particular, this theoretical framework allowed identifying and situating two political factors that may influence the implementation of research knowledge from mathematics education: (1) interest-based coalitions —such as mathematics teachers and their associations, and (2) issues of (mis)communication within decision venues. It would be necessary to analyze other implementation experiences to corroborate the potential of this conceptual framework for the uncovering of the intricate relationships between implementation initiatives and politics.

We are aware that the empirical method used in this study—which is based on an in-depth interview of a single key informant—may have some reliability issues. However, it is possible to enhance the rigor and reliability of this method. One way to do this is by increasing the number of key informants, and trying to corroborate and triangulate the consistency of their testimonies and interpretations. Another possible strategy is to use the "respondent validation" technique where the interviewee is asked to assess whether the researchers are accurately interpreting their experiences that were the focus of the study.

Our intention is to continue and expand the study reported here, interviewing more key informants (brokers) and implementing strategies to enhance the rigor and reliability of the research method.

To get an overview of how many and which studies in the literature specifically address the implementation of innovations from mathematics education research, we have conducted a systematic literature review. We report on the subset of 19 studies from the review, dealing with the implementation of instructional sequences aiming to enhance students' learning of mathematical concepts or competencies. The research question is: Which mathematical concepts and/or competencies are in play, and what characterizes the implementation of the instructional sequences? Results show that spatial reasoning, patterns, and structure gained the most interest, addressed in 6 studies. The other studies are relatively evenly spread over the concepts: algebra, arithmetic, calculus, number theory and proof, and the competencies: proportional reasoning and problem-solving. Seven studies, with long-term goals, describe a design for scaling the implementation.

Keywords: Implementation research, mathematical concepts, mathematical competencies, goals.

Introduction

That implementation research (IR) in mathematics education research (MER) has gained momentum during the past few years is beyond any doubt. Since 2017, a thematic working group (TWG 23) at CERME has been dedicated to the topic. In 2021, a new journal—*Implementation and Replication Studies in Mathematics Education* (IRME)—was launched by the well-established Dutch publishing house, Brill. Finally, also in 2021, a special issue of ZDM was dedicated to the topic of implementation research in mathematics education. Ongoing discussions in relation to IR in MER concern, for example, the use of theoretical constructs from outside the field of MER (e.g. health science, economics, etc.) versus those available inside of MER; what we should take implementability to mean in relation to IR in MER; to what extent IR should mainly address large scale studies; etc. (Jankvist et al., 2021). Yet, it seems to us that to engage in these discussions on a more enlightened basis, a natural starting point is to get an overview of both how many and which studies in the MER literature specifically address "implementation". We have taken on this task by conducting a systematic literature review.

Taking on this task involved a few delicate considerations on our behalf, since most of the reported research studies in our field, at least from an inclusive standpoint, may be considered as studies addressing some kind of implementation. Two criteria were decided upon and enforced in order to avoid a too large number of papers to consider. Firstly, we limited the review to include papers that clearly stated dealing with some kind of implementation. Secondly, we limited the review to only consider studies published in the top twenty quality-ranked MER journals following the recent journal categorization by Williams and Leatham (2017). The literature search was carried out on February 4-5, 2021, and initially resulted in 1,093 papers, which through a screening process (see the following section) were reduced to 98 papers. In this paper, we focus on a smaller subset, consisting of 19 papers, dealing with the implementation *of instructional sequences to enhance students' learning* on specific mathematical concepts, or competencies. The research question is: *Which mathematical concepts and/or competencies are in play, and what characterizes the implementation of the instructional sequences?*

Review methodology

We conducted the literature searches in ERIC (EBSCO) searching for manuscripts with implement* in the title and/or abstract, journal by journal of our top 20 samples (Williams & Leatham, 2017). The advantage of doing the entire search in one database is that it is easy to collect the results in one folder. To ensure that no article had been overlooked, we repeated the search implement* in the title and/or abstract on each journal's website. We found 1,093 peer-reviewed articles fitting the inclusion criteria. We used the software *Covidence* to manage our literature review.

Each paper was screened by two reviewers. The screening was made in two steps. First, we screened the title and abstract. In cases where we were hesitant, e.g., because the abstract did not provide sufficient information, we chose to forward the paper to full-text screening. In the full-text screening, papers were included if they followed Century and Cassata's (2016) definition of IR:

> ... as systematic inquiry regarding innovations enacted in controlled settings or in ordinary practice, the factors that influence innovation enactment, and the relationships between innovations, influential factors, and outcomes. (Century & Cassata, 2016, p. 170)

As evident from this quote, another central term in IR is that of *innovation*. Innovation refers to the practical implementation of ideas resulting from research that involve a change (e.g., in behavior or practice) for the individuals enacting them. (Century & Cassata, 2016).

Of a total of 139 papers, 97 remained after the full-text screening (see table 1). These were categorized in terms of, Curriculum reform (31); Curriculum materials (22); Professional development projects (25); and finally, Mathematical concepts, competencies, and instructional sequences, (19). The latter is the focus of this paper. We define an instructional sequence as one, or more, cohesive series of lessons that address a concept (e.g., fractions) or a competency (e.g., problem posing and solving). There are no clear cuts between the categories. An instructional sequence may stem from a new curriculum material, that is implemented through a PD project, due to curriculum reform. Decisive for how the categorization is done is the focus of the paper.

The data extraction from these papers included general information on the author(s), title, purpose statement(s), country where the study was conducted, research question(s), methods, target group, and results. The specific information about the implementations included what kind of innovation from mathematics education the study concerned, specific or general goals in the short- or long term, phase of implementation studied, stakeholders responsible for the implementation, and identified factors of influence for the outcomes of the implementation.

Table 1: Process for inclusion of studies

	Inclusion Criteria	Exclusion Criteria	Excluded
Title and abstract screening 1093 studies imported	Implement* in abstract or title	Innovations that do not stem from results from ME Studies that do not involve a change in behavior or practice Papers not belonging to the sample of 20 journals	955
Full-text screening 139 studies imported 97 remained for data extraction	The studies should fit the definition of implementation research and one or more criteria for doing implementation research (Century & Cassata, 2016)	Does not fit the definition of implementation research. The innovation is not from ME. Not in the sample of 20 journals. Full text is not available. Duplicate	21 8 5 4 3

IR theoretical constructs applied

While most MER studies aim at investigating and improving student learning, implementation studies often consider a dimension of scaling (Coburn, 2003). Scaling, in turn, is entirely dependent on the timing of scaffolding (Helenius, n.d.) between three major groups of *stakeholders*, namely agents from *practice*, *research*, and *policy* (Krainer, 2021). Agents from *practice* include all teachers who carry out teaching but also principals and other staff who are responsible for the teaching that is carried out in an educational context. Agents from *research* refer to both actively involved researchers and the overall production of reported research findings from the research community that informs implementation projects. Agents from *policy* refer to all agents with the power to spread innovations over school districts, make decisions on the direction and budgeting for educational efforts, as well as the administrative superstructure required to implement political decisions.

Our interpretation of *goals* draws on Krainer's (2021) description of four different kinds of goals for IR: 1) Concrete and short-term goals; 2) Concrete and long-term goals; 3) General and long-term goals, and 4) General and short-term goals. While the *general-concrete* dichotomization is introduced by Krainer, we find it more linguistically natural to instead speak in terms of the opposites, *general* versus *specific*. Therefore, when we operationalize Krainer's goals in our analysis we use *specific* instead of concrete. For the dimensions short-term and long-term, we conceptualize the longevity aspect in terms of scale-up possibilities for the innovation (Coburn, 2003).

Specific and short-term goals: In this category we put papers addressing a specific limited goal to enhance teaching and learning. The innovation concerns a mathematical concept or competency. When we classify something as belonging to short-term goals, we consider the intended life-cycle of the innovation. As a consequence, implementations without a scaling plan that are studied with a longitudinal research methodology will be classified as short-term. Our definition of scaling follows Coburn's (2003) notions of depth, sustainability, spread, and shift in reform ownership. *Depth* refers to change in classroom practice that goes beyond a shift in teaching resources and the introduction of specific activities. Coburn argues that scaling includes a shift in teachers' beliefs, norms for communication, and pedagogical practices. *Sustainability* concerns the scaffolding tools that are left to maintain the vitality of the innovation after the support of the reform leaders are withdrawn from the organization. When Coburn considers *spread,* she, in addition to scaling to other schools and classrooms, also includes spread within the organization. Finally, Coburn adds the dimension of a *shift in reform ownership* to the notion of scale. When reform is launched, the ideas and activities are owned by the creators of the reform. According to Coburn, the authority to scale the implementation needs to shift to the districts, schools, and teachers. Only then can scaling in depth, sustainability, and spread be maintained. If none of these scaling dimensions are discussed, or implied, the paper is considered to be a short-term implementation. *Specific and long-term goals,* on the other hand, discuss at least some dimension of scaling.

General and long-term goals refer to innovations that intend to change the practice of mathematics teaching in general, as opposed to a focus on changing the teaching of a specific concept, subject, or competency. For example, as a result of alarms from international tests, politicians may plan for increasing the mathematics teachers' general content knowledge at scale and/or state-wide curriculum reforms, to be implemented with long-term goals. At the other end of the spectrum, we find locally introduced projects within organizations that aim to fundamentally change teaching locally. Thus, with *general and short-term goals,* we refer to non-content or non-competency-specific innovations. For example, limited periods where a new model of the organization of classroom teaching in mathematics is tried without an existing plan for scaling.

Results

We summarize the answer to our question: *Which mathematical areas of concepts and/or competencies are in play, and what characterizes the implementation of the instructional sequences?* in terms of specific- or general-, and short-term or long-term goals in table 2 below.

Table 2: Results

Concepts/competencies	Author(s)	Target population(s)	Characteristics of goals
Algebra (2)	(Adiredja et al., 2020) (Tsai & Chang, 2009)	Undergraduate Grade 8	Specific and short-term Specific and short-term
Arithmetic (3)	(Savard & Polotskaia, 2017) (Tyminski et al., 2014) (Polotskaia & Savard, 2018)	Grades 1-4 Pre-service teachers Grade 1-2	Specific and short-term Specific and short-term Specific and short-term
Calculus (1)	(Carter et al., 2016)	Undergraduate	Specific and long-term
Fractions (2)	(Osana & Royea, 2011) (Thanheiser et al., 2016)	Pre-service teachers Pre-service teachers	Specific and short-term Specific and short-term
Number Theory (1)	(Strømskag, 2017)	Pre-service teachers	Specific and long-term
Problem-solving (1)	(Leung, 2013)	Elementary in-service teachers	Specific and short-term
Proofs (1)	(Stylianides & Stylianides, 2009)	Pre-service teachers	Specific and short-term
Proportional reasoning (2)	(Howe et al., 2011) (Wright, 2014)	Grade 7 Grade 8	Specific and long-term Specific and short-term
Spatial reasoning and patterns (6)	(Papic et al., 2011) (Mulligan et al., 2018) (Mulligan, Oslington, et al., 2020) (Mulligan, Woolcott, et al., 2020) (Patahuddin et al., 2020) (Pollitt et al., 2020)	Pre-school Grades 3-5 Pre-school Grades 3-4 Inservice teachers Pre-school in-service teachers	Specific and long-term Specific and long-term Specific and long-term Specific and long-term Specific and short-term Specific and short-term

Concluding discussion

The first thing that we notice from table 2 is that the targeted concepts and competencies are well spread, although with one exception, namely spatial reasoning. The reason that spatial reasoning and patterns have gained greater interest than other concepts and competencies is that the same research group, working on a large-scale implementation, authored four of the six studies on spatial reasoning and patterns (Mulligan et al., 2018; Mulligan, Oslington, et al., 2020; Mulligan, Woolcott, et al., 2020; Papic et al., 2011). Second, concerning goals, we notice that all studies are specific; a result driven by the delimitation of the category's focus on some concept or some competence. Third, only seven studies address implementation where scaling is a part of the project. Of these seven studies, four belong to the large-scale project, mentioned above, about patterns and structure in Australia (Mulligan et al., 2018; Mulligan, Oslington, et al., 2020; Mulligan, Woolcott, et al., 2020; Papic et al., 2011). The Mulligan et al. studies describe (briefly) plans for *depth*, *sustainability*, *spread,* and *shift in reform ownership*. The intervention program in Papic et al. (2011) reported on *spread* through replication and adaptions to other preschools. One paper belongs to a large-scale project on proportional reasoning in the UK (Howe et al., 2011), where *sustainability* is supported by free web-based modules with lesson plans. One paper is a theoretical paper drawing a picture of how an instructional design for teaching number-theory could be *spread*, within the organization, and also to other schools and classrooms, without the drawback of considering limitations in the organization (Strømskag, 2017). Finally, one paper has a plan for *spread* within the organization but no plan for scaling to other schools and classrooms (Carter et al., 2016).

Reviewing the 20 top-ranked journals ended up in only 19 papers addressing specific instructional sequences on concepts and/or competencies. How can that be? We hypothesize that the discourse surrounding implementation research is somewhat new in MER. The papers in this sample are from the year 2009 to a peak in 2020, with five papers. Further, given that we limited the categorization addressed here to specific instructional sequences on concepts and/or competencies, all goals in this subset are classified as specific. Taken together, that can constitute a problem if we want to understand how large-scale projects work. This is because stakeholder groups of policymakers, in particular those on a school-district level, seldom operate with just specific goals. On the contrary, curriculum reforms are often justified by general goals. We believe that the picture will change when we deepen our study to the other identified categories, i.e., curriculum reform, curriculum materials, and PD projects. Regarding short-term and long-term goals, only papers belonging to large-scale projects, where stakeholders from all levels are involved, explicitly discuss scaling. Depending on the goals, different requirements are placed on the involvement of different stakeholders. Stakeholders with the power to make general decisions are necessary for scaling in school districts. Projects aiming at long-term implementation thus need a plan—and a theory—for how to involve stakeholders at different levels at the 'right' points in time.

Acknowledgments

This paper was written in the frame of project 2020-04090 under the *Swedish Research Council*.

Inquiry-based mathematics teaching in practice: a case of a three-phased didactical model

During the latest decades, inquiry-based teaching (IBMT) has become one of the top issues at the agenda for educational politics. IBMT is seen as having a potential for enhancing the students' motivation for and appreciation of mathematics as a field of activity and as a tool for understanding the world. IBMT can be conceptualized and operationalized in different ways. In this paper, we focus on a three-phased didactical model for IBMT, which can frame the students' inquiry in and with mathematics, and support the teachers' planning and implementation of an inquiry based activity. More specifically, we present a case study of how the use of the didactical model can facilitate the implementation of IBMT, and what are the challenges that remain and need to be addressed.

Keywords: Inquiry based learning, professional development, case studies.

Introduction

During the latest decades, inquiry-based teaching has migrated from science education into mathematics education, and inquiry-based mathematics teaching (IBMT) has become one of the top issues at the agenda for educational politics (Artigue & Blomhøj, 2013). Inquiry-based approaches have also found their way into mathematics curricula documents in Norway as well as in other countries. IBMT is seen as having a potential for enhancing the students' motivation for and appreciation of mathematics as a field of activity and as a tool for investigating the world. In this context, at The Arctic University of Norway in Tromsø (UiT), researchers designed a four-year research and development project SUM (Sammenheng gjennom Undersøkende Matematikk-undervisning) funded by The Norwegian Research Council (FINNUT) for 2017- 2021. SUM is a four-year research and developmental project, in which researchers and mathematics teachers collaborate with the overall aim of contributing to coherence in children's and students' motivation for, activities in, and learning of mathematics throughout the entire educational system. The objective of SUM is the implementation of research findings related to IBMT as a means for better coherence across transitions in the educational system. In a previous CERME paper, we reported on some preliminary findings related to how the design of the project itself affected the implementation of IBMT in educational settings (Haavold & Blomhøj, 2019). One of the main findings was that the use of a three-phased didactical model used in the project was highlighted as an important enabler for implementing IBMT in the classroom. Most teachers participating in the project had stated that the model provided them with a more structured approach for designing IBMT for their practice. The model reduced a large and complex task to several smaller less complex steps of planning. Furthermore, the teachers said that the model helped them to be aware of and maintaining their own and their students' different roles at each phase of the model. However, the teachers also found it quite uncomfortable to give up control, and allow the students to investigate and explore more freely.

In this paper, we focus on one particular case and present and analyze an IBMT lesson with regard to how this model provides a frame for the students' work and for the teachers' planning and implementation of IBMT. More specifically, we attempt to answer the following research questions: *How can the use of a particular three-phased didactical model facilitate the implementation of IBMT, and what challenges regarding the students' learning through IBMT can be identified?*

The keywords facilitate and challenges can be reframed within determinant frameworks of implementation theory, as enablers and barriers, or more generally as influential factors, that have an impact on implementation outcomes (Nilsen, 2015).

Inquiry based mathematics teaching

In SUM, IBMT is conceptualized with reference to Artigue and Blomhøj (2013). Here the historical threads are retracted back to John Dewey (1859-1952), who developed an educational theory with inquiry as the main driver for humans' development of knowledge. Learning by doing has become parole for this theory, focusing on students' research-like activities. An essential point in Dewey's theory is, however, that knowledge is produced in an interplay between inquiry in problem situations and related reflections – denoted reflective inquiry (Dewey, 1938). Therefore, IBMT should engage students in relevant inquiry activities and challenge them to reflect on their experiences in order to support their learning of key mathematical concepts and methods. Artigue and Blomhøj (2013) discus how IBMT can be understood and characterized in relation some theoretical frameworks such as problem-based learning, problem-solving, modelling, realistic mathematics education and the theory of didactical situations. Seen from the perspective of practice, IBMT has considerable overlaps with all these frameworks, and to some extent, IBMT can be seen as an overarching umbrella. From a theoretical point of view, however, the foundation of IBMT in Dewey's philosophy emphasizes the importance of anchoring the students' learning in memorable experiences and related reflections.

At seminars in the SUM project with the teachers, common factors in how IBMT can be operationalized across the different educational levels have been discussed and illustrated with concrete examples of different types of inquiry activities. Moreover, as common starting point the teachers were introduced to a three-phased didactical model for IBMT (Blomhøj, 2016, chap. 6). This model is summarized in figure 1. In the first phase, the scene should be set for the students' inquiry activities. Multiple approaches is possible, essentially the students should be motivated to investigating a phenomenon or a problem, which make sense for them. In the second phase, the focus is on the students' investigative work. Here the students should have sufficient time, freedom and support for their inquiry activities. The crucial challenge for the teacher is here to help and support just as much as needed without depriving the students the essential mathematical challenges and the related learning opportunities. In the third phase, students' experiences, results and reflections are systematized and shared in the class. The teacher can draw on the students' presentations or products and pinpoint essential elements for the class. Alternatively, the teacher can organize the results from the students' work in dialogue with the class, providing explicit and concrete anchoring to the students' work. Combinations of these formats are of course also possible. The shared experiences and results can serve as a basis for reflections in class. It is the task of the teachers to identify key points in the students' work and to link them to content and learning objectives in the curriculum.

A three-phased model for inquiry based mathematics teaching

1. Setting the scene for the students activities
- creation of questions, amazement or challenges
- establishing the didactic environment for the work
- dissemination of the temporal and practical framework
- clarification of product requirements and success criteria / form of assessment

2. Students' independent inquiry oriented activities
- sufficient time, freedom and support for students' work
- support and challenge through dialogue, cf. the principle of minimal guidance
- preparation through construction of possible dialogues

3. Shared reflections and learning
- experiences, results, and reflections from the activity are systematized and shared
- mathematical points are drawn from the shared results and reflections
- points and results are linked to institutionalized knowledge, e.g. the curriculum

Figure 1: Three-phased didactic model for IBMT

Methods

In this paper, we focus our analyses on an IBMT-lesson implemented in upper secondary school by one of the teachers (Ann) participating in the project. Ann has three years of experience teaching upper secondary and a masters' degree in mathematics education with a particular focus on secondary mathematics education. The lesson took place in a first-year upper secondary class consisting of 25 students aged 15-16 in a small to medium-sized school outside of a city in Northern Norway. Based on a survey directed at the students in the SUM project at the beginning of the school year, it seemed like the students in this class had mostly little to some experience with IBMT from their previous teaching. During interviews and in a questionnaire handed out early in the project, Ann had expressed interest for and curiosity about IBMT, but she had also said that it was difficult to find the time and the resources for designing and implementing IBMT in her classes. Furthermore, she was unsure that students' learned "what they were supposed to learn" in IBMT lessons. Ann had therefore decided, sometime during the third year of the project, that she wanted to use a so-called taxicab-geometry as a starting point for a 90 minute IBMT lesson, as it offered some "structure and clear learning targets related to proportionality and linear growth" as she put it. Prior to the lesson, Ann had been exposed to the three-phased model during the first two years of the SUM project, and had recently began using it as a tool for planning IBMT lessons in her regular practice.

Taxicab geometry is a form of non-Euclidian geometry, which can be thought of as taxicabs roaming a city with streets forming a lattice of unit-square blocks. The taxicabs can only move horizontally and vertically and U-turns are not allowed. The difference between the taxicab system and Euclidian geometry is that the usual distance function is replaced by a new metric in which the distance between two points is the sum of the absolute differences of their Cartesian coordinates, hence the distance between points in the lattice can be counted, see figure 2.

Before the lesson, Ann had prepared the following system of tasks:

1. *Can you draw roundtrips that start and end at point A with lengths 8, 9, 12, and 17?*
2. *Can you mark all points, which have the same distance to point A and B?*
3. *Can you mark all points that have distance three to point A? How many points like this are there? Can you name this pattern of points?*
4. *Make a formula for the number of points with distance r to a specific point.*
5. *Make a formula for the number of points with distance less than r to a specific point.*

Figure 2: Points A and B with distance 5

In line with best practice regarding case studies, we used multiple data sources (Yin, 2014). We collected data from semi-structured observations of the lessons, short interviews with the teacher before and after the lesson, sound recordings of the teacher and groups of students during the lesson, and focus group interviews with students after the lesson. The main purpose of the analysis was to identify how the three-phased model provides a framework for the teachers' work in the classroom. Although there are no routine procedures for analyzing case studies, the analysis must logically piece together the available data into broader themes that capture essential aspects (Yin, 2014). Here, we attempted to identify and explain important episodes during the lesson that could help us understand both the challenges and opportunities the teacher experienced during each of the three phases of IBMT. First, we identified interesting episodes from the case based on our observational notes and sound recordings. We then cross-checked these episodes with data from our interviews before and after the lesson, in order to better understand why these episodes occurred. Finally, we discuss the potential for the students' learning, and possibly missed opportunities during these episodes.

Results

The lesson began with Ann handing out the tasks and an explanation of the rules of the taxicab geometry to the students and telling them to sit in groups of 2-3. She then explained to the class that "this lesson is about thinking, exploring and conjecturing" and that the students had to "investigate and come up with solutions themselves". After letting the students look at the tasks and rules for a minute, she explained the rules of taxicab geometry to the whole class and she demonstrated an example of finding the distance between two points in taxicab geometry. She then told the students that they could start working on the handed out tasks. For the next five minutes, the classroom was quiet and the students did not write anything down in their own notebooks. Ann then asked the whole class to pay attention. She showed the students an example of a roundtrip of distance 8 from point A, before challenging them to find other roundtrips with distance 8, and then 9, 12, and 17.

Observations in phase 1 thus show that the students' did not immediately go to work on the tasks after Ann's short introduction and explanation. This indicates that phase 1 was not without its challenges for the teacher and students. Observation alone cannot tell us why the students sat quietly at their desks, seemingly unwilling or unable to work on the tasks. However, interviews with the teacher and groups of students after the lesson point to at least some factors.

First, the students said that the tasks were difficult, and they were unsure of what to do. Asked why they thought the tasks were difficult, they explained that the tasks were new and unusual. One student, for instance said that; “the tasks were difficult…to understand. I did not know what to do. They were new and I have not seen this before.” The students also mentioned that the tasks lacked clear instructions, and they had to read the tasks several times before realizing that they had to solve them on their own. Second, the teacher said she expected the students to begin working on the tasks after her short introduction, and that she was surprised they sat quietly at their desks. After seeing this, Ann told us she thought the students needed a specific example to show the students how to get started. Third, we also noticed from our interviews an apparent disparity between the teacher and students regarding the purpose of the lesson. In the interviews, Ann mentioned that the lesson was built around the concepts of linear and quadratic functions and direct proportionality, as those were the key subjects in the curriculum “they were working on right now”. For instance, task 4 according to Ann, should “build a better understanding of direct proportionality and linear functions”, and in task 5 the students are challenged to develop a quadratic function. In the interviews, the students, on the other hand, expressed confusion about what the lesson was really about. As one student said, “I do not know what this has to do with the other stuff we have been working on lately”.

Based on these observations, it would seem as the students did not lack motivation or interest, but rather that their expectations caused some miscommunication at the beginning of the lesson. From the teacher’s perspective, both the purpose and intention of the tasks were clear. However, from the students’ perspective, the tasks were difficult; as they did not knew how to get started on them and because they did not fully understood the learning purpose of the tasks. The issues mentioned here are not specific to this particular lesson. They are relevant for IBMT in more general. Dissemination of the temporal and practical framework and clarification of product requirements, success criteria and forms of assessment are general key issues in the first phase of IBMT. In other words, students and the teacher need to have a similar understanding of the task; what are the students expected to do, and what types of intellectual products should they produce. Brousseau and Warfield (2020) refer to this as a situation of devolution, where the students accept the challenge of an engaging and instructive mathematical situation. Similarly, Stein et al. (2008) have highlighted the importance of anticipating how students might interpret and attempt to tackle mathematical problems when implementing cognitively challenging tasks.

In the second phase, the focus is on the students’ investigative work. We observed several episodes that indicate challenges for both the teacher and the students during this phase. One issue we repeatedly noticed was that groups of students would often sit quietly, raise their hands and wait for the teacher to help them. For instance, at one point, only about five minutes into the second phase, students in seven groups raised their hands and asked the teacher for help. Only after the teacher had provided some form of guidance did the students proceed with their work. The following sequence illustrate this. Two boys raise their hands, and Ann approaches them:

Ann: How are things going? Did you get an answer to task 4?

Boy1: No, we did not understand it.

Boy2: We gave up.

Ann: No, tell me. What is it you do not understand?

The boys then show the teacher what they have done so far, and the teacher notices that they have marked points outside the intersections between the horizontal and vertical lines in the grid. The teacher asks the boys if it is possible to mark points outside the intersections.

Boy2: Aha, now I get it. The points have to be here (points to an intersection). Then it is easy. We have 4, 8, 12 points.

Boy1: I get it. We just multiply 1 by 4, then 2 by 4, then 3 by 4 and so on.

Boy2: This is brilliant! What a genius way of doing it.

Boy1: Very clever!

During the interview after the lesson, the teacher mentioned this episode with an explanation for why it occurred. According to Ann, this was an example of something she had noticed almost every time she had tried out IBMT lessons. The students are often passive during the investigative phase, and they quickly give up and ask for help from the teacher – even though they have not tried any strategies or approaches themselves. According to Ann, this is something that applies to almost all students in her class; “The students enjoy these IBMT lessons, but they give up quickly. They do not seem to want to think for themselves. They want me to tell them what to do”.

Another point worth mentioning about this episode is that the students’ solved the task by generalizing the empirical pattern of the number of points when the distance increased by one. Neither the teacher nor the students ever asked themselves why this pattern occurred. A key activity in both IBMT and mathematics in general (e.g. Barbeau & Hanna, 2008) is proving and reasoning deductively, and this was an excellent opportunity for the teacher to ask the students why this pattern appeared or if this pattern would continue when the distance became larger. The reason we bring up this point is that this was something we have noticed in several other IBMT lessons as well. Both teachers and students often seem to be satisfied with empirically based solutions. However, challenging the students’ schemas of reasoning and proof from empirical to more deductive schemas as defined by Harrel & Sowder (2007) could be seen as one of the potentials of IBMT.

In the third phase, at the end of the lesson, and after a short break, Ann told the class that they would now look at the tasks together. She asked the students if they have found any answers to the tasks, and then worked her way through each of the five tasks. For each task, she asked the students if they have an answer for her. The incorrect answers from the students were mostly sidestepped, and instead, she wrote down the correct answers from the students on the board. During this phase, Ann was very focused on connecting the students’ work to the topic of proportional growth and linear functions, as that was the topic they were currently working on. For instance, when she asked the students for solutions to task four, she stressed the importance of connecting the answers to concepts like proportionality, linear functions, and straight lines. After the lesson, Ann said in the interview, that one of the main goals of the lesson was that the students would get a better understanding of “the relationship between tables, graphs and equations of linear functions”. Ann went on to explain that “ideally, the students’ would have been more active and more responsible for the third phase”. However, because she thought the students were a bit passive and quiet, she felt the need to make sure that the lesson ended with clear solutions to the tasks and a clear connection to the curriculum.

The interviews with the students after the lesson help us explain why the students were “passive and quiet”. As one student said, “this is just how we do it. At the end of the lesson, the teacher goes through the tasks and explain the solutions”. Another student added; “I did not quite understand the purpose of the lesson, so I prefer that teacher explain it to us”. Here we notice two things. First, it seems as if there are an expectation and habit of the lessons ending with the teacher explaining solutions and the resuming purpose of the lesson to the students. Second, it seems that the students were unsure of the purpose of the lesson in terms of the intended learning, even after the activity, and therefore they wanted the teacher to explain it to them. This observation shows that for the students, the activity constitutes a break of the didactic contract (Brousseau & Warfield, 2020).

Conclusion

In this paper, we analyzed a case of IBMT with particular emphasis on the role and function of the three-phased model as a framework for the activities in the classroom. Although there are idiosyncrasies tied to the taxicab case, it illustrates several characteristics observed across many IBMT lessons in the SUM project. Thus, the points made concerning the role and function of the model in the case are to a large degree concretizations of general trends observed across many teachers, grade levels, and subjects in the SUM-project.

The taxicab lesson adhered clearly to the three-phased model. As noted by (Haavold & Blomhøj, 2019), a general observation from the SUM project is that the teachers have adopted the model as a didactical tool for planning, conducting and reflecting on their IBMT lessons. The teachers carefully separate their lessons into an introduction, an investigative phase, and a plenary summary. This might seem like an obvious and minor effect. However, in data collected at the start of the project, teachers expressed reluctance to let students investigate on their own without much guidance from the teacher (Haavold & Blomhøj, 2019). Thus, the careful use of the model is an important change of practice for many teachers. The taxicab lesson also illustrates certain challenges teachers face developing their IBMT practices. The students appeared relatively passive during the investigative phase, and according to Ann, this was something she frequently noticed when trying out IBMT lessons. In part, this may be due to the students being relatively unfamiliar with inquiry activities. Implementing IBMT lessons may necessitate renegotiating the classroom didactical contract (Brousseau & Warfield, 2020), and the teachers in the SUM project have indeed expressed views that the students need to be gradually accustomed to inquiry activities. The taxicab case illustrates this, as Ann specifically implemented a very structured IBMT lesson closely tied to the goals in the curriculum they were currently working on. Nevertheless, students’ independent work during phase two was still somewhat of a challenge. Concerning the three-phased model, it is clear that merely allocating some time for students’ independent inquiry (phase two) is not sufficient. Teachers also need to prepare for supporting students during their independent work, for example through anticipating how students may interpret the task and how they might approach solving it (cf. Stein et al., 2008).

Additionally, the taxicab lesson illustrates that phase three can be somewhat of a challenge for the teachers. Although the teacher linked the lesson and work to the curriculum, i.e. institutionalized mathematical knowledge, it is clear that the third phase lacked a systematization of and reflection on the students' solutions, as well as student engagement and active participation. Instead, the teacher mostly highlighted correct solutions without contrasting them with other solutions. The teacher mentioned in the interview that the students were passive, so she felt the need to take control and link the lesson to the curriculum. However, her aspiration to link the taxicab activity to specifically linear functions and proportionality may have contributed to hinder a productive discussion of the taxicab activity in itself and other key mathematical ideas.

To summarize, our analysis of the taxicab case illustrates how the three-phased model provides a frame for the teachers' planning and implementation of inquiry activities. In addition, it highlights the need for finding ways of supporting the teachers in planning and executing phase two and three of IBMT lessons. This plays directly into the dual nature of SUM: On the one hand, SUM as a research project aims to elucidate the extent to which teachers develop their competence for using investigative approaches in their teaching. On the other hand, SUM as a development project aims to support the teachers in developing a practice for IBMT. In that respect, the insights we gain from observing the teachers' implementation of IBMT in their practice in turn shapes how we as researchers collaborate with teachers in SUM. Hereby, SUM explores both the potentials and the limitations in developing practices of IBMT in collaboration between teachers and researchers.

Active, bodily experience mathematics learning activities. Looking at implementation from the teachers' perspective

Alessandra Boscolo

a.boscolo@lumsa.it

LUMSA University, Department of Human Studies, Rome, Italy-Australian Catholic University, ILSTE, Brisbane, Australia

Despite both the research in cognitive psychology and neuroscience, and in mathematics education has increasingly highlighted the relevance of active, bodily experience in mathematics learning, often school teaching seems to be far removed from these perspectives, still largely transmissive. The research presented in the paper is part of an ongoing study, carried out in two different cultural contexts (Italy and Australia), aims to explore the reasons for that distance, by investigating the perspective of primary and secondary school teachers on these teaching proposals and their implementation in the classroom. In addition to the direct involvement of teachers, the designed research includes interviews with experts in the field of mathematics education. After presenting the investigative perspective on the implementation of active, bodily experience learning activities proposed in the research project, an explanatory example will illustrate how the analysis of experts interviews could contribute to identifying determinants of implementation.

Keywords: Mathematics activities, enactive pedagogy, embodied cognition, manipulatives-based learning, teachers' beliefs.

Introduction

The role of the body and movement in the exploration and construction of mathematical concepts is a central topic in much of the relevant literature in mathematics education. The roots of this tradition can be found as far back as the early 1900s, in the well-known Italian contributions of Maria Montessori and Emma Castelnuovo, as well as in Jean Piaget, John Dewey, and Jerome S. Bruner's theoretical works. More recently, cognitive psychology and neuroscience have highlighted the profound interrelationship of perception-action and conceptualization in learning processes. This research has been key to the development of the embodied cognition theory (Lakoff & Nunez, 2000; Varela et al., 1991). In recent decades, the role of students' active, bodily experience in the exploration and construction of mathematical concepts has assumed increasing relevance in the research in mathematics education. As pointed out by Drijvers in the ERME-11 plenary (2019), the growing interest in research from this perspective is evidenced, for example, by the fact that two special issues of *Educational Studies in Mathematics*, have been devoted to the embodiment in mathematics education. Furthermore, several theories that focus on perceptual-motor involvement in the teaching-learning process of mathematics have been proposed. Although conceptualized differently, examples include *enactivist pedagogy* (Abrahamnson et al., 2022), *inclusive materialism* (de Freitas & Sinclair, 2014), and *multimodal approaches* (Radford et al., 2017). On the other hand, the European tradition of the so-called *experimental approach*, and the important recent contributions from these perspectives in research in mathematics education, have found a foothold in most national policies, which encourage teaching strategies in which students are actively involved through the use of manipulatives and tools (e.g. Bartolini Bussi et al., 2010). In Italian national policies, for instance, we could find it in the references to the *Mathematical Laboratory*, elaborated in the intended curriculum, both in the programmatic document *Materiali UMI-CIIM Mathematica 2003,* and in the institutional documents National Guidelines (MIUR, 2012) and National Guidelines and New Scenarios (MIUR, 2018). However, this growing interest in research and developments at a theoretical level has not been matched by an equally wide resonance in classroom practice, which is often far removed from this perspective. Indeed, everyday teaching practice is often inconsistent with this, still largely based on a purely transmissive approach (OECD, 2009, pag.98; OECD, 2016, pag.65) and tend to focus on the implementation of clarity-of-instruction (e.g., procedural) rather than cognitive activation practices (OECD, 2019).

This gap between research findings and indications and the uneven proposal of these activities in classrooms warrants a research interest in active, bodily experience learning activities implementation. In our research, we are particularly interested in exploring what is the current implementation of these activities at school, since, as highlighted by Century and Cassata (2016):

> Documenting implementation as conducted enables researchers to understand the ways that innovations are operationalized in practice, the influential factors that affect the practice (…), the different patterns of practice, or “configurations” (…), and in some studies, the relationship between these patterns and outcomes. (p. 190)

This paper will present an investigative perspective that looks at active, bodily experience learning activities, that we identify, somewhat improperly, as an innovation or research finding, investigating teachers' perceptions in this regard. We also aim to show how we want to use the analysis of interviews with selected experts in mathematics education to create a conceptual framework that, along with insights from a literature review, will allow us to interpret teachers' survey findings. These interviews are designed to investigate the experts' views on what the core elements and expected outcomes of these activities are, and to identify the factors believed determinant in and for their implementation. In the following lines, we will provide a brief justification of the proposed perspective of inquiry, illustrating the main conceptual statements assumed in the study.

The object of implementation: an all-embracing construct

The variety of theories mentioned in the paragraph before, develop theoretical constructs that are the result of the specific philosophical, psychological and pedagogical perspectives that determine them. Looking at the implementation with an exploratory study aimed to understand teachers’ perspectives, the research cannot move within a specific theoretical framework but needs to be based on a negotiation of meanings. Due to this fact, we need to individualize a comprehensive construct as *the object* of our research on implementation, which acts as an umbrella for the multitude of theoretical proposals developed, and which should be clear and easy-accessible for teachers.

We will use the terminology *active, bodily experience mathematics learning activities* to refer to activities designed in the perspective of enactive-embodied learning or, more generally, to activities in which students are actively engaged in exploring mathematical concepts using manipulatives, tools (virtual or physical), or the whole-body movement. Descriptions and appropriate commonly known examples will introduce the definition. We are attempting to clarify the characteristics of the construct under analysis, with an explorative study conducted with experts in the field of Mathematics Education, selected both for their experience as theoretical developers in this research field or in professional development courses with teachers.

An old matter, a current issue

Although the proposal of active, bodily experience learning activities in schools has such a long and widely debated tradition, the presence of this perspective in teaching practice is uneven. Furthermore, these theoretical perspectives, encouraged by experimental findings, are recently developing a wide range of innovative educational artifacts and proposals. Through a new point of view with which to look at the implementation of these approaches in schools, this study is shaped as research on the implementation of research findings (Century & Cassata, 2016).

In the research, we look at implementation from the perspective of teachers, assuming that they can give us precious insights on the current implementation as conducted in classrooms. These include, for instance, the teacher's beliefs and experience which plays a central role in educational change (Coburn & Talbert, 2006; Peterson, 2013), and the perception of the activities studied, that has a drastic impact on their implementation (Domitrovich et al., 2008; Ruiz-Primo, 2006), as highlighted in the case of the introduction of manipulatives by Golafshani (2013) and Vizzi (2013).

Research Aims

As briefly outlined in the introduction, many research findings and theoretical results have been developed over years concerning the importance of actively engaging students in hands-on activities and the role played by perceptions and movements in mathematics teaching and learning processes. Nevertheless, in our study, we want to go beyond the different theoretical perspectives, with the intention of investigating teachers' perspectives regarding the proposal and implementation of active, bodily experience learning activities, "to describe the extent and nature of innovation use in practice, including adaptations and omission of core components, and explore the contextual factors that support or inhibit innovation use" (Century & Cassata, 2016, p. 190). The research presented in this article first aims to present the perspective adopted to explore the implementation of learning activities of this type in the study. Secondly, it aims to illustrate how the analysis of interviews with experts in mathematics education, on these research findings and their implementation, can be used to identify the core elements and outcomes considered essential parts of this *innovation* and the key characteristics that determine their implementation.

Research framework and state of the art

The presented research is part of an ongoing doctoral research project investigating the proposal and implementation of active, bodily experience learning activities in classrooms. The research project aims, firstly, to offer an overview of the literature on theoretical perspectives and empirical research focused on the involvement of the body and movement in learning mathematics activities consistent with an experimental, hands-on approach; secondly, to highlight the presence/absence of official national and international guidelines, educational policies and curricular documents in this direction. As a third goal, the research aims to investigate the perspective of mathematics teachers, both primary and secondary, with respect to the implementation in the classroom of active learning strategies, which involve the body and movement of students and to identify possible hindering and facilitating factors, such as teachers' beliefs.

The research project is an exploratory mixed-method study, that includes desk research, designed to achieve the first two goals. To reach the third goal, we have designed an explorative study that aims to investigate primary and secondary mathematics school teachers' perspectives regarding the proposal and implementation of these activities. This stage of the research includes:

- semi-structured online interviews with experts in Mathematics Education aimed at documenting experts' views on active, bodily experience activities to identify a conceptual framework on the main issues outlined in the teachers' survey.

- an online questionnaire to reach a convenience sample of primary and secondary mathematics teachers, working in diverse schools or localities, using a web-based instrument combining rating items, multiple-choice items, two vignette-items, and a few short open-ended questions.

- individual or focus group semi-structured online interviews with a smaller number of teachers, grouped according to school levels, complementing the survey. This phase aims at deepening some topics for which the questionnaire might not yield sufficient information.

The explorative study is being carried out in two very different cultural contexts, Italy and Australia. The involvement of such different contexts may offer the opportunity to observe some latent and implicit variables that may not emerge by conducting the investigation immersed in a single educational and cultural system.

Research design and methodology

The instrument

To collect experts' opinions on the implementation of active, bodily experience learning activities in classrooms, we are carrying out individual semi-structured interviews via Zoom, approximately one hour-long, with a small number of experts in mathematics education, both in Italy and in Australia. The interview prompts are designed to get the experts' views on key aspects of implementing active, bodily experience mathematics learning activities at school, especially in relation to teaching practice. The first goal of the interviews is to collect the experts' opinions on the proper terminology to define the activities under investigation in a clear and easily accessible way for teachers. This exploratory phase should also provide a set of examples that might be commonly known and recognized by teachers, at different school levels. Furthermore, with the interviews we aim to shape a conceptual framework of experts' views around the main questions underpinned the survey on teachers' perspectives:

I. Whether and why is it important to implement active, bodily experience mathematics learning activities at school?
II. What are the beliefs that should guide teachers in proposing these activities?
III. Which levels of awareness and knowledge should accompany teaching when implementing these activities? (e.g., in terms of teaching strategies, assessment, etc.)
IV. Which characteristics concerning the implementation of these activities at school determine their teaching effectiveness?

V. What are the main limitations of the use of these activities in daily teaching practice? What are factors that hinder/favour the implementation of these activities at school?

Interviews are transcribed and analysed according to the thematic content analysis method, using open, inductive coding in the first instance and then refining the results with a focused, axial coding that will lead to the construction of concept maps. A tool to represent narrative material will be used to analyse these qualitative data and to compare and contrast individual responses to each question. Analysis of the narrative material will produce a conceptual framework that highlights the overall and variety of experts' opinions on core elements and expected outcomes of these activities are, and that identify the factors believed determinant in and for their implementation.

Participants

In Italy, we have selected and interviewed 8 experts in mathematics education. The experts were contacted via email, and their participation in the study is voluntary. They are 7 accomplished academics and a teacher-researcher, who have a wide range of different research interests: mathematics difficulties and the use of representations, teachers' beliefs and problem-solving, teacher education, semiotic mediation, proof and argumentation, cultural transposition, multimodal approaches and gestures, Montessori method education. Overall, all of them have long experience in teachers' professional development courses and empirical research in classrooms and they are familiar with the topic.

The scheduled interviews in Australia are 6 and we are currently conducting them. The experts, contacted via email and voluntarily involved, are all academics, in some cases former teachers, and they were selected on the basis of their research interests and experience in the field of teachers' professional development.

A preview of how the analysis of Italian interviews is being carried out is presented below. The interim analysis is partial and has not yet been subjected to triangulation.

An illustrative example of Data Analysis: Question 1

In this paragraph, a brief presentation of the conceptual framework identified by the experts around question 1 of the previous list will be provided, showing the main themes that emerged in their answers. The map shown in Figure 1 is a simplification for illustrative purposes of this conceptual framework. The construction of the map started with the analysis of a first interview. The themes that emerged analyzing the transcript of the interview were categorized with an inductive analysis, and a first concept map referring to the individual interview is created starting from these categories. Around the key concept, consisting of the topic of the question, we positioned the themes that emerged in the expert's answer as nodes in a graph, and, using directional arrows, we represented the network of internal relations between the various themes. Next to the arrows, labels were juxtaposed in order to specify the nature of the links identified between the emerged themes. A similar analysis was carried out for the other interviews; the opinions, that emerged from these, added new thematic nodes or strengthened the links already identified. The analysis process was not linear and evolved through the renegotiation of the emerging categories, depending on continuous re-readings of the narrative material. The map, in Figure 1, presents the set of themes that emerged and the totality of the links identified by the analysis of all the interviews conducted. The themes and relations referred to each single contribution are identifiable, due to the assignment of an identifying colour for the arrows which indicate the links narrowed by the same expert. In this way, we were also able to represent the recurrence with which a theme emerges in the various contributions analysed.

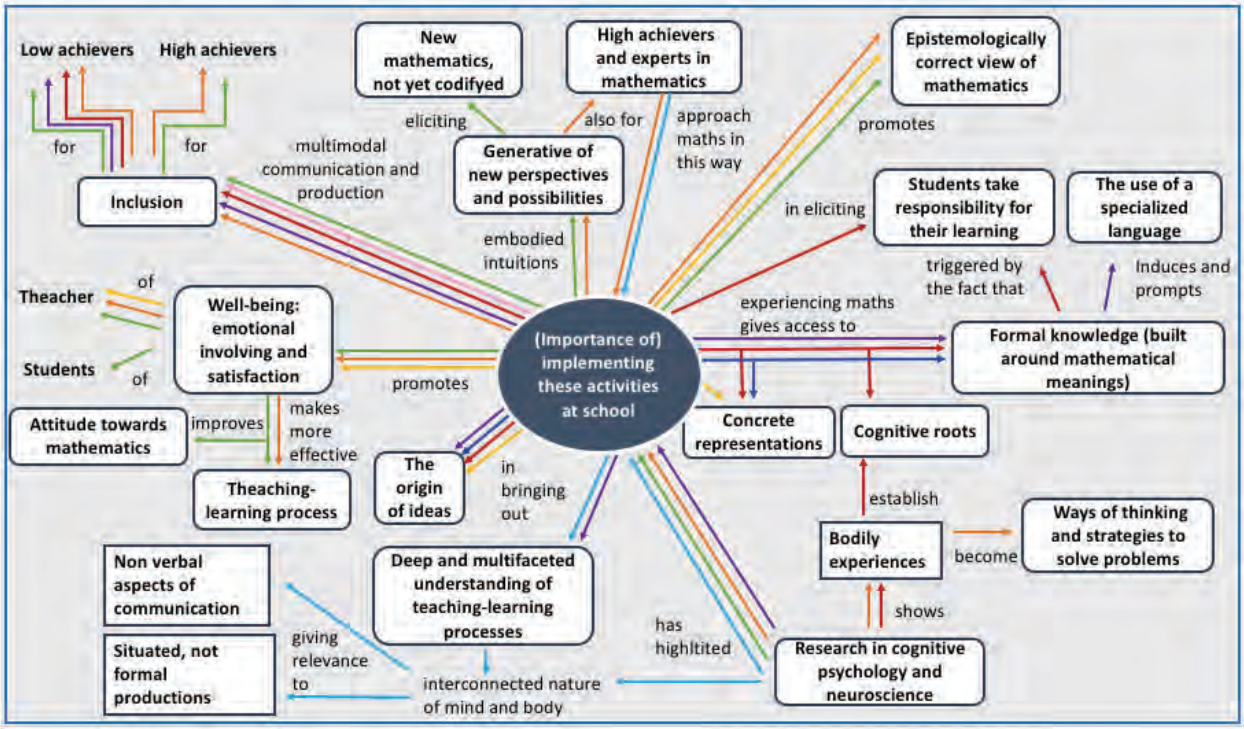

Figure 1: Interim concept map of experts' framework around the question: "Do you think it is important to implement such activities in school? Why?"

Briefly discussing the partial and provisional results analysed so far, some strong and shared themes clearly emerge. First, the activities under consideration are considered to be more inclusive, as they use more channels for accessing and producing information than the traditional verbal one. While the focus is mainly on the difficulties developed in mathematics, it is also stressed that such inclusion is to be considered in a broader sense, also with regard to high achievers. References to experimental cognitive studies are also frequent, testifying to the validity of these proposals for the construction of mathematical meanings, insofar as they offer cognitive roots, for instance in motor schemes, on which to anchor the manipulation of mental and abstract concepts. Moreover, these activities are considered capable of promoting situations of well-being, centred on involvement and satisfaction, both for students and for teachers. Furthermore, two experts have highlighted that in the proposal of these activities, which take into account the profound interweaving of perceptual-motor and conceptual aspects that occur in learning processes, more complete interpretations of the teaching-learning process of the discipline emerge. From a more disciplinary point of view, there is a broad agreement that these activities are able to put students in direct contact with the origin of mathematical concepts, which find their basis in the human experience of exploring the world. Experimenting with mathematics, constantly moving from the concrete to the abstract, leads to the achievement of a meaningful understanding of formal knowledge. In addition, the intuition that passes through the body is hypothesized by two experts as generating new possibilities and perspectives for the discipline itself, in the creation of new knowledge. It is also emphasized that even professional mathematicians often use bodily artifacts and intuition to think about mathematics. Therefore, by proposing these activities, we enable students to develop a more epistemologically correct view of mathematics as a dynamic discipline that proceeds in an exploratory and creative way, advancing by trial and error, employing all available cognitive resources to solve meaningful problems, and only then becomes formally structured.

Conclusion: Limitations and further directions

In this paper, we have presented the state of the art of research project. Structured analyses will be conducted on the collected narrative materials, of which we have presented only an exemplar preview. However, even from such a cursory presentation of preliminary analysis of the interviews, in the provided example emerged insights about, for instance, the overall and variety of outcomes that the researchers believe can be achieved by implementing this type of activity.

From the analysis of the Australian interviews that we are currently conducting, we will see if, overall, the two groups of experts, referring to a different cultural context, identify similar or different core elements of the object under study and key variables that play a central role in the implementation of these activities. Furthermore, from the data collected with the questionnaire addressed to teachers, and subsequent follow-up interviews, a comparison will be made to see whether and to what extent teachers' perspectives are aligned with the directions that emerged from the analysis of the experts' interviews, also considering the differences emerging from the two contexts involved.

The research presented is part of a doctoral study aimed to contribute to a hoped-for narrowing of the gap between research findings and their implementation in schools by highlighting specific needs emerging from the survey of teacher perspectives. The research findings could inform the design and development of innovation, indicating directions that could be taken to address these emerging needs, and providing support in practice settings.

Problem-solving implementation chain: from intended to experienced

Jason Cooper[1] and Boris Koichu[1]

[1]Weizmann Institute of Science, Department of Science Teaching, Rehovot, Israel;
jason.cooper@weizmann.ac.il; boris.koichu@weizmann.ac.il

The importance of mathematical problem solving (PS) has long been recognized, yet its implementation in classrooms remains a challenge. In this theoretical essay we put forth the notion of problem-solving implementation chain as a sequence of intended, planned/enacted and experienced activity, shaped by researchers, teachers and students respectively, where the nature of the activity and its aims may change at the links of the chain. We propose this notion as an analytical framework for investigating implementation of PS resources, and illustrate this framework in a case of middle-school teachers enacting a particular problem they encountered in professional development. We show how adaptation along the implementation chain can be viewed not merely as loss of fidelity, but rather as an opportunity for researchers, teachers and students to refine their perspectives on PS activity, and to learn through the implementation process.

Keywords: Implementation, fidelity, adaptation, boundary-crossing, documentational approach to didactics.

Introduction

Problem solving (PS) was put on the mathematics education agenda decades ago (Pólya, 1945/1973; NCTM, 2000; Schoenfeld, 1985), and remains one of the spotlights of mathematics education research to this day (Felmer et al., 2019; Lester & Cai, 2016; Schoenfeld, 2013). It is considered both as a self-contained goal and as the means of accomplishing other significant objectives of mathematics education (Schroeder & Lester, 1989). In addition, PS is considered one of the central activities in mathematics as a living science, and thus it has been hoped that it would also become a central activity in mathematics education (Mamona-Downs & Downs, 2005; Lester & Cai, 2016). However, implementation of PS in the school reality is relatively rare, and even when implemented, activities that designers of instructional resources intend as PS are liable to be enacted as drill and practice, a kind of activity that still tends to be dominant in mathematics classrooms (Lester & Cai, 2016; Felmer et al., 2019). Lester (2013) attributes “this unfortunate state of affairs” (p. 251) to the fact that research on mathematical problem solving remains largely a-theoretical. Schoenfeld (2013) suggests that the current challenge is to specify the theoretical architecture of PS activity, in order to explain “how decision making [on PS implementation] occurs within that architecture” (ibid., p. 17) and to theorize on “how ideas grow and can be shared in interaction” (ibid., p. 20). The conceptual framework of *problem solving implementation chain* (PS-IC) aims to address these lacunas. Briefly, we consider PS-IC as a sequence of actions and interactions beginning with the development of a problem-solving resource by researchers, which teachers then engage with in professional development (PD), and finally teachers and students make use of in classrooms.

Problem-solving implementation chain – a conceptual framework

Current research (e.g., Aguilar et al., 2019, Koichu et al., 2021) conceptualizes implementation of innovation, such as incorporation of PS resources in a classroom that normally features drill and practice, as a change-oriented process that takes place between proponents of an innovation (often education researchers) and its adapters (often mathematics teachers) who adapt the resource while taking agency over it. Taking inspiration from Stein et al. (2007), who distinguished between intended, enacted and experienced curriculum, we propose the term *intended PS* to denote the proponent's vision of enactment for a particular problem, *planned PS* to denote the vision of the teacher, *enacted PS* to denote what actually takes place in the classroom from the perspective of the enacting teachers, and *experienced PS* to denote what takes place from the perspective of students. Thus, PS-IC can be operationalized as a dynamic sequence of intended–planned–enacted–experienced PS perspectives that are shaped by interactions between the stakeholders involved.

From the perspective of the resource proponent, the intended PS is implicit in the problem, and may also be communicated orally or in writing, for example in a teacher guide. There is a duality in teachers' interactions with resources that is conceptualized in the documentational approach to didactics (DAD, Trouche et al., 2020) as *instrumental genesis*. An *instrument* is taken to be an artifact (e.g. a problem) along with schemes for its use. On the one hand, teachers are invited to appropriate the intentions of the designer in a process called *instrumentation*. On the other hand, "the conceptions and preferences of the user change the ways in which he or she uses the artifact, and may even lead to changing or customizing it" (Drijvers & Trouche, 2008, p. 368) in a process called *instrumentalization*. We consider intended and planned PS as *documents* (Trouche et al., 2020), in the sense of a particular resource (problem) along with an elaborated *scheme of usage*, which includes the *aim* of the activity (e.g., to engage students with particular mathematical competencies), *rules of action* (e.g., orchestrating a classroom discussion based on students' ideas), *operational invariants* for PS activity in general (e.g., students should first "get stuck" and then attempt to invent a solution over a period of 20-30 minutes), and *possibilities of adaptation* (e.g., what to do if some students do not make any progress on their own). The process in which teachers develop such documents is called *documentational genesis* (Trouche et al., 2020).

The use of a new resource is not dictated by its proponent, but neither is it completely in the hands of the adapters (as is often tacitly assumed in DAD). In PD, researchers and teachers may engage in a kind of co-documentation, which may give rise to a new hybridized scheme of usage. A similar process may take place through interactions between teachers and students. Thus, to understand why and how PS documents evolve, we propose to study the "links" in the chain – interactions between researchers and teachers at the link between intended and planned, and between teachers and students at the link between enacted and experienced. Cooper et al. (2020) have conceptualized the kind of expansive learning that can take place between researchers and teachers in PD as *boundary crossing* (Akkerman & Bakker, 2011), and have demonstrated various learning mechanisms that may take place when these communities interact, such as *coordinating* perspectives in attempting to translate the discourse of others (e.g. what do you mean by *problem*?), *reflecting* on each other's practice (e.g. researchers considering the practical rationality of teachers' actions), and *transforming* practice through hybridization. Robutti et al. (2020) have investigated the role of mathematical tasks in such learning as *boundary objects*.

Thus, the notion of implementation chain provides a conceptual framework to address two classes of research questions: 1. What are the differences between PS at various phases of implementation, from intended to experienced? 2. How and why do these differences develop through interaction between researchers, teachers and students?

Illustrative analysis of a PS implementation chain

We now illustrate how the notion of PS-IC can support research. For this we rely on a particular problem, drawing both on empirical data (what took place) and on thought experiment (what could have taken place). The context of this example is a PD program that aims to encourage and support PS in

"Factoring" exam grades

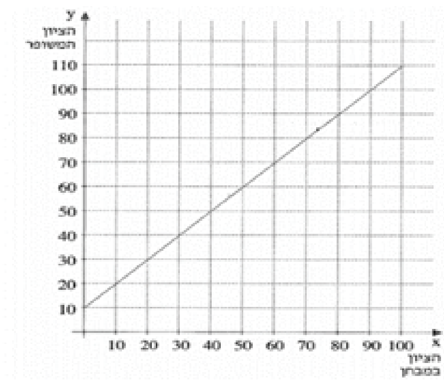
Grades in a math test were rather low. The teacher considered 4 proposals for raising the grades:

Proposal B

Original grade	Factored grade
20	24
40	48
60	72
80	96
100	120

Continuing according to the same linear rule

Proposal A



Proposal D

x – the original grade
y – the factored grade
$y = 10\sqrt{x}$

Proposal C

Add to the original grade half the difference between 100 and the grade.

1. Think about a grade you received recently, and about how the 4 proposals would influence your factored grade.
2. Av said: "My grade was 81, and one of the proposals would increase my grade significantly more than the others.

   Debby said: "it isn't fair for students who failed the test to receive such a significant increase, while those who passed receive a smaller increase.

Which proposal did each of them have in mind? Explain your reasoning!

3. The teacher decided to accept the following conditions:

   a) The factored grade should not be less than the original grade.

   b) The factored grade should be between 0 and 100.

Which proposals should the teacher consider?

The teacher eventually adopted proposal D. Try to explain what her reasons might have been.

Figure 1: The problem

middle-school mathematics classes. Challenging problems were designed and piloted by a development team comprising researchers, teachers and teacher educators. Then, in a 30-hour PD program, teachers solved problems, discussed and planned classroom enactments, enacted problems in their classrooms, submitted reflective reports on the activity, and discussed their enactments. Both authors observed the PD meetings, and we rely on our observations and on the reflective reports. We elaborate on a particular problem (Figure 1), which was enacted in 6 classrooms. Our analysis has five focal points: The intended, enacted and experienced schemes of enactment, and interactions between researchers and teachers and between teachers and students.

Intended enactment scheme

The scheme of enactment as intended by the proponent – the didactic aims of PS activity, rules and principles of its enactment, and its potential adaptation – are captured across a collection of documents, including teacher guides for each of the developed problems. We lay out some of the main aims and principles, and demonstrate them in the context of the problem under consideration.

Aims: Mathematical problem solving is both a goal in its own right and a means toward deepening mathematical understanding. As a goal, students should learn to solve problems in authentic contexts, applying a variety of generic and mathematical competencies. Seeking a fair rule for factoring grades is challenging due to the need to explicate a mathematical model of fairness, translate data between 4 different representations of functions (verbal, symbolic, numeric, graphic) and to come up with an innovative strategy. As a means, it can contribute to students' flexible translation between representations of functions, and foster an appreciation of the importance of this competency.

Rules of action (local and invariant): Teachers should allow students to struggle in their attempts to make sense of the problem and to find a solution strategy. Telling students what to do (e.g. "calculate the result of factoring the grades 50, 75, 100 in each of the proposals") can demote PS to mere drilling of procedures. The PS environment should be *choice-affluent* (Koichu, 2018), in the sense that students can choose whether to try to solve the problem individually, critique or contribute to a peer's solution, make sense of or explain a proposed solution, etc.

Adaptation: Teachers' enactment of PS should not be prescribed. There are many different valid rules of action, and teachers should be aware of many of them, and have the agency to make informed decisions on such factors as class organization (individual, pairs or small groups, whole class), time allocation, etc., adapting the activity to their local context. Accordingly, the teacher guide avoids prescription of rules of action, and instead highlight affordances of different possible modes of enactment. When students get "stuck", teachers should provide guidance that alleviates frustration without eliminating the challenge. For example, the teacher guide suggests that students might be provided all 4 functions in a single representation (Figure 2), possibly without specifying which graph corresponds to which proposal, and without specifying how this hint might prove to be helpful.

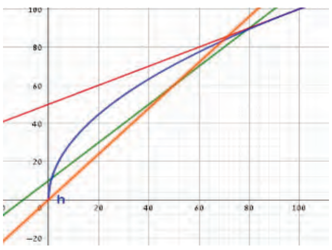


Figure 2: A possible hint

Scheme as planned and enacted

Teachers' planned schemes were inferred through their participation in the PD, where PS activities were discussed, and their enactment schemes were inferred through analysis of a structured 4-page detailed, semi-structured report that they submitted following classroom enactment of the problem.

Aims: Teachers' discourse on PS was dominated by two main concerns: what are their students capable of (e.g. "it's too difficult"), and what is institutionally possible (e.g. "I have no time for lengthy activities that are not aligned with the curriculum"). As a result, some of the teachers did not have the patience to engage with problems deeply enough to appreciate their didactic potential. Yet in the particular problem under consideration, three teachers noted curricular aims – to summarize and assess the topic of functions, or to practice the topic after formal instruction was completed, noting that it provided opportunities for students to deepen their understanding. Some teachers mentioned aims that were not directly related to the curriculum, including practicing collaboration in group work and encouraging mathematical reasoning.

Adaptation: Three teachers modified the problem. One merely omitted the last section to leave time for a significant discussion of sections 1 and 2, having decided not dedicate more than a single 45-minute lesson to the problem. Two others attempted to make the problem more relevant for their students. One did this by rephrasing section 3 in the first person ("which proposal should I consider"?). Another teacher took this idea of relevance one step further. She enacted the problem after returning a graded test, and instructed each student to calculate the result of each proposal on their own grade and to submit the results on a google form that she had prepared. The authentic data that was collected – the result of applying 4 different factors to 27 distinct grades (in total 108 calculations) – was then made available to all students as a resource for working on the problem. While this denied students the initial struggle, it added an element of personal relevance.

Rules of action: There was much variation in the way the six teachers enacted the problem. The total time that students worked on the problem ranged between 30 and 90 minutes. Two teachers began the activity with a whole class introduction, while the others immediately launched students' work on the problem. All teachers held a whole-class discussion at the end of the activity. Work that led up to the discussion was in two cases individual, and in 4 cases was in pairs or small-groups. All of these schemes fall within the range of the intended scheme. Yet all the teachers appeared to be rather quick to defuse students' frustration by providing hints or guidance as soon as they began to struggle.

Emerging invariants of PS enactment: Teachers' reflection on the activity provided a glimpse on their emerging invariants for PS activity (i.e. how they are likely to enact their next PS activity). One teacher valued the fact that her students were challenged, though she reported that she helped them during their individual work on the problem. It remains to be seen how she will come to balance challenge with her tendency not to let students remain "stuck". Two other teachers stressed the need to provide ample time for students to work and reason individually, suggesting that selecting short problems (or shortening longer one) may become a PS invariant for them. Two teachers were coming to adopt an invariant of small-group work, affording quiet students an opportunity to be heard.

Experienced PS

Based on the PS as enacted, it seems unlikely that students would have the opportunity to experience PS as intended, mainly because teachers were quick to assist struggling students. Nevertheless, one teacher indicated that here students were successful "after many attempts", suggesting that they were allowed to struggle, and some teachers were surprised by their students' capabilities (e.g. to represent functions on Desmos), suggesting that they may in future pose problems that they consider difficult.

Intended-planned link (teacher-researcher interactions)

Both the problem and the reports can be considered boundary objects in the following sense: Teachers planned lessons around problems designed by researchers, seeking pedagogical affordances they were not previously aware of, and reflecting on the activity attending to aspects that researchers considered significant. Researchers attempted to make sense of teachers' actions in PD discussion and through their reports. Beyond the obvious opportunities for learning through coordination and reflection on each other's perspectives, we bring some examples of learning through transformation of practice: One teacher's omission of the final, most challenging section of the problem may appear at first to "cripple" it by lowering the challenge. Yet making explicit the practical constraint of fitting the activity into a single 45-minute lesson has encouraged us to rethink how this can be reconciled with our views on PS, and has given birth to a kind of hybrid activity – a principle for designing "condensed" problems that fit into a single lesson without compromising crucial aspects of the PS activity. We are also coming to appreciate the role of teachers in motivating their students' PS activity by creating local relevance. This relevance is multi-faceted, and includes curricular relevance (carefully timing the enactment to serve a didactical purpose at a well-defined point in the curriculum), personal relevance (improving one's grade on a test) and social relevance (co-generating data to solve a problem, engaging in group work).

Enacted-experienced link (teacher-student interactions)

We are encouraging teachers to elicit feedback from their students to gain access to their experiences. We do not yet have data on this practice, yet can hypothesize on its potential to negotiate shared meanings and aims for PS activity (e.g. "it's not about getting the right answer") and to develop practices that will provide all students with opportunities to engage in mathematical reasoning.

Discussion

This paper proposes the analytical framework of *PS implementation chain* (PS-IC) for analyzing the evolution of problem solving activity as it passes from the proponent (intended), to teachers (planned/enacted), and finally to students (experienced). In combining DAD (Trouche et al., 2020), and the notion of boundary-crossing (Akkerman & Bakker, 2011) we propose a framework that can describe aspects of PS evolution, along with mechanisms and rationalities for this evolution.

Some might consider divergence from the intended activity as loss of fidelity (e.g., Brown et al., 2009), and as such undesirable. In contrast, we hold that local adaptation of the activity and its aims is desirable and even necessary. While the proponent of an educational resource can attempt to convey the rationale for some proposed scheme of enactment, it is ultimately the teacher who is the expert on the contextual parameters of local implementation (students, curriculum, institutional norms and expectations, etc.) and who should decide on the aims and rules of enactment that are appropriate for a particular setting. Nevertheless, we can easily imagine how PS can diverge from the activity as intended beyond recognition as what we would consider PS, particularly if resources migrate between very different educational systems. Our analysis suggests how this fidelity-adaptation dichotomy can be reconciled. Interactions at the IC links around the enactment of PS, conceived as learning through boundary-crossing, may instigate researchers to generalize their intended scheme to accommodate a broader set of educational contexts, or even revise their schemes – recognizing new aims and affordances of new rules of action, and modifying invariants of the intended PS. Thus, fidelity may be maintained not by keeping the enacted scheme close to the intended, but by continually realigning the intended with the enacted.

We briefly note the implications of our theoretical perspective for upscaling. One may hope, through the accumulation of data and experience, to provide an "ultimate" set of problems and teacher-guides. However, the theoretical perspective we have put forth denies the existence of such a set. Rather, it is the very notion of PS-IC that needs to be made visible to teachers at scale. A community of teachers, sharing their documentational genesis (resources, practices and insights) can achieve this.

[3]Aarhus University, Danish School of Education, Denmark; utj@edu.au.dk

The paper addresses the role of educational task design in implementation research. Its point of departure is the first revision of a task developed for 4th grade in collaboration with a Danish school teacher. The authors informed the task from a hypothetical learning trajectory that requires students to draw on their knowledge both of mathematics and programming and computational thinking. From a task-design standpoint, the teacher's experience proves necessary to adapt the task to local reality. The collaborative process illustrates broader implementation issues, such as problems and roles of different stakeholders, innovation adaptation and capacity building. The lessons are consistent with the emergence of design-based implementation research as a more comprehensive model.

Keywords: Computational thinking, design-based implementation research, hypothetical learning trajectories, programming, task design.

Introduction

The mathematics education community has recently gained a renewed interest in programming and computational thinking (PCT) as related subject matter areas. Although there is consensus on the potential synergies between mathematics and PCT, exploiting them has proven to be a difficult task (Misfeldt, Szabo & Helenius, 2019). Research in mathematics education has taken several approaches to address this difficulty. For example, by considering how to train and prepare mathematics teachers to teach PCT (e.g., Kilhamn & Bråting, 2019), coming up with ways to conceptualise its relation with mathematics (e.g., Benton et al., 2017; Weintrop et al., 2016), and trying to understand better students' learning processes and dispositions in computational thinking-driven mathematics classrooms (Pérez, 2018).

More locally, Denmark is planning to implement technology comprehension as a new subject in K-9 education comprising four competency areas: digital empowerment, digital design and design processes, computational thinking, and technological knowledge and skills—including programming (Smith et al., 2020). The Danish Ministry of Education is conducting a pilot project at 46 schools is seeking to gain experience with implementing it (1) as a subject in its own right and (2) as an element integrated into existing subjects, here among mathematics. In both cases, the ministry has published a tentative curriculum with added technology comprehension learning goals and prototypes of teaching resources.

This paper takes an implementation perspective on the challenges of intertwining PCT with mathematics teaching, anchored in the Danish school context. The broader aim of the research project is to support mathematics teachers in connecting PCT and mathematics in their everyday practice through the development of carefully designed tasks. By engaging in an educational design process, we draw on this approach to iteratively design, implement, and refine activities developed to fit the mathematics teachers' needs and support students' learning.

We anchor the content of this paper at a school that is part of the aforementioned pilot project, where we collaborate with a mathematics supervisor to refine a task developed to integrate PCT and mathematics in grade 4. In this context, matters of implementing a new subject and of task design interweave.

Design-based implementation research

Implementation research in mathematics education seeks to close the gap between research and practice (Jankvist et al., 2021), including the characterisation of a particular innovation and the factors conditioning its implementation (Century & Cassata, 2016). We aim to illuminate the characteristics of the new subject as embedded in the mathematics curriculum as a factor. In particular, we narrow down the innovation to a particular task.

One emergent model acknowledging the role of educational design in the context of implementation is design-based implementation research (DBIR). As noted by Fishman et al. (2013), DBIR is different from conventional design research, which only focuses on student learning, in that it points out "how the deployment of new tools (e.g., curricula, technologies) can bring to light new needs for coordination across different system levels and for capacity building" (p. 144). DBIR is then characterised by four principles "(1) a focus on persistent problems of practice from multiple stakeholders' perspectives; (2) a commitment to iterative, collaborative design; (3) concern with developing theory and knowledge related to both classroom learning and implementation through systematic inquiry; and (4) a concern with developing capacity for sustaining change in systems." (Fishman et al., 2013, pp. 136–137). Based on this framing, we ask the following research question: *What can we learn about the implementation of PCT in mathematics education by designing a single task with a teacher from a DBIR perspective?* The second and third principles pertain to standard design research (Bakker & van Eerde, 2015). In this paper, we focus on the first and fourth principles to organise our discussion, which is anchored in the early stages of designing a programming and geometrical task.

An essential conceptual tool for developing the design and learning from iterations is that of a Hypothetical Learning Trajectory (HLT). In the context of one or two lessons, an HLT is "the consideration of the learning goal, the learning activities, and the thinking and learning in which students might engage" (Simon, 1995, p. 133). Artigue (2021) highlights HLTs as a critical theoretical resource from design-based research to connect research and practice. An HLT seeks to make explicit what will happen when the design is brought into the hands of the practitioners concerning the real-world problem it aims to address. It describes the process that ought to take place during the intervention with the design. An HLT is informed by theory and should be sufficiently exhaustive so that its assumptions can be challenged by a real-world enactment of the design (Cobb & Gravemeijer, 2008). The HLT enables one to expose unforeseen interplays between intention, design, and reality, thereby challenging and qualifying our theoretical assumptions. After an intervention, one is thus able to consider whether it led to the desired outcome or not and point expressly to where our understanding of the design was confirmed or challenged—and what needs to be modified (Doorman et al., 2013). In the following, we describe the HLT informing our task design.

Designing a programming and geometrical task

Before the interaction with the expert mathematics teacher, the authors developed an a priori HLT addressing what we anticipated to be the main challenges in implementing PCT in mathematics. We envisioned that to ensure that students engaged in learning processes involving both mathematics and PCT, it was necessary to develop a task that required them to activate knowledge from the domains of both geometry and programming. Moreover, we believed that creating such a task would have a positive side effect for mathematics teachers in that the relevance of integrating PCT in mathematics would be clear. The learning goal is to deduce and test a general expression for the internal angle of any regular polygon. To solve the programming task, students should do the mathematical action of conjecturing a general expression for the internal angle of an *n*-gon. In turn, to test out such an expression, they must find a way of programming it in *Scratch*. A sample solution is depicted in scratch.mit.edu/projects/541978601.

The learning activities, depicted in Table 1, scaffold students' work by drawing on the *use-modify-create* principle from programming education (Lee et al., 2011), which states that it is easier for students to start with a pre-made script and adapt it to solve variations of a problem before elaborating new code. We also envisioned a progression in the task based on increasing difficulty by starting from a square, then a triangle, hexagon, pentagon and finally generalised polygons.

Table 1: Original hypothetical learning trajectory

Learning activities		Hypothetical learning process
Use	a *Scratch* code that draws one segment.	Become familiarised with basic *pen up*, *down*, *move* blocks.
	a *Scratch* code that turns the pen 90°. Explore what happens when run repeatedly.	Become familiarised with *turn*(degrees) block. Realise that four repetitions suffice to draw a square.
Modify	the code to draw a square with one run using a repeat loop.	Intuitive inclusion of a *repeat*(4)-block.
	the code so that it draws an equilateral triangle.	Modify to *repeat*(3) and *turn*(60°), revising to turn (120°) distinguishing between internal and external angles.
	the code so that it draws a regular hexagon.	Modify to *repeat*(6) and *turn*(60°), after previous experience or trial and error.
	the code so that it draws a regular pentagon.	A trial-and-error strategy will be slow or unsuccessful, prompting to find the 72° external angle with pen and paper.
Create	a code that draws any regular *n*-sided polygon. Teacher introduces *variable* block.	After registering previous cases, students find collectively a pattern that can be generalised for internal/external angles.

The design decisions and hypothetical learning processes were rooted in the literature on embedding PCT in mathematics classrooms. One of the mathematical courses from technology comprehension available in tekforsøget.dk/forlob involves programming *BeeBots*[1] to draw polygons in first grade. The robots, however, can only turn 90°, limiting the tasks to squares and rectangles. Drawing

[1] BeeBot is a robot designed for use by young children, which can be used for teaching sequencing, estimation, problem-solving and more.

polygons is also part of the *ScratchMath* project's "Beetle geometry" module (see, e.g., Benton et al., 2017). Their design proposes exploring four increasingly difficult polygons, figuring the turning angle: square, rectangle, equilateral triangle, and regular hexagon.

Furthermore, Herheim and Johnsen-Haines (2020) explored two seventh-grade students' productive struggles while drawing a pentagon. From here, some of the expected obstacles are mistaking internal by external angles and a trial-and-error strategy that will not suffice to reach a solution, thus calling for reasoning and calculating the exact 72° angle. Accordingly, students should overcome sequential challenges. First, students would use a loop to draw a square in one run. Secondly, they will sort out the internal angle for a triangle and hexagon and adapt their code. Next, they will require a pen-and-paper solution for the pentagon, as opposed to trial-and-error. Finally, they would generalise the latter case, introducing a variable for the number of sides.

Upon designing the task described above, the two first authors interviewed an expert mathematics teacher who acted as a supervisor at the school on which the task is to be implemented. The purpose of the interview was two-fold: (1) to test and reach a mutual understanding of the core implementation challenges to address and (2) to refine the task according to these challenges. The interview was semi-structured and 60 minutes long. The teacher agreed to have the meeting recorded for research purposes. Below, we describe the insights regarding our initial HLT that this interview brought.

Revisions of the task based on teacher interview

The teacher agreed on the learning goal, but the sequence of activities and hypothetical learning processes are revised in Table 2. Based on her input, three changes are worth mentioning: starting with a blank script, as opposed to using a working code, further use of pen-and-paper, and sequential order of polygons according to the number of sides.

Table 2: Revised HLT based on teacher's input

Learning activities	Hypothetical learning processes
What are polygons? Write your findings in *Book Creator*.	Students collectively activate their previous knowledge on polygons and their elements (sides, angles, vertices).
Create a *Scratch* code that draws an equilateral triangle. Create a *Scratch* code that draws a square. Create a *Scratch* code that draws a regular pentagon. Create a *Scratch* code that draws a hexagon.	Students engage in a trial-and-error strategy, registering in *Book Creator* the parameters used for *repeat* and *turn* blocks in increasing order. These are tools for the next activity.
Create a code that draws a figure of your choice: a flag, a labyrinth, a logo, or your own artwork.	This motivation is set up in the introduction but executed in the end. It gives students purpose to explore polygons' properties and how to depict them in *Scratch*.

The teacher challenged the pedagogy of *use-modify-create* by proposing that students should start creating their own code. The idea of starting with a given script is that it avoids frustration and makes the first step easy.

Teacher: It's easy to do it. But … instead of giving the code from the start, the first thing is to let the children make it themselves. Maybe they can do it; maybe they can't. But they need to understand what are we doing now. Instead of just having the code,

> “how can we do this?” “What is the problem?” “What do we need to know?” “Which kind of code do we need to do to code a triangle?”

Overall, her take is that more relevant than a smooth start in terms of difficulty, the students ought to perceive the posed problem as their own. Moreover, enabling struggle (Pérez, 2018; Herheim & Johnsen-Haines, 2020) and debugging (Weintrop et al., 2016) is consistent with the literature on computational thinking in mathematics classrooms.

Since an essential part of our HLT was requiring students to activate both mathematical and programming knowledge, all mathematical operations in our task were conducted in *Scratch*. We envisioned that the students would occasionally enter a flawed code, which the *Scratch* drawing would make clear (a flawed figure), and that the students iteratively would correct the code to draw the desired one. While the teacher acknowledged and agreed with the importance of this iterative approach, she anticipated that the students would not by themselves engage systematically in a new iteration if they were not encouraged to document their working process. Therefore, she suggested supplementing the task with pen and paper for students to log their attempts and use these logs actively in the next iteration.

> Teacher: I call it [to] scribble. They have to take notes of what they did. After all, the idea is not that they randomly should enter numbers from 1–200. What they enter should be based on their thinking. They have to learn to be systematic, you know.

In the original design, pen-and-paper was reduced to a minimum and based on the idea of computational thinking as a thought process that becomes concretised by programming in a programming environment. In technology comprehension, programming is considered a technological skill detached from computational thinking (Smith et al., 2020). However, the teacher had a different approach:

> Teacher: I think the children start, and then we need to engage [them] in the thinking along the way. They are not sitting and planning.

The task ultimately aims at educating students to draw an n-sided polygon, for which they require to find a general expression for its internal angle. Though the literature supports the scaffolding in our initial design (e.g., Benton et al., 2017), the teacher suggests arranging the sequence in increasing order. She draws on the Swedish researcher Olof Magne’s juxtaposition of arithmetic operations in teaching:

> Teacher: And I have worked with that. Instead of just starting with addition, then I took it all [i.e. all arithmetical operations], and the children didn’t have the same problems as they usually have. They learnt to make divisions in the first grade because we learnt it all. That’s part of my mindset.

Overall, these proposed changes to the task respond to letting students *own* the problem and *explore* possible solutions systematically instead of solving a fixed sequence of exercises and offering scaffolded solutions.

Discussion

As described previously, DBIR consists of four main principles, namely persistent problems from multiple stakeholders, iterative and collaborative design, theory development, and building capacity for sustainable change. Although we believe the study reported in this paper has accommodated all of these principles, the teacher interview led to refinements of the task that we anchor in the first and fourth.

Discussing the task gave perspective towards different stakeholders and their presumed roles. In particular, the new version of the task will be more open, thus engaging students to solve a problem perceived as their own. Moreover, we envision tackling the issue of teacher training in programming by seeing students coding themselves:

> Teacher: They (…) think that [the] responsibility for teaching *Scratch* in on their shoulders; they don't take it. But then they see that the children can manage *Scratch* and they have (…) seen what the children can do, and have seen the children's eyes, and they have felt the good spirit about working with math and *Scratch*, then they are convinced.

Tasks supporting PCT and mathematics integration should accommodate both aims of ensuring students' mathematical learning processes *and* anticipated or perceived challenges from teachers' perspectives. The design process reported in this study corroborates that these ends are compatible by meaningfully relating the two subject matters and acknowledging that teachers do not feel sufficiently proficient in PCT to teach it. On the same line, it is worth mentioning that the teacher did not question the HLT's learning goal, as it addresses one of the main issues of technology comprehension tasks, namely their connection to the mathematics subject matter:

> Teacher: The teachers know math, and they know the didactics around that. But they don't know the didactics around technology comprehension. (…) Suddenly it was something they had to work with (…) and then, they saw the math and they thought the math wasn't... eh... very good.

The case of this first design iteration illustrates how one can anticipate adaptation and reduce the distance between what is supposed to be and actually being implemented. For example, the initial design included a working code assuming that students had not been introduced to the pen environment on *Scratch*. However, the teacher challenged this claim.

Although previous research has found *use-modify-create* to be an appropriate approach to scaffold students who are not accustomed to coding, the teacher had experience and knowledge of the importance of showing students that they are able to develop code on their own from very early on. Besides informing refinement of the task, this insight indicates that while theory on the didactics of PCT can inspire initial task design, it does not necessarily align with what is likely to work in a specific context. That is not to say that one particular teacher's opinion must be generalised at face value. In turn, these conflicts can be tried out as hypotheses for theory development, in its humble sense (diSessa & Cobb, 2004). Furthermore, from a DBIR perspective, the quest for designing resources that build capacity over time must account for the diversity of pedagogical choices.

Conclusion

In this paper, we have investigated what we can learn about the implementation of PCT in mathematics education by designing a single task with a teacher from a DBIR perspective. Revisions to the task were made by interviewing a teacher involved in the future process of implementing such a sequence. The new version promotes further ownership on behalf of the teacher by making her take part in the design process and revise implicit and explicit assumptions. Further, working on a particular HLT goes beyond local task design. Fidelity is a recurrent theme in implementation research (Century & Cassata, 2016), likely because the design of innovations may conflict with teachers' established and preferred practices. Involving the teacher in the initial design phase allowed us to anticipate such conflicts and to alter the innovation design in accordance with her reality. Our future collaborative endeavour with the teacher will teach us more about whether it leads to high or low degrees and innovation enactment adaptation.

The openness to practitioners' needs can make theory development more grounded (Bakker & van Eerde, 2015), but it leaves at least three options to move forward. In a humble sense, the educational design enables developing a local theory of how a task could successfully implement innovations that integrate mathematics and PCT at a specific school. A second alternative is to inform the conjecturing of hypotheses to try out at a larger scale. For example, one may validate or dismiss the pedagogical choice for *use-modify-create*. DBIR, however, offers a broader perspective. For capacity building's sake, a variety of possible approaches can be provided to practitioners, who may pick and adapt tasks according to their priorities. In that sense, theory development ought to be at a higher level than a particular HLT. Instead, resources that sustain change for embedding PCT in mathematics may refer to general domain-crossing themes or scenarios, such as drawing geometrical figures with programming.

The components of Vergnaud's notion of scheme as frame for designing diagnostic tasks in the area of linear equation solving

Morten Elkjær[1] and Jeremy Hodgen[2]

[1]Danish School of Education (DPU) Aarhus University, Denmark; me@edu.au.dk

[2]University College London (UCL), UK; jeremy.hodgen@ucl.ac.uk

This paper formulates an implementation process model for designing and implementing tasks for formative feedback in an online learning environment for mathematics classrooms using Vergnaud's notion of scheme. In Denmark, the online environment matematikfessor.dk is used by more than 70% of Danish k-9 students. Using variations on one task, we illustrate how Vergnaud's notion of scheme can be used to aid teachers in assessing students' understanding of problems involving linear equations. Specifically, we focus on the intentional, computational and generative aspects of students' schemes.

Keywords: Implementation, diagnostic tasks, task design, online environment, linear equations.

Introduction

There is a great deal of evidence that formative assessment can have a positive impact on learning (Black & Wiliam, 1998). Attempts to promote formative assessment have often resulted in teachers having substantial difficulties implementing these ideas (Bennett, 2011). A key issue is that teachers face challenges inferring students' learning needs based on those students performance on tasks (Thompson & Thompson, 1994). Several programs have been launched historically in the attempt to document specific difficulties in learning mathematics. These projects have contributed to the understanding of many misconceptions and other obstacles to learning mathematics (Rhine et al., 2018). Tasks of a diagnostic character have in many cases been a part of these projects. There is an extensive literature on how the tasks performed, why they were chosen and why the tasks are believed to be sensible choices for exploring certain areas of difficulty in learning mathematics (Küchemann, 1981). However, few papers systematically address the considerations or design principles underlying the construction of these tasks in order to provide relevant feedback to teachers.

In this paper, our focus is on formulating an *implementation process model* to guide the process of translating research into practice (Nilsen, 2015). In this case, the model is directed at the design of formative tasks within online learning environments (OLEs) that implement Vergnaud's (2009) notion of scheme to enable teachers to better interpret, and respond to, learners' errors. We do this in the specific learning contexts of the concepts of linear equations and the equals sign, and draw on research on learners' errors and difficulties with these concepts (Rhine et al., 2018). OLEs can play a significant role when implementing research-based knowledge into the classroom, since OLEs can provide feedback directly to the end users, namely the teachers (Dyssegaard et al., 2017). In addition, these environments can produce substantial assessment data almost immediately with relatively little effort from teachers. However, a key restriction, and challenge to the implementation of Vergnaud's scheme, is that learners' responses to tasks are restricted due to input and marking constraints and thus cannot be fully open-ended.

In this paper, we propose the following research question: *How can the notion of scheme guide the design of diagnostic tasks for implementation in OLEs about known difficulties with the concept of linear equations and the equals sign, in order to enable teachers to better interpret learners' difficulties?*

The context: *matematikfessor.dk, a*n OLE for mathematics

In Denmark, as in many other systems, OLEs are increasingly used by teachers and students. *Matematikfessor.dk*, the environment discussed in this paper, has been running for over 10 years. More than 500,000 students in primary and lower secondary schools have access to the environment and, on a typical day, 45,000 unique students use the variety of tasks offered by the site, and collectively answer 1,500,000 tasks. OLEs like *matematikfessor.dk* therefore have access to a large amount of data and can potentially provide valuable feedback to teachers about the difficulties that students encounter in learning mathematics. As such OLEs become more ubiquitous, it is crucial to develop an explicit understanding of the process of designing tasks for implementation in online environments in order to enable teachers in preparing better teaching.

Theoretical constructs

Difficulties in learning mathematics related to linear equations

We adopt the view of Jankvist and Niss (2015) that identifies genuine difficulties in learning mathematics as, *"those seemingly unsurmountable obstacles and impediments – stumbling blocks – which some students encounter in their attempt to learn the subject."*(Jankvist & Niss, 2015, p. 260). One kind of stumbling block that many students experience in the beginning of lower secondary school or when attempting to learn the solving of more 'abstract' (Vlassis, 2002) linear equations is the role and interpretation of the equals sign (Kieran, 1981). Jones et al. (2012) argues that in order to achieve a better understanding of the role of the equals sign, one must learn to substitute one representation for another equal representation. Many strategies for solving equations exist and are all sensible tied to different tasks and/or situations. However, at some point even linear equations can become abstract or complicated to an extent where only one strategy truly remains. Many of the strategies such as 'guess-and-check' or 'working backwards' do not necessarily require a deep understanding of the role or interpretation of the equals sign (Linsell, 2009). However, in order to apply more advanced equations solving strategies students must become more flexible in their understanding of the equals sign (Kieran, 1981).

The notion of scheme and its role in activity

In Vergnaud's (2009) work, we become familiar with how the scheme as a concept works as an organizer of action or activity when faced with a situation or a class of situations:

> [Schemes] describe ordinary ways of doing, for situations already mastered, and give hints on how to tackle new situations. Schemes are adaptable resources: they assimilate new situations by accommodating to them. Therefore, the definition of schemes must contain ready-made rules, tricks and procedures that have been shaped by already mastered situations (p.88)

Such a situation or class of situations could be exemplified as working with algebraic expressions or engaging in solving linear equations. If we accept that schemes are organizers of the activity of an individual, we can create assumptions about students' schemes by observing their action and activity in desired situations. Ahl and Helenius (2018) claim that this is why schemes are both didactically as well as analytically more interesting than the idea of conceptual understanding.

Vergnaud (2009) defines a scheme as having four aspects:

> The **intentional aspect** involves a goal or several goals that can be developed in subgoals and anticipations. The **generative aspect** involves rules to generate activity, namely the sequences of actions, information gathering, and controls. The **epistemic aspect** involves operational invariants, namely concepts-in-action and theorems-in-action. Their main function is to pick up and select the relevant information and infer from it goals and rules. The **computational aspect** involves possibilities of inference. They are essential to understand that thinking is made up of an intense activity of computation, even in apparently simple situations; even more in new situations. We need to generate goals, subgoals and rules, also properties and relationships that are not observable.
>
> The main points I needed to stress in this definition are the generative property of schemes, and the fact that they contain conceptual components, without which they would be unable to adapt activity to the variety of cases a subject usually meets. (p. 88)

Essential to the schemes from Vergnaud's perspective are the operational invariants (the epistemic aspect of schemes), consisting of *concepts-in-action* and *theorems-in-action*. A *concept-in-action* Vergnaud describes as *"an object, a predicate, or a category that is held to be relevant."*(Vergnaud, 1988, p. 168). In every mathematical action, we choose certain objects, predicates or categories of such that are believed to be relevant in the current situation or setting. A *theorem-in-action* as a proposition held to be true. When we engage in a mathematical situation, we believe certain "theorems" to be true or false, about the objects relevant to the situation. Vergnaud states that there is a dialectic connection between theorems and concepts, and this emerges from the fact that more advanced mathematical concepts originate from theorems and vice versa. Nonetheless, is it important to distinguish the cognitive function of the operational invariants in this very specific manner. Concepts-in-action are individually available concepts in a for the enactor relevant representation to the situation. Vergnaud's (1988) interpretation of the representation is similar to what others call a conception or a concept image (Tall & Vinner, 1981). Concepts-in-action bear no value of logical truth, just relevance to the situation. Theorems-in-action are by nature true or false. These entities are sentences (or propositions) that provide the concepts with the possibility of inferences to take place. The *rules of action* are not to be confused with the *theorems-in-action*. The function of the *rules of action* (the generative aspect of the scheme) is to be appropriate and efficient, but they rely implicit on theorems-in-action (Vergnaud, 1997). Vergnaud (2009) emphasizes that schemes are efficient organizers of activity by nature, and, should they also become effective, the scheme can be considered an algorithm. He further clarifies that schemes do not have all the characteristics of algorithms. The effectiveness of algorithms lets them find a solution to a task in a finite number of steps (if a solution is possible).

Task design and implementation considerations

In this section, we present the task design and the reasoning behind it. The design will focus on the role and interpretation of the equals sign as presented in Jones et al. (2012). The formulation is guided by the four components of the scheme (Vergnaud, 2009). An added discussion of the considerations of the implementation in an online environment precedes each task formulation. The overarching design principle idea comes from Ahl and Helenius (2018) who present a situation where a student is asked to calculate the average speed. The student invokes a scheme seemingly capable of handling average speed to some extent but ends up invoking and working with a scheme that incorrectly interprets average speed using an alternative (and incorrect) scheme involving a different average, namely arithmetic mean. Inspired by this, we formulate a set of tasks that invoke two potential paths to solution. The aim is to setup situations where two different schemes might be in play at the same time but the answer to the task should reflect which of the schemes that got the upper hand. We also reformulate the task in different ways to attempt to address the different aspects of the scheme.

In *matematikfessor.dk*, the tasks must meet certain criteria regarding structure and user input types. The input types are restricted to inputting either a number or a multiple-choice selection. Each task must have a unique 'right answer' and must be presented in such a way to make immediate feedback possible. Our task design is intended to disrupt the 'typical' didactical contract (Brousseau, 2006) in that that 'right' answer highlights aspects of the student's scheme.

In the following, we demonstrate the task design in examples focused on the intentional, generative and computational aspects of the scheme. We do not focus explicitly on the epistemic aspect of the scheme, because this aspect, focused on the operational invariants, is such an essential part of the scheme that this aspect and its elements inform or are present in the other three components. For example, one would simply not be able establish goals without having at least partial access to a concept relevant to the situation, a concept-in-action. The focus will be on evaluating whether students invoke schemes capable of handling substitution based on equality or rather a scheme suitable for solving equations in order to solve the task and thus provide teachers with information on their students' schemes.

For the task design, we have chosen the following setup, in order to attempt to possibly invoke two schemes at the same time. We have chosen the following sequence of tasks to illustrate this design principle. Given the special constraints, we have chosen to only provide a single sequence of tasks, all adaptations of one item. Using a scheme for handling and exchanging equal terms should be the 'easier' path to the goal of solving the following task that serves as an outset for the variations in the following sections. An expert equation solver would choose the most efficient scheme to solve the task - "I know x has a specific value and I could easily calculate it, but I don't need to for this task'.

What number should go in the empty space?

$$\begin{aligned} 3x \quad &= 11 \\ 3x + 4 &= \_\_ \end{aligned}$$

If students are able to insert 11 instead of the term $3x$ in the second equation (swap $3x$ and 11), our assumption is that the task is then easily solved by a secondary school student. However, if students are more inclined to determine the value of *x*, because that is what is ‘expected’ when faced with linear equations, then they might have a difficult experience, because the numbers are chosen in such a way that 3 is not a divisor of 11 (and *x* has a rational value).

Setting ‘Goals and anticipations’ (the intentional part of the scheme)

In this category, we present the task in a formulation where setting a goal for, or an anticipation of the task form of the solution. In many cases, one expects that, when confronted with a task containing a linear equation. finding the unknown value is crucial. We propose that when focusing on the goals and anticipation part of the scheme, the task could be formulated like the following;

Is it necessary to know the value of *x* in order to fill in the empty space?

$$\begin{aligned} 3x \quad &= 11 \\ 3x + 4 &= \_\_ \end{aligned}$$

Goals and rules are set and established based on the concepts-in-action and the theorems-in-action. Whether a student regards the equality between $3x$ and 11, and the fact that the term $3x$ is present in both equations as relevant information (concepts-in-action), could provide about whether s/he is capable of swapping the terms 11 and $3x$ in the two equations. Should a student not choose the substitutional link between the two equations to be relevant we expect that s/he would argue that they would like to know the value of *x* in order to fill in the empty space. One might argue that the goal of the task is blurred by the new formulation, since there is an empty line ‘begging’ for a number to be put on it, but the task is answered by a simple yes or no. However, for the purpose of assessment for learning, teachers might learn about their students’ schemes, with this formulation as opposed to just receiving a correct or incorrect answer from students filling in the empty space.

Establishing ‘Rules of action’ (the generative part of the scheme)

In this category, we attempt to uncover the rule, or strategy, for solving the task the student’s would apply. As mentioned in the above category, the operational invariants help set the goal or apply rules. When forming a strategy for solving a task, theorems-in-action might be more in focus. Therefore, we formulate the task not in terms of concepts relevance but rather in theorems that lead to rules. Now we confirm that the equation $3x = 11$ is in fact important in order to achieve filling in the empty space. We propose a task where the formulation hints at what ‘path to the goal’ a student chooses, an equation solving strategy or a substitution of equal terms strategy.

How is $3x = 11$ important in order to fill in the empty space?

$$\begin{aligned} 3x \quad &= 11 \\ 3x + 4 &= \_\_ \end{aligned}$$

1. Because $3x$ and 11 can be swapped in both lines
2. Because I can calculate the value of *x*
3. It is not important

In this formulation, the teacher will get a slightly different view on what path a student is willing to choose. A further formulation of the task focusing on *rules to generate action* could look like;

How would you attempt to find out that number go in the empty space?

1. I would find the value of x
2. I would swap $3x$ for 11
3. I don't know

If the scheme(s) the student is drawing upon are only able to apply the rule of action to determine the value of the unknown, the teacher is provided with valuable information. In this way, a teacher gets a different perspective on basically the same task but in a different formulation and with a different focus or aim.

Generating space for 'Possible inferences' (the computational aspect of the scheme)

In this last example, we attempt to address the computational part of the scheme with another formulation of the initial task. In order to address whether a student make inferences about the element $3x$ when they compare it to a similar looking task, but where the scheme for solving equations should be rendered useless, because $3x$ has been replaced by a blue box.

Is it the same number that go in the empty space in both tasks?

$$\begin{array}{lcl} 3x & = & 11 \\ 3x+4 & = & \_\_ \end{array} \qquad\qquad \begin{array}{lcl} \boxtimes & = & 11 \\ \boxtimes + 4 & = & \_\_ \end{array}$$

If a student does in fact not see the similarities between the two tasks, but uses a scheme for solving equations working with the left most task and however is able to swap the blue box and the number 11 in the right most task, the student might become suspicious. One might expect the student to wonder why this is the case or why the tasks performs differently yet so similarly. A different formulation could therefore be;

Is it surprising the same number go in the empty space in both tasks?

Is it for the same reasons that the same number go in the empty space in both tasks?

The reason for wording the task this way is establish a cognitive conflict with students that are in fact surprised that 15 is the correct solution for both empty spaces. We attempt to create a link to a scheme we consider similar to the scheme capable of swapping mathematical equal terms by introducing the task with the blue box.

Concluding remarks

For this paper, we have explored considerations and the reasoning behind an implementation process model to guide the diagnostic task design in an OLE. This exercise was to implement Vergnaud's scheme in order to enable or improve teachers' opportunities to interpret learners' errors within the constraints of the OLE. We based the task around different formulations or variations of an item using the components of the scheme. We have shown such slight reformulations of a task, guided by the components of the scheme, have the potential to reveal different aspects of students' understanding related to linear equations and the equals sign. The tasks could be presented to the students in the order presented in this paper or they could be presented each to one third of the class for a subsequent discussion. The strength of the online environment is that teachers, as well as students, can get easy access to feedback. We believe that because the tasks call for two specific schemes as generators in the situation, students would get a unique opportunity to be shown why it is in fact not necessary to know the value of the unknown.

We have used Vergnaud's intentional, generative and computational aspects of the scheme to demonstrate how an 'exemplar' item can be designed to distinguish between the different schemes that students use to tackle a task. The intentional aspect relates to *what* needs to be done to solve the task or *what* is expected of the student in this situation. The generative aspect relates to *how* the expectation are met or *how* progression is to be made in the situation. Finally, the computational aspect relates to *why* the desired goal is achieved or *why* new connections to other schemes or concepts make sense or might be established. We have touched briefly on omission of the epistemic part of the scheme and will leave a deeper explanation for further work. The *what*, *how* and *why* might potentially contribute to shared or agreed upon *theory of change* (Jankvist et al., 2021) and thereby strengthening the implementability of the tasks by sharing the idea of respecting the *what*, *how* and *why* with teachers using matematikfessor.dk (Jankvist et al., 2021).

Teachers can be provided clear feedback on what different scheme their students are most willing to invoke when solving these tasks. In the implementation of these items, teachers are not provided a guide to interpret the answer their students provided to the items. Teachers become aware of a possible need to teach substitution of equal terms. We have selected a task that illustrates the approach of the design frame for varying the task respecting the *what*, *how* and *why*. The next step in the process is to implement this framework with a range of tasks for relevant online feedback to teachers using *matematikfessor.dk*. Knowledge sharing and feedback from teachers using the tasks in their classroom will pave the way for a sensible implementation of a range of sequences of tasks.

Depth as a key issue for implementing DEM: The case of a teacher

Åsmund Lillevik Gjære

University of Stavanger, Norway; asmund.l.gjere@uis.no

This case study examines one Norwegian teacher's enactment of an innovative system for mathematics teaching called developmental education in mathematics (DEM). The findings show that despite appropriate textbooks, high motivation, a belief that its principles are effective for mathematics teaching and learning, and indications of a shift of ownership of DEM, the teacher did not follow the fundamental principle of appropriate mathematical challenges for the students. Based on the findings, this paper identifies challenges regarding qualitative aspects, such as depth, of the implementation of the DEM project, while suggesting a path forward for a type of scaling-up process that does not necessarily include spreading to the largest possible number of schools.

Keywords: Developmental education in mathematics, Zankov, Vygotsky, scale of implementation, depth of implementation

Introduction and aim

In Norway, some teachers have had success using a system for teaching elementary mathematics called *developmental education in mathematics* (DEM). DEM consists of mathematics textbooks adapted from Russia and a didactical theory developed by Russian psychologist Leonid V. Zankov (1901–1977), who was a student of Lev S. Vygotsky. Inspired by the excellent results of the pilot class (Melhus, 2015), around 100 schools across Norway have now adopted DEM.

However, a recurring issue in mathematics education is turning small-scale successes into improvements of practice on a larger scale (e.g., Jankvist et al., 2021). A main problem of the DEM project is a lack of systematic knowledge about the teaching practices of the various schools since much of the effort so far has focused on curriculum development and dissemination. In addition, some schools simply use the textbooks without consulting DEM facilitators, leading to an even wider knowledge gap. In this sense, DEM remains an innovation at an early stage despite the history of the first teacher going as far back as 2009 (Gjære & Blank, 2019). To begin to address this knowledge gap, a PhD project seeks to characterize both the potential for DEM to support students' mathematical development and the challenges that some teachers face along the way.

The aim of this paper is to analyze one teacher's enactment of DEM to answer the following research question: How is the main principle of teaching at an optimal level of difficulty realized in a 4th Grade mathematics classroom? The findings will form a basis for discussing more general challenges pertaining to scale, specifically the *depth* of implementation (Coburn, 2003) of the DEM system.

A short introduction to DEM

DEM builds on the didactical theory developed by L. V. Zankov. Its use in mathematics education in Norway depends on a series of textbooks written in the 1990s under the guidance of Iren Arginskaya, a mathematician and member of Zankov's research group. These books follow Zankov's principles and have been translated and adapted for Norwegian schools. The main goal of DEM is not only to increase the mathematical abilities of the students, but more so to stimulate their general development (Melhus, 2015; Zankov, 1977). The didactical principles of DEM are as follows (Zankov, 1977):

1. Teaching at a high (optimal) level of difficulty
2. The leading role of theoretical knowledge
3. Proceeding at a rapid pace
4. Promoting students' awareness of the learning process
5. Systematic development of each student in the classroom

The five principles form a whole; they are interconnected and augment each other (Zankov, 1977). Nevertheless, this paper focuses on the first principle. Zankov's system has been called "implementing the zone of proximal development" (Guseva & Solomonovich, 2017), since this concept lies at its core and its realization is fundamental and necessary to promote students' development. Zankov (1977) built on Vygotsky when he wrote that the ZPD

> is identified by noting the kinds of problems that the child is unable to cope with himself, but can solve with the aid of grownups, in collaborative activity, or through imitation. But what a child can do in cooperation with someone else today, he will be able to do alone tomorrow (p. 18).

This can be contrasted with problems students can do by themselves, in their actual zone of development. Zankov (1977) underlined the importance of the students' emotional engagement needed to spend the intellectual effort to cooperate with others and overcome difficult problems. DEM teachers said that they saw "challenge-as-fun" as a central characteristic of DEM and something that had changed their views about teaching and learning mathematics (Gjære & Blank, 2019).

Framing the study within a discussion of *scale* in implementation research

An increasing number of schools now use the DEM textbooks. However, a discussion of the scale of an implementation cannot rely on numbers alone. Addressing this issue, Coburn (2003) suggested four major dimensions for assessing both quantitative and qualitative aspects of *scale* of educational implementations: Depth, sustainability, spread, and a shift in ownership of the innovation (Figure 1).

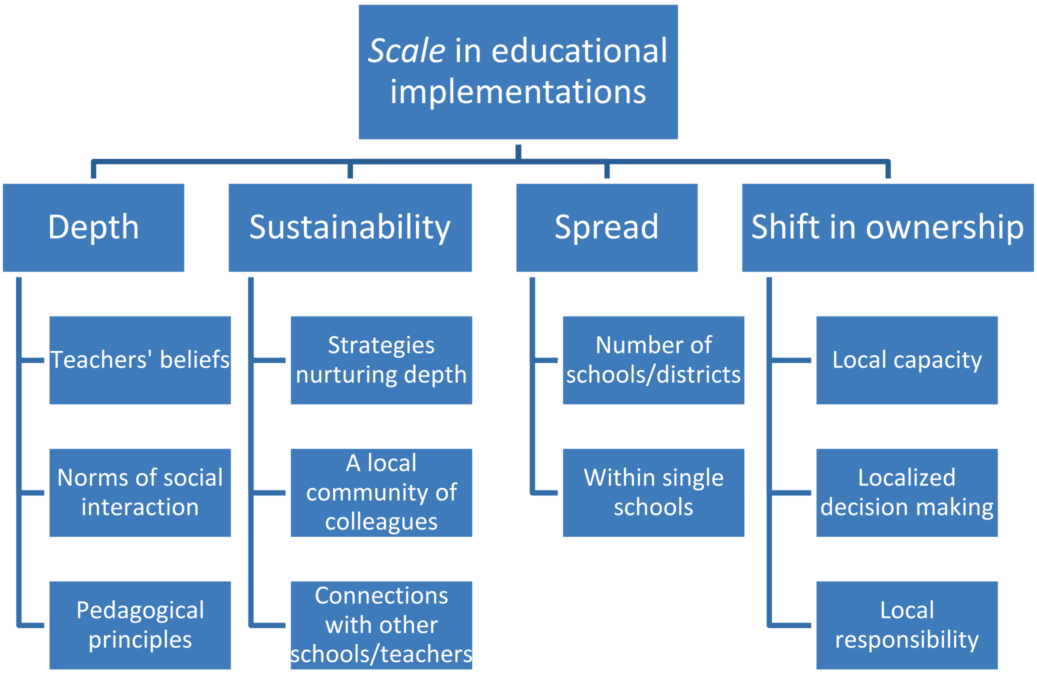

Figure 1: A conceptualization of scale of implementation, adapted from Coburn (2003) by the author of this paper.

The explicit goal of the DEM project is not to spread to as many schools as possible but to offer an alternative for teachers who are interested and find the system to suit their students' needs (Gjære & Blank, 2019). Thus, attention shifts to the other aspects of scale, namely, depth, sustainability, and a shift in ownership of the DEM system. These will form the foundation of the discussion in this paper.

Case description and method

This case study draws its data from a wider set of classroom videos, where four experienced DEM teachers participated. They were all "early movers", meaning that they were among the first to use the DEM textbooks in Norway. The 4th Grade teacher in this study works at a school that functions as a "model school" for DEM, where those who are interested can come and observe DEM lessons and talk with the teachers there. She has also participated in dissemination activities, such as writing about DEM in a journal for mathematics teachers and giving presentations about the positive experiences at her school. The same teachers also participated in focus group interviews before and after classroom videos were recorded. These interviews were analyzed separately and indicated that implementing DEM had changed their views on teaching and learning mathematics (Gjære & Blank, 2019), including the teacher in this case study. The teacher was asked to plan her lessons as usual and not think about the video cameras.

According to Eun (2019), the concept of the ZPD encapsulates Vygotsky's theory of learning and development and can profitably be used as a lens to analyze various aspects of teaching-learning situations. In this paper, the concept of the ZPD serves as an analytical frame to interpret the way the teacher engaged with the students to challenge them mathematically. While all three of this teacher's lessons were analyzed in whole in the preparation for this paper, the data presentation has been shortened to include only one task from each lesson due to space limitations.

Findings

Episode from Lesson 1: Solving an equation

The equation to be solved was $(3n + 10) : 8 = 35$. A possible solution method, introduced in the 4th Grade textbook, is based on doing opposite operations: If $a : b = c$ and a is unknown, then you can find a by multiplying c by b. Here, $(3n + 10)$ takes the role of a and you can find its value by multiplying 35 by 8. However, the teacher introduced the activity by reminding the students that they had to do the same operations on both sides of the equal sign, a slightly different and more general approach. Student 17 suggested beginning by multiplying 8 by 35, which corresponds to the textbook method, but had difficulties explaining further. Student 8 was asked to elaborate on Student 17's response:

206	S8	(*comes up to the board*) Well, you could say that one (*points at the left-hand side of the equation*) equals that one (*points at the right-hand side*).
207	Teacher:	Aha! Let me see if I understand you two correctly. It is divided by eight, times eight, really, on both sides (*she transforms the equation, see the second line in Figure 2).*
208	S8:	Um, yeah.
209	Teacher:	Is that your thinking, Student 17?
210	S17:	Yeah
211	Teacher:	That you multiply by eight on both sides. Yes!

S8 addressed the main concept of equality (utterance 206) but did not explicitly connect it to solving the equation. The teacher, however, went directly to the conclusion and wrote the transformation of the equation herself (207). The students' responses (208 and 210) were not convincing. This pattern persisted during the whole solution process, with the teacher leading and writing, and students only supplying short answers along the way (see Figure 2).

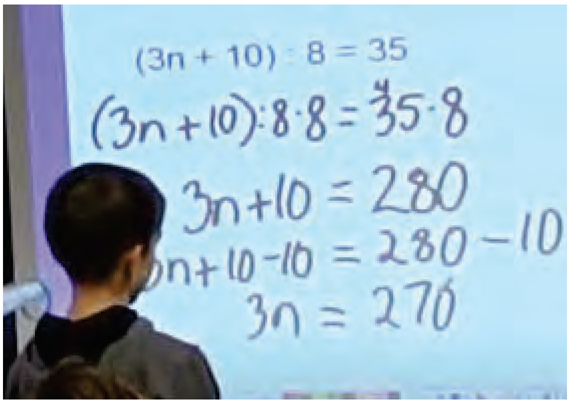

Figure 2: Student 8 watches as the teacher helps him write the solution of the equation.

This activity did not follow the DEM principle of teaching at an optimal level of difficulty. Zankov (1977) was clear that the students themselves must make the effort to solve challenging problems to develop their abilities. The beginning of this episode suggests that the task could suit the students' ZPD nicely since S17 and S8 both contribute with mathematically productive statements about the equation although their reasoning is incomplete. In utterance 207, however, the teacher completed a reasoning step for them, based on her own solution method and not the textbook method. This took away the challenge for the students to solve the equation themselves, resulting in a lack of mathematical activity.

Episode from Lesson 2: Finding the volumes of right rectangular prisms

This activity was mostly a whole-class discussion about how to find the volumes of right rectangular prisms. During the discussion, some students expressed frustration by moving about on their chairs, sighing audibly, or answering in odd voices. Two prisms, 1 and 2, were pictured on the board, along with a table to fill out with length, width, height, and volume of each prism.

277	Teacher:	OK! Let's use the formula to fill out this table and calculate the volume of these two figures. What then, can we say about the <u>length</u> of figure 1? (*She pauses. The students are unrestful and only a few have their hands up*) The length of figure 1? The length of figure 1, people. S11.
278	S11:	Um, it's five, I think. Yeah.
279	Teacher:	Yes, five (*writes "5" under Length, figure 1, in the table*)
280	S11:	But I found out what the whole was, too.
281	Teacher:	The length is five. What about the width? (*pause*) S17?
282	S17:	Two.
283:	Teacher:	Two. (*writes "2" in the table*) and the height? S6?
284:	S6	THREE! (*answers in an odd voice*)
285:	Teacher:	And then the volume is?
286	Students	Twenty-four / thirty (*both numbers are heard*)
287:	Teacher:	Five…? Five time two is…? (*speaks very slowly and clearly*)
288:	Students:	Ten!
290	Teacher:	Ten times three?
291	Students	THIRTY! (*shouting*)

Note that S11 was ready to provide an answer in utterance 280. This, along with some signs of unrest, suggests that the students found the progression too slow. When given a worksheet on the same topic, some students expressed a lack of challenge:

307	Teacher:	You are to find the volume of these prisms. But you see, they aren't quite filled up with cubic centimeters. Can you still find the <u>length</u>, the <u>width,</u> and the <u>height</u> of these prisms?
308	A student:	Um, yeah.
309	Another:	°That's easy° (*heard whispering to his desk mate*)

The whole activity, with different examples of prisms, took around 17 minutes, 10 of which were whole-class discussion. This activity also lacked the kind of challenge that characterizes a "Zankov's lesson": The students found calculating the volumes of these prisms easy and they could do it by themselves, meaning that the activity was within their actual zone of development, and the extended whole-class discussion reduced the pace of progression.

Episode from Lesson 3: A numerical pattern

The task was: "Find the pattern of the sequence and write the next number: 2, 5, 11, 23, 47, 95, …". The students first discussed in pairs for a couple of minutes before presenting their results, and three different ways of describing the pattern were presented (Figure 3).

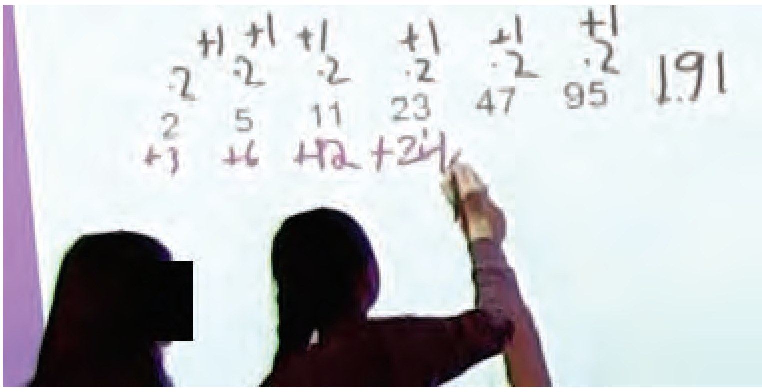

Figure 3: Students describing the number pattern.

The students' three ways to describe the pattern were: To get from a number to the next, multiply by 2 and add 1 (written ·2+1 in Figure 3); that the "add on"-numbers double for each step (+3, +6, +12, …); and finally, to get from a number to the next, add one more than the number itself (e.g., to get from 5 to 11, you add 6, which is 5 + 1). The whole task was quickly done; from thinking time in pairs to students having presented three different pattern descriptions it took about 6 minutes. The teacher did not interfere with the students' thinking. She took the role as a discussion moderator while checking if the other students understood or agreed (they used hand signs to indicate this).

Notably, the teacher allowed her students a lot more room to discuss and present ideas in Lesson 3 than in the other two lessons. This can be gleaned from the description of the pattern activity above. However, she also refrained from interfering and did not push the students further, e.g., by directing their attention toward relationships between the three pattern descriptions. The students did the task on their own and presented their results without further explorations, and the activity therefore remained within their actual zone of development. While they were successful in solving the task, the teacher did not seize the opportunity to challenge them further. However, both this and the other two lessons demonstrated another important aspect of DEM, namely, cultivating a sympathetic and respectful community of learners (Zankov, 1977). For instance, the teacher called for an appreciative applause for the presenting students after this episode, which she also did several times during the three lessons.

Discussion

In general, the analysis showed that the teacher did not follow the didactical principle of optimal difficulty in the three observed lessons. In one sense, this finding could be interpreted as a lack of *fidelity* in the sense of "the extent to which an innovation in enacted according to its intended model" (Century & Cassata, 2016, p. 171). However, the word "fidelity" usually has meanings associated with *loyalty* or *faithfulness* (Cambridge Dictionary, 2022), so in this sense, a lack of fidelity could imply a lack of loyalty to DEM, which is clearly not the case here. On the contrary, this teacher spoke highly of DEM and showed indications of having given it a central place in her teaching practice.

According to Coburn (2003), a *shift of ownership* of the innovation is necessary to achieve a lasting impact on teaching practice at scale. At the school of this teacher, the staff have formed a local DEM community, they have decided to let DEM take a central place in the school system and influence other school subjects, and they (including the teacher in this case) have taken part in dissemination activities; all of this across an extended period of time with only limited support from university facilitators. These are indicators not only of taking ownership of DEM, but also of sustainability and spread within the school (see Figure 1, p. 3). This means that the school is well positioned to continue using DEM independently from university facilitators. However, as the findings above show, there are still challenges to work out.

Realizing pedagogical principles of the system in practice relates to what Coburn (2003) refers to as *depth* of implementation scale. In her conceptualization of scale, depth is both a key dimension in its own right and an underpinning of the other dimension. In this case, there were in fact indicators of depth of the implementation for this teacher since she reported to have changed her beliefs about mathematics education (Gjære & Blank, 2019). Also, the norms of social interaction in her mathematics classroom corresponded with the sympathetic community of learners suggested by Zankov (1977), although it is not clear how much this has changed in her practice as she was not observed prior to DEM. However, the main goal of DEM is to stimulate students' development (both general and mathematical) by engaging them in solving challenging problems and encouraging them to be persistent, analytical, investigative, self-reflecting, critical and creative. There is also the question of whether whole-class problem-solving discussions are suited for realizing the principle of optimal difficulty, since one must expect diversity among students within a class. Considering these issues, it becomes clear that depth, and in particular the realization of the principles of the system, must take center stage in any discussion of scale of the DEM project.

Concluding remarks

The discussion of this case study demonstrates the usefulness of Coburn's (2003) conceptualization of scale to bring an alternative and more varied perspective on scaling-up processes for innovation projects that do not aim for the greatest possible spread. *Scale* in educational innovations often implies spreading to many schools. The DEM project, however, is concerned with providing an alternative system for teaching elementary mathematics that could possibly improve the practice of those teachers who are interested and motivated. For assessing the scale of such projects, qualitative dimensions such as depth, sustainability and a shift in ownership becomes even more important. This could also raise the general question of whether spreading to many schools should always be implicit in scaling-up processes of innovations in mathematics education.

Challenges ahead for the DEM project include supporting a greater depth for the various DEM schools as well as sustainability and a shift in ownership of the project for the involved schools.

Addressing issues of depth requires a more nuanced understanding of the difficulties with realizing the didactical principles like those that the teacher of the case study experienced. Such research efforts could be combined with either initiating the formation of "satellite communities" in the various municipalities where DEM is used or reaching out to contact already existing communities, with the purpose of improving the scale of the DEM project across all four dimensions of Coburn's (2003) conceptualization.

Keywords: STEM Education, Teacher education programs, Educational technology.

During the past 5 years, we have been experimenting with a wide range of educational technologies in elementary schools and higher education with a focus on STEAM (Science-Technology-Engineering-Arts-Mathematics) integration and exploring role of mathematics within STEAM. These projects included STEAM integrated approaches for teacher training, special needs education with Augmented Reality and 3D Printing, remote teaching and automated tutoring systems. Over this period we observed a shift towards technology-based teaching and learning in education, and we aimed to identify how educational ecosystems with a variety of technologies such as Augmented Reality, 3D Printing, or tutoring systems could provide increased accessibility and opportunities for STEAM-based educational approaches. In this poster, we will give an overview of how the above-mentioned technologies could be employed by different users for teaching and learning STEAM-based educational ecosystem. Thus, in our research, we evaluated effects on students' learning in our educational projects. These projects involved automated tutoring systems, mathematical modelling of real-world objects with CAD Software, Dynamic Mathematics Software and 3D Printing devices, and outdoor mathematical trails with GPS-supported software and a number of Erasmus+ projects contributed to our studies Each study originate from the projects mentioned above was embedded within a joint research framework, nurtured by the results and participants' feedback from our studies. Building on this framework we focused on identifying how students, teachers, pre-service teachers and parents could access learning tasks and settings with different educational technologies and experience new opportunities in STEAM learning. From complementary findings of these studies we identified the importance of an interconnection of the different tasks and technologies, which can contribute to a creative, learning ecology (Szabó et al., 2021) of mathematics learning. Each kind of technology supports different approaches to learning and teaching, and in the combination of various technologies offers a wider accessibility to skills and knowledge for both teachers and students. Hence, in this poster, we present how the different educational technologies utilizing our findings could be used in an educational ecosystem, supporting with technology-based creative approaches.

Methods

Tasks and uses of technologies were based on the interplay of Blums and Leiß modelling theory (Blum & Leiß, 2007), problem-solving approaches (Liljedahl et al., 2016), Dienes' principles on learning (Dienes, 1960) and STEAM pedagogical frameworks (Haas, 2021). The tasks we elaborated in these projects are linked to school curricula and based on reliable methodologies implemented in schools and higher education training (e.g.: active discoveries, peer learning, student-centered learning). We followed recent studies on creative ecologies of everyday learning to identify structures for a system implementation (e.g.: Szabó et al., 2021). In every study, we followed a design-based research methodology (Lee & Hannafin, 2016). However, we adapted the methodology slightly for the different studies, due to the used technologies, environment, or possibilities and the restrictions imposed by the COVID-19 pandemic. Moreover, we used quantitative, qualitative and mixed-methods triangulation in the different studies. We will present methods separately for each study in the poster. We obtained results indicating that those educational technologies with real-world connections are likely to engage students, parents and teachers in new motivating and creative ways.

Discussion

Through addressing open-ended problems using guided support with decreasing feedback and scaffolding, our learners and teachers were able to develop their process skills and content skills in STEAM disciplines at their own pace. These task designs can be implemented in creating new learning settings and each technology supports students in their learning and teachers or parents in their teachings. Students could use the automated tutoring system in class or at home to train process skills with scaffoldings and learn to apply these skills in active mathematical modelling approaches with real-world information, situations, objects, or places. Thus, over time it could be a valuable asset to support students individually or in groups or even the entire class with the automated tutoring system within traditional courses. With the dynamic geometry software, CAD software and 3D printing, students learned new strategies and skills. The solving behaviour in geometric tasks gained in structure and the visual-spatial ability was developed (Haas, 2021). Further, students gained confidence and experience through a play-based approach to tasks with enjoyment. Finally, with GPS-supported software, we were able to transfer learning directly into students' real world in combination with Augmented Reality, 3D printing, and Dynamic Geometry Software.

Designing stakeholder scaffolding for implementing a teaching model at scale

Ola Helenius

University of Gothenburg, Sweden; ola.helenius@ncm.gu.se

The challenge of implementing pedagogical innovations at scale is discussed by looking at the set of stakeholders. A large-scale multi-municipality implementation of a highly specific research-based teaching model for elementary school arithmetic in Sweden is used as an exemplary case. To create a lens through which the stakeholder structure can be discussed, the concept of stakeholder scaffolding is introduced. The main message is that what is to become a stakeholder in an implementation program should not only be decided through making an inventory of possible stakeholders and deciding which ones to engage. It is also a matter of designing new groups with given roles and responsibilities in the implementation program.

Keywords: Professional development, design research, large scale, arithmetic, implementation.

Introduction

In organization theory, the concept of stakeholder refers to "any group or individual who can affect or is affected by the achievement of the firm's objectives'' (Freeman, 2010, p. 25). When the stakeholder term is used in connection with implementation research in the field of education it is rarely explicitly defined. Certainly, when an educational innovation is implemented, there is not often a firm with particular objectives at the center. Instead, it makes sense to view many implementation efforts as coordinated by networks of parties. Therefore, I will look at multi-stakeholder network theory (Roloff, 2008) for guidance and, define a stakeholder as *any group or individual who can affect or is affected by the approach to the educational issue addressed by the network of collaborating parties*.

By *stakeholder scaffolding*, I shall mean the intended interaction patterns between identified or constructed stakeholder groups and how these intended interaction patterns are designed to support the implementation process of a pedagogical innovation. In this sense, the stakeholder scaffolding is an aspect of the program theory of the implementation project. I use the theoretical construct *program theory* in the same way as Chen, that is, "as a set of explicit or implicit assumptions by stakeholders about what action is required to solve a social, educational or health problem and why the problem will respond to this action" (Chen, 2012, p. 17). In Chen's conceptualization, a program theory has two components, the change model and the action model. The *change model* specifies how activities in the program are supposed to affect certain determinants in the system that are to be changed in order to reach specified goals or outcomes. The *action model* is "a systematic plan for arranging staff, resources, settings, and support organizations to reach a target group and deliver intervention services" (Chen, 2012, p. 18). Stakeholder scaffolding, as I will describe the concept, is hence a part of the action model. The purpose of the concept of stakeholder scaffolding is to provide a lens that helps researchers and program designers to focus on the specific roles different stakeholder groups can assume in relation to the action model.

The aim of the present paper is to discuss stakeholder scaffolding in relation to the scaling of educational interventions. The theoretical basis for my discussion builds on Coburn's (2003) characterization of scale as a four-dimensional construct concerning depth, sustainability, spread, and change of ownership. Further, the issue of scaling will be discussed from a design perspective where I do not only discuss which potential stakeholders a particular educational system might already involve, but also how to deliberately design stakeholder groups with the purpose of achieving scalability.

The discussion will be carried out by exemplifying the stakeholder scaffolding in a large-scale multi-municipality implementation of a highly specific research-based teaching model for elementary school arithmetic in Sweden. This means that this is not an empirical article but descriptive and theoretical. Because of space limitations, I will discuss Coburns construct directly in relation to how the implementers have tried to take the four components of scale into account in the implementation program design. For readers that prefer an introduction to Coburn's (2003) conceptualization of scale, the original article is a very worthwhile read as are many of the shorter summaries (e.g., section 5 in Roesken-Winter et al., 2015). I will now go on to describe the implementation program, before moving on to discussing it relative to Coburn's four scaling dimensions.

Thinking, reasoning, and reckoning (TRR) 1-3

The pedagogical program I will describe has two roots. On one hand, it builds on a specific teaching model communicated through descriptions of teaching sequences in the form of very detailed teacher guides. On the other hand, it builds on a professional development (PD) program that is a collaboration between the National Center for Mathematics education (NCM) in Sweden, a multitude of municipalities, and Sveriges Kommuner och Regioner (SKR). SKR is a national organization of municipalities and regions that stands free from the national political system. In what follows, the Swedish acronym TRR will be used to designate both the teaching model and the collaborative program for implementing it. Before describing the structure of TRR as an implementation program, I will briefly describe the TRR teaching model.

TRR for grades 1-3 comprises four themes for each grade where each theme is a collection of five teaching cycles. A cycle covers three lessons. The teacher guides include sequenced descriptions of which representations to use, which terminology and expressions that are supposed to be used by the teacher, which questions to use when probing pupils reasoning, suggestions for how to sequence qualitatively different types of pupil reasoning and so on. Each cycle focuses on a particular mathematical phenomenon from one of the conceptual fields number, additive structures, or multiplicative structures (Säfström et al., 2019). A cycle has six phases: chanting, introductory whole class discussion, pair work, follow-up discussion, individual documentation, and follow-up discussion of the documentations. For each phase, the social arrangements and expectations of teachers' and students' roles are different. The TRR teaching model builds on a randomized control trial evaluated design research project for grade 0 in Sweden (Sterner et al., 2020; Sterner & Helenius, 2015).

The core of TRR is that participating teachers use the TRR cycles as a basis in their teaching. Each year, about half of the teaching time will then be directed by the TRR model. The rest of the time teachers can plan as they please. Participating teachers are formed in professional development (PD) groups of at least three teachers, teaching the same grade and teaching the same cycle at the same time. Before the first cycle in a new theme, between cycles and after the last cycle of the theme, the PD groups meet and discuss the upcoming cycle and the experience of teaching the previous cycle guided by structured PD-questions from a booklet under the guidance of a local facilitator appointed by the municipality.

I will now move on to discuss TRR from a top-down perspective. The initiative is joint between NCM and SKR and there is a joint steering group but no clear ownership of the project as a whole. TRR is run in (so far) yearly rounds, each engaging around five municipalities working together in so-called working networks of normally five municipalities. After a municipality has agreed to participate and signed a formal agreement with SKR, they appoint a process leader, which is normally a mathematics teacher that already has certain special leadership assignments in the municipality and a networking group consisting of the highest responsible politician for school matters in the municipality, the highest non-political leadership, two principals, two teachers, and the process leader. What I have described so far can be called the institutional scaffolding of TRR and is illustrated in Figure 1.

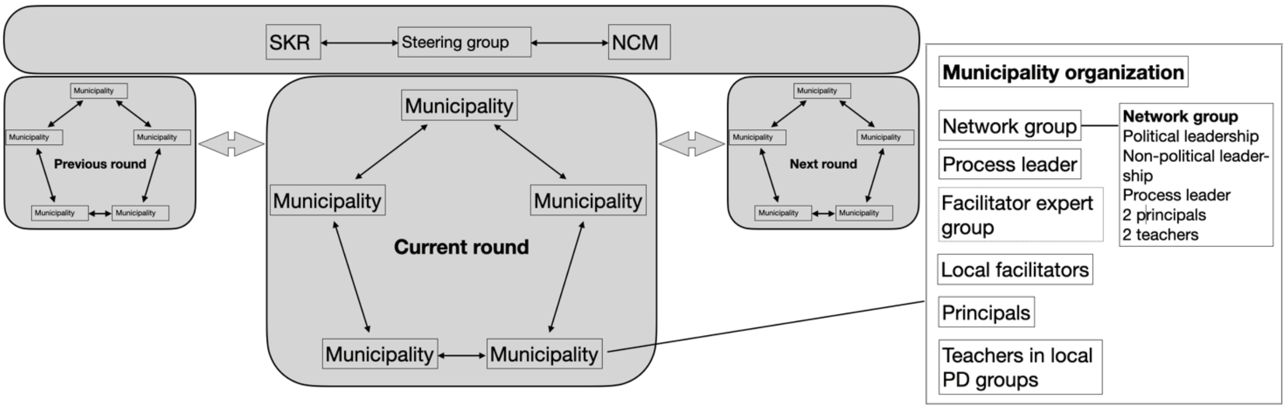

Figure 1: The institutional stakeholder scaffolding of TRR

The temporal scaffolding, which is how activities are distributed over time, is illustrated in Figure 2. In Sweden, a school year begins in the autumn. Therefore, in the temporal description of TRR what we describe as, for example, year 1 (Y1) is the year that starts in the autumn when the teachers of an attending municipality start to use the TRR teaching model at scale as well as the associated PD-program. Y2 is hence the second year of TRR usage and Y0 is the preparatory year before.

The first thing that happens after the municipality has signed the contract to participate is to appoint the process leader and the network group. All process leaders in the current round then meet for a process leader conference (PLC). This is a first or a rather tight series of PLCs that during the pandemic has been held almost every month. Slightly after, the network conferences (NWC) are repeated two times a year. To ensure knowledge transfer between the different rounds, around half of the PLC and NWCs in Y0 and into Y1 are joint with the previous round and later joint with the next round. Both PLCs and NWCs are two-day sessions.

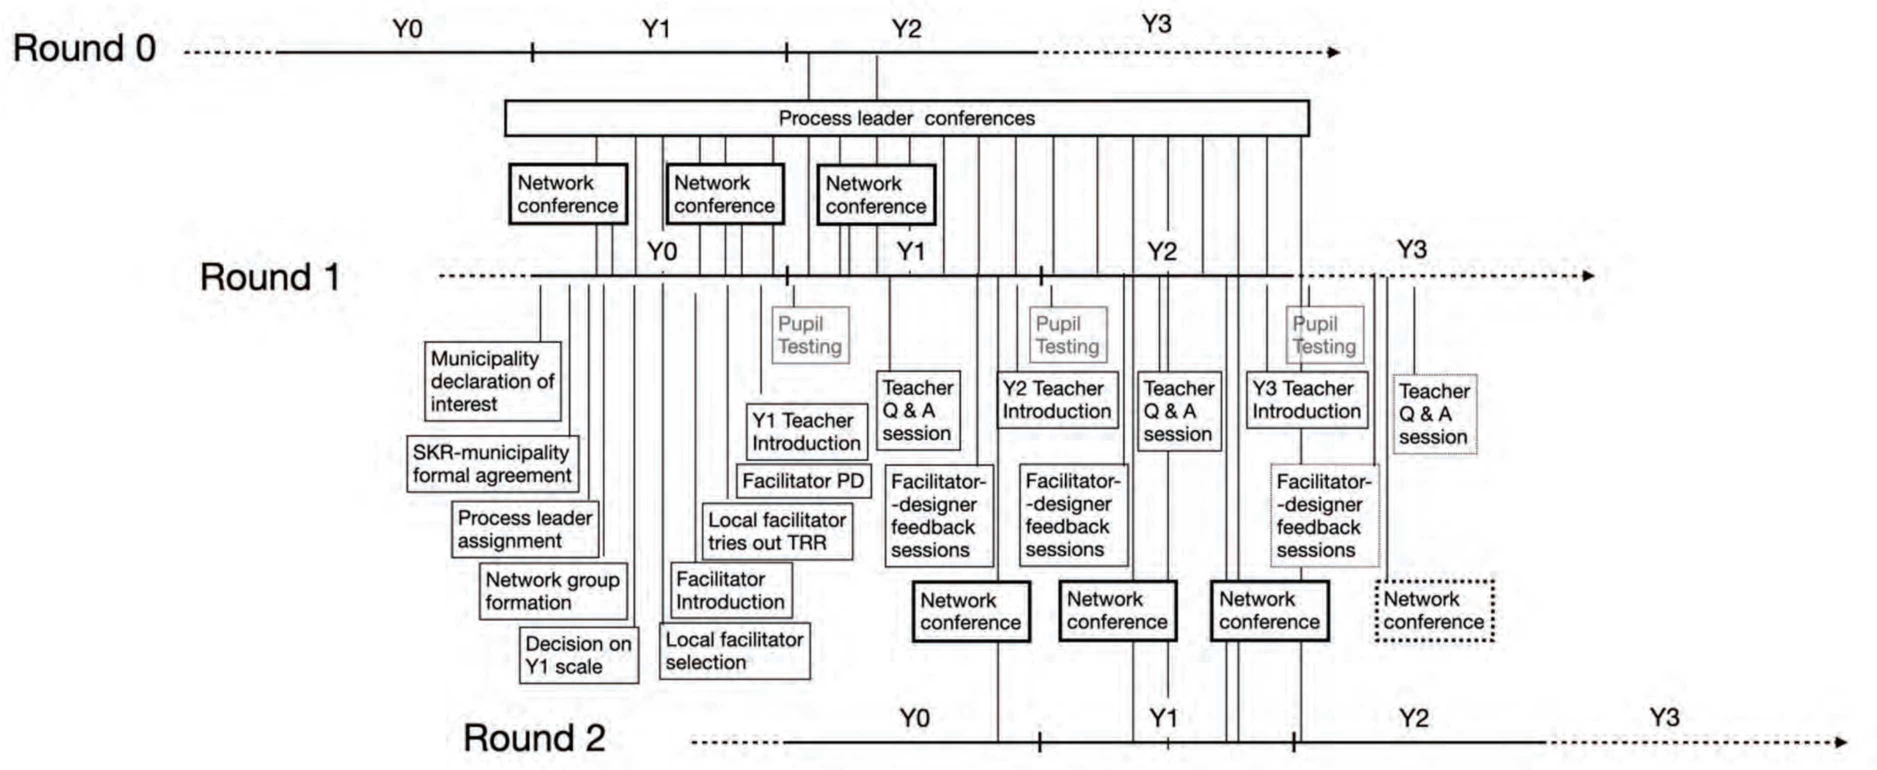

Figure 2: **The temporal stakeholder scaffolding of TRR**

An important decision that municipalities have to take early is at what scale to run the program. We have examples where municipalities have joined with all their teachers and schools in all grades 1-3, some that join with all grades in a few schools, some that join with all teachers in grade 1, and one municipality that only joined with one school. An early decision on the scale is important because the number of teachers and how they are distributed between grades and schools determine the number of local facilitators and we want the local facilitators that are to work with PD-groups when Y1 starts to start preparing, by being introduced to TRR in Y0 and start to use some cycles in the classes they currently teach. Municipalities are then responsible to book introductory sessions with NCM for the teachers to start in Y1. Some want two such sessions and some stick with one. In subsequent years, the individual municipalities can also decide to book Q&A sessions with NCM for both facilitators and teachers. These are normally local events. In the temporal diagram in Figure 2, I have also indicated where pupil testing can be, but that can vary between municipalities depending on their scaling plan and how to set up a control group design.

Formally, the project runs three years for each municipality, but in practice, it has so far continued with less and less PLCs and NWCs. Municipalities in Y3 and beyond have so far continued to book introductory sessions for new teachers and Q&A sessions for working teachers with NCM.

Four dimensions of scale and how it applies to TRR

I shall now discuss the stakeholder scaffolding in TRR described above, from the perspective of scale as Coburn's (2003) four-factor construct: depth, sustainability, spread, and shift in ownership. It should be noted that the stakeholder groups I describe below are intended to be examples of possible roles for stakeholders in relation to scaling. I make no claims that the particular stakeholder scaffolding of TRR is particularly good or that it is always well functioning.

Depth

Coburn's conceptualization of depth concerns "change that goes beyond surface structures or procedures [...] to alter teachers' beliefs, norms of social interaction, and pedagogical principles as enacted in the curriculum" (Coburn, 2003, p. 4). The focus in Coburn's description is on students' and teachers' roles in the classroom, like for example the patterns of communicational interaction. As described, TRR gives very strong guidance for teachers to follow particular interaction patterns, as well as particular ways of treating the mathematical content. Obviously, not all TRR intentions are followed. The implementers recognize that small adaptations from teachers affect how the content is portrayed to the pupils (Koljonen et al., 2022). Therefore, highly prescriptive teaching designs still need deliberate stakeholder scaffolding to support depth. In TRR, the local PD-groups are one such structure intended to create a support for interpreting the intentions of each cycle as well as following up the classroom implementation and also induce a form of peer pressure. The local facilitators are a stakeholder structure designed to support the PD groups. Forming the facilitators as a group with a particular role is a key element in the stakeholder scaffolding. It is our experience from previous large-scale PD-programs (Helenius, 2021) then letting one group of teachers, the facilitators, work ahead and giving them some additional PD as well as officially designating them as a facilitator group tends to shift of identity from a receiver of the PD to a deliverer of the PD which enforces loyalty to the program intentions and supports them in their role relative the PD groups.

Sustainability

Sustainability concerns the chances that deep changes stay in effect in classrooms, schools, and municipalities where they have been established. Referring to a wealth of literature, Coburn describes sustainability as dependent on four factors, which all reinforce a professional community of colleagues in the school that supports depth of change of which we will deal with two here. The first of these is the need for knowledgeable and supportive school leadership. In TRR, all levels of school leadership from principals and up are specifically engaged. The principal level is represented in the network group, which is the most complex of the designed stakeholder groups. It is also a common arrangement that the PL is co-opted into the municipality principal group, typically led by the municipality school leader, which further allows the process leader to influence and engage principals. The second factor I will mention is the connection with other schools and teachers engaged with a similar reform. Since TRR is a municipality driven there is plenty of such interaction within municipalities.

Spread

Spread may be the most obvious factor of scaling, as it involves the fundamental factor of replicating the implementation of some reform or innovation with more students, teachers, schools, or districts. Coburn makes a point of considering spread also within different levels. Spread within classrooms could for example involve pedagogical innovations proposed in one subject spreading to a teacher's teaching in other subjects. Spread within a district or municipality could involve certain norms related to a pedagogical teaching innovation spreading to local school policy (Coburn, 2003).

The stakeholder scaffolding of TRR has several elements designed to support spread to other schools and classrooms. The scaling that occurs to new municipalities with new rounds obviously leads to scaling, and so far all participating municipalities have decided to continue from Y1 to Y2, and beyond and have included more schools and teachers except in the cases where all schools were already engaged.

Shift in Ownership

The aspect of scale that Coburn perhaps puts the most emphasis is on a shift in ownership. It is worth noticing that the metaphor of shift of ownership presupposes an initial owner, an item to be owned, and a new owner. In Coburn's description, it is some reform program that is the item and the initial owner is some actor external to teachers, schools, and districts. With such a shift, knowledge of the reform can become local and a theory-based practice can arise so that the reform can become self-generative (Coburn, 2003). With TRR, the stakeholder scaffolding sets up a quite advanced structure for shared ownership right from the start, that gradually can shift towards municipalities and teachers. Municipalities have to themselves decide the scale with which to enter the program, depending on how much they believe in the program and in their own ability to administer it and later decide how to scale it up. Recall, the arrangement that teachers should meet regularly in PD-groups and be able to teach the same cycles in parallel puts quite high administrative demands on all levels of leadership. It is questions like this that are discussed in the early PLCs and NWCs. Because municipalities are responsible for scaling also makes it important that teachers remain positive and even when feeling like the teaching is very difficult keep feeling that they have support from the organization. It is so far our experience that facilitators, but also many teachers, identify with the program and help to spread the word to teachers in the municipality that are yet not engaged. A final note on ownership is the several of the municipalities, without consulting SKR or NCM, have produced their own professional videos on TRR, to share with parents, the general public, and other teachers.

Discussion

Designing models for implementing pedagogical innovations at scale is a vital concern in contemporary implementation research. In the present paper, I took a closer look at the stakeholder issue related to scale and coined the concept of stakeholder scaffolding, which I presented as a part of the action model of the program theory (Chen, 2012). Chen already identifies particular types of stakeholders when schematically describing an action model, the implementing organization, peer organizations and community partners, and the program implementers. It is worth noting that Chen is discussing a wide section of innovations spanning over the social, educational, and health sectors. This means that the specificity when discussing the roles of the stakeholder groups he mentions is low. In the case of TRR, it is for example not very easy to separate what is the implementing organizations from the peer organizations. But a point Chen is making when pointing out different types of stakeholders as part of the action model is that types and roles of the stakeholders *should* be planned in advance and *be* part of the action model. Going back to the description I gave drawing on Roloff (2008), it states that a stakeholder can be *any group or individual who can affect or is affected by the approach to the educational issue addressed by the network of collaborating parties*. A main message in the present article is that what is to become a stakeholder in an implementation program should not only be decided by reviewing groups that can be affected by the program and can affect it, like researchers, policymakers, principals and teachers. Instead, the view I am advocating is that stakeholder groups can be deliberately created as crossover groups between such levels as part of the design of a program.

In TRR, one such designed stakeholder group is the group of process leaders in each round. By identifying such a group and giving them opportunities to work together, their roles in the respective municipalities will be strengthened. The process leader group is formed through the multitude of process leader conferences, which also ensures that the process leaders are the most informed persons which further strengthens their authority and agency within municipalities. The arrangement with process leaders coworking with the peer group from a previous round, and eventually, with the peer group from the successor round further strengthens their agency. Other examples of designed stakeholder groups are the network groups in the municipalities with the role of giving coherent support for TRR across all institutional levels in the municipality.

In summary, TRR F-3 is an example of a teaching model that is very demanding for teachers that are to use it in their classrooms. Despite the highly scripted form of the TRR teacher guides, we believe it is virtually impossible for an individual teacher to operationalize TRR in their classroom. It can only be done in deliberate collaborative settings with a high degree of organizational support. In short, it can only be done by ensuring that all of Coburns four aspects of scale are accounted for in the implementation program. Designing and implementing a well-thought-out stakeholder scaffolding is hence an important part of the program design. When researching effects of large-scale implementation programs, I see it is a good idea to put special focus on if the stakeholder scaffolding worked as intended or not.

Implementing research in the practice of curriculum designers: Barriers and an example approach

Ellen Jameson, Darren Macey and Lynne McClure

University of Cambridge, United Kingdom; emj38@cam.ac.uk; djm249@cam.ac.uk; lm409@cam.ac.uk

Barriers to educational designers' engagement with research, including barriers to access, interpretation of implications, implementation, and interpretation of outcomes, can limit the translation of research into practice through educational design. Our aim in this paper is to define four challenges to implementing research through the processes and products of curriculum design and to explore theoretically-grounded principles for addressing these challenges through an example of a design tool, the Cambridge Mathematics Framework. To illustrate the principles underlying this tool, we give a brief concrete example of its use in a curriculum design implementation.

Keywords: Curriculum, concept mapping, design, evaluation

Introduction

The benefits of engaging with research in educational design have long been recognised in a range of approaches which place value on developing explicit, well-supported reasoning to inform design decisions, and on iterative refinement using data from implementation in authentic contexts (McKenney & Reeves, 2012). Lowering barriers to implementing research through educational design may allow these benefits to be realised more often and more fully. In this paper, we aim to characterise four challenges to implementing research through the processes and products of design and explore the question of how these challenges might be addressed. Using the example of a design tool, the Cambridge Mathematics Framework (CMF), we present principles and underlying theoretical influences for addressing these challenges with respect to research implementation and evaluation methods, and briefly illustrate its use in a curriculum design implementation. In the following section, we begin by describing research implementation challenges.

Challenges to research implementation through processes and products of design

In our examination of factors which might potentially affect educational designers' ability or opportunity to implement research in design, we have identified four challenges.

1. There are factors which limit engagement with research. The resource-intensive nature of research implementation presents a challenge to engagement with educational research (van Schaik et al., 2018). Even in national-level curriculum design, time and resource constraints have been noted which can limit the amount and depth of engagement with research (Jameson et al., 2021). Smaller-scale design efforts may be more narrowly focused but may bring proportionally fewer resources to bear on research integration, or on evaluating the influences of research-informed features when designs are implemented.

2. Design is an intermediary construct. We hold that any designed resource or experience is an artifact which serves as an intermediary between the theories and intentions of the designer and those of teachers and students, because designers typically do not enter classrooms to directly implement and explain the resources they have created. The distance in time, space and perspectives between researchers, designers, teachers and students often leads to differences between what is stated by researchers, intended by designers, enacted by teachers and experienced by students (Barab, 2014). Koichu and Pinto (2019) call implementation a “multiparty enterprise” and the CERME11 TWG23 adapted a definition of implementation to include the notion of distance between communities of resource proponents and communities of resource adapters (Artigue, 2021). With respect to curriculum design, Remillard and Heck (2014) describe this distance within their curriculum model, an update to Stein et al.’s (2007) model of curriculum phases, which the participants of TWG23 in CERME11 adapted in a model of research implementation (Aguilar et al., 2019). The new research implementation model highlights the transformations that research implications undergo as they are first used to structure objectives (intended implications), are translated into classroom experiences (enacted implications), and result finally in particular outcomes (attained implications).

3. Research is one influence among many on outcomes. There is a dilution of research implications which is not made explicit in the CERME11 model (Aguilar et al., 2019). Design itself (the “attributes of the innovation”) is only one of many factors which may contribute to the final impact of innovations on learning (Century & Cassata, 2016, p. 186).That is, the further down the chain from published research, the more room there is for other factors to influence what happens and the less research influences may be contributing to observed outcomes, even taking differences in intentions, background and interpretation between researchers, teachers and students out of the picture. Therefore, the enacted and attained implications may be impossible to separate from the individual instances of enactment and subsequent learning outcomes as a whole, which may take their specific forms for a variety of reasons. A third challenge, then, is one for implementation research: How can we analyse the contributions of research influences, particularly when research is being translated into practices which occur at some distance from the classroom (as with some forms of educational design practice including curriculum design)?

4. Research implications are not always straightforward. The final challenge we will highlight here is that research in mathematics education does not inherently add up to a coherent whole. It is a heterogeneous body of work reflecting a wide range of perspectives, assumptions, goals and practices, serving numerous wider agendas shaped by research communities rather than by the requests of teachers or administrators (Burkhardt & Schoenfeld, 2003). Knowledge from research likewise differs in nature and focus from pedagogical knowledge (McIntyre, 2005). Implications for teaching and design are therefore seldom straightforward. Moreover, while there are strong reasons for researchers and educators alike to consider implications from very different sources together as a coherent set, the diversity of the field can make this a complex undertaking involving detailed understanding of a wide range of relevant theories and experimental designs (Prediger et al., 2008). Despite this, it is important for designers to be able to access research influences at this level of detail, to navigate a variety of theoretical frames appropriate to different aspects of design problems, and to use available data accordingly (Kieran et al., 2015).

There is no one-size-fits-all solution; however, next we present one approach developed to help designers overcome these challenges when developing mathematics curricula.

An approach to addressing challenges of implementing research through design

In this section we provide as much detail of the components, use, and theoretical basis of the CMF as space permits. The CMF is a conceptual mapping tool which designers can use to explore, analyse and accommodate research implications for the interdependence of mathematical ideas when discussing and justifying the writing and ordering of curriculum content. It consists of the following key components: (1) a dynamic network of selected mathematical ideas in the domain of school mathematics and connections between them, which we have developed based on thematic review, synthesis and interpretation of the mathematics education research literature, along with connections to research sources; (2) tools for exploring, analysing and visualising the network and the research base; (3) Research Summary documents which explain the research justification for specific groups of mathematical ideas and relationships and which undergo external review; (4) descriptions of how students engage with these ideas in practice, in a form designed for teachers and designers to relate to their own experience; and (5) external content such as curriculum statements or mathematical tasks which can be mapped on to the network of mathematical ideas and analysed in terms of content and ordering. Ideas in the network are not ordered in an absolute sense, by year or age, but by how ideas contribute to one another. This ordering is not linear but allows for many paths from one idea to another which a designer may find useful to consider. Importantly, it is a conceptual ordering and not meant to imply teaching order or student trajectories, as students often need to go back and forth as they develop experiences working with a set of ideas. Finally, (6) the CMF can be used to produce concrete artifacts for analysis and discussion in the form of maps in which designers have gathered relevant collections of waypoints and linked them to their own content.

In a typical curriculum development scenario, a designer using the CMF might start by searching for mathematical ideas relevant to the section of the curriculum they're working with and display them in the order they depend on one another, from left to right, together with curriculum content on the screen as a map. Then curriculum content can be linked, or "mapped onto" to the mathematical ideas, which helps designers to explore possibilities within the map as a whole for reordering, adding, subtracting or changing curriculum content. When changes are made to the curriculum content on the basis of the CMF, the research justification provided in the CMF for the mathematical ideas and connections can serve as a reference for designers in documenting and communicating their justifications to stakeholders.

We structure the theoretical underpinnings of the CMF around several key design assumptions; in this paper we describe three which are most relevant to research implementation. We have drawn on literature in multiple areas: domain coherence in mathematics, conceptual mapping, and shared representations as boundary objects. Our first design assumption is that support for research-informed perspectives on domain coherence in the design of curricula or resources can contribute to their value for teaching and learning by allowing designers to consider a wider range of implications and develop curricula and resources with greater domain coherence as a result. This assumption is related to challenges 1 and 4, since it involves providing support (i.e. making it more straightforward, thorough or feasible) for using research perspectives in design decisions and provides aid to designers in synthesizing research from multiple sources and perspectives. It is based on strands of research involving the conceptual structure of mathematics learning and notions of coherence. Thurston (1990) describes this structure as being "like a scaffolding, with many interconnected supports"; he conceives of it as tall, because concepts build on one another, broad because of the multitude of interconnections necessary to provide foundations for building, and connected, with the connections helping students and mathematicians to compress sets of ideas to make use of them more efficiently (Thurston, 1990, p. 2). Tall (2013) suggests that this structure is built through categorization (the "recognition of essential properties"), encapsulation ("repeating actions" that "can be manipulated as mental objects") and definition, using "language to formulate specific concepts as a basis for reasoning and proof" (Tall, 2013, p. 51). Research on learning in different topic areas of mathematics often has implications for the particular mathematical ideas and connections of importance, and we have applied Tall's principles for learners to our expression of conceptual structures implied by research for designers. On this basis we view designs with high domain coherence as those which aim to leverage conceptual dependencies that are well-aligned with those reported in research. This definition is in agreement with the idea of "learner-centered curricular coherence as…an organizational means to promote a high likelihood that each learner traverses one of many possible paths to understand target disciplinary ideas […] by building on and continuously broadening and modifying their ideas and experiences." (Confrey et al., 2017, p. 719) and has also been informed by perspectives emphasizing the logic underlying sequences of ideas (Schmidt et al., 2005; Stark, 1986).

The second design assumption is that our goals from the first assumption can be aided by a mapping approach. This assumption is related to challenges 1 and 2, as mapping can make detailed relationships explicit and easier both to work with and to discuss. The affordances of conceptual mapping for analysing and communicating relationships between mathematical ideas have been demonstrated in research on learning trajectories and related constructs (Confrey, 2019). These affordances are also well characterised more generally in studies of knowledge management (Eppler, 2004).

The third design assumption is that the maps and mediating documents of the CMF can serve as shared artifacts which may facilitate discussions about design both within and between communities of practice, and that doing so may help design intents to be realised more fully by teachers or adapted for them more effectively by eliciting feedback. This assumption is again related to the need for communication in challenge 2. For this we draw on Remillard and Heck's (2014) characterization of curriculum and resource implementation as taking place in a system of communities between which designs are translated and possibly transformed as they are documented by designers, enacted by teachers and received by students. This has led us to shape aspects of the CMF according to the properties of shared knowledge representations, especially boundary objects as proposed by Star & Griesemer (1989); in particular the qualities of being adaptable yet structurally consistent and of allowing members of different communities to recognise information from their own perspectives and connect this to others' through a common space or artifact.

Taken together, these design assumptions are intended to address challenges 1, 2 and 4 by helping designers to deal with issues of coherence and the complexity of the research base and by providing a shared frame of reference for design discussions and support within and between communities. Challenge 3, however, is the issue of how research influences in design contribute to design process and teaching and learning outcomes. Much of this challenge involves implementation research rather than the design of the CMF itself.

The CMF is currently being implemented in a number of different curriculum and resource design contexts at different scales. In all cases so far, the CMF as a design tool is being implemented with designers, whose designs are subsequently implemented in learning contexts. The contributions of the CMF are therefore directly related to design outcomes and somewhat indirectly related to teaching and learning outcomes, as any design influences would be. We are developing a preliminary evaluation framework to helps us to analyse the direct and indirect contributions of our research interpretations in the CMF across a variety of authentic implementation contexts. Such contexts can be expected to have uncontrolled external factors (Barab, 2014) and multiple influences determining outcomes (Stern et al., 2012), making contribution analysis a useful approach for evaluating impact and gaining insight into specifically how our approach might be improved.

This framework helps us to characterise implementations according to several factors. First, we have identified four categories into which our evaluation goals might fall (adapted from Stern et al., 2012): Attribution: how much influence did the CMF have on the outcomes?; Contribution: Did the desired outcomes occur?; Mechanism: By what means did the CMF contribute?; and Translation: What circumstances are conducive to achieving intended outcomes using the CMF? The first two categories involve the value and relevance of the CMF; the last two may help us to learn about broader contexts in which use of the CMF is more likely to be successful. In addition to goals, this framework will help us to position an implementation according to meaningful duration, conceptual range, systemic scope, and distance of the CMF from measured outcomes, and will help us to frame outcome indicators and measures accordingly. Below, we briefly discuss some design outcomes from a recent implementation of the CMF which further illustrate this approach.

A brief description of some illustrative implementation outcomes

Our most recent case study took place as we were beginning to develop the evaluation framework. In the summer of 2020, the CMF was used in work on Statistics and Probability strands of the Australian Curriculum as part of the review currently being carried out by the Australian Curriculum, Assessment and Reporting Authority (ACARA). The ACARA team worked with the CMF and the Cambridge Mathematics (CM) team and described design outcomes from this work through face-to-face meetings and semi-structured diaries. Below we give a very brief description of the context and summarise the outcomes we have synthesized from meetings and diaries with respect to the four research implementation challenges; this synthesis contributed to identifying these challenges.

1. There are factors which limit engagement with research; 4. Research implications are not always straightforward. The ACARA team reported that while they spent just as much time thinking about research, using the CMF they were able to use this time to bring much more research from sources which were new to them into their discussions. They felt in some ways that there would always be some research that they would not have time to fully engage with, but that the way it was presented in particular topic areas in the CMF helped them to address specific questions and introduce new ones. They made use of a variety of CMF features in order to access research; they began with Research Summaries and CMF content curated for them according to their existing curriculum statements, and branched out by using search features and following connections to look for other aspects of topics to consider. In the course of this, they reported being unable to find some things; we realised that while some of what they were looking for was implicit in some CMF content, it was not explicit enough for the ACARA designers to recognise, and they had to spend more time looking for it than we intended. This helped us to revise not only the presentation of that content but to examine other areas of the CMF for similar issues.

The ACARA team also reported engaging with research implications in a mix of forms. They looked back and forth from research summary text to maps to descriptions of map elements. They were able to find some useful ideas through their own queries. The flexibility of the multi-representational approach in the CMF meant that to the extent required the ACARA team was able to develop and follow their own lines of inquiry beyond the starting points curated by CMF writers, with a few exceptions mentioned in 1. Moreover, the Research Summary starting points contributed substantively to several of the discussions we observed.

2. Design is an intermediary construct. We observed the ACARA team using CMF maps and Research Summaries in discussions with us, and they felt the information they found helped them to provide useful research justifications for their decisions to ACARA colleagues and teachers, who reviewed initial changes in reference groups, by illustrating (in a different form) some of the connections highlighted in the CMF. These justifications were positively received and the ACARA team felt they had been effective. The ACARA team also was able to highlight specific changes to the wording of curriculum statements which they made to bring in influences they found in the CMF and make them more explicit for teachers. See 3. for examples.

3. Research is one influence among many on outcomes. The ACARA team was able to clearly identify specific changes in their internal discussions due to use of the CMF, some of which led to curriculum changes. Two examples are provided below:

- In one set of statements about data, they changed language to explicitly reference the shape of distributions. Distribution and shape were major themes in the research they engaged with through the CMF, and they wanted teachers and students to be aware of the shape of distributions when interpreting data. Across Years 4 and 5, for example, the words describe and interpret have been expanded to acquiring, validating and representing types of data.
- They referred to research encountered in the CMF to develop a progression in statistical investigation through Years 3–10. This progression moves from guided statistical investigation involving categorical or discrete data to planning and carrying out statistical investigations, analysing data, communicating findings, developing questions, incorporating summary statistics, sampling, and working with multiple data sets and with bivariate data.

Conclusions

In our illustration, when using the CMF designers were able to engage productively with a larger number of research implications than they had before in a similar amount of time, and encountered ideas that led to specific adjustments in their approach, as well as ideas which validated many of the directions they had been going in the review. However, while they felt this enhanced their work, it did not save them time as there is always more research available than time to engage with it; the CMF simply created a higher limit to engagement. They were able to build and communicate research justifications including themes from the CMF, and they were able to directly attribute some of their design decisions to the CMF. In many cases the research synthesis aided the ACARA designers as the CM writers intended, but some cases in which this did not take place were identified for further work. These outcomes from our work in progress on evaluation suggest that the CMF might be a reasonable example of one approach to addressing the research implementation challenges we have described.

Acknowledgements

We greatly appreciate the ACARA team's depth of engagement and participation.

The documentational approach to didactics as a gauge of fidelity of a teaching model implementation

Tuula Koljonen[1], Ola Helenius[2] and Linda Marie Ahl[3]

[1]Linköping university, Faculty of Education, Sweden; tuula.koljonen@liu.se

[2]University of Gothenburg, Faculty of Education, Sweden; ola.helenius@ncm.gu.se

[3]University of Gothenburg, National Center for Mathematics education, Sweden; linda.ahl@ncm.gu.se

We examine the feasibility of using the Documentational Approach to Didactics to gauge the fidelity and character of teachers' implementation of scripted teaching sequences for the teaching of arithmetic in primary school. By analyzing a video-recorded lesson, we found that the teacher adapted the scripted teaching sequence by merging it with other resources such as self-made worksheets and an interactive whiteboard. The teacher also made adaptations to the prescribed organization of the teaching. Through the analysis, we gain insight into the nature of the adaptions and find that Documental Approach to Didactics can be used as a lens to distinguish between surface adaptions, that do not interfere with the program theory and adaptions that violate core ideas of the innovation. The results provide a background for a discussion of pro-fidelity versus pro-adaption point of view in implementation research.

Keywords: Documentational approach to didactics, fidelity, implementation, mathematics, education

Introduction

The extent to which an educational innovation implemented in classrooms reaches its desired outcomes depends on how teachers adapt the innovation in their practice. The extent to which teachers faithfully follow the instructions and intentions of an intervention can be discussed in terms of fidelity. The rationale for measuring fidelity and striving for high fidelity is to allow analytical separation of the quality of an educational innovation from the quality of the implementation of it, as well as to provide a reference for scale-up or replication research involving the intervention. Century and Cassata (2016) call the view that more fidelity is better the pro-fidelity perspective. They argue that to understand the nature of implementations of pedagogical innovations rather than just the effects of them, the pro-fidelity perspective ought to be complemented with a pro-adaptation perspective encompassing a research focus on "why adaptations are made, where implementation challenges come from, and how the nature of an adaptation matter for outcomes" (p. 200).

It has been noted by researchers that innovations that are general, non-specific, and involve little prescribed structure might need more adaptation (Cohen & Ball, 1990) and hence would benefit from a pro-adaptation research design (Century & Cassata, 2016). Highly structured innovations that are specifically prescribed could on the other hand benefit from a pro-fidelity research design (O'Donnell, 2008). The study presented here reports a case from a context where the innovation is a highly prescribed curriculum based on a specific teaching model, but as we will show, a pro-adaptation perspective still has merits.

The context of the study is a large-scale intervention, spanning 14 municipalities and over a thousand teachers, where the outcome on the student level is being evaluated with a control group, pre-post-test design. Yet, despite an intricate implementation design involving collegial collaboration to stimulate high fidelity, the project team was aware that adaptations would be made, and that fidelity would vary. To evaluate the intervention and gain worthwhile feedback, we were therefore in search of a theory base for researching teachers' adaptations of resources. This methodological paper reports on the use of the Documentational Approach to Didactics, DAD, (Trouche et al., 2020) for this purpose. DAD has previously been used to characterize teachers' use of and blending digital online resources. However, we see the potential to use DAD to characterize teachers' implementation of a highly prescriptive curriculum resource. Therefore, the present paper aims to examine the feasibility of using DAD to characterize the fidelity and adaptation of a highly prescriptive curriculum resource.

Theory

The theoretical framework DAD can be used for studying teachers' goal-oriented work through their interactions with resources used in their teaching (Trouche et al., 2020). An objective with DAD is to achieve a comprehensive understanding of teachers' work through elaborating what it can mean "to use" a resource. To understand the relevance of the term documentational, it helps to know the etymology of the word document. The word originates from Old French where it, in the late 15th century came to mean "teaching, instruction". The concept is also linked to the Latin "documentum" which refers to "lesson" and "to teach".

DAD builds on French didactics' theory and the tradition of the instrumental approach. The instrumental approach takes as a point of departure, normally, a digital artifact that is to be used by teachers or pupils. The fundamental observation is that when an artifact becomes incorporated in an individual's handling and thinking scheme, there are two processes involved: instrumentation and instrumentalization. The instrumentation process is when the affordances of the artifact shape the persons' practice. The instrumentalization process is when an individual uses her knowledge and dispositions to use the artifact for fulfilling her needs and goals. Combined, the instrumentation and instrumentalization processes interact to create the instrumental genesis, the transformation where the artifact becomes an instrument for the individual (Artigue & Trouche, 2021). The instrumental genesis, in turn, involves an interaction in which the user and the potentialities of the artifact (the physical tool) are reciprocally constituted in action (Artigue, 2002).

In the documentational approach, the role of the artifact is replaced by the role of one or several resources that a teacher might use or be influenced by in her teaching. The concept of resource encompasses any artifact with the potential to promote mediating teaching activities, including textbooks, curricular guidelines, digital resources, student worksheets, or work with a colleague. In DAD the teacher's role is to be a designer who, guided by a goal, transforms resources into documents in the process of interacting with a resource or a set of resources. This process is called documental genesis, in line with how instrumental genesis is described above (Trouche et al., 2020). This process ends with a document that is the product of a teacher's resource design work in each situation. The totality of a teacher's developed documents is called a document system.

A document is thus a combination of when a resource is appropriated and reshaped by a teacher, in a way that reflects their professional experience with the use of resources. *Document = Resources + schemes of usage*. A teacher's resource system is developed and formed by all the resources the teacher uses for a given activity (Trouche et al., 2020). The resource systems will be different for different teachers, even though they use the same resources since the resulting documents are dependent on the teacher's characters and prior knowledge. Thus, the process of documental genesis is ongoing since teachers' utilization schemes, how teachers adapt and are adapted by the resources they use change with experience (Vergnaud, 1998).

Method

We have compared the enacted actions of a teacher involved in a large-scale implementation program, with the scripted actions that carry the core ideas of the program, the program determinants. To set the stage for this study, we will elaborate on the implementation program by explicating elements of its program theory. When we use the concept *program theory*, we refer to Chen (2012), where we refer readers for further elaboration. Briefly, a program theory is an explication of a program's goals and how the program is supposed to achieve its effects. The change model of a program theory is the description of the "leverage or mechanism upon which [the program] can develop a treatment or intervention to meet a need. That leverage or mechanism is variously called the determinant or the intervening variable" (Chen, 2012, p. 18).

The teaching model builds on a randomized control trial evaluated design research project for grade 0 in Sweden (Sterner et al., 2020; Sterner & Helenius, 2015). The program has a comprehensive organization and involves municipality collaboration, teacher professional development, and local facilitator and leadership organization (Helenius, n.d.). In what follows, we will designate both the teaching model and the program for implementing it by its Swedish acronym TRR. In its current form, TRR is implemented in a program run in 14 municipalities in Sweden with over 1000 teachers. The TRR teaching is arranged in cycles composed of six phases, each comprising a particular pedagogical arrangement (see Sterner et al., 2020 for a description). Participating teachers complete 20 cycles that cover half of the mathematics teaching over a school year. A cycle normally covers three lessons and is communicated by a resource book, with detailed descriptions of how to carry out teaching. The detailed descriptions carry the program determinants and view as the desirable outcome in instruction. Of the large selection of possible determinants to distinguish in TRR, we present four of relevance in the sequence of teaching we will analyze.

Determinants of TRR resource book

Determinant 1 (D1). Building on the pupil's productions and reasoning. While the tasks, representations, and language to use are explicitly described in the TRR resource book, the main role of the teacher is to get the pupils to reason about their work and engage pupils in reasoning about each other's work. To aid the teacher, the material contains advice on how to sequence student presentations, depending on different approaches taken to the task and on particular types of questions or prompts to use when engaging pupils to talk about their work.

Determinant 2 (D2). The problem-solving strategy. In TRR, we endorse a particular strategy for approaching word problems: Formulate in your own words, use one of the endorsed representations for the situation type represented by the problem, write a mathematical expression, and find out the answer. A normative choice in TRR is that we prefer if pupils write the mathematical expression as close to the mathematical situation that is represented in the problem as possible. In this case, we prefer the situation: *The rabbit jumps five times farther than the bear* to be represented as rabbit's jump = 5 · bear jump, regardless of if the task continues: *The bear jumps 3 meters, how far does the rabbit jump?* or *The rabbit jumps 15 meters, how far does the bear jump?*

Determinant 3 (D3). The multiplicative model. In TRR we use three different models to build the multiplication concept on, none of which is repeated addition. One of them is rectangular arrays, initially built by cubes and later cut out from square paper. In the second teaching cycle on multiplication, the class constructs what is referred to as the big multiplication table which is a 10-by-10 matrix of rectangles, where the entry (i, j) displays the i times j rectangle with the product $i \cdot j$ written on it (Säfström et al., 2019).

Determinant 4 (D4). The chanting phase of the teaching cycle. The first phase in a teaching cycle is always chanting. The chanting signals that a mathematics lesson starts and connects to the mathematics to be treated in the teaching cycle. The chanting phase is not supposed to contain teacher explanations. But despite that, it might contain mathematical information not apparent to the pupils. In the cycle under scrutiny here, the chanting comprises variants of If 3 times something is 12 then something is 4. The resource book instructs the teacher to have the big multiplication table visible and pointing at the 3-row, while uttering three, moving the hand along the row and stopping at the rectangle with 12 on it when uttering twelve, and then moving the hand to the top column and stop at 4 when uttering four. The chanting is hence supposed to be accompanied by a gestural indication of how to solve an open multiplication problem of the type $a \cdot \_ = b$ by using the big multiplication table.

The data for the study presented here comes from a 49 minutes iPad video recording of one lesson with 8-year-old children (grade 2). The teacher has a formal teacher education for grades 1-7 and 24 years of teaching experience. At the time of the data collection, he had been involved in the TRR program for three years but had not taught the cycle discussed here before. The parts showing the teacher's use of resources were transcribed. Only the excerpts that are presented in this paper were translated into English. In collaboration, all three authors conducted a thematic analysis of the teacher's actions. With the theoretical lens of DAD, we describe the teacher's document system, that is his schemes of usage of the two resources, the TRR resource book and the whiteboard. Then we compare his document with the determinants D1-D4 from TRR's change model.

Results

Two resources, the TRR resource book and an interactive whiteboard with an attached document camera, are in play in our excerpts. D1-D4 are references to the TRRs determinants presented in the method.

As per TRR resource-book instructions, the chanting of the type: *If 1 times something is 2 then something is 2* is displayed on the whiteboard, which in the teacher's case is an interactive whiteboard. For each chanting, the teacher draws the corresponding rectangle next to the chant, e.g., *if 3 times something is 12, then something is 4*, the 3 by 4 rectangle with 12 printed on it is drawn. Next to the rectangle, the teacher has also written the open multiplication statement 3 $\cdot$ _ =12 on the interactive whiteboard.

The sequence starts 01:26 minutes into the lesson and is close to two minutes long. In line with the teaching model, the teacher leads a collective chanting phase (D4).

Teacher: We now start with the chanting, so read with me. If 1 times something is 2 then something is 2 (points at the chanting text). So, 1 times something is equal to 2 (points at the open statement) then it is 2 of course (points at the rectangle) /.../ If 7 times something is 42 then something is 6 (points at the chanting text). Here (points at the rectangle) we can see sixes, 7 pieces, 6 pieces of sevens, and 7 pieces of sixes, so ... hm, we stop here, and we move on to the presentations.

The teacher uses the whiteboard through instrumentalization, where using the whiteboard is a part of his utilization scheme. The use of the resource, the interactive whiteboard, forces instructions in the TRR resource book to be instrumented through the interactive whiteboard, leading to a transfer of the instructions. In this transfer, the chanting instructions themselves pass through unchanged. But, the inclusion of the arithmetic expression in the form of an open multiplication problem is an addition that does not conflict with the determinants. The omitting of the use of the large multiplication table (D3, D4), in favor of a single rectangle image, circumvents the idea of the 10-by-10 matrix as a support for pupils' reasoning. As a result, the gestural indication (D4) of how open multiplication problems can be solved using the big multiplication table (D3) will make the pupils less prepared for treating the word problem in the cycle, according to the preferred strategy (D2).

The second excerpt, starting at 03:10, displays a whole class discussion aiming to build on pupils' reasoning (D1). The teacher starts by asking a pair of pupils to come forward to discuss their work, from the lesson before. The pupils do not bring any work with them, because the teacher has beforehand created a slide for the whiteboard. He simultaneously displays the problem formulation at the top, and the pupils work, followed by three representations: the number line, a rectangular array, as well as the instructions from the TRR resource book (D2, D3). The teacher says:

Teacher: Can you explain what you have done? Tell us what you have done, and start with the number line. So, can you tell us a little about it?

Presenting pupil: We know that Pi has 30 cucumbers [the teachers encourage them with mmm] and if Pi has 5 then Nitty has ehh… Nitty had...I do not know...you…

The TRR resource book encourages open questions. Can you describe in your own words what you have done? But, the teacher's call to start with the number line deprives the pupils of the initiative. The pupils end up having difficulties telling what they have done, and how they reached their answers. The teacher moves on to leading questions, to guide the pupils:

Teacher: Hm, aha...help...if Pi has 5 (points at the number line), so how many did Pi have?

The pupils that have approached the whiteboard to describe how they worked with the problem (D1, D2) turn their attention to the whiteboard and say 5.

Teacher: Yes, and how do you know? It says here (pointing at the task formulation on the whiteboard)

The initiative has transferred from the pupils that should have been asked to describe their work in their own words, leading to a loss of fidelity to D1 and D2.

What follows next is that the teacher takes over the initiative and explanations more and more. The teacher uses the picture of the pupils' work on the interactive whiteboard, which enables him to draw and write on the picture when explaining. When it is time for writing mathematical expressions, the teacher leads the discussion, even more. At this stage, the teacher also involves the rest of the class (D1). The excerpt below is 10:43 minutes into the lesson

Teacher:	What kind of expression fits this one (points at a rectangle, $3 \cdot 6$). Now I want you in the audience to think as well. What fits that rectangle? What is the multiplication for this (points at the rectangular array)? You too are audience. Now you are an active audience (addressing a pupil) and so you have to think. Ehh
Teacher:	(points at the class) ... shshh ... (the teacher asks a pupil in the class for an answer)
Pupil in class:	3 times 6
Teacher:	Yes, why is that? (writes on the board $3 \cdot 6 =$)
Pupil in class:	It's 3 pieces of sixes
Teacher:	Because it is 3 pieces of sixes, sure. And how much is 3 pieces of sixes? (asks the presenting pupil)
Presenting pupil:	18
Teacher:	You remembered, great! Thank you for your presentation.

The teacher successfully led the pupils to reason about the properties of multiplication with the rectangles (D3). However, the fidelity to using pupils' productions and reasoning (D1) is low.

High fidelity can be traced in the teacher's document, the instrumentalization of the whiteboard and the choice to place the pupils' solutions projected on the board instead of having pupils posing their solutions on the static board. As a consequence, the teacher saves time, and the class can easily participate in the discussion since the written solutions are visible to everyone in the class (D1). Through the instrumentation of TRR, the teacher includes the rectangular array (D3) and open multiplication statements (D2) into pupils' worksheets and presentations.

Discussion

To examine a method for gauging fidelity, we have reported a single case study of a teacher with several years of experience in implementing TRR - a pedagogical innovation in the form of scripted teaching sequences. We examined the teaching by focusing on the concept of the document system from the theory Documental Approach to Didactics, DAD. The analysis showed adaptions of the highly prescriptive curriculum resource in the teacher's documents. Some adaptions retained fidelity to the determinates in the program theory's change model, while others led to less fidelity relative to the determinants. The two resources, the TRR resource book, and the interactive whiteboard shaped the document system. It is expected that when a teacher already has an established document including a particular resource (here: whiteboard) and a new resource (here: TRR resource book) is to be incorporated and joined with the previous resources, an adaptation takes place. This adaptation results in a new document including the use of both resources.

The teachers' utilization scheme involving the interactive whiteboard shaped the teaching. The teacher's instrumentalization of the interactive whiteboard on one hand strengthened the instrumentation of certain TRR determinants, for example enabling swift and easy presentation of pupil's work (D1). On the other hand, the usage of the whiteboard drives a tendency to reshape TRR instructions away from the instructions in the TRR resource book. One example is when the reference to the big multiplication table is replaced by the reference to individual rectangles that symbolize a particular multiplication. In principle, the transformation of the TRR chanting instructions (D4) to the whiteboard format could have been done as faithful instrumentation but ended up involving an adaptation of the TRR instruction, essentially breaking D4 as well as D2, by not presenting the big multiplication table (D3) as a resource in the problem-solving strategy (D2). The instrumentalization of the whiteboard can be said to affect the instrumentalization of the TRR resource book so that the resulting document system breaks some of the TRR determinants. The other example from our result section can be understood in similar ways.

A pure pro-fidelity stance could perhaps indicate a need to complement the printed TRR instructions with ready-made interactive whiteboard resources. Some teachers have asked us, developers, for such supporting resources. Despite our choice to present TRR in a highly prescriptive form, we are however worried that more specific resources could lure the teachers into a surface adaption of TRR, omitting the determinants. Instead, in line with Century and Cassata (2016), we think a pro-adaptation perspective is vital. The DAD framework provides a good basis for examining the nature of adaptations. In the presented case, we could for example conclude that some adaptions made were related to the mixing of resources. Since we know it is a relatively common practice to use interactive whiteboards, we can suspect that similar adaptions might be made by other teachers too. As developers, this is useful information since it might for example call for revisions of the teacher guides concerning how careful we describe the core features of certain figures or practices in the material.

A downside of the DAD-based analysis reported in this paper is that it is too extensive to carry out on a large scale. But even examining some distinct cases can inform us on why and how adaptations are made, as in this case. Through DAD analyses we can gain insight into the nature of the adaptions. We get a tool to distinguish between surface adaptions that do not interfere with the determinates in the change model from the program theory (Chen, 2012) and adaptions that violate core ideas of the innovation. The insights from the analysis give important feedback for future development of the professional development program that goes with the implementation, as well as the structured teaching instructions it builds on.

From ‘technical rationality’ and ‘reflective rationality’ to ‘societal rationality’

Konrad Krainer

University of Klagenfurt, Austria; konrad.krainer@aau.at

Keywords: Implementation, practice, research, policy, societal rationality.

‘Implementation’ as a challenge for policy, practice, and research

This contribution builds on Koichu, Aguilar, and Misfeldt (2021), who regard implementation as “an ecological disruption to a particular mathematics education system, through the gradual endorsement of innovation in conjunction with an action plan” (p. 986), and follows Willke (2005), who regards observation as noticing a “meaningful difference”, and intervention as “effecting” (generating, making) the “meaningful difference”, thus ‘implementing’ steps towards the desired situation.

Based on four examples, Krainer (2021) argues that the implementation of research, and its implementability, are dependent not only on researchers and on practitioners, but also on policymakers, too, in particular if scaling up is regarded as important. Writing a paper for a special issue on implementation-related research in mathematics education (see Koichu, Aguilar, & Misfeldt, 2021), reflecting on the long-lasting Austrian initiative IMST (which mainly aims at scaling up innovations in mathematics, computer science, science, and technology teaching), inspired the author to theoretical considerations on the interplay between policy, practice, and research in the IMST context. He describes two contrasting approaches related to implementation and implementability of research, namely ‘technical rationality’ and ‘reflective rationality’, and develops a third approach named ‘societal rationality’.

In the following, these three approaches are sketched for further discussion in the TWG.

‘Technical rationality’, ‘reflective rationality’, and ‘societal rationality’

‘Technical rationality’ was introduced by Schön (1983) and follows three basic assumptions:

- There are general solutions to practical problems.
- These solutions can be developed outside practical situations (in research or administrative centres).
- The solutions can be translated into practitioners’ actions by means of publications, training, administrative orders, etc.

In contrast to technical rationality, reflective rationality (e.g., Altrichter et al., 2008, p. 270), building on the notion of “reflective practitioner” (Schön, 1983), follows three very different assumptions:

- Complex practical problems require particular solutions.
- These solutions can be developed only inside the context in which the problem arises and in which the practitioner is a crucial and determining element.

- The solutions can only rarely be successfully applied to other contexts, but they can be made accessible to other practitioners as hypotheses to be tested in practice.

Comparing the strengths and weaknesses of these two approaches leads to the insight that the ‘meaningful difference’ (Willke, 2005) lies between the ‘general’ (main focus of ‘technical rationality’) and the ‘particular’ (main focus of ‘reflective rationality’). However, they should not be regarded as opposite, but as complementing each other. When implementations aim at spreading to a larger number of people, the perspectives of practice, research, and policy need to be included. All these stakeholders should be jointly co-responsible for a successful implementation. Therefore, a third approach, building on the strengths of the two mentioned approaches and on the societal dimension of this process, Krainer (2021) proposes ‘societal rationality’ as a third approach, following three alternative assumptions:

- Practical problems require an adequate link between general and particular solutions. The more complex the problem, the more important the particular.
- The solutions gain in quality if all concerned (including policy, research and practice) are involved in the problem definition and in the solution and evaluation process.
- The solutions can at best be partially applied to other contexts. Concrete examples, critical reflections, theoretical considerations, empirical findings, general guidelines, specific or general quality criteria can be used to adapt solutions context-sensitive.

Reflections on these approaches may lead to new questions and insights on teacher educators’ identity and professional growth (Krainer, Even, Park Rogers, & Berry, 2021).

Comparing the implementation of programming and computational thinking in Denmark, Sweden and England

Keywords: Programming, computational thinking, implementation, mathematical competencies

Background

The mathematical competencies that students need in the 21st century contain a sizeable digital element and include programming and computational thinking (PCT). Many countries are attempting to implement PCT in compulsory education (Bocconi et al., 2016), calling for a range of national and local decisions about the relation between mathematics and technology teaching. These decisions regard content, the group of teachers responsible, and the school subjects adopting PCT.

Different countries are investing massively in pursuing different paths relating PCT and digital mathematics. Still, there is currently no solid knowledge foundation on which decisions about these matters can rely. In some cases, PCT is considered part of mathematics. Others view it as part of an integrated science topic, a transdisciplinary element in all topics, or a subject in its own right.

The Danish government is experimenting with a two-tier strategy where PCT is both a subject or specialization and an approach integrated into subjects. In Sweden, programming has been a compulsory part of the mathematics curriculum from grades 1-9 to since August 2018. Here, PCT is strongly associated with algebraic thinking and the concept of algorithm. In the UK, programming has been part of the curriculum since 2013 as an individual topic, with an explicit dedication to algorithmic and computational thinking. Being a first-mover, the UK has solid experiences with the various challenges of implementing programming into compulsory school, including mathematics.

Approach

The so-called second wave of focus on PCT in compulsory education can be traced back to Wing (2006), who described computational thinking (CT) as decomposition, data representation and pattern recognition, abstractions, and algorithms. Building on Wing's definition, educational research has attempted to clarify and activate CT as a set of teachable competencies. This endeavour is often done by highlighting the relations to mathematical competencies such as abstraction, problem-solving, modelling and algorithm building.

To study the relation between mathematics and programming, we apply the Danish competencies framework (Niss & Højgaard, 2011) augmented with the notion of "Mathematical Digital Competencies (MDC)" (Geraniou & Jankvist, 2019). MDC involve "being aware of which digital tools to apply within different mathematical situations and contexts, and being aware of the different tools' capabilities and limitations" as well as "being able to use digital technology reflectively in problem-solving and when learning mathematics" (p. 43). It also entails "being able to engage in a techno-mathematical discourse" (p. 42), which we envision becomes crucial concerning PCT.

Besides giving theoretical meaning to PCT and MDC, we acknowledge the need to study implementation aspects, such as the lack of PCT-trained teachers and curricular compatibility. We relate to the work in implementation research in mathematics education (Koichu et al. 2021; Jankvist et al. 2021) to frame the inclusion of PCT as an educational innovation set to be put into practice.

Method and Plan

The project combines a comparative study of how PCT is integrated with mathematics teaching at the compulsory level in three countries with design experiments and the development of exemplars. To develop synergies between mathematics teaching and PCT in the Danish school system, we are in the process of comparing approaches and collecting resources from the three countries (mid-2020 to mid-2022). This work is described in Elicer and Tamborg (forthcoming). Based on these findings, we are planning design-based interventions to verify and refine our understanding of potential synergies between PCT and mathematics (early 2021 to early 2023). The refined teaching sequences and model of synergies will be developed as educational resources in the last part of the project (2023 and 2024).

When researcher and teacher talk past each other: an IR analysis

Maria Kirstine Østergaard[1,2] and Uffe Thomas Jankvist[2]

This paper discusses influential factors in an implementation of a longitudinal innovation based on results from research on beliefs, especially reflection, in mathematics education. As part of this innovation, the researcher constantly found herself to be "talking past" the involved expert teacher, who was responsible for implementing the innovation in the classroom. In particular, three influential factors appeared to play a central role in the case presented in the paper: characteristics of the particular end-user; attributes of the innovation; and not least implementation support strategies.

Keywords: Implementation research; influential factors; reflection; beliefs; probability.

Introduction

In a longitudinal study aiming to develop middle school students' beliefs about mathematics, the first author experienced that despite good intentions, long preparations, careful planning, and coaching of the involved teacher, the "reality" of what was implemented in class was far from the agreed-upon initially designed activities. We hypothesize that constructs from IR may shed light on this. Hence, our research question may be phrased as: *Can theoretical constructs from IR provide explanations as to why the researcher and teacher of our longitudinal study managed to talk past each other for a period of two years on the topic of 'reflections'? And if so, then in which respects, and to what extent?* With our answer, we hope to provide some illustration that IR may have something to offer the explanation of phenomena present in qualitative studies in mathematics education research. This paper thus addresses influential factors in relation to the implementation of designed teaching units to foster reflections with students concerning the nature of mathematics as a discipline.

IR theoretical constructs

When attempting, as in our longitudinal study, to change educational practices, the complexity of the setting fosters a variety of factors influencing the process, depending on both the characteristics of the innovation and the level of change (e.g. individual or organizational level). On an individual level—as in the case in this paper—a change in practice, e.g. for a teacher, can be both challenging and psychologically threatening, as well as cause doubts and uncertainties (Century & Cassata, 2016), even when the intended change might not seem difficult to its promoter. Other influential aspects might be the character of the innovation, environmental factors, support strategies, or time. Century and Cassata (2016) present a list of factors that might influence the implementation of an innovation. Here, we address and connect three of these in the analysis of the implementation in our selected case: *characteristics of end-users*; *attributes of innovation;* and *implementation of support strategies*.

The *characteristics of individual end-users* of an innovation (who in this case are the teachers, as we investigate the process of implementation of teaching principles) can potentially play a crucial role in an implementation process, not least in innovations that give room for the users' interpretations and adaptations. Prior knowledge, individual competency, professional identity, and feeling of agency are all examples of factors that might influence the implementation. In this regard, Rogers

(2003) mentions different types of knowledge connected to the implementation process, e.g. *how-to knowledge*, (practical knowledge about how to apply the innovation) and *principles-knowledge* (understanding the thoughts behind the innovation). Century and Cassata divide the characteristics of the end-users in two: (a) those related to the innovation, "e.g. level of understanding, expertise, prior experience, beliefs, values, attitudes, motivation, or self-efficacy" (p. 185); and (b) those existing independently of the innovation, "e.g. willingness to try new things, organizational skills, classroom management style, or views about teaching and learning in general" (p. 185).

Attributes of the innovation include both objective characteristics of the innovation (e.g. number of components or design features) and subjective user perceptions (e.g. relevance or ease of use). Some innovations are rather explicit, specifying the innovation in detail, which does not leave room for the users' adaptations. Others are more ambiguous and thereby more dependent on the interpretation and realization of the users.

Support strategies can be essential in an implementation process, and should according to Century and Cassata (2016) ideally be included in an innovation, based on underlying theories. Support to the users in their process of change can appear in various formats, e.g. professional development, strategic planning, or evaluative processes.

Setting the scene—the overall project and the central element of 'reflection'

Our two-year longitudinal study began in 2019 in two Danish 6th grade classes. The study used a Design-Based Research approach, involving two mathematics teachers in designing certain teaching principles, as well as in the implementation, evaluation, and adjustment of these principles in iterative cycles. The hypothesis behind the study was that a longitudinal change of focus in the teaching of mathematics can contribute to a change in the students' beliefs about mathematics—specifically that an increased focus on (1) the application of mathematics; (2) the historical development of mathematics; and (3) the nature of mathematics as a subject (Niss & Højgaard, 2019), can influence their beliefs about mathematics as a discipline. Hence, the main focus of the overall study is the development of students' beliefs, and not as such the teachers' professional development. However, as the present study addresses issues related to the implementation process within the overall study, the teachers thus become the focus here.

Philipp (2007) defines beliefs as "lenses through which one looks when interpreting the world" (p. 258). Because of the stability and psychological importance of beliefs, changing students' beliefs can be both difficult and time-consuming (Green, 1971). A central element in this process is *reflection*. Beliefs that are developed based on experiences or reason can be said to be *evidentially* held. In contrast, *non-evidentially* held beliefs are either transferred from others (e.g. teachers, parents, stereotypes, etc.) or derived from already existing beliefs, and these tend to be more difficult to change with reason. Non-evidentially held beliefs can often be illustrated as convictions of the sort that are impossible to argue against. Hence, when educating students, attention must be paid to providing examples and opportunities for experiences on which they can base and develop their beliefs to ensure that these are evidentially held. However, if such beliefs are to last, the provided evidence must necessarily be followed by reflection. Relations between beliefs are established when reflections are considered and assessed (Green, 1971), and these relations are what include and maintain beliefs in a cluster, hence making them more stable. "Reflection" thus played a central part in the study.

Even though the designed teaching principles were adjusted along the way, four main principles were consistent during the two years of intervention. That is, all teaching modules included: (1) concrete examples of the application and/or the historical development of mathematics; (2) mathematical problems and methods; (3) dialogue about the application, the development, and/or the nature of mathematics; and (4) *individual and/or shared reflection.* As Gregersen et al. (2019) point out, teachers' *principles-knowledge* can increase their experience of an innovation's relevance. The participating teachers were thus introduced to the importance of reflection in the initial phase of the study. The connection between changing beliefs and students' reflection was communicated in two ways: First, in a document stating the purpose of the intervention and the role of reflection when aiming to change or develop students' beliefs. The word "reflection" was highlighted and mentioned five times in the document to illustrate its centrality. Second, the document was discussed in a subsequent meeting between teachers and researcher, where the importance of reflection was further emphasized. In the following, we present an illustrative case of how one teacher attempts to realize the intended teaching principles, with a special focus on *reflection.* The case revolves around a lesson concerning probability that was planned in collaboration between researcher and teacher. We investigate three phases of the implementation process: planning, implementation, and evaluation. Thereby, we are able to compare the intention, the realization, and the teacher's considerations behind any deviations from the intention. The data include sound recordings of planning and debriefing sessions, as well as video recordings and field notes from the lesson. Furthermore, we include excerpts from a meeting six months prior to the lesson to illustrate the teacher's general considerations about students' reflections. In our analysis of the data, we apply the above-mentioned theoretical constructs from IR, thus seeking an explanation to the apparent miscommunication between researcher and teacher regarding the concept of reflection within the overall study.

An illustrative case of one teacher

Six months into the intervention, the teacher in our case explained how the teaching principle related to reflection had caused her to be "more systematic about individual and shared reflection, and what it can be used for". Although she had 20 years of teaching experience and was the school's mathematics counselor, she still felt that the principles, in general, made her more aware of her teaching choices. When the other participating teacher described her difficulties with implementing reflection, the teacher of this case even argued why reflection is important, and how she motivated her students to reflect:

> I have spent time in the class talking about short-term memory and remembering to bring it [the learned content] back to the working memory—you need to think about it and bring it back. And if you don't do that several times, the brain will toss it. (…) So there is a reason that we do it [reflect].

Hence, the teacher appeared to be conscious of the importance of reflection and its role in the project. However, she also gave a small hint of doubt, expressing that she was not sure that she was always able to transfer her intentions "all the way into the classroom". The following case, which confirms this doubt, took place six months later (a year into the intervention).

Planning: To ensure that the purpose of the intervention was met, the researcher participated in the planning of at least one lesson within every teaching sequence. In a sequence about probability, the topic of a 90-minute lesson was chosen to be the historical development of the field, exemplified in

Pascal and Fermat's approaches to solving the question of distributing stakes in an unfinished game of chance, as presented in a simplified version by Berlinghoff and Gouvea (2004). The problem concerns a game of flipping a coin for two players. Each player stakes €10 and tosses the coin in turn. If heads, the player tossing the coin gets a point; if tails, the other player receives a point. The winner is the first to reach three points. However, the game is interrupted, when the score is 2-1 in favor of the player about to toss the coin, and the distribution of the €20 stakes is to be decided. The planning of the lesson was based on Chapter 21 of Berlinghoff and Gouvea (2004, p. 207-214): "What's in a Game? The Start of Probability Theory". This chapter describes the story and the mathematical theory behind the problem as well as the methods used for solving it. Since both teachers had expressed some doubts about how they could implement the teaching principle concerning reflection, it was agreed that the students' considerations, suggestions, reflections, and discussions should be the focus of the lesson. Space for reflection would be given in the students' discussions of each other's solutions, and the relation to the solutions of Pascal and Fermat. Our teacher expressed her intention to "let the students consider a solution themselves", with the purpose of allowing them to "experience frustration and give their contributions". She also suggested that part of the students' reflections could regard the validity of the methods presented by Pascal and Fermat. She wanted to engage the students in the role of experts to act as mathematicians by showing them that some of their considerations and conjunctions could be compared to those of Pascal and Fermat. After an exchange of ideas, the lesson was planned to include five activities, which are listed below. Each of these activities was thoroughly discussed, both in regards to the content and the purpose in relation to the goals of the lesson. Several activities relied on the mentioned book chapter, and thus the teachers should make themselves familiar with its main points, especially regarding the mathematical methods involved.

Implementation: Below, the five activities of the 90-minute lesson are described in terms of the content of each activity, the intention decided by the teachers and the researcher in the planning process (purpose), and the actual realized implementation (reality).

<u>Activity 1:</u> Presentation of game, the distribution problem, and Pascal and Fermat. Told as a story.
<u>Purpose:</u> Engaging the students by telling a story, and inviting them to "play along". Introducing the historical persons involved, and inviting the students to consider a distribution of the stakes.
<u>Reality:</u> The teacher told a story about a rich, French, 17th-century nobleman, who liked to gamble. Concept of 'stakes' and rules of the game was explained. Pascal and Fermat were never mentioned.

<u>Activity 2:</u> In pairs, the students play the game and consider the distribution of stakes. Coins are available. The pairs present their suggestions. Subsequently, pairs with deviating solutions are put together in groups of four, who discuss their suggestions and try to agree on a shared solution.
<u>Purpose:</u> Becoming familiar with the game and the problem. Expressing immediate suggestions for a solution, which might involve discussion and argumentation. Considering possible scenarios of the outcome of the game, leading to mathematical considerations. Making the students reason and argue by pairing groups with different solutions.
<u>Reality:</u> Handed a wooden coin and eight pieces of paper (money bills working as stakes) on which they could write the number 10, the nine pairs of students played the game four times. After a while, the teacher stopped the games and asked the class if they believed this game to be fair. Several students complained that their coin always landed on the same side. However, the teacher neither engaged in a dialogue about the concept of fairness, nor what such a bias would mean in regards to

the game. Instead, the students were asked to play again and stop when one player had 2 points and the other 1—and then discuss how the stakes should be distributed if the game could not be completed. The students did, and the teacher circled between them asking guiding questions: “How is your distribution fair?”; “Would you both be satisfied with that solution?”. She noticed that most pairs either assigned all the stakes to the player with 2 points, or shared the stakes evenly, and she stopped the students. When asking each pair for their solution, this tendency was affirmed. Even though the teacher asked questions that might make the students reflect on probability (e.g. “Who has the largest chance of winning?”), they never engaged in any mathematical consideration. The teacher asked them to play again, this time stopping when the points were even. Expectedly, they found the distribution easier now that the probability of winning was equal for both players, which was pointed out by the teacher. She now encouraged the students to have a “serious discussion” about the distribution in the case of 2 points versus 1, making them aware of the possibility to exchange the €10 bills. The pairs were sent on a 2-minute “walk-and-talk”, which should result in an agreed solution to put on the whiteboard. Thereby, the original intention of putting pairs together with different solutions was never realized. Neither was the intention of having the students prepare a mathematical argument for their solution.

Activity 3: Presentation of solutions, the arguments behind them, and the strategies to reach them.
Purpose: Having the students explain their suggestion for a certain solution, and the method for reaching it. Comparing different solutions and different methods and arguments. Including arguments and strategies behind the solutions to emphasize that reasoning and methods are important aspects of mathematics, which are needed to make well-informed and accurate decisions.
Reality: The students put their solutions on the whiteboard. Out of nine pairs, four suggested that the €20 were distributed evenly, four suggested a 15-5 distribution, and one suggested that ⅔ of the money would go to the player with 2 points. The teacher merged the last suggestion with the 15-5 solution and asked the class to explain why this solution was fair. One student answered: “Because the player with the most points should have the most money.” The teacher asked for an argument behind the 10-10 solution, and another student answered: “Because they have equal chances of winning”. The teacher questioned this by drawing the students’ attention to the minimum number of tosses needed for each player to win. Another student exclaimed: “The chances are not equal, because one player has a 75% chance of winning, and the other has 25%”. Unfortunately, the teacher did not elaborate on this rather clever observation, although it appeared an excellent opportunity to engage in mathematical considerations. Neither the mathematical argumentation nor the strategies to reach a solution were discussed.

Activity 4: Shared classroom reflection: can we all agree on a solution? Which methods did we use? Were some solutions, methods, or arguments better than others? Which methods did Pascal and Fermat use? Did they resemble our methods?
Purpose: Comparing and discussing the solutions and arguments from the presentation. Offering the students an opportunity to reflect on their process and the mathematical ideas behind the different solutions as well as the validity of a mathematical argument. Placing the problem and their ideas in both a historical and a mathematical perspective by comparing the methods used by Pascal and Fermat. Illustrating the character of mathematical methods, and that the students too can engage in problems that mathematicians struggled with.

Reality: This activity was not realized in any way.

Activity 5: Follow-up on the historical development of probability theory.
Purpose: The work of Pascal and Fermat is considered one of the initiators of probability theory, soon followed by theories about e.g. the Law of Large Numbers, expected outcome, and analytical theory of probabilities. All of which are now applied in many fields such as medicine, insurance, business, law, etc. Making the students aware of this development and the importance of the field that sprung from the problem that they had just worked on, inserts mathematics in a context that exceeds school and illustrates its role in the world.
Reality: The teacher returned to the story of the French nobleman, who actually met this exact problem and asked "some mathematicians". Pascal and Fermat were still not mentioned by name. Their methods and solutions were only mentioned as follows:

> What they came up with was actually some of what you suggested. Their solution is 15-5. Because there is a difference in the players' chances of winning. They reached their solutions in a slightly different way as you reached yours differently. And they were great mathematicians (...). And you were also able to do this. And this was the beginning of the kind of mathematics that deals with probability.

Hence, the intentions of comparing the solutions and methods of both each other and of Pascal and Fermat were never realized, despite being the main goal of the lesson. The mathematical content was neither presented nor discussed, and the historical significance was only mentioned in bypassing. Most unfortunate was that the students were not offered the intended opportunities for reflection.

Evaluation: After the lesson, the teacher expressed that the class was not used to working in such an "unstructured manner", and neither was she (not specified any further, though). She also admitted that she did not thoroughly read the chapter on probability. This may be the reason for the lack of mathematical content in the lesson. However, after a suggestion from the researcher, the teacher presented a mathematical argument for the 15-5 solution in a lesson four days later, by studying the possible scenarios if the game had been continued. In the subsequent debriefing, the teacher described her criteria for success in the lesson: "that the students are able to say 'we have conducted an investigation, and it seems that…'". Even though all the pairs did reach a conclusion during the lesson, the teacher appeared somewhat unsatisfied. She appreciated having a story to start from but felt that it was difficult to get the students to use mathematical argumentation. Furthermore, she regretted not making the students aware of the possibility of exchanging the bills earlier: "It was not until I told them that the bills could be exchanged that they started thinking about it. If they had received ten €1 coins instead, I wonder what might have happened." She never addressed the skipped activities of reflection, nor the lack of the historical dimension. Her considerations—and the researcher's observations—formed the basis for a discussion on how the students could be supported in their argumentation so that it could be more mathematically founded.

Analysis and discussion of case in terms of IR

Characteristics of end-user: There appeared to be a discrepancy between the teacher's characteristics in relation to the innovation and those existing independently of the innovation. The teacher was an expert teacher, with a strong professional identity. She often advised her colleagues on mathematics teaching and learning. Concerning the innovation, she was highly motivated and perceived the innovation as relevant, both for her teaching and in her professional development. Her statements in the planning phase indicated that she was very aware of the innovation's intention and that she had a clear idea of how this intention was to be implemented. Our case, however, reveals that even though she possessed this *principles-knowledge* of the innovation, she might not have had adequate prior experience with the intended teaching approach, and thus her *how-to knowledge* was insufficient. Furthermore, her comments during the evaluation phase may be a sign that her identity as an expert teacher was threatened by the uncertainties and doubts that she experienced during the lesson. The fact that she did not mention the skipped activities of the lesson plan, which primarily involved reflection, seemed to indicate that she was not as aware of this purpose, contrary to what she expressed during the planning. Yet, it could also be a sign of denial of a feeling of failure or inadequacy.

Attributes of the innovation: As the innovation was based on a small number of somewhat general principles (cf. above), the level of explicitness was quite low. Hence, the implementation of the principles was highly dependent on the interpretation and realization of the teacher, requiring a high level of *how-to knowledge*. This meant that the final and determining decisions in the classroom were in the hands of the teacher, and thus became the realized innovation. Despite the shared planning of the presented lesson (supporting the teacher's *how-to knowledge*), and the regular discussions regarding the centrality of *reflection* for the development of beliefs (*principles-knowledge*), the teacher still decided to leave out the activities offering possibilities for the students to actually reflect. Furthermore, to promote the teacher's feeling of agency in the innovation, the allocation of contributions was that the researcher would primarily function as a theoretical expert and the teacher as an expert on practice. Consequently, the teacher was responsible for the detailed planning and preparation of lessons. On the one hand, this enabled her to adapt the teaching to her individual approach and to the students. On the other hand, the researcher had even less control of the actual implementation of the innovation, and the risk of non-intended realization increased (significantly).

Implementation support strategies: As suggested by Century and Cassata (2016), several theoretically based formats of support were included to assist the teacher in the implementation process. For example, the 'whys and hows' related to the concept of reflection were thoroughly discussed to enhance the teacher's *principles-knowledge*—a strategy that seemed to benefit their experience of relevance, as seen in Gregersen et al. (2019). These support strategies were further developed during the study. Central to the cooperation between researcher and teacher was the shared planning and evaluation sessions. In our case, the planning not only included discussions and clarification of focus and main purpose of the lesson (*principles-knowledge*), but also a description of the lesson's activities and their individual purpose (*how-to knowledge*). This kind of detailed planning had not previously been conducted in cooperation with the researcher, but an increased awareness of the challenges connected to the implementation had led to this initiative from the researcher, which was welcomed by the teacher. Likewise, the described case became the cause of further adjustments of the support strategy, eventually including shared preparation and considerations of potential student responses and appropriate teacher reactions.

When these three influential factors are compared and connected, interesting issues related to the implementation process are revealed. Firstly, the attributes of the innovation define the teacher as an expert on practice, thus making her responsible for the realization of the intention. However, the characteristics of this specific teacher make this realization unpredictable. In addition, the support strategies intended to account for this problem are complicated by the allocation of expertise between the teacher and the researcher. A possible dilemma occurs when deviations from the intention that are observed in the teaching are to be addressed in the evaluation. It is, on the one hand, essential to the success of the innovation that the intention be realized. On the other hand, the communication between researcher and teacher must remain respectful of their respective areas of expertise while at the same time supporting and benefiting future cooperation and innovation. Addressing problematic issues related to practice thus becomes a difficult act of balance. In this case, the evaluation session led to adjustments in the support strategy that increased the explicitness of the innovation, thereby changing its attributes and affecting the level of the users' autonomy. Studying the influential factors of this case clearly illustrates that the attributes and overall goal of this innovation may to some extent be incompatible. The goal of developing the students' beliefs through teaching principles may demand a *change* that is too ambitious in terms of *the culture of practice*—the influence of which was at first hand underestimated by the researcher. For example, this case shows how the implementation of opportunities for reflection is hindered by a gap between the intentions of the researcher, the apparent intentions of the teacher, and what is practically possible within the context of the culture of practice and the teacher's *how-to knowledge*. Returning to the research question, it is clear that IR constructs do have something to offer our qualitative case study in terms of explanatory power to the lack of mutual understanding between researcher and teacher. The IR analysis made it clear that when the innovation is not specific or explicit enough, then the implementation of it is proportionally dependent on the characteristics of the end-users. This should be dealt with both in the innovation design and in the support strategy.

Developing an instrument to connect problem-posing strategies and mathematical habits of mind

Nafsika Patsiala[1] and Ioannis Papadopoulos[2]

[1]Aristotle University of Thessaloniki, Greece; npatsiala@eled.auth.gr

[2]Aristotle University of Thessaloniki, Greece; ypapadop@eled.auth.gr

Successful problem posing is heavily based on the ability to see and use the structure of the given problem. Therefore, the students must develop the mathematical habit of mind of 'seeking and using structure'. Up to now, these two areas of problem posing and mathematical habits of mind are examined separately in the relevant research literature. In this paper, we present an instrument that attempts to bridge these two areas. The instrument monitors the student's problem-posing strategies and assigns a numerical weight in the solver's choices according to how powerful they can be considered from the mathematical point of view. Finally, some suggestions for the instrument's implementability in the research, mathematics teachers' education, and classroom settings are made.

Keywords: Problem posing, habits of mind, structure

Introduction

Problem posing is gradually gaining more attention in both the research community and in school daily practice in mathematics. Since one can find more than one definition in problem posing (Papadopoulos et al., in press) we choose in this paper to align with Silver's (1994, pp. 19) definition who sees problem posing as "both the generation of new problems and the re-formulation of given problems". Cai et al. (2015, pp. 4) mentioned that "despite the interest in integrating mathematical problem posing into classroom practice, our knowledge remains relatively limited about the cognitive processes involved when solvers generate their own problems, the instructional strategies that can effectively promote productive problem posing, and the effectiveness of engaging students in problem-posing activities". So, to go deeper into how students generate their own problems, we shift our attention to the mathematical habit of mind (HoM) called *Seeking and Using Structure* (Goldenberg et al., 2015) since the essence of the successful problem posing is the ability to recognize and use the structure of the given problem. Despite Silver's (2013) acknowledgment that it is worth measuring the development of certain mathematical dispositions or habits of mind, these two areas of mathematics (e.g., problem posing and habits of mind) have not been connected yet. To meet this challenge, we attempt (as a part of a broader study) to develop an instrument to monitor the students' development of the habit of mind called *seeking and using the structure* through their effort to pose new problems. We aim to show its future implementability in the research, teachers' education, and classroom settings.

Literature review

The theoretical underpinning of the design of this instrument lies in the realms of both the notions of *structure* and *mathematical habits of mind*. Understanding the structure of mathematical problems is considered critical in problem solving and posing. According to Mamona-Downs & Downs (2005) "structure can be thought of as a unity […] but it also offers access to its 'parts'[…]. Hence, a structure has simultaneously a global aspect and an analytic one" (p. 390). Schoenfeld & Herrmann (1982) claim that problems can be perceived by the solvers on the basis of *surface structure* which refers to the items described in the problems themselves or of *deep structure* which refers to the mathematical principles necessary for a solution. A correct perception might lead to a straightforward solution whereas an incorrect one may send the solver on a "wild goose chase". Moreover, it is supposed that the solver does not have easy access to a procedure for solving the problem but does have an adequate background to make progress on it.

Problem posing activities are cognitively demanding tasks (Cai & Hwang, 2002) requiring students to think differently than in problem-solving to improve their understanding by reflecting on the deeper structure and goal of the task. In relation to the structure of the problem-posing situations, Stoyanova and Ellerton (1996) describe three problem situations: free, semi-structured, and structured. Moreover, Ellerton (2013) in her Active Learning Framework (ALF) aiming to incorporate problem posing in primary school mathematics, claims that students are actively involved in posing problems with similar structure to given ones but in a different context. Kwek (2015) tried to identify patterns in students' mathematical learning and thinking during classroom-based problem-posing tasks. The findings gave evidence that the students' ability to identify the mathematical structure of the problem was a vital cognitive factor.

In our work, we define mathematical habits of mind as considering mathematical problems in very specific ways that look like the ways mathematicians use. It is about a way of thinking -almost a way of seeing a particular situation- that comes so readily to mind that one does not have to rummage in the mental toolbox to find it (Goldenberg et al., 2015). One habit particularly important for problem posing is the habit of *seeking and using structure*. In the context of solving and generating problems in early mathematics, the notion of mathematical structure concerns relationships between quantities, group properties of operations (e.g., associative and/or commutative operation), relationships between the operations (e.g., distributive property of one operation over another), relationships across the quantities (e.g., transitivity of equality) (Warren, 2005). Therefore, the development of the habit of *seeking and using structure* helps the students to see the logic and coherence in every new situation they encounter. Both, the identification of the information in a given problem that would be suitable to generate a new problem and posing questions that fit a particular situation are strong signs that students can see and use the problem's structure. The *seeking and using structure* habit has been recently investigated in other settings. Papadopoulos (2019) examined the potential contribution of puzzle-like activities in exhibiting this habit in the context of early algebraic thinking in primary school students.

Given that this habit is considered vital for successful problem posing and is developed through an accumulated experience with problem-posing activities we attempted to develop an instrument that would capture the relevant students' ability.

An implementable research instrument

According to our knowledge, the only instrument related to habits of mind is the one developed by Matsuura and his colleagues (2011) to measure secondary teachers' mathematical habits of mind in problem solving. It contains items rooted in familiar secondary mathematics and is for use for research purposes only. Inspired by this tool, we tried to think and design an instrument related to problem posing that would be based on the different problem-posing strategies used by the students. The application of such strategies is considered an indication of *seeking and using the structure* of a given problem since problem-posing strategies are heavily based on the use of the structure of the given problem. The whole effort of designing this instrument followed a series of certain steps.

Step A – Collecting strategies from the existing literature

The first step was to follow the literature to collect the suggested problem-posing strategies. This step resulted in the following collection:

Reversing known and unknown information: This strategy (also known as the 'symmetry' strategy) is one of the most common and frequently met strategies in mathematics textbooks. The answer to the original problem would now be part of the given data and some of the given information would be the unknown (Grundmeier, 2015).

Change the context: The structure of the original problem is kept but the original context is changed. Ellerton (2013) said that the process of designing a different context for a problem that has a similar structure to the given problem proved to be challenging for most students.

Change numbers: The students change the numerical data of the original problem to create a new one keeping the structure unaltered. Depending on the nature of the change, the new problem could be either similar or interestingly different from the original one.

Change the question: The data of the original problem remain the same, but the question is removed and replaced with a different question that could fit the given data (also known as the 'goal manipulation' strategy).

The answer is a method: The original question remains the same, but the numerical data are left off. The potential solvers will have to find how they'd solve the problem if the numbers were known, which means to find the method to solve the problem (Goldenberg et al., 2015).

"Frontless" problems: Only the question is retained. In that way, these questions are in many senses as close to real-life as we can get. So, the question comes first, and then we have to figure out the information and the method we need (Goldenberg et al., 2015).

Missing middle problems: The original question is kept but some numbers are left off and the solvers are asked to find what additional information would be required to answer the question (Goldenberg et al., 2015).

"Tailless" problems: In this case, the question at the tail end is omitted. The goal is for the students to derive what they can from the given information. It looks similar to the *Change the question* strategy. However, in the former, the question of the initial problem has already been substituted and the aim for the student is to solve the new problem. In the latter, the problem is left open and the aim for the solver is to think: what information is here and what can I do with it? (Goldenberg et al., 2015).

What-if-not: This is the most known strategy in problem posing (Brown & Walters, 1983). According to this, we form a list with all the problem's attributes and then we start negating each one of them using the what-if-not questions which means to ask what would happen if these attributes were different. Each negation results in a new problem. This strategy allows students to discuss a wide range of ideas and dive into the structure of the problem.

What-if-yes: A variation of the "What-if-not" strategy is put forward by Leikin and Grossman (2013) and Grundmeier (2015) based on adding attributes and/or properties to the given problem instead of removing or negating them.

Step B – Forming the instrument

In the second step, we contacted experts in the area to evaluate these strategies in relation to how powerful from the mathematical point of view can be considered. There were three options for each strategy (A, B, and C, from the most powerful to the less one). Eight experts from the USA (2), Germany (2), Hungary (2), France (1), and Greece (1) participated, and their answers were combined to form the final categorization in Table 1. Each problem posed by students can now be labeled as A, B, and C according to the strategy used. In case no strategy evidence is present at the students' answer the proposed problems is labeled in category D.

Measuring the *seeking and using structure* HoM	**Category**
The answer is a method	A
What-if-not	
What-if-yes	
Change the context	
"Frontless" problems	B
Missing middle problems	
"Tailless" word problems	
Change the question	
Change numbers	
Reversing known and unknown information	C
Change numbers	
No evidence	D

Table 1: Problem posing strategies

The *Change numbers* strategy is included in two groups according to whether this change results in a similar problem or another open or more mathematically interesting problem.

Step C – Instrument's exemplification

The third step of the process was to exemplify the instrument using a specific given problem. The following problem will be used to generate new problems using the above-mentioned strategies: *Every day I save 50 c. to buy a book which costs 8.50 €. How many days would it take to save that amount of money?*

Below we present how this problem could be reformulated or a new problem could be generated using the above-mentioned strategies.

Reversing known and unknown information: The answer to the initial problem is 17 days ($8.50 \div 0.5 = 17$). This information will be part of the given data so that the given and the goal will be swapped. The new problem is: *For the next 17 days I will save 50 c. per day to buy a book. How much does the book cost?* (Type C).

Change numbers: Depending on the way this strategy is applied it might be possible to have different problems of different weight. The new problem could be a simple one, in which the student simply mimics the original one by changing numbers (example a). But there are cases (example b), in which the new problem still resembles the initial one, but the new numbers may lead to interesting situations.

a. *Every day I save 20 c. to buy a book which costs 6.20€. How many days would it take to save that amount of money?* (Type C)
b. *Every day I save 1€ to buy a book which costs 8.5€. How many days would it take to save that amount of money?* (Type B)

This second example leads to an interesting situation. How long does it take me? 8.5 days? Or 9 days?

Change the question: The challenge here is to find another question that fits the already given data. Example: *Every day I save 50c. to buy a book that cost 8.5€. What is the smallest number of coins I need to buy the book?* (Type B)

"Tailless" word problems: The question at the tail end is omitted and the problem is open for statements or questions. For example: *Every day I save 50 c. to buy a book which costs 8.50€. What can you figure out from this information?* The absence of the question also helps kids notice that more than one sensible question could be asked. For example: "Will I have enough money in two weeks?" (Type B)

Missing middle problems: The original question will be the same, but some numbers will be left off. The missing number is part of the required information that is not given. This number is not the answer to the question the problem poses but it is necessary to solve the problem. Example: *Every day I save some money to buy a book which costs 8.50€. How many days would it take to save the amount of money I need?* (Type B)

"Frontless" problems: Only the question is retained. Clearly, the question can't be answered without information, and we must then figure out what information we need and what method we must use to answer. An example: *There's a book I want to buy. How many days will it take me to save up the money I need? What information do I need to know in order to figure this out?* (Type B)

Change the context: This strategy is indicative of a deep understanding of the problem's structure. The core idea remains the same, but it is transferred in another setting (e.g., from coins and their relations to numbers and halves): *How many halves do I need to get 8.5?* (Type A)

The answer is a method: The required answer is a description of how the problem would be solved if there weren't numbers. Example: *Every day I save the same amount of money to buy a book. How can I figure out how many days it will take me to get the amount of money I need?* (Type)

What-if-not: One attribute of the given problem is that a certain amount of money per day is saved. So, **what if** that amount was **not** saved per day but, for example, every three days? The new problem becomes: *Every three days I save 50 c. to buy a book which costs 8.50€. How many days would it take to save that amount of money?* (Type A)

What-if-yes: An additional information is added which has an impact on the solution process. For example: *Every day I save 50c and I share this amount fairly with my brother. How many days would it take me to buy a book which costs 8.50€?* (Type A)

Step D – Use in a real case study

The final step for the instrument is to use it in a real case study. There is a pilot study running this year. The aim is to gradually familiarize the students with this range of strategies in problem posing to see later whether they can use some or all of them in different problem-posing situations. The sessions start with problem-solving activities and then the students are asked to generate new ones inspired by the solved problem. To be successful they need to see the structure of the problem and apply those of the problem-posing strategies that fit the given data. Their problems will be collected and categorized according to the strategy they used. A score will be assigned to each student according to the produced problems and the type of strategies used. This score assigned does not determine the extent to which the habit of *seeking and using structure* has been developed by the specific student. It rather serves as a way to monitor the efforts done by the student to notice whether advanced problem-posing strategies are used over time.

Concluding remarks

This paper aimed to present an instrument we developed to record and examine whether students develop over time and through an accumulated experience on problem posing the habit of mind named *seeking and using structure*. The instrument works on the basis of the problem-posing strategies the students use. The more they use advanced problem-posing strategies (e.g., types A and B), the more they seem to have developed the *seeking and using structure* HoM. We see the potential implementation of this instrument in the sense of 'if and how the innovation achieves desired outcomes for the target population' (Koichu et al., 2021, p. 978). This problem-posing intervention is the innovation that constitutes the object of implementation (Century & Cassata, 2016) aiming to develop structure-sense to students. The instrument will help to determine whether the expected results are produced in the target population. So, from this point of view, researchers' understanding of the issue of problem-posing strategies that effectively promote students' structure-sense which finally result in productive problem posing (Cai et al., 2015) will be deepened. Further insights into the relationship between problem posing and the habit of seeking and using the structure of the given problems will be gained. The instrument can also be useful in the context of educating future mathematics teachers. They need to be familiar with problem-posing strategies, recognize the structure of a problem, and use it to formulate new problems. This starts from the fact that future mathematics teachers very often-and in relation to problem posing- emphasize the result instead of the process (Klinshtern et al., 2015). However, it is the latter that is closely related to the notion of structure. So, it is important to shift their attention from the result to the process. The instrument will be useful to monitor the potential development of the *seeking and using the structure* HoM. Finally, the instrument might also be useful for in-service teachers. Following the whole classroom or each one of their students across the school year using this instrument, they will have the chance to identify any progress in the development of the habit of *seeking and using structure*. The variation in scores over time will facilitate the understanding of the students' crucial ability to see and use the structure of a given problem situation.

What is the most important however is that this instrument is bridging two areas, problem posing and mathematical habits of mind, that are still unconnected. Our long-term aim is to use this instrument to follow a primary school classroom in a year-long intervention in the context of a problem-posing intervention.

This paper concerns what a successful implementation of an innovation in mathematics education can be and how that can be achieved. Focus is on sustainability of an innovation and the role of textbooks. We use two historical Swedish development projects in mathematics education for the discussion. The material is official reports and governmental documents concerning the projects.

Keywords: Implementation, sustainability of an innovation, textbooks.

Introduction

This paper is part of the project *Implementation research as an emerging field of mathematics education*. The project's aim is to create a theoretical framework for implementation research (IR) in the field of mathematics education research (MER), in particular for research on large-scale development projects. The overall project examines which existing IR theories and which parts of these are applicable to implementation and development projects related to mathematics. To verify this, we test the theories and related concepts that we find relevant through comparisons of five development projects.

This paper concerns two of those projects—New Math and PUMP[1]—and the aim is to understand how the concept of *sustainability*, a key IR concept, is applicable in MER. This concept is essential for how to conceive what a successful implementation of an innovation is. The analysis is focused on textbooks, since that is a characteristic of school subjects. Textbooks also involve a type of stakeholders—publishing companies— that we do not find in many other subfields of IR. Our research question concerning the New Math and PUMP projects is: *What was the role of textbooks in the implementation process, and how were textbooks related to efforts of sustaining or maintaining an innovation?*

Previous research

In their overview of IR on large-scale innovation, Century & Cassata (2016) identify a number of factors that influence whether an implementation of an educational innovation is a success or a failure. In what respects an implementation is a success can be understood in different ways. One way is to consider outcomes in terms of student results or changed behaviours of teachers or students. However, there are two other aspects of success, which the outcome perspective is

[1] PUMP = *Processanalyser av Undervisning i Matematik/Psykolingvistik* (Process analyzes of Teaching in Mathematics/Psycholinguistics)

depending on. One aspect is *fidelity* to the innovation or the reform program. That is, to succeed in getting a great number of teachers to use the innovation as planned. The rationale is that teachers need to apply the innovation as planned, if it is to make sense to talk about positive or negative effects on outcomes. The second aspect is to succeed in getting the teachers to apply the innovation for a long time, or at best, forever. In that perspective a successful innovation endures. The rationale here is that positive effects are pointless if the innovation does not endure.

These two other aspects or perspectives on success can to some degree be conflicting. One way to obtain endurance is to have innovations that allow for adaptions to local and changing circumstances over time. Such innovations are then considered sustainable. However, adaption is in conflict with fidelity. In a fidelity perspective, endurance is then a matter of maintenance in order to preserve the innovation. The weakness of that perspective is that the context of an innovation can and do change, which means that adaptions may be necessary.

This paper concerns factors and conditions that may contribute to innovations in mathematics education (ME) becoming sustainable or maintainable for longer periods of time.

The overview of Century & Cassata (2016) is efficient as it guides us to essential issues in IR, for instance the ideas concerning sustainability. However, it is not possible to discern if there are certain factors or conditions that are more or less relevant to achieve sustainable or maintainable innovations in different areas. Neither is it clear in what respect textbooks and publishing companies constitute factors or conditions that facilitate or inhibit successful implementation of an innovation. A similar problem we find also in the publications Century & Cassata (2016) refer to. Regardless of field—for instance mathematics education (Clements el al., 2015), kindergarten (Lieber et al., 2009), positive behaviour support (McIntosh et al., 2013), sex education (Rijsdijk et al., 2014), and science education (Century & Levy, 2002)—the researchers apply concepts and theories from IR as if they were applicable in all fields. Some of them do address the role of textbooks or other teaching materials to obtain sustainability (Century & Levy, 2002; Lieber et al., 2009; Rijsdijk et al. 2014), but others do not.

In some cases, such as positive behaviour support (McIntosh et al., 2013), it seems natural not to include textbooks and other teaching materials as a factor for obtaining sustainability; the teachers in the McIntosh et al.'s (2013) study were supposed to follow a certain program for positive behaviour support and it did not concern the teaching of school subjects. In the other extreme, we find mathematics education and science education. These are contexts where textbooks have existed for a very long time and should not be considered non-essential parts of the teaching practices. However, only Century & Levy (2002) address the role of textbooks, in science education, not Clements el al. (2015) in their paper on mathematics education.

Our contribution to previous research is about deepening the understanding of how textbooks can be managed in different ways in development projects to sustain or maintain innovations. In particular, we are interested in how project managers or reformers tackled the publishing companies. These companies must be considered stakeholders in educational reform processes as their existence rests on teachers and schools buying their products. Moreover, we should not assume that the purpose of an innovation coincides with the interests of publishing companies.

Theory and method

Our analysis of strategies for obtaining sustainable or maintainable innovations is based on Coburn's (2003) theory of scaling up an educational reform, which in our view also includes implementation of innovations. According to Coburn (2003), scale comprises four interrelated dimensions: depth, sustainability, spread, and reform ownership.

Depth concerns in what respect teachers change beliefs, norms of social interaction, and pedagogical principles. This is in contrast to so-called superficial changes such as changes in materials, classroom organization, or the addition of specific activities.

Sustainability concerns time and schools' ability to make innovative changes to remain in the teaching practice. This often means allocating tools and resources (e.g., financial, staff, and administration) for that end. In our analysis, we also use the concept *maintenance* in order to capture different ways to make an innovation endure, see previous section.

Spread is what traditionally is associated with scaling up. The implementation of an innovation is scaled up when an increasing number of classrooms and schools get involved.

Reform *ownership* is a matter of external reformer handing over control to districts, schools, and teachers. Or more precisely "creating conditions to shift authority and knowledge of the reform from external actors to teachers, schools, and districts".

By our study, we want to supplement Coburn's (2003) theory by relating textbooks and other teaching materials to the four dimensions just mentioned. We argue, from a theoretical point of view, that textbook and teaching material can be involved in the four dimensions in a substantial way. As to *depth*, textbooks and teaching material are designed according to some pedagogical principle; explanations and exercises are not developed and organised at random. Thus, using a textbook is then a matter of applying that principle. Innovations brought by textbooks are then sustained or maintained by publishing companies, not just school authorities. As to *spread*, that is the raison d'être for commercial publishing companies. Nobody has to remind them of that. And a textbook can give more or less *ownership* to teachers.

An important point is that school authorities, which often initiate and drive reforms, and publishing companies, can have different interests. And those interests may be in conflict with each other. Our assumption is that if you try to scale up the implementation of an innovation and make it sustainable, the chance of success is affected by the extent to which you work with or against publishing companies. And if you are not working with them, it can be a good idea to have a strategy of managing potential conflicts and fending of companies.

In our analysis, two development projects are compared. For each project we identify a strategy for managing textbooks and publishing companies and each strategy is tied to an aim of sustaining or maintaining innovations. The analysis includes Coburn's (2003) other three dimensions of depth, spread, and ownership. The materials are official reports and governmental documents concerning the development projects and to minor extent communication with people involved in the projects. The material has been treated as narrative sources concerning what intentions people had and what happened during the development and implementation of innovations. None of the sources contain an explicit strategy for managing textbooks and potential conflicts with publishing companies. But some sources do concern textbooks, quite a lot and very explicitly in fact, and we have then sought to identify how the treatment of textbooks gave the reformers an advantage over publishing companies. As to the New Math project, we rely on findings presented in already published studies. But the studies are also based on official reports and governmental documents.

New Math project (1960–1975) and the role of textbooks

If we consider the plans for the New Math reform in Sweden, it contained a lot of innovations that altogether were deep. By far, it was not a matter of adding sections of set theory in some school years. On the contrary, it was a matter of providing new principles for structuring and teaching all school courses in mathematics (1–12). Set theory was supposed to constitute a foundation on which the other school topics should rest. In teaching, concepts should be introduced and explained by means of concepts, expressions, and illustrations related to set theory. In this way, coherence between all topics should be created. This would also facilitate a teaching focused on understanding rather than just procedures, which was in line with the theory of cognition, learning and mathematics that guided the reform. But, apart from set theory, New Math also brought other innovative concepts, for instance from vector geometry, trigonometry, and functions (Prytz, 2018).

The spread was supposed to be total in the sense that the innovations concerned all school years 1 through 12 and all Swedish schools. The way to achieve this was to implement the innovations in connection with the national curriculum reform of 1969, which then brought a radically new course program for mathematics.

To maintain the innovations, textbooks were an essential component. Much of the development phase (1961–1968) concerned textbook development, which was financed and driven by central school authorities. The overarching aim was to develop textbooks that could fit the radically new curriculum. The idea seems to have been to provide the publishing companies with an extensive example of what a new type of textbook should look like. In practice, many publishing companies managed the conversion by hiring people involved in the New Math project. However, compliance with the new curriculum was secured by a mandatory textbook review. And if we consider the content of the textbooks published in connection with the curriculum reform of 1969, the compliance with the new course program in mathematics was indeed good. Since the textbooks review was a matter of controlling the fidelity with the innovations, we find it relevant to talk about maintaining rather sustaining innovations when it comes to New Math (Prytz, 2018).

As to transfer of ownership, teachers were given in-service training concerning the New Math, which is a clear example of providing teachers knowledge of the innovation. However, the focus was on mathematical content rather than teaching methods. And in comparison, e.g. to the Boost for Mathematics project, it was brief. And do not forget the national textbook review that limited the possibilities to deviate from the curriculum. Thus, the central school authorities will and ability to transfer ownership do not appear to have been great (Prytz, 2018).

Regarding textbooks and the strategy to maintain the innovations, the New Math project's attitude versus publishing companies was of a brutal kind. In the devolvement phase during the 1960s, all people involved authoring the experimental textbooks, except one, had a background as textbook author for school years 1 to 12. So, there were no ties to publishing companies in that respect. The trials and testing were done in a scientific context with researchers in charge and almost without involvement of publishing companies. Thus, the companies had little influence on the process that led to the example they had to follow. On top of that, there was the textbook review (Prytz, 2018).

If we then consider the demise of New Math in Sweden, this brutish attitude towards the publishing companies appears to have been functional. A few years after the 1969 curriculum reform, the central school authorities decided not to drive important components of New Math, not least the parts concerning teaching principles. However, the mathematical course program did not change. And in 1974, the textbook review became optional. After that, publishing companies began to issue more traditional textbooks, in parallel with New Math textbooks (Prytz, 2018).

This shows how willing and able the publishing companies were to act quickly and produce textbooks that were in conflict with the innovative components of New Math. Most likely they aimed at making a profit of teachers' dissatisfaction with New Math. To what extent teachers were dissatisfied is hard to estimate, but critique was aired well before the reform. This indicates how important the mandatory textbook review was to prevent publishing companies from interfering with the original plans for the implementation.

PUMP project (1970–1985) and the role of textbooks

In comparison to the innovations of the New Math project, the PUMP innovations can appear to have had little depth. They concerned just arithmetic in school years 1 through 6 and the central innovative component was an assessment material. Moreover, no particular pedagogical principle for teaching was prescribed. On the other hand, the assessment material and its underpinnings were very carefully crafted, tried, and tested. And they prescribed a detailed sequence in which exercises in arithmetic should appear in teaching. There were also good arguments for this sequence since the material had been tried and tested empirically. In addition, there was a cognitive theory about working memory to further support the sequencing of the content (Kilborn, 1979). Our point here is that this type of sequencing concerns the very basics of teaching. How and what a teacher communicate with the students is depending on how the content, for instance exercises, are sequenced (cf. Bernstein, 1974). So, in that respect the PUMP material had depth, but it was another type of depth than in the New Math material. In brief one could say that the New Math gave principles and examples for the sequencing of the content and principles for teaching; PUMP gave the sequence for the content.

The spread of the PUMP material was very modest in comparison to the New Math reform. There was no policy demanding all teachers to use the material (Kilborn, 1979). But the fact that a developed version of the PUMP material is still in use today indicates that the material had spread.

This endurance suggests that the efforts to sustain the material were successful. Different aspects of how that was done will be studied in our project. In this paper, we consider more closely how the PUMP people could avoid threats to their sequencing of the content from publishing companies.

Here it is important to notice that textbooks in essence constitute a sequencing of the content. So, there is a potential conflict.

For the PUMP people, the fight had two fronts: on the one hand the publishing companies, on the other, the New Math curriculum. And they launched massive critique in both directions. It was massive in the sense that they had a solid and detailed assessment material; this material was used in classroom studies to detect what type of difficulties students had in arithmetic, many of the difficulties appeared to be connected to textbooks and the curriculum; and the material was finally used to study the structure of textbooks. The analysis of the textbooks was thorough. The PUMP people mapped the amount of exercises the student encountered each week for a whole school year. And the level of difficulty of each exercise was estimated by means of the assessment material. In this way, they could estimate in what respect the progression was too steep or too flat. Often the textbooks raised the level of difficulty very fast. The PUMP people tied these problems to the New Math curriculum which they considered too unclear in terms of progression. They also found some directives misleading (Kilborn et al., 1977).

According to one of the leading persons in PUMP (personal communication), their textbook critique had great impact on the publishing companies. There was even an expression for it: textbooks were “pumped” before they went to the market. However, this claim needs further studies of the textbooks to be corroborated.

As to transfer of ownership, the PUMP assessment material was a readymade tool for the teachers to use. It was not something a teacher could own in the sense that they could gain knowledge about it and modify it. That was not the intention. However, the PUMP people argued that the material would make teachers less dependent of publishing companies and their textbooks. The idea was that teachers could use the PUMP material to plan their teaching and choose textbooks that fitted their plans. For that end, the material could also be used by teachers to evaluate textbooks (Kilborn et al. 1977). So, here we see another type of ownership. This is also the reason why we find it relevant to talk about sustaining rather maintaining innovations when it comes to PUMP.

Conclusions

We have applied Coburn’s (2003) theory of scaling up an educational reform to characterize the implementation of innovations in two historical Swedish development projects in mathematics education: the New Math project (1960–1975) and the PUMP project (1970–1985). This theory comprises four dimensions: depth, sustainability, spread, and reform ownership. In addition, we have made a distinction between maintaining and sustaining an innovation. We have also analysed the role of textbooks in strategies for sustaining or maintaining innovations in the projects. Our characterisation of the projects is summarised in Table 1 below.

Our analysis of strategies for sustaining or maintaining innovation has also involved the reformers attempts to manage publishing companies—the producers of textbooks—and potential conflicts of interest. In both projects, this management was done in a purposeful manner. In the case of New Math, textbook development was the centre piece in the development phase. A process publishing companies had very little influence over. And in the implementation phase, the companies were forced—through a national curriculum and a mandatory textbook review—to follow the examples set by the textbooks that were the results of the development phase. In the PUMP project, we can observe another strategy. Textbook development was not part of the PUMP project, but it included a comprehensive textbook review, based on the detailed assessment material (a key innovation) that had been developed and empirically tested. This material laid out a very detailed sequence in which exercises should appear in teaching. The review resulted in harsh critique of the textbooks. We have indications that this criticism had a great impact on the publishers. But further research is needed.

Table 1. Characterization of the New Math and PUMP projects

Project	*Maintain or Sustain*	*Spread*	*Depth*	*Ownership to teachers*
New Math	Maintaining innovations, mainly through formal curriculum and textbook control	Whole country through curriculum and textbook control. Concerned all schoolyears and all mathematical topics.	Through general principles and examples that sequenced the content	Limited in-service training of teachers.
PUMP	Sustaining innovations by giving a tool (an assessment material) for developing teaching methods and evaluating textbooks	Modest due to voluntary use of assessment material. And it concerned school years 1–6 and arithmetic.	Through a concrete and detailed sequencing of the content	Teachers should use assessment material for pedagogical develop-ment. Not possible to modify the material

We also have evidence of these strategies being necessary in the sense that publishing companies pursued aims other than those of the reformers. This became visible later on in the implementation phase of New Math, when the central school authorities made the textbook review optional in 1974 and refrained from driving key innovative elements of the New Math reform, even though the New Math curriculum was still in effect. The companies reacted quickly and were able to start production of more traditional textbooks. This is an example of how publishing companies respond to market force and how it can undermine the maintenance of an innovation. If there is a demand for a certain type of textbooks, the publishers tries to meet demand without losing the market share that rests on product recognition. Consequently, publishers balance on a fragile thread between the diametrical poles of change and tradition, when considering which path yields the most profit.

Regarding contribution to previous research, in particular Century & Cassata (2016) and Coburn (2003) which concern IR in general, we stress the theoretical relevance of our findings. In a previous section we have explained that existing IR models does not in greater detail concern the role of textbooks and publishing companies in processes of sustaining or maintaining innovations. We argue that this is something to consider when developing IR models specific to mathematics education and large scale implementation projects. Our findings indicate that the characteristics of the process of implementing innovations on a larger scale (sustainability/maintainability, spread, depth, and ownership) can be related to strategies for managing textbooks and publishing companies in the implementation process. Our findings also indicate that success in sustaining/maintaining innovation and achieving spread may be depending on such strategies.

These indications point at more general issues of innovation, education, and market forces. Issues we find extra relevant for mathematics education research since not only textbook companies but also technology companies have influenced school mathematics for a very long time.

Towards designing a comparative survey for implementing PCT in Danish, Swedish, and English K-9 mathematics education

This paper reports on the development of a survey tool to investigate how programming and computational thinking (PCT) is implemented in Denmark, Sweden, and England. The survey is targeted at mathematics teachers and aims to understand their enactment of PCT in their field and their perceived attributes of the innovation. Developing this kind of survey is difficult as implementation strategies differ significantly. This paper argues that one way to build a foundation for comparison is to inform its focus by utilizing 1) implementation theory and 2) innovation-specific theory.

Keywords: Computational thinking, design-based implementation research, implementing PCT in mathematics.

Introduction

During the last decade, an increasing number of countries have implemented curriculum revisions to include elements of programming and/or computational thinking (CT) in K-9 schools. These countries have adopted different approaches to this implementation process (Bocconi et al., 2016), which involve variations in the nature of the implemented innovation, the offered support strategies, the characteristics of the end-user, and the organizational and environmental factors surrounding the implementation process. While PCT as a compulsory school subject is not always explicitly linked to the mathematics curriculum, both researchers and practitioners in mathematics education acknowledge that there are potential synergies when integrating PCT within the subject. Despite this, previous research indicates that the establishment of meaningful synergies is far from a trivial endeavor (Misfeldt et al., 2019). At this point in time, mathematics teachers from many countries are likely to have encountered elements of PCT in their teaching; more than 50% of all math teachers in The International Computer and Information Literacy Studies' (ICIL) measurement of computational thinking reported an emphasis on computational-thinking-related tasks in their subject (Fraillon et al., 2020). ICIL's framework investigated information and communication technologies in schools across the subjects, including both explicit and implicit aspects, and it found similarities in the content, resources, methods to support learning, and priorities, despite rather different formulations of plans and curricula (Fraillon et al., 2020). Each of the nations did however focus more on computer and information literacy than on computational thinking. From an implementation perspective, this leaves us in a situation where it is still unclear how and to what extent experiences of teaching PCT and mathematics differ when situated in divergent contexts This would be valuable in gaining an understanding of the implications of various implementation strategies for mathematics teachers' practices. Still, the differences that make comparisons interesting represent a challenge when developing a research design. Although many nations have implemented an innovation, which can be labeled under the broad umbrella term of CT, there are substantial divergences in what aspects of the concept are emphasized. Moreover, national implementation strategies regarding PCT are often comprehensive and organized differently. These differences make it difficult to develop a design that is both broad enough to build a foundation for comparison and still sufficiently sensitive towards country-specific contexts. Previous research has studied teachers' conceptions of PCT in national contexts (Misfeldt et al. 2019) and across countries (Manila et al. 2014). However, this research mainly focused on mathematics teachers' ideas about PCT, while Manila et al. (2014) studied educators in all subjects. Additionally, none of these studies explicitly concentrated on implementation. This paper reports on our work of developing a questionnaire that enables us to find variations in how PCT and mathematics are enacted and experienced by teachers in three broadly different contexts. We chose Denmark, England, and Sweden for comparison as they have adopted distinct strategies for implementing PCT. Here, we will discuss how to design an implementation study that is sensitive to country-specific variations, creates meaningful survey items for educators in all nations to ensure reliability and validity (Wikman, 2006), and can thus provide a meaningful foundation for comparison. In this paper, we intend to spark a discussion about what properties we should expect from comparative implementation studies in relation to mathematics education. To engage in this debate, our starting point will have its basis in our reflections relating to developing a survey for mathematics teachers in Denmark, Sweden, and England on how they 1) teach mathematics and PCT and 2) what they see as the main difficulties and potentials of doing so. From an implementation perspective, our survey thereby specifically concentrates on what Century and Cassata (2016) refer to as the end-users' innovation enactments and their perceived attributes of the innovation itself. The overall aim is to address the following research question: *How can we develop a survey to compare mathematics teachers' enactments of PCT in mathematics education and their perceived attributes of the innovation in different national contexts?*

We begin the paper by outlining the situation in the three countries. Next, we describe the issues we encountered when developing a survey that can be both applied to the different situations in the countries and provide a meaningful foundation for comparison and the theoretical sources that we drew on to address these difficulties. Finally, we present how this was translated into a survey design and the limitations and strengths of this approach in terms of reliability and validity.

The situation in the three countries

As described in the introduction, Denmark, Sweden, and England have adopted different approaches to implementing curriculum revisions regarding PCT. In this section, we describe the nature of the approaches in the three countries and summarize their main differences from the point of view of implementation as well as investigate the relationship between PCT and mathematics.

Sweden

In 2018, the Swedish K-9 curriculum was revised as part of a national strategy to build students' digital competency. The rationale for this strategy was dual. First, the Swedish government highlighted that being digitally competent in the sense of understanding and mastering technology has become a prerequisite for being an active part of a democratic society, making it imperative.

Second, reports from the Statens Medieråd identified substantial differences in the digital habits and competencies of young Swedish people based on variations in gender, ethnicity, and demographic/socio-economic backgrounds. The national government referred to the increased focus on digital competency in compulsory schools as an approach to address this issue (Skolverket, 2018). This increased concentration on digital competency was cemented by revising the curriculum for several subjects in compulsory schools and by adding certain elements to legal documents, which re-establish the purpose of schooling in Sweden. Both initiatives aimed to make the responsibilities of Swedish schools clearer (Skolverket, 2018). This strategy led to revisions of all major subjects in schools (including mathematics, technology, civics, biology, chemistry, physics, Swedish/Swedish as a second language, and handicrafts), which were altered to include digital competency. In the context of mathematics education, this led to an innovation consisting of a revision of the curriculum, meaning programming was introduced as part of problem solving and algebra. The new programming component was thus embedded in the curriculum by rephrasing existing descriptions of the subject to integrate the skill. For example, in the case of algebra levels one to three, the curriculum specifies that students should learn "how unambiguous step-by-step instructions can be constructed, described and followed as a basis for programming" and that they should have knowledge of the "use of symbols in step-by-step instructions". Meanwhile, in problem solving for grade levels seven to nine, the curriculum specifies that students should acquire knowledge of "how algorithms can be created, tested and improved in programming for mathematical problem solving".[1]

Denmark

Denmark is yet to implement computational thinking in the Danish K-9 curriculum. Nevertheless, mathematics does include many aspects of CT-related teaching, especially with regard to problem solving, modelling, and tools/aids. The related goals incorporate the following: "The student can plan and undertake problem-solving-processes" (problem solving), "The student can undertake modelling processes, including with the use of digital simulation" (modelling), and "The student has knowledge of different concrete materials and digital tools" (remedies)[2]. However, these desired competencies have not been formulated as items specifically relating to PCT in the curriculum. From 2018–2021, a new subject entitled technology comprehension (TC) was implemented at 46 schools across the country as an experimental pilot project (Smith et al., 2020). The project included two implementation strategies, namely 1) implementing TC as a subject in its own right and 2) integrating it into other subjects (into mathematics in this instance). In both cases, TC was comprised of four areas of competency: digital empowerment, digital design and design processes, computational thinking, and technological knowledge and skills—including programming (Smith et al., 2020). The Danish Ministry of Education (UVM) also published a tentative curriculum with added TC learning goals (UVM, 2019). Although the new subject might forecast that an actual PCT-oriented subject is on its way into Danish schools, it has not yet been settled on as to how or when it will be fully implemented.

England

England was among the first countries in Europe to absorb programming into the curriculum in 2013/2014 as a mandatory subject in its own right called computing. A key attribute of this innovation is its emphasis on technical and computer science-related content. The curriculum thus states that the aim is to ensure that all pupils, among other things, can understand and apply fundamental principles/concepts of computer science, analyze problems in computational terms, evaluate and apply information technology (including in relation to new or unfamiliar technologies), and analytically solve problems. In this respect, the computing subject in England can be considered a simplified version of what is taught in computer science at a university level. These attributes of the innovation reflect that the computing subject in England is intended to address a challenge that is phrased differently compared to the Danish context. In the former nation, one of the main aims of implementing the new computing subject was to lay the stepping stones for creating a workforce with adequate competencies to teach the next generation of programmers. In England, teachers of the now defunct ICT subject were assigned the responsibility of teaching its new computing counterpart. These educators received no formal training on how to disseminate the new subject to students, and there were no central initiatives to develop teaching materials. According to Larke (2019), the rationale behind not developing such initiatives was to ensure teacher-based autonomy when using and developing the materials they found were adequate to meet the needs of the curriculum. Although the computing subject in England is not related to mathematics, there are several ongoing research projects that explore the potential synergies of integrating programming into it. One of these projects is Scratch Math[3] which has developed a number of teaching materials that integrate mathematics and programming that are accessible to all teachers.

Theoretical background

As evident above, the implementation scenarios in the three countries differ in several ways, making it challenging to design a comparative research design that can adequately examine the three contexts. One particular challenge is that the implementation processes are comprehensive and organized very differently across the countries. To provide a solid foundation for comparison, it is thus important to ensure there is a theoretically delineated focus on the implementation process in which teachers are the appropriate respondents to answer the questions in the survey. To guarantee this, we informed the survey's implementation focus by drawing on research by Century and Cassata (2016) who developed an influential characterization of implementation research in education; they described it as both an inquiry into the innovation itself but also of factors that influence how it is enacted, the relationship between multiple innovations, and the outcomes of it. They outlined five key aspects of major importance for implementation in education, namely the characteristic of the individual user, organizational and environmental factors, implementation over time, implementation support strategies, and attributes of the innovation. Using Century and Cassata's (2016) wording, we were able to define our primary interest in the survey as trying to gain insights into 1) how mathematics teachers enact the innovation and 2) their perceived attributes of the innovation they enact. While

[3] https://www.ucl.ac.uk/ioe/research/projects/ucl-scratchmaths

Century and Cassata (2016) argue for the importance of studying the innovation, they distinguish between its actual (or objective) characteristics and the perceived attributes by the end-users. In the survey, we focused on the latter. Although the innovation (PCT) is described in somewhat loose terms in the three countries concerned, the relationship between PCT in mathematics and PCT is relatively clear. We therefore believe that available policy documents provide sufficient information about the actual characteristics of the innovation. Moreover, the existence of loosely described curriculum innovations makes understanding teachers' enactments of them even more important. We will return to the implications of this choice in the discussion.

A second challenge relates to the fact that the innovation being implemented is similar in that it focuses on CT, yet it is outlined in significantly different manners within the curricula and policy papers across the three countries. Although the innovation in all three nations addresses what could be labeled as aspects of PCT, there are differences in terms of which parts of the broad concept of PCT are emphasized. This is problematic as we intend to quiz mathematics teachers from the three countries on what aspects of PCT and mathematics they combine by providing a number of pre-determined content areas of PCT and mathematics for the respondents to choose from. These content areas are thus at risk of either being too comprehensive (if they were to include all elements of CT from each country) or biased towards the context of only one of the nations. To address this, we informed our questionnaire by employing Weintrop et al.'s (2016) framework for computational-thinking practices in mathematics education, which was developed to provide teachers with guidelines on how they can assimilate CT into their mathematics teaching; it also specifies four main areas of CT: data practices, modelling and simulation practices, computational problem-handling practices, and systems-thinking practices. With regard to which content areas of mathematics teachers combine with PCT, we utilized the 10 subject areas described in the KOM framework that was developed by Niss and Højgaard (2002). They are numbers, arithmetic, algebra, geometry, functions, infinitesimal calculus, probability, statistics, discrete mathematics, and optimization (Niss & Højgaard, 2002). Drawing on these models, we developed questions that ask teachers which PCT/mathematics subject areas they combine in their teaching; at the same time, we were careful not to bias what we asked towards the situation in one of the countries. More generally, by informing our survey with these theoretical frameworks, we aimed to ensure alignment between the survey questions and variations in the innovation across the three contexts and saw to it that the survey includes questions for teachers to answer that provide insights into their enactment of the innovation and their perceived attributes of it. Below, we describe how we operationalized these guiding theoretical principles within concrete survey questions.

Designing a comparative implementation survey

The survey is organized into three main sections: a background section, a section on teachers' enactments of the innovation, and finally a section on their perceived attributes of it. In this paper, we have especially focused on the last two sections, which we describe below.

Items in innovation enactment and perceived attributes of the innovation

The first obstacle when developing survey items is adhering to the need to concentrate on specific aspects of the implementation process, which mathematics teachers can provide comparable answers to (Wikman, 2006). As described, we define this focus as innovation enactment and perceived attributes of the innovation by drawing on Century and Cassata's (2016) research. Even though this provided a focal point for the differing innovations, to ensure the reliability of our survey items and thus the validity of our survey, we still needed to provide a foundation for comparison without being biased towards the context in one of the countries. As previously mentioned, we chose to employ a relevant framework by Weintrop et al. (2016) to ensure that the examined elements of PCT were based on generally accepted models. With regard to the areas of math content, we relied on the 10 subjects from the KOM framework (Niss & Højgaard, 2002).

The issue of potentially biasing the questions towards one of the countries' modes of implementation stems from the major differences in relation to the focus of the innovation. With the Swedish implementation, we would expect a high number of teachers working extensively with computational problem-handling practices due to the heavy emphasis on this in their curricula. On the other hand, with regard to Danish schools, we expect there to be a preoccupation with computational problem-handling practices but also with modelling and simulation practices as it is an explicit learning goal in mathematics (see the section on Denmark). As England has implemented programming as its own subject, it is still rather unclear to what extent teachers recognize their practices as computational thinking and what math-related subjects are connected to this. This is where the practices of Weintrop et al. (2016) become useful. As this CT definition has been developed for science and mathematics, we anticipate that teachers in all three countries will be able to recognize the four practices. When employing the country comparison by ICIL (Fraillon et al., 2020), we also expect there to be some similarities between the practices and context areas, even though the innovations are rather different. Using the more fine-grained sample of 10 math subjects, we are also equipped to enable a comparison of how mathematics teachers enact PCT in their educational activities and to ascertain to what extent the different practices highlighted by Weintrop et al. (2016) are signified. This construction of items not only allows us to look at what CT-related practices educators employ in their teaching but also to investigate what subjects in the math field they are coupled with. This facilitated our investigation into the different practices that are utilized across countries and made it easier to look into the relationship between the innovation and the practices themselves. In the questionnaire, we thus asked teachers if they include programming and computational thinking via each of the four practices described by Weintrop et al. (2016): "One can work with programming and computational thinking in different ways. To what extent is working with data practices part of your teaching?" If teachers reply that they include it to some or a large extent, we then ask which of the ten outlined content areas from the KOM framework that they are coupling the PCT practices with.

After forming the item construction of PCT practices and math subjects, we created a framework for comparing innovation enactments instead of the innovation itself. As an add-on to that, we aimed to compare teachers' perceived attributes of the innovation, both across country-specific innovations and the enactments by teachers. With regard to the perceived attributes of the innovation, we drew on a survey made for Swedish teachers (Misfeldt et al., 2019), yet we excluded questions that were too strongly influenced by the Swedish implementation of PCT into the math subject. The survey addresses teachers' perceived attributes of the innovation by including relevant questions, such as those relating to educators' experiences of the integration of PCT and math (e.g., "To what extent do you agree with the following statement: Teaching programming supplements math teaching to a large extent"), how teachers experience programming as it relates to the enactment of the praxis (e.g., "My students are using their math capabilities when they are programming"), and finally the relationship they perceive between math and programming. In sum, the survey described above allows us to inquire about what aspects of PCT and mathematics educators in the three countries combine in their teaching and their experiences of doing so. We expect that the survey will enable the gathering of valuable insights into the different ways teachers navigate and experience teaching PCT and mathematics in the three contexts.

Discussion and conclusion: Comparative implementation studies in mathematics education

There are variances in how Danish, Swedish and English mathematics educators combine their subject and PCT within their teaching; their experiences of doing so are also contextualized by significantly different implementation strategies. This is exactly why a comparative investigation is interesting. Although our development of the survey tool described here is still at an early stage, we believe that our approach could provide inspiration for how to conduct comparative implementation studies within mathematics education. Our survey design is informed by two main types of theoretical frameworks: one is a theory that is specific to the innovations that are being implemented and the other relates to implementation research. We chose to inform our survey in line with these theoretical resources to address the concrete challenges we encountered. This relates to the need for a delineated focus on certain aspects of the implementation process (as opposed to the entire thing) and finding ways of developing questions for the teachers that were not biased towards one of the three countries; this would ensure the reliability of the survey items and thus the validity of our questionnaire. Furthermore, adhering to these models enabled us to compare similar enactments across contexts and their correlation to perceived attributes of the innovations. By focusing on innovation enactment and the perceived attributes of the innovation, we have to assume to some extent assume that we have an understanding of said innovation and the related implementation strategies in the three countries. This assumption is based on the fact that both the curriculum revisions and the relationship between PCT and mathematics are well-described in policy documents in all three nations. However, the delineated focus on enactment and the perceived attributes of the innovation come at the cost of gaining insight into other, potentially equally important aspects of the implementation processes. This choice mirrors our primary interest in understanding the daily practices of mathematics teachers with regard to what they do and how they experience their practices of combining PCT and mathematics. Fully addressing all aspects of the implementation in detail would require other respondents to partake in the survey (managers, supervisors, municipal staff, etc.) and a much larger population to gain significant results into national variations and stabilities. Since policy documents provide rich descriptions of the implementation processes that are sufficient to pinpoint substantial differences, we believe that understanding mathematics teachers' enactments and perceived attributes of the innovation across these countries can provide important indications as to how such strategies are received by the end-users. Although our survey has not yet been tested, we believe that this work deals with an issue that has not been addressed explicitly in implementation research within mathematics education, specifically comparative implementation research in relation to mathematics education. We hope that the work reported here can spark interest, which will then lead to further engagement in more systematic discussions about this matter.

Introduction

When TWG24, *Representations in Mathematics Teaching and Learning*, was initially opened at CERME10 (Robotti et al., 2017) it included 24 participants from 13 countries with 16 accepted papers and 2 posters; at CERME11 (Baccaglini-Frank et al, 2019) it grew to welcome 31 participants from 16 countries, with 18 accepted papers and 4 accepted posters; and at CERME12 TWG24 enjoyed the online participation of 28 researchers from 10 different countries with 19 papers and 2 posters presented. At CERME12 the structure of the working sessions allocated for discussion of each paper or poster was designed to stimulate interaction and collaboration among participants, even though the conference was held entirely online. Each paper or poster was allocated to one of six working sessions, which typically included three or four papers with theoretical, methodological or thematic similarities. All papers were shared with the participants in advance of the conference, and each presenting author was asked to concentrate especially on providing feedback or questions on the papers presented within his/her session. Presenting authors were asked to prepare a short presentation of their paper, including one slide explicitly addressing the theoretical perspective taken on "representations". The allocated time (20 minutes for papers and 10 minutes for posters) was split equally between author presentation and working group discussion. There was also a workshop session dedicated entirely to working in smaller rotating subgroups on questions designed by the co-leaders, which had emerged from the previous four days' discussions. The final session was devoted to a conclusive discussion chaired by TWG co-leaders with contributions from each of the morning's subgroups.

In this short report of the main themes that were discussed, we divide the themes between more practice-based ones and more theoretical ones.

Practice-based emerging themes

In thinking about representations in practice, important themes emerged related to sharing representational practices in three overlapping zones: 1) across educational systems, 2) within interpersonal learning activities and 3) inside encounters with various mathematical technologies and tools. At the largest scale, we found ourselves asking: *What can we observe about how representations are used across different educational systems? What issues arise when we 'import' something from one education system to another?* This macro-level question was inspired in large part by Palop del Río and Santaengracia's paper exploring the introduction of a concrete approach to the bar-model imported from Singapore educational system into a fifth-grade classroom in Spain. Interested in the bar-model's flexibility in a wide variety of problem scenarios, Palop del Río and Santaengracia sought to test the implicit assumption in Spanish curricula that this representation must be introduced to students in their earliest years of schooling to be an effective tool for thinking.

Although the potentials of (and contested approaches to) the “Singapore bar” remain a paradigmatic example of “importation”, the theme of working across educational systems also surfaced in papers which sought to better understand a variety of under-studied educational activities, asking to what extent these activities can be understood as “systems” in their own right. Angeloni, Wille and Hausch, for example, explicitly challenged the concept of “importation”, arguing that the invention and development of mathematical representations in Austrian Sign Language was a much more complicated affair than “importation” or “translation” might imply. While papers like this one did not directly address the complex politics of national educational systems, their ideas were expanded in the subsequent discussion, highlighting and exploring the emergence of representations in minority or marginalized linguistic, pedagogical, and digital spaces (some more of which are noted below). Challenging views of learning about or with mathematical representations as being static, normative or universalizable experiences, pratice-based evidence inspires us to find new ways of drawing on marginalized mathematical experiences as sources of broader pedagogical insight in their own right.

Several papers focusing on students working collaboratively on mathematical tasks (either with peers or a teacher/researcher) also led our group to focus on the development of interpersonal/interactional representational strategies, thinking about the generation and sharing of representational systems within both individual learning support and whole class contexts. These papers led us to discuss: *How much and in which ways should learner-generated representational strategies be encouraged and incorporated into educational discourse by the teacher (in her classroom or beyond)?* Finesilver, for example, provided a vivid case study of one student, struggling with division problems, personalizing and modifying pictorial representations and metaphors as ways to engage with multiplicative structure, including eventually more abstract tasks. This case demonstrated how idiosyncratic representations can be harnessed to combat exclusion of marginalized learners, in this case neurodiverse experiences. Lisarelli and Poli also reported on a teaching sequence in a class which aimed at developing responsive representational strategies drawing on student-generated imagery as a tool to think with while problem solving. While on the first activity students used a collection of representations, the subsequent whole class discussion helped the teacher navigate towards a consensual representation in the class. Meanwhile Velez, Serrazina and da Ponte aimed to understand exactly how a teacher managed his pupils’ use and interpretation of representations during whole class discussion. Hence their focus was predominantly on the verbal interactions, such as the ways the teacher changed the question type as students’ representations varied.

In thinking about the empirical evidence presented within our group, we also sought to engage with the fundamental question: *What representational practices are demonstrably effective (and less effective) in promoting meaningful mathematical learning? How might this vary in different educational environments?* In our general discussion of the questions highlighted above, many participants talked about expanding from or avoiding overreliance on conventional and ubiquitous representations. They discussed encouraging a mix of speech, gesture, and tool-use as powerful multimodal representational activities in the classroom and beyond. In encouraging and incorporating learner-generated representations, the group discussed balancing freedom and creativity with learning the necessary conventions for participating in the wider mathematical community. The power dynamics of classrooms were also addressed in our efforts to differentiate between representations that are an integral part of thinking and problem solving, as opposed to those produced on request just for pleasing the teacher, or retroactively after having already solved the problem without observable external representational strategy.

Theory-based emerging themes

As for the representations in theory, various themes emerged. We decided to focus the group discussions around the three questions, introduced below:

a) Of the theoretical and analytical frameworks presented, which have synergy? Where are conflicts? What might be fruitful combinations?

b) What hidden assumptions might we have about representations that will be made by or offered to different kinds of learners? How does this affect our choices regarding research participants, methods, and theory? What assumptions need to be uncovered and changed, and how to do this?

c) What are the links between representations in our research data and how we (re)present it to others? What representations serve us well in our professional practices as researchers and how can we develop them further?

Regarding question a), identifying synergy in representational frameworks proved quite challenging, and is deserving of more sustained consideration. However, the variety of analytical systems presented gave rise to many lively discussions considering how complementary aspects might be adapted, combined or developed for research in other contexts or with different types of datasets. Conflicts included some based on familiar divisions, such as between more platonic perspectives, according to which mathematical objects are pure and abstract, accessible only via representations, as opposed to others, in which mathematical objects do not reside in some hyper-reality, but in the discourse itself; there were also competing systems of terminology and classification to navigate. Nevertheless, we consider this diverse and multifaceted – yet interconnected – form of 'rhizomatic' theory-building to be a strength of the field (Deleuze & Guattari, 1980/1987).

In thinking through question b), we recognised that researchers in our group have worked with a wide variety of participants in terms of age, stage of education and level of expertise – from primary education up to PhD students – but also diverse learner groups, not only in terms of the different national educational systems from which we hail, but including e.g. sign language users, one-to-one intervention work with struggling students, and mathematics clubs or communities outside of formal schooling. One example of an assumption that came up was that students perceived as high achieving can easily work with multiple representations, together with the assumption that those perceived as low achieving have trouble transitioning between one representation and another. The result of such thinking is that in many educational settings, the latter students are offered narrower representational experiences, which limits learning opportunities and so disadvantages them even further. This was noted by many of our participants.

An interesting consideration, which emerged from discussion of question c), was about the difficulty of selecting and pairing appropriate and creative analytical tools with representations for communicating data interpretation and results. Choices and decisions about analytical tools, frameworks and procedures may highlight certain aspects of the data, but result in the loss of other aspects, particularly when we then communicate these to others. It was proposed to look to other fields for representational inspiration (e.g. computer science, media studies, dance); however, our group's papers already included interesting examples. Ott and Wille explored patterns of communication in one-on-one teacher-student support, seeking to understand individual learning support through the analysis of how and when communications between students and their instructors moved between two diagrammatic representations of number: the natural numbers and the field of twenty. To do this, the authors developed a visual system for coding the flow of diagrammatic conversation, which allowed them to make general observations about pedagogical patterns in their empirical study. Miragliotta and Lisarelli drew on Sfard's (2008) *realisation trees* in their research. This allowed them to make predictions about the ways in which classroom discourse might take hold of the geometric concept of "the height of a triangle". After analysing the lesson, the realisation tree helped them to map missing strategies and connections, as well as highlight novel ways of thinking about a triangle's height that occurred inside the classroom discussion.

Looking forward

As these questions and examples highlight, issues related to representations – both at the practical and theoretical levels, and in the relationships between practice and theory – seem to be of continued (or perhaps increasing) interest to the educational research community. This includes exploring underlying tensions between the multiple theoretical lenses through which representations can be conceived and studied (Baccaglini-Frank et al., 2022), a theme that was also addressed in the plenary panel at CERME12. Hopefully, both an exciting new fusion of theoretical and practice-based observations will be further discussed in the near future. We welcome more researchers to join our group over the next CERME in Budapest!

A way of uncovering students' metaphors through scripting

Aehee Ahn

University of Bristol, United Kingdom; aehee.ahn.2018@bristol.ac.uk

How can I make use of students' metaphors to look into their understandings of mathematical concepts? This study is aimed at exploring a new use of lesson play scripting as a novel way to investigate written metaphors used by students. Metaphor is a powerful linguistic approach, and I examine students' personal mathematical understanding of fraction concepts through their metaphors. Lesson play refers to scripting for an imagined lesson scenario, and I extend the common use of lesson play for teacher education to a research method applying to students. I implement scripting tasks with 28 Korean primary through eight times scripting classes. The process from preparation to results is described with an example of a student's script, and I discuss the applicability of scripting as a research method.

Keywords: Students' understanding, metaphor, lesson play, scripting, fraction.

Understanding in mathematics.

'Understanding' is regarded as the main goal of mathematics learning, a pre-requisite for further learning, or a way of mathematics teaching (Sierpinska, 1990), and its importance in learning and teaching mathematics has been emphasised. Many types of understanding have been discussed, e.g., conceptual and procedural understanding (Rittle-Johnon & Alibali, 1999), but my fundamental question here is what it means for students to understand mathematical concepts rather than which types of understanding students have. Students actively construct their own knowledge based on their subjective experiences rather than passively accepting information (von Glasersfeld, 1995). Pirie and Kiren (1994) proposed individual understanding as a recursive dynamic process that can be developed and be observed. Tall (2011) regarded understanding as a development process from emerging to forgetting, and to remembering. In line with these perspectives, I am taking understanding mathematical concepts as a constructing process of relationships among concepts in an individual's mental network. Mathematical understanding might be influenced by a particular environment around a student, but the focus of this study is on the manifestation of these influences within an individual.

In terms of the construction of mathematical concepts in embodied minds, De Freitas and Sinclair (2017) pointed out the limitation of the binary approach of abstract and concrete (or mind and body) and proposed the need for rethinking mobility and flexibility in learning mathematical concepts. I regard mathematical concepts as not fixed nor absolute ideas for any individual. Rather, mathematical concepts constitute a network through the constructive progression of an individual's mental network (Olive & Steffe, 2002), and there is no determined end in the network. Our embodied mind creates our language, and we communicate in a consensual domain which refers to a "shared physical context in which interactions occur" (Kravchenko, 2012, p.3). In a consensual domain, human beings interact with environments endlessly and (re)generate networks of interactions in a recursive way. These interactional actions are the basis of linguistic behaviours. Language is not just a tool for transferring individuals' thoughts but a way of living, described as 'languaging' by Maturana (2002, p. 28). Knowledge is generated in language through consensual co-ordinations, and thus languaging is part of how we express our understanding of concepts. As a way of investigating students' understanding of mathematical concepts, I look into metaphors as a powerful linguistic approach for creating, representing, and extending the meanings of concepts. This study focuses on a methodology which gives insight into student metaphors. Davis (2020) presented a summary of the potential different number metaphors used by students, based on teachers' experiences and textbooks; my longer-term aim is to provide a similar list of the range of metaphors students using in dealing with fractions.

Metaphor.

Metaphors naturally exist in our language (Lakoff & Johnson, 2003). Traditional metaphor theory considers metaphors as a role in enriching language. According to the conceptual metaphor theory, however, metaphors are fundamentally regarded as human thoughts. Metaphors are the conceptualisation of one concept in terms of another concept, based on the similarities between the concepts. Abstract concepts are understood via metaphor in terms of more concrete concepts. The conceptualisation is called 'cross-domain mapping' and cross-domain mapping consists of two domains, a target domain and a source domain. The concepts that we want to understand are the target domain (which is a relatively abstract concept), and the concepts in the source domain conceptualise target concepts. For example, arithmetic (target domain) is understood from collecting, constructing, and moving objects (source domain) (Lakoff & Núñez, 2000).

Metaphorical mappings as conceptual structures represent one's mental network between concepts. Lakoff and Núñez (2000) proposed embodied metaphors that are based on mathematical ideas from one's everyday experience and from different mathematical areas, called 'grounding metaphor' and 'linking metaphor'. These metaphors are elaborated not from a single mapping but from integrating many mappings between concepts, and the elaborated mappings develop an emergent structure of an integrated mental network (Fauconnier & Turner, 2008). In this regard, metaphor represents a mental structure in which we live and think and thus can allow exploring students' understandings that underlie their written language.

Fraction.

In this study, I chose a fraction concept for the investigation, inspired by my teaching experience in which I witnessed students struggling with fractions. Fraction is considered the most complex concept addressed before the secondary school. One of the factors contributing to the difficulty of the concept is that a fraction consists of two numbers. For fractional knowledge, students need to consider relations between a numerator and a denominator, rather than the two numbers separately. The two numbers can be regarded as parts and the whole, respectively; in this case the student is using what is referred to as the part-whole scheme. According to the part-whole scheme, a fraction indicates some parts out of a whole. The numerator is regarded as the parts or pieces to consider and the denominator is regarded as the whole. An equipartitioning scheme involves dividing actions that partition a continuous unit into equal-sized segments (Steffe & Olive, 2010). Whereas the partitioning scheme refers to breaking a unit, the iterating scheme refers to duplicating a segment several times to constitute a unit. The iterating scheme suggests that the fraction is freed from parts of the whole and can be often related to understanding the concept of "improper fraction". For 5/4, for example, students iterate 1/4 (a unit fraction) three times to constitute 5/4.

This study is aimed at investigating students' metaphors to understand their understandings of a fraction. Here, I need to engage in the question of how to explore students' uses of metaphors: how can I learn about students' metaphors, to look into their understandings of fraction?

Methodology.

Scripting, lesson play.

I suggest a new way of using lesson play as a research method for investigating each learner's conceptions. Lesson play refers to scriptwriting for an imagined lesson scenario with a dialogue format between a teacher-character and student-characters, which is originally designed for teacher education (Zazkis et al., 2013). Scripting is based on "virtual duoethnography" (Zazkis & Koichu, 2015, p. 166) which is narrative research producing a dialogue with multiple voices of fictional characters, from one person (who can be a researcher or a student), and it is inspired by the dialogue of Lakatos (1976). For scripting, prompts that include mathematical situations are provided, and teachers are asked to write a dialogue script for the ensuing situation of the provided prompts.

Here, however, I implemented scriptwriting to primary students as creating an imagined role-playing scenario. Wille (2017) has conducted imagined dialogues with students to discuss their mathematical thinking processes. Similarly, I provided prompts for mathematical situations to students, and they created a dialogue script for the given prompt. I intended to provide a certain mathematical classroom situation to students in order to understand the mathematical language that they naturally use. Role-play encourages students to participate in a specific situation as a specific person, so that students are able to deeply engage in learning and teachers are able to see their perspectives on the topic (Alkin & Christie, 2002). Scripting is an individual task that can be done by many students simultaneously, and it is less constrained by time and participation than real role-plays. Mathematical writing is encouraged for students to develop their mathematical understanding (Sierpinska, 1990), and the Korean National curriculum emphasises writing under a strong calligraphy culture. In fact, in follow-up interviews with student participants, many students mentioned math writing was easier than math speaking because they have enough time to think instead of having to answer immediately. When making scripts, students might use of their knowledge of mathematical concepts related to the situations of the prompts. Moreover, through the written contexts, a student's view on mathematical concepts can be examined.

Data Collection.

The participants are six grade (11-12-year-olds) Korean students from the same classroom and the number of students is 28. I had eight scripting classes with the students in a primary school. For script writings, I designed eight prompts, based on previous research and my teaching experiences about students' common errors, misconceptions, and difficulties in dealing with the concept of a fraction. If students had similar misconceptions with prompts, I would be able to track the root of their misconceptions. If students had a different understanding of the erroneous situations in prompts, they would describe their thinking to correct the misconceptions.

The fraction concepts dealt with in prompts are neither complicated situations nor beyond the scope of sixth-grade students learning according to the Korean national curriculum so as not to interfere with students writing. The prompts are related to many aspects of a fraction, such as fraction representation, fraction calculation, and fraction comparisons. The following is one of the prompts I used.

A teacher shows two fractions 5/6 and 7/8. Tom suddenly raises his hand.
Tom: Teacher, I have a question.
Teacher: Yes, Tom.
Tom: 5/6 and 7/8 are equal?
Teacher: Why do you think that?

The prompt above implies ‘gap thinking’, with regards to equivalent fractions. Gap thinking, as one of whole number thinking, is considering the gap between a numerator and a denominator by dealing with them separately, rather than considering the ratio between them (Pearn & Stephens, 2004). Gap thinking can lead students to draw either an incorrect answer or a correct answer with erroneous reasonings. Specifically, students can regard fractions having the same gap (e.g., 5/6 and 7/8) as equivalent. In scripts, students may or may not agree with Tom (or both), but my focus is on how the students describe their understanding of the two fractions. While creating the prompt, I anticipated students discussing their understanding or meanings of a fraction. Students work on writing in Korean (their first language), and I analyse the writings in Korean so that I can grasp the meaning and nuance of the contexts more appropriately.

Instruction.

In the first class, I introduced scriptwriting by presenting an example of a prompt and a script and then I asked students to practice writing a script for a prompt that was not related to a fraction. This practice is not only meaningful for students as a practice, but it was also important to me, because through it I could check whether my explanation was enough for students to carry out scripting. In writing, I encouraged students (1) to focus on the dialogue format rather than the contexts of the example script I showed them, (2) to approach the prompt situation with various perspectives (with various characters) so that I could explore their metaphors related to the concept in-depth, and (3) to use visual images such as diagrams, tables, and drawings to support their writing if needed. After the first class, I read students’ first scripts, and on what seemed to be unsuitable (e.g., texts are completely not related to the prompt), I left comments to help students carry out writings.

In the second class, I started with a five-minute ice-breaking time, a five-minute explanation for today’s prompt, and a 20-minute script writing. After scripting, I read the students' writing and left comments. The comments were to encourage their participation, for example, ‘you explained your idea logically’, ‘thank you for your detailed explanation’. Also, I left question comments on sentences where I was not able to understand them well, so that students would write additional explanations for the sentences. Then in the next class, before writing a new script, students read my comments and added answers to my questions.

Findings.

Translating students’ scripts from English to Korean is based on ‘interlinear morphemic gloss’ which is the way of translating in each morpheme or meaning, in order to show grammatical structures and the detailed, direct meanings of the original language (Lehmann, 2004). The translation uses three steps: 1) word by word (or phrase by phrase) translation, 2) direct translation, 3) natural English translation. For example,

	선생님은	전체 몇 조각	에서	몇 조각을	먹으려고	하는 걸까?
Step 1	Teacher	how many pieces of a whole	out of	how many pieces	eat	trying to

Step 2 How many pieces is a teacher trying to eat out of how many pieces of a whole?
Step 3 How many pieces am I trying to eat out of the whole?

The utterance is what a teacher-character said in a student's writing. The teacher-character herself is described as 'teacher', not I, comparing that student-characters themselves are described as 'I'. In Korean classes, it is common for teachers to refer to themselves as teachers instead of 'I', and this student perhaps may have seen many teachers referring to them as a teacher. Or in Korean culture, it is considered rude behaviour for students to call a teacher (adult) 'you' or name, so she might try to avoid it even in scripts. Thus, although the subject is a teacher in the original Korean sentence, it refers to the teacher-character herself, so the subject is translated as I in step 3 translation. The step 2 translation 'how many pieces of a whole' explicitly shows the student's countable numerical understanding of a whole. Though step 2 translation can have ungrammatical parts, it is effective to covey what words the student chose and how s/he describes concepts in Korean. Thus, also due to space limitation, I describe student scripts with only direct translation instead of all the three steps.

I illustrate some parts of Aiden's (the pseudonym of a student) scripts as examples of students' outcomes (scripts) and analysis, with the aim to explore nuances. In Aiden's scripts, I found two grounding metaphors that are related to each other. According to the utterances of the teacher-character Aiden created, she uses an equipartitioning and a part-whole scheme for fractions.

Teacher: How many pieces are there now?
Teacher: But a teacher tries to eat 2 pieces. Then, how many pieces is a teacher trying to eat out of how many pieces of a whole?
Teacher: Thus, a denominator is a total number of something, and a numerator is the number included out of the whole.

While explaining the meaning of a fraction to student-characters, the teacher-character assumes a situation in which she eats pizza with a pizza drawing. By partitioning, pizza as a continuous unit is separated into equal-sized segments. The teacher chooses two pizza slices by shading them and represents a fraction 2/6 as two pizza slices out of the whole pizza divided into six slices, which is a part-whole scheme. At the part-whole representation, I focus on that the parts and the whole are described with countable 'pieces'. She does not compare the size or number of pieces for a fraction but considers the number of pieces (how many) of a numerator and denominator. In her conception, a fraction consists of a numerator out of a denominator, and a numerator refers to the number of pieces as parts and a denominator refers to the number of total pieces in a whole. Aiden's metaphor of a fraction seems to be *pieces* as a grounding metaphor. In other words, she regards a fraction as pieces out of pieces. A denominator is regarded as the number of pieces that partition a unit, and a numerator is the number of pieces chosen. Figure 1 summarises this metaphor.

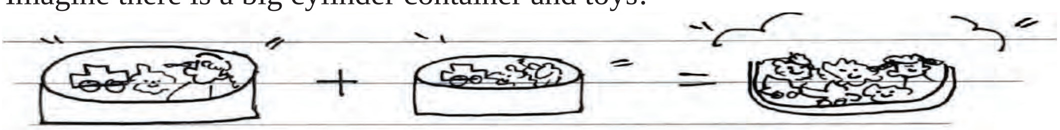
In addition to the pieces metaphor, through the used word 'something' in the last utterance of the teacher, I can see that she thinks of a fraction with objects. A numerator and denominator are objects, which is countable as a cardinal concept.

Source Domain Pieces		*Target domain* Fraction
Pieces out of pieces	→	Fraction
The number of equal-sized pieces that partition a unit	→	Denominator
The number of pieces taken	→	Numerator

Figure 1: Fraction metaphor as pieces

Her countable conception of a numerator and denominator seems to link to her understanding of fraction addition. In her other script, a student-character Jack who reflects her thinking explains the fraction addition 3/5 + 3/5. For the explanation, Jack uses metaphors for a numerator and denominator as a toy and a toy container, respectively.

Jack: Imagine there is a big cylinder container and toys!



When overlapping the same container here, the containers can be overlapped. But toys are the same but do not overlap each other! Thus, the containers are the same, but the number of toys does not overlap each other, so [numerators] become different.

With the toys and container metaphor, Jack describes the principles that denominators are not added to each other but only numerators are added, in the addition of fractions with the same denominator. Jack looks at a numerator and denominator as countable objects (pieces). In her conception, a numerator is the number of objects, and a denominator is the container of the objects. It can be seen as the pieces metaphor, but the difference is that the denominator 5 does not refer to five pieces but one container named 5 itself. Thus, 3/5 means there are three toys in a container named 5, and 3/5 + 3/5 means putting a total of six toys and two containers named 5 together. Since the toy containers as denominators can be completely overlapped, denominators in the fraction addition do not need to be added. On the other hand, the number of toys as a numerator should be added because toys cannot be overlapped. Therefore, fraction addition is combining objects, and Figure 2 summarises this metaphor.

Source Domain Combining objects		*Target domain* Addition of fractions
Put objects together in the same container	→	Addition of fractions with the same denominator
Container of objects	→	Denominator
The number of objects	→	Numerator

Figure 2: Fraction addition metaphor as combining objects

This understanding of a fraction is freed from partitioning. Character-Jack does not split a container into equal-sized parts and does not consider the ratio between a numerator and a denominator. The fraction addition metaphor of Aiden, especially a numerator metaphor, is similar to an arithmetic metaphor of Lakoff and Núñez (2000). They proposed an ‘Arithmetic is object collection’ metaphor: Numbers are collections of objects and arithmetic addition is putting collections together. Similarly, Aiden thinks of a fraction as objects and the fraction addition as putting objects together. The difference between the metaphors of Lakoff and Núñez and Aiden is that their view of numbers is based on a set or collection, while her metaphor of numbers is based on a numerical counting scheme.

Her fraction addition metaphor seems to be related to the multiplication of a fraction and a natural number. In her drawing, the toys in each container are the same, which means that there are two 3/5s, instead of that there are "three toys" and another "three toys". She can use this metaphor for 3/5 × 2. Her conception, however, can have limitations in understanding the addition of fractions having different denominators. When making denominators equal, she can represent denominators as using different containers, but it is unclear how the change of numerators can be described.

Implications.

This study proposes a new use of lesson play as a research method. Through this study, I explored the applicability of lesson play scripting to students. All students in this study finished one scriptwriting in 20 minutes and successfully created their scripts. This enabled me to attain students' data referring to mathematical concepts at a certain mathematical situation and to examine students' conceptual schemes of a fraction. I was able to conduct scripting tasks with many students simultaneously. Through the length of their script over time, I could see that students had participated more actively rather than losing interest in scripting. Although the length of writing is not directly related to the quality of the data, more active participation is more likely to obtain high-quality data through which I can understand students' thoughts. As the class progressed, students became accustomed to mathematical writing by creating various characters.

I am exploring student scripts to find fractional metaphors and will be analysing the work of the other students in my study, as well as Aiden's. I have found more metaphors: e.g., fraction is equipartitioning amount, fraction is iterating, fraction is division, and fraction is a number form. In the future, more findings about fraction metaphors and an in-depth analysis of these metaphors will have to be conducted, and then I would be able to provide a metaphor model that can be used to understand fraction concepts and a framework of metaphor analysis. Lastly, as scripting can be extended as a teaching activity such as writing a scenario for the real performance of mathematics role-plays, I hope to pursue further studies on the use of scripting in mathematics classrooms.

Signing about elementary algebra in Austrian Sign Language: What signs of the notion of variable can represent

Flavio Angeloni[1], Annika M. Wille[2] and Christian Hausch[3]

Universität Klagenfurt, Austria;

[1]flavioan@edu.aau.at; [2]annika.wille@aau.at; [3]christian.hausch@aau.at

Languages have a significant impact on mathematics learning, with visual languages and spoken languages in particular differing. The study presented here investigates how one can sign about notions in elementary algebra in different ways in Austrian Sign Language. In particular, the focus is on the question of what sign language signs of the notion of variable can represent and thus how they may impact on the understanding of variables. Distinctions from spoken language are identified. The study is part of a larger investigation into communicating about elementary algebra in sign languages.

Keywords: Language, learning mathematics in sign language, classifiers, elementary algebra.

Introduction

Sign languages are full-fledged natural languages with their own grammars. They are in no way inferior to spoken languages (Beecken et al., 2014) and can express concrete as well as abstract things just as those. Therefore, communication about mathematics is just as possible as in spoken language. There is not only one sign language used around the world but many different ones (Braem, 1995). Their development does not necessarily coincide with that of the respective national spoken languages. Sign languages organize ideas and convey content, meaning and significance in a different way than spoken languages. That means a person who thinks in sign language thinks differently than one who is thinking in spoken language (Grote, 2010). Therefore, the conceptual understanding that is typically oriented toward hearing contexts – i.e., based on the characteristics and features of spoken languages – often does not match the conceptual understanding of students who use sign languages, and thus may not be appropriate for this audience (Krause, 2016, 2019; Krause & Wille, 2021; Wille & Schreiber, 2019). The study presented here is part of a longer series of investigations on the topic "sign language and mathematics education". The specifics of sign languages will be considered with the aim of developing and evaluating approaches and concepts for teaching mathematics in sign language. Language plays an essential role in both teaching and learning mathematics (Fleming, 2007; Thürmann & Vollmer, 2017). Therefore, the research focuses first on sign language, especially on its lexemes and classifiers, two important components of sign languages. The first multiphase investigation concerns specifically talking about mathematical activities in elementary algebra. The mathematical focus is on different aspects of variables (see below): object aspect, substitution aspect and calculus aspect (Malle, 1993). The linguistic focus is on the Austrian Sign Language (ÖGS). The general interest of the study is to investigate how these aspects occur in ÖGS and how mathematical notions and their aspects are represented in this sign language. Knowledge of these two points about sign language is necessary to teach mathematics in this language. In the following, the general question is specified in terms of the object aspect of variables: Which lexemes (signs) are used for the object aspect of variables in ÖGS? In what way are classifiers used for this? What are the differences between sign language and spoken language in this regard? High knowledge of these topics about language is on the one hand necessary for the translation between spoken language and ÖGS regarding mathematical teaching and learning. On the other hand, it provides the basis for the next investigations in mathematics education regarding sign language.

Aspects of variables

The word "variable" corresponds to its etymology: It can appear in different forms, denote different things and it can have different aspects. For example, there are "word variables". These are single words or groups of words that are representative of something else – e.g. of numbers (Akinwunmi, 2012; Küchemann, 1978; Malle, 1993). The "usual" variables used in mathematics are the "letter variables". According to Malle (1993) at least three aspects can be identified for variables: object aspect (the variable is an unknown or unspecified object of thought), substitution aspect (the variable is a placeholder into which numbers may be inserted) and calculus aspect (the variable is a sign without meaning, but which may be operated with according to certain rules) (Malle, 1993; Schoenfeld & Arcavi, 1988; Wille, 2008). If a variable is considered under the object aspect, then the object of thought itself can be different: a figure, a number, a number as a quantity of something etc. Thus, with a single word in spoken language such as "number", one can refer to various things. Therefore, "variable" can denote many different things. When such terms are translated into other languages, phenomena such as diversification may well occur. In translation studies the term "diversification" means the phenomenon in which for one word in the original language there are several words in the target language (Koller, 2011). Vice versa there is a "gap", if for one word there exists no translation. Thus, the first question that arises at this point is:

- *Which sign language's sign or signs are used for the manifold term "variable" (from the point of view of the object aspect)?*

Classifiers in the sign languages

Classifiers have an important function in sign languages. Classifiers (CL) or depicting handshapes are a complex and a highly discussed topic in sign language research. Definitions often diverge. In the presented research a classifier is an element whose meaning is related to the context. It represents "entities" based on their characteristic features and is involved in a morphologically complex structure. With a classifier objects or processes are classified based on common features (e.g. the index finger represents a "person") (Zwitserlood, 2012). Classifiers can be used to refer to the property, position and movement of the signified (Beecken et al., 2014). They follow certain rules of sign language grammar. For instance, if they refer to a noun, they are signed after the sign for that noun. If classifiers refer to a verb, they are signed before the sign for that verb. For the classification of classifiers there are several possibilities concerning semantics or linguistic context. Regarding the mathematical background of the study, first of all, the following classification is made: semantic classifiers (representing a "stylized" shape of the object: e.g., flat hand for cars or tables, claw hand shape for a clock or picture frame, etc.), instrumental classifiers (which denote objects according to how they are handled) and size and shape classifiers (representing size, extent, etc. of an object). The last group of classifiers – if it is considered to be a part of classifiers – can be further divided into static classifiers (to represent the size and shape of the object) and tracing classifiers (by moving one or both hands they outline the shape or size of that object) (Beecken et al., 2014; Zwitserlood, 2012). The use of classifiers for real objects (including humans and animals) is quietly clear. However, when signing about mathematical notions – as about variables – the second question arises:

- *Which classifiers are used when signing about variables with regard to the object aspect?*

The formation of new groups of classifiers related to the mathematical nature of the represented objects is not excluded here. Since mathematical notions in the school context mostly originated from spoken languages the third question investigated is*:*

- *What differences exist between spoken language (German) and ÖGS regarding the object aspect of variables?*

Learning environment

In each session of the learning environment the students get tasks[1] concerning two persons that have to distribute brochures. In the beginning they have one thousand brochures to distribute, but it is unknown how many the one person and how many the other person is going to distribute. Then one person gives a stack with two hundred brochures to the other person. The students are now asked to answer two questions about the amount of the brochures that each person has – before and after the stack of two hundred brochures was moved from one person to the other person.

The students have to perform those tasks in the given order according to the dialogic principle "me-you-we" (Green & Green, 2018; Ruf & Gallin, 1995, 1999). This principle provides for three phases. In the "me-phase" each student deals with the problem alone. The student does not necessarily have to come up with a solution in this phase. Notes or sketches of a solution idea are sufficient – that means: "this is how I do it". In the "you-phase" the students exchange ideas with each other (in pairs of two or in small groups): "how do you do it?". Results and open questions are to be recorded here. In the "we-phase" the results of the "you-phase" are presented, discussed and compared in the plenum in order to arrive at a joint solution and find a convention: "this is how we will do it". The phases "this is how I do it", "how do you do it?" and "this is how we will do it" can be rephrased from the point of view of sign languages as follows: "this is how I sign it", "how do you sign it?" and "this is how we will sign it". However, the last phase cannot always take place in this form, because there are rarely conventions for mathematical terms in ÖGS. The basic idea of the learning environment presented here is that the students become as active as possible – not only mathematically, but first of all in their language, the Austrian Sign Language. The influence of spoken language should be reduced as much as possible, on the one hand with the aim to not disturb the natural communication in ÖGS, on the other hand to not distort the observations of sign language communication. Spoken language could transport elements into ÖGS that are not compatible with the specifics of a sign language and specifically of the ÖGS. Therefore, from the beginning the material was developed in a sign language perspective and not as a translation of a material that was developed in a spoken language. The material contains no text, but only pictures (comics) and QR codes linking to videos

[1] Task card no. 1 at https://me.aau.at/~awille/mathe_in_oegs_variablen_01.html; task card no. 2 at https://me.aau.at/~awille/mathe_in_oegs_variablen_02.html; task card no. 3 at https://me.aau.at/~awille/mathe_in_oegs_variablen_03.html

in ÖGS with explanations and tasks. The students are able to watch these videos as often as they want to on their own smart phones. All videos are signed by a deaf person who also has ÖGS as basic language. A script for the videos is not used in order to avoid any interference errors (that are typical expressions of spoken language but not of ÖGS). Mathematical terms (e.g. variable), for which no signs (in ÖGS) are known, are not mentioned in the videos and in the sessions. These terms are not even finger spelled.

Methods

The research took place in form of two 60 minutes sessions in July and August 2021– with three people in the first and four people in the second session. The participants were deaf adults (age range 30 to 65) and their basic language was ÖGS. Basic language means the language in which a person thinks – his or her "inner" language. Adults were selected for this first part of the study because they were the most competent in ÖGS of those available. They were no more familiar with variables from their school background. Two teachers moderated the sessions. They announced which tasks had to be solved and answered technical questions. The order of the tasks is given as a structured interview. After the "you"-phase, the teachers led the "we"-discussion as an unstructured interview: getting the participants in the discussion and asking further questions (e.g. why is it like you say?). Both sessions were recorded by video and the participants were aware of that. So that is a direct observation with continuous monitoring. The videos were glossed (transcribed with glosses) according to the notation system of (Prillwitz & Wudtke, 1988), but simplified for the aim of the investigation. Glossing means the practice of writing down a sign language text sign-by-sign. Afterwards, the classifiers and signs of the notion of variable were determined. The data were then analyzed according to the principle of content analysis (Kuckartz, 2018).

Findings

With regard to the core of the tasks – the number, i.e., the quantity of brochures that are stacked – five different classifiers occur (Fig. 1). Since the meaning of the classifiers can only be deduced from the context this was also considered. Here are transcribed examples of each that the participants used:

P1: WIEVIEL CL_1-STAPEL FLAVIO WIEVIEL CL_1-STAPEL SANDRA
How many pieces does Flavio have? How many pieces does Sandra have?

P2: ZUSAMMEN EIN-TAUSEND IX CL_2-STAPEL CL_2-STAPEL
In total there are one thousand [stacked brochures].

P1: SANDRA DA EIN-TAUSEND CL_3-STAPEL
Sandra has one thousand [pieces].

P3: ERSTENS DREI CL_4-STAPEL CL_4-STAPEL CL_4-STAPEL
At the beginning there are three stacks.

P1: ZWEI-HUNDERT CL_5-GEBEN
[Flavio] gives 200 [brochures] to [Sandra].

P6: HAUFEN GEBEN WEISS-NICHT CL_1-STAPEL WIEVIEL WEISS-NICHT
From the pile [Flavio gives her] some. But you don't know how many there are in the pile.

For statements about the unknown or unspecified number of brochures on a stack the first classifier was used (Fig. 1a). It is introduced by the “question sign” WIEVIEL (*how many*). In the recordings this classifier occurs when unknown quantity is concerned. The execution of the classifier, moreover, reveals what exactly it refers to: The splayed dominant hand (“sh” hand shape) moves upwards. It represents every single brochure on the stack. Since those brochures are a lot the movement of the hand is smooth. So, the sign was used to denote the unknown or unspecified number of brochures. In particular, the information that the brochures are stacked are by the sign transmitted as well.

Fig. 1a. CL_1-STAPEL (*stack*)

Fig. 1b. CL_2-STAPEL (*stack*)

Fig. 1c. CL_3-STAPEL (*stack*)

Fig. 1d. CL_4-STAPEL (*stack*)

Fig. 1e. CL_4-STAPEL (*stack*)

Fig. 1f.CL_5-STAPEL-GEBEN (*to give a stack*)

Figure 1. Classifiers and a “simple” sign for the representation of a known or unknown quantity of stacked brochures

However, with this classifier one additional information is given simultaneously to the information about the unknown quantity. The dominant hand moves upwards, then downwards and once again a little upwards. This can be a representation of the possible height of the stack depending on what height the signing person imagines. This means that the classifier additionally conveys how large the range of the variable is. Summing up, ÖGS can express with a single sign the following: there are many brochures, they form stacks, we don’t know their height, it can be zero to something, that however will not be “too much”. The other classifiers occur in relation to a known quantity: the classifiers CL_2 and CL_3 in Figs. 1b and 1c represent the one thousand stacked brochures. The difference between the two classifiers is the repetition. So it is with CL_3 clearly represented that there are multiple stacks. With the fourth and the fifth classifier the stacks have the same height as if they would have been divided into three stacks of the same height. The sixth classifier (Fig. 1f) is an instrumental one that together with the verb “to give”. It represents how the stack (of 200 brochures) is given to the other person.

Out of the topic “classifiers”, at the lexical level the sign NOCH-NICHT (*not yet*, see Fig. 2) occurs. It refers many times to a missing (piece of) information. A few examples (from study unit 1 and 2):

P6: NORMAL STÜCK MUSS ERST HAUFEN [pfff]. WIEVIEL STÜCK NOCH-NICHT GEBÄRDEN NOCH-NICHT NOCH-NICHT
Usually, it should be given at first how many pieces there are. However, this has not been said.

P6: WO GEBÄRDEN EIN-TAUSEND WO. NOCH-NICHT GEBÄRDEN NOCH-NICHT
Where has it been said that it was one thousand? Where has it been said? This has not been said?

Figure 2. the sign NOCH-NICHT (*not yet*)

Discussion

Regarding the first question of which sign(s) exist(s) for “variable” under the object aspect in this context, the sign for the first classifier CL_1-STAPEL (*stack*) can be identified (Fig. 1a). This sign can be interpreted as a “sign variable” for the word variable “number” from the spoken language and as a variable itself in terms of the object aspect. Moreover, the sign NOCH-NICHT (*not yet*, Fig. 2) was used to express that an information is unknown.

Regarding the second question of which classifiers are used and how, it can be stated that the classifier CL_1-STAPEL (*stack*) is used to express the indeterminacy of the number of stacked prospects. This classifier differs from the others (for a known quantity) especially in the movement of the dominant hand, which moves once upwards, once downwards and once again upwards, but not the same height as before. This could be related to the fact, that the height (the quantity) is unknown. If the quantity is known, other classifiers are used – and each of them expresses a different detail about the signified: size, how stacks look, if all stacks have the same size etc. However, since a classifier is very closely related to the signified, a strong diversification can be assumed for other contexts as well: Depending on what a variable refers to different signs could be used to define that variable. One reason for this phenomenon could be the nature of the sign languages themselves: they are complex languages that have many slides also on the side of the “factual information” (Schulz von Thun, 2011). Thus, the need for a single equivalent sign for the word variable “quantity” does not seem to exist. Rather, for teaching mathematics in ÖGS, it should be necessary to know how and under which aspect a variable is used in order to render this variable according to the peculiarities and characteristics of sign language. Due to the difference in the movement of the dominant hand, the definition of a new group of classifiers could be possible and meaningful.

In this first part of the study, it was possible to state, on the one hand, possibilities with which signs and with which type of classifiers the object aspect of a variable in ÖGS can be represented. On the other hand, regarding the third question about the differences between spoken language (German) and Austrian Sign Language, it was found that in the sign language communication about the object aspect of the variable a lot of information was given simultaneously: In a single sign such as CL_1-STAPEL (*stack*, Fig. 1a) it is expressed whether the quantity is large or small, what shape or arrangement is meant and in which domain the quantity is located. In contrast, the word "quantity" is not enough to convey all this information in the spoken language. In the ÖGS this is possible in a natural way and can thus describe and represent variables very accurately. This indicates that a translation of (written or spoken) texts – e.g. of teaching material or of teacher explanations – from spoken language into ÖGS should be clearly detached from the source text. It is not only about transferring the texts or the grammar of ÖGS, but also about which information is transferred and how. Typically, for example, in mathematics teaching one could speak about the "quantity of stacks" in this context. In this phrase it is explicitly given that there is a stack and we talk about its quantity. It remains implicit that we do not know the quantity at the moment or in which range this quantity is. With signs, in contrast, more of the implicit information is expressed explicitly. This does not mean that ÖGS is "underrated" compared to spoken language and therefore needs more information and explanations to express complex and abstract content in a meaningful way. Rather, that one must take into account and can use the representational power of sign language. The next step in the study will be to investigate the other aspects of variable and to vary the context.

Pre-structured learning of heuristic strategies: types and potential of post-reflection tasks in heuristic worked-out examples

Annika Bachmann

University of Rostock, Germany; annika.bachmann@uni-rostock.de

Keywords: Heuristics, problem-solving, worked-out examples, reflection.

Various approaches have already been developed and studied to support students in mathematical problem-solving processes. Most of them aim at supporting students by indirectly or explicitly addressing strategies that are typically helpful for a problem solver (Pólya, 1945) - so-called *heuristic strategies*. These appear in situationally different forms and types (e.g. Schoenfeld, 1985).

Pre-structured learning formats are formats that predominantly initiate learning activities with little (or no) guidance from the teacher. *Heuristic worked-out examples (HWEs)* (Reiss & Renkl, 2002) are one possible pre-structured learning format for supporting secondary school students' problem-solving processes in mathematics classrooms. Bachmann and Müller-Hill (2021) have theoretically analysed the potential of different design elements of HWEs, focusing on promoting learners' development of heuristic strategies as a component of successful problem solving. This analysis underpins the thesis that so-called *post-reflection tasks* can generally initiate learning activities that support the acquisition of heuristic strategies (Bachmann & Müller-Hill, 2021). In this context, the poster contribution addresses the following specific research question: *Which types of post-reflection tasks in heuristic worked-out examples with the potential to acquire an individual heuristic strategy can be identified?*

Sketch of the theoretical framework.

Following general action-oriented learning theories (e.g. Aebli, 1994) and research on mathematical problem solving (e.g. Pólya, 1945), having a heuristic strategy at one's disposal develops out of an individual's concrete problem-solving actions, starting from actions in suitable situations within concrete problem-solving processes to achieve specific (sub-)targets that can be assigned to a heuristic strategy. This development occurs primarily in the form of two complementary processes: internalising and classifying, mediated by language. Based on such a conceptualisation of an individual heuristic strategy, a two-dimensional learning field to acquire heuristic strategies (Figure 1) is developed in Bachmann and Müller-Hill (2021), which refers to four types of learning activities: *performing an action*, *describing an action in one's own words*, *verbalising the target and situation of an action*, and *verbalising the target and situation of an action more generally*.

Applying the theoretical framework to the case of post-reflection tasks.

In Figure 1, we see three types of learning activities that aim to *compare actions within and across problem categories and relate actions across similar situations and similar (sub-)targets*. These activities enable individuals to communicate about problem-solving actions (at a more concrete level) and about heuristic strategies (at a more general and abstract level). Thus, they support the individual construction of an appropriate language and the gathering of experience about concrete problem-solving actions.

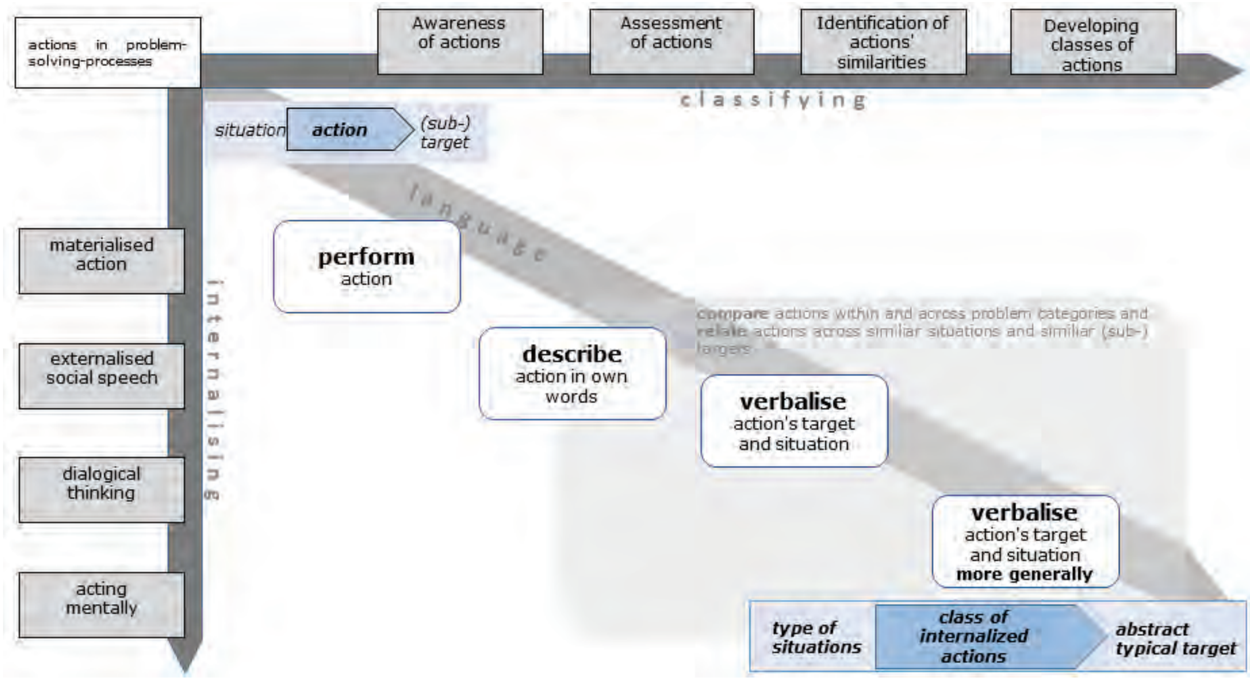

Figure 1: Learning field to acquire an individual heuristic strategy (Bachmann & Müller-Hill, 2021)

Post-reflection tasks focus on such descriptive and verbalisation activities. They are the final task at the end of an HWE. Therefore, it is possible to refer back to the entire solution process presented when working on these tasks. By setting suitable post-reflection tasks, a guided reflection on the solution process and individual actions within it can be initiated for the overall process. Different formulations and presentations of post-reflection tasks can initiate different learning activities of describing and verbalising (Bachmann & Müller-Hill, 2021).

The poster proposes a theoretically based characterisation of types of post-reflection tasks and illustrates concrete examples for each type using different formulations and representations. The possible strengths and weaknesses of the different types and representations derived from the theory form the starting point for future empirical work.

Second-order covariation: it is all about standpoints

Sara Bagossi

University of Ferrara, Italy; sarabagossi@gmail.com

Second-order covariation is a quite recent theoretical construct in the field of Mathematics Education: it differs from the already existing construct of covariation in placing greater emphasis on the role of parameters, with respect to the other variables, as characteristic of a certain family of functions and as relevant in modelling classes of real phenomena. In this contribution, we address the novelty and importance of this type of reasoning based on a teaching experiment concerning modelling of a thermodynamic situation. Starting from the analysis of three episodes, we highlight some features of this construct, and the emerging interpretation as a change in standpoint that results in different graphical representations suitable to interpret globally the specific mathematical situation.

Keywords: Covariation, variables, parameters, graphs.

Introduction to the research problem.

Covariational reasoning is an essential skill necessary to enter deeply into the processes of mathematical modelling (Thompson, 2011): it can help to model "the change and the relationships with appropriate functions and equations, as well as creating, interpreting and translating among symbolic and graphical representations of relationships" (OECD, 2022). Italian mathematics curricula for secondary schools also address the importance of "represent[ing] the same class of phenomena through different approaches" (MIUR, 2010, p. 337). To pursue this goal, using multiple representations (Ainsworth, 2008) turns out to be of great importance for students in order to fully embrace all the aspects of the mathematical situation under investigation. An example of meaningful graphical representation which lends itself to multiple educational purposes consists of the "psychrometric chart" or Carrier diagram. It describes the thermodynamic parameters of moist air at constant air pressure, so it is a graphical representation of an equation of state. This type of representation requires sophisticated forms of covariational reasoning to grasp how magnitudes are varying and to identify their mutual relationships. To better introduce this chart, we comment on a real chart displayed in Figure 1a and/or on a slightly simplified simulation[1] of it created with Wolfram software, shown in Figure 1b. The dry bulb temperature is shown on the horizontal axis while the vertical axis is the absolute humidity. The chart in its complete form contains many parameters: wet bulb temperature, dew point temperature (the temperature at which the air becomes saturated with water vapor), relative humidity, specific enthalpy, and specific volume; indeed, reading a psychrometric chart is very challenging, but if we just focus on temperature (abscissa), absolute humidity (ordinate), and relative humidity (the parameter), the relation between temperature and absolute humidity is given by an exponential-like function (green curve) and a different curve corresponds to each value of the percentage of relative humidity. Indeed, the Carrier diagram shows the mutual relations between the three variables involved crushed onto a two-dimensional

[1] This simulation is available online at this link: https://demonstrations.wolfram.com/ReadingAPsychrometricChart/.

representation: this flattening makes the reading and the interpretation more complicated than a three-dimensional representation in which the three magnitudes assume the same ontological status of variable. Again: why choose relative humidity as the parameter instead of absolute humidity? How would this choice affect the bidimensional representation?

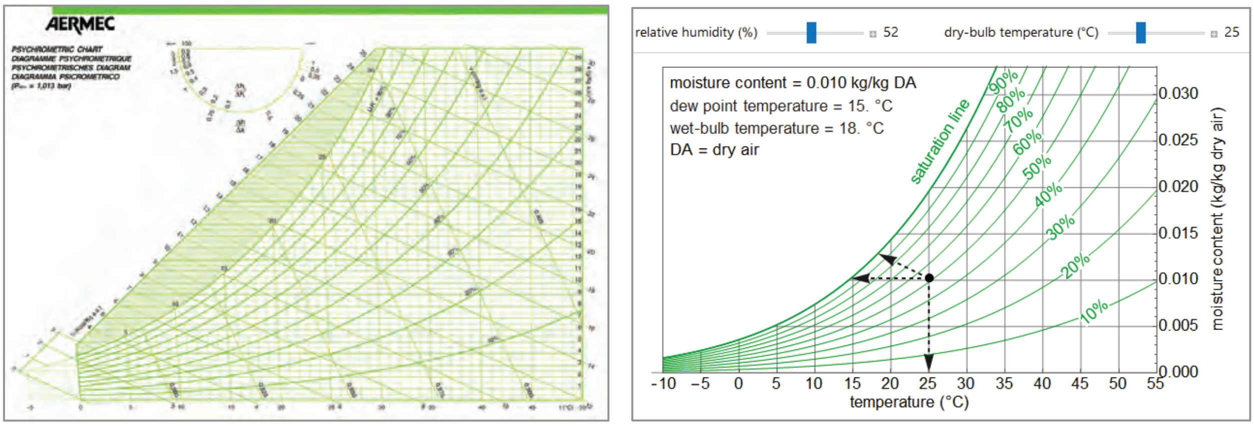

Figure 1: a) An example of psychrometric chart; b) Simulation of a psychrometric chart created with Wolfram software

To answer these questions, the theoretical construct of second-order covariation is introduced. While the construct of covariation focuses on the relation between two or more variables, second-order covariation focuses on the role of characteristic parameters as specific of a certain family of functions. What is defined as being "of second order" depends on the way a specific variable is extrapolated from the assigned scenario and interpreted as a parameter: this determines the standpoint from which the mathematical situation can be represented.

The main purpose of this contribution is to enter the complexity of second-order covariational reasoning required to fully understand the relations between the above magnitudes. Consequently, our research question can be formulated as follows: *how can second-order covariational reasoning be characterized when interpreting representations, like the psychrometric chart, where at least three magnitudes are involved and one of these can be mathematically interpreted as a parameter?*

In this paper, we are going to initially provide a characterization of the construct of second-order covariation referring also to other theoretical contributions in the literature. Then, thanks to the analysis of a few episodes from a teaching experiment involving an Italian secondary school classroom, and based on the interpretation of the psychrometric chart, we are going to explore the covariation emerging in students' reasoning. Finally, we propose a refinement of the construct of second-order covariation which could be interpreted as a change of standpoint suitable to interpret different mathematical representations.

Theoretical framework.

The use of multiple representations strongly supports the learning of mathematical concepts, and among their various functions they provide information that complement each other and/or foster the development of deeper understanding when they support additional information (Ainsworth, 1999). Although multiple representations are beneficial to the learners, they are non-trivial for students to use to relate and identify connections (Ainsworth, 2008). Beyond this, single representations themselves can be challenging: for instance, reading, interpreting, and reasoning about graphs requires grasping the relationship between the values of the magnitudes involved, and so it demands good covariational skills.

Being able to reason covariationally means being able to envision two or more magnitudes that vary simultaneously, as presented in Thompson and Carlson (2017). The last version of this theoretical construct, presented in the same work, and that we are going to refer to as first-order covariation (COV 1), consists of six levels of covariational reasoning ranking from absence of covariational reasoning to smooth continuous covariation. These levels can be interpreted as classes of behaviors or descriptors of a person's ability to engage in covariational reasoning. In this contribution, we consider covariation in a broader epistemological sense, i.e., as the ability to grasp relations of invariance that are more complex than the simple covariation between two magnitudes. Specifically, the construct of second-order covariation (COV 2), recently introduced by Arzarello (2019), is a form of reasoning that consists in suitably envisioning the relationships in which not only variables but also parameters are involved mathematically. In particular, the latter allow to represent classes of real phenomena as families of relations between variables, which are mathematically represented by specific parameters. These determine the peculiarities of the mathematical model. Furthermore, the label “second-order covariation” seems particularly suitable to underline the role played by parameters: indeed, Bloedy-Vinner (2001) already used the expression “second order function” to address those functions whose argument is a parameter and whose output is a function or an equation depending on a specific parameter value.

The necessity of introducing this new order of covariation emerges predominantly from the need of better describing students’ reasoning when dealing with situations of mathematical modelling, such as the law of the inclined plane as presented in Arzarello (2019). However, it also emerges in other studies in literature. For example, Hoofkamp (2011) introduced the term “metavariation” to refer to a variation of the mathematical situation itself and the function as a whole: it is related to the object view of the function and to a qualitative view of the functional dependency and its local and global characteristics. While our approach to second-order covariation mainly focuses on the mathematical and cognitive characterization of this form of covariational reasoning, metavariation emphasizes the instrumentation of second-order covariational processes adopting suitable activities mostly designed with Interactive Geometry Software. This way of reasoning covariationally seems to be more cognitively demanding than the one presented in the already existing taxonomy. Hence, this contribution supports and contributes to the perspective of an enlargement of the theoretical framework that aims at coherently including more complex forms of covariational reasoning and opens up to the possibility that other orders of covariation may exist.

Method.

Participants and task design. The episodes presented and analyzed in this paper are part of a teaching experiment that was held in a 11th grade classroom of 21 students in a scientific-oriented school in Italy. It was conducted at the beginning of the school year 2020/2021 in a mixed modality due to Covid pandemic. Ever since the first year of secondary school the students involved were accustomed to working with different mathematical representations (algebraic, graphical, numerical) and to using Dynamic Geometry Softwares such as GeoGebra. Moreover, in the academic year 2019/2020 the students had already been involved in a teaching experiment concerning the law of the inclined plane, the so-called Galileo experiment (Bagossi, 2021), so they had already experienced covariational reasoning in a context of mathematical modelling. This experimentation had the main purpose of elaborating mathematically on the relationship between temperature and humidity adopting multiple representations and various digital supports. The first task consisted of analyzing the mathematical and physical relationship existing between temperature and humidity through a household experiment during which for an entire day, at regular intervals, students collected the values of temperature and humidity in their rooms with the request to eventually elaborate some hypotheses on a possible relationship between the collected data. In a subsequent lesson, students' hypotheses were discussed, and the teacher commented on a GeoGebra graph displaying some of the data collected. The students, together with their teacher, concluded that the two magnitudes could be related in some way, namely whilst the temperature increases, the humidity decreases, and vice versa. The activity continued with an experiment in class: in a metal pot with some water at room temperature, ice was gradually added until droplets of water appeared on the outside of the pot. At regular intervals of time the students recorded the time spent and the temperature of the water in the pot itself and took note of the temperature when the dew drops appeared (that is the dew point). After a working group session devoted to the understanding of a real psychrometric chart, through a classroom discussion (Discussion 1) led by the teacher, the students investigated the relationships between time, water temperature, room temperature and the reason for the creation of dew drops on the outside of the pot. At the end of the discussion, the teacher provided students with a slightly simplified psychrometric diagram created with GeoGebra (Figure 2a) and a worksheet with a real chart (Figure 1a).

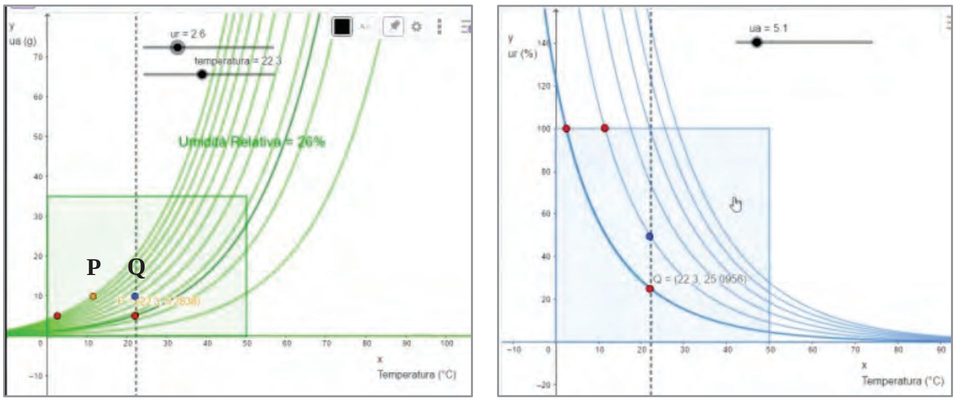

Figure 2: a) GeoGebra applet simulating the psychrometric chart; b) GeoGebra applet describing the relation between relative humidity (y-axis) and temperature (x-axis)

Working in small groups on some guide questions, the students were able to read relative humidity values from the graph representing absolute humidity as a function of temperature and, conversely, to read the values of absolute humidity from a new graph, provided in a second moment, representing relative humidity as a function of temperature (Figure 2b). At the end of the group work, the students discussed with the teacher (Discussion 2) the roles of the magnitudes at stake in the mathematical representations (independent variable, dependent variable, or parameter). We note that the multiple representations involved, such as the real psychrometric chart and the two applets have a complementary function, while the pot experiment with respect to these provides extra information but it will reveal crucial for students to disentangle the meaning of the graphical representations.

Methods of data analysis. The analytic method used in our qualitative study was that of a descriptive coding of the emergent forms of covariational reasoning (Saldana, 2015). A preliminary phase consisted of watching the videos of all the lessons repeatedly in order to identify episodes revealing covariation. During the first cycle of coding, we classified the orders and levels of emerging covariational reasoning describing their features and the quantities involved; then we transcribed the most significant episodes. During the second cycle of coding, we deepened the qualitative description, focusing on the identification of the representations that most influenced the students' reasoning, i.e., the pot experiment or the graphical representations, the use of a qualitative or quantitative narrative, and terms denoting change and movement. Eventually, we revised the coding in light of the qualitative descriptions of the episodes we had elaborated.

Data analysis.

The first episode analyzed here is an excerpt from the 1-hour discussion in presence (Discussion 1) led by the teacher after the working group session on the psychrometric chart. During this episode, students, guided by the teacher, tried to retrace what happened during the experiment with the pot on the psychrometric diagram. The applet reproducing the psychrometric chart was shown on the interactive whiteboard and students had already identified point P representing the point on the saturation line in which the temperature coincides with the temperature of the dew point. Point Q instead has the same ordinate as P and the ambient temperature as abscissa (Figure 2a).

1	Teacher	On the graph, how can I read these passages? We said this is the starting point because we said we do not go from P to Q, but we start from Q. Starting from Q, where did we go?
2	Giorgia	We decreased the temperature hence we moved to the left.
3	Teacher	We decreased the temperature hence we moved to the left. In which way? Did you just decrease the temperature or not? We are during the moment in which you continued to pour and pour [the ice].
4	Emanuele	Only the temperature decreases.
5	Teacher	Only the temperature decreases. And so, on the graph, how do you move?
6	Emanuele	Horizontally.
7	Teacher	Horizontally. We have point Q and we move horizontally to decrease the temperature. Until when do we move horizontally?
8	Emanuele	Until the dew point.
9	Teacher	Until the dew point that is until when we find on which of these green curves?
10	Emanuele	Until that of 100%.

All the episode is centered around a game of displacement between the graphical representation and the experiment facilitated by the mediation of the teacher that constantly asks the students how they would move on the graph, inviting them to relate to the experiment with the GeoGebra applet. This game of displacement results in the interlacing of two different narratives: a qualitative one, used to describe what happened during the experiment that manifests with the use of personal pronouns (e.g., "*we* decreased the temperature" [2]); a quantitative one used to describe how the magnitudes involved are changing (e.g., "Only the temperature decreases" [4]). The students already possess the psychrometric diagram representing the covariation of magnitudes involved and they are moving on this representation: we can recognize the enhancement of a global approach supported by the involved representations.

Discussion 2 was mainly focused on reconstructing the cycle of the pot experiment on the new chart, the one describing the relationship between absolute humidity on the y-axis and temperature on the x-axis. In this second episode, one of the graphs made by the students as homework is shown on the interactive whiteboard (Figure 3). The teacher is commenting on the second step of the experiment the one during which students continued to decrease the temperature in the pot by adding ice cubes and then some drops of water formed on the wall, represented by a horizontal segment, colored in yellow.

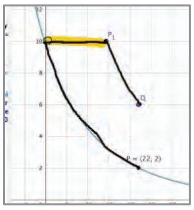

Figure 3: Relative humidity – temperature graph made by one of the students

11	Teacher	What is happening instead on the horizontal trait [of the graph]?
12	Arianna	The relative humidity maintains constant.
13	Teacher	The relative humidity maintains constant.
14	Arianna	And the temperature decreases.
15	Teacher	The temperature decreases. The absolute humidity? Does it decrease or remain constant?
16	Adele	Decreases.
17	Teacher	Decreases. Why?
18	Emanuele	You have the condensation.
19	Teacher	Ok, you have the condensation, and this is what happens practically. But on the graph why? […]
20	Adele	The curve changes.

As in the previous episode, students' linguistic expressions "The relative humidity maintains constant" [12] and "You have the condensation" [18] suggest that the combined and synergic use of the two representations, the chart and the experiment, helped students in reflecting on which magnitudes change and how they change during the different steps of the experiment and the corresponding traits of the chart. Even in this case we can observe the enhancement of a global approach supported by the involved representations.

Finally, this third episode below, coming also from Discussion 2, shows the approach used by the teacher to reflect on the similarities and differences between the two psychrometric charts and it can be intended as a form of conceptualization of the different roles of variables and parameters.

21	Teacher	Are they two different situations/scenarios?
22	Matteo	No.
23	Teacher	No. Why do the two graphs are different if they are not two different situations?
24	Matteo	The value represented on the y-axis is different.
25	Teacher	The value represented on the y-axis is different. If you should make a comparison with something that is not mathematical but concerns real life… We have the same situation/scenario, but the value represented on the y-axis is different… If you should make an analogy…?

26	Giorgia	From the physical point of view, they represent the same thing but from the graphical point of view no… because they are two different values.
27	Teacher	Oh! From the physical point of view, they represent the same thing but from the graphical point of view no because they are two different values. […] Two different situations depending on what?
28	Matteo	A different point of view.

At this point of the discussion, the teacher projects on the interactive whiteboard a new applet showing simultaneously the relationship of absolute humidity versus temperature (Figure 2a) and of relative humidity versus temperature (Figure 2b). The teacher asks to the classroom if the graphs are two different situations or scenarios [21]. Matteo obviously replies no [22], so the teacher asks why the graphs are different if they are not representing different things [23]. When Matteo states that the value represented on the y-axis is different [24], the teacher invites the students to provide a holistic interpretation, an analogy with something non-strictly mathematical [25]. Giorgia suggests that from the physical standpoint the situation is the same: what differs is the graphical representation [26]. Answering a teacher's question [27], Matteo adds that the difference between the two situations depends on "a different point of view" [28]. This interpretation suggests that the different role assumed by variables and parameters does not determine a different situation but a change of standpoint resulting in a different graphical representation.

Discussion.

After a first overall reading of the three episodes presented in the previous section, the question arising spontaneously is: where is covariation? If we think of some typical examples of covariational reasoning such as "A increases, while B decreases", they are surely absent in the excerpts described before. The psychrometric chart at disposal of the students synthetizes in a unique diagram and flattens in two dimensions the relations between three different magnitudes (temperature, absolute humidity, and relative humidity). The students implement forms of reasoning revealing a global approach supported by the adopted representations. In particular, in the physical interpretation of the relations described in the chart, students are deeply supported by the classroom experiment with the pot: all the classroom discussion develops through an interpretation of the diagram with respect to the various steps of the experiment. What the students observe in the last episode is that considering relative humidity as a variable or a parameter does not change the situation, but the perspective with which you look at the situation: the students claim that the relationship is always the same, only expressed in different terms. Second-order covariation is the construct that enables one to read the same mathematical situation from two different standpoints and to recognize a correspondence between the representations: in the real psychrometric chart the parameter is the relative humidity, and this magnitude is the one of second order; in the blue graph (Figure 2b) absolute humidity becomes the parameter and so it is the second order variable determining a different standpoint.

As it is for COV 1, second-order covariation is a cognitive act that cannot be reduced to the reading of a formula choosing to interpret one of the variables involved as a parameter. It is a form of reasoning that consists of envisioning the invariant relationships in a family of functions and this study sheds light on one of its facets that manifests when dealing with graphical representations.

Finally, even if it is not the focus of this paper, we cannot fail to observe the essential role of the teacher in mediating between the multiple representations helping students in relating them.

Moreover, the teacher supports students in better expressing their thoughts and enhances the transition from COV 1 to COV 2, and also from COV 2 to COV 1.

Conclusion.

Second-order covariation requires a complex cognitive engagement: it is a form of covariational reasoning that in activities of mathematical modelling involving multiple representations can be theorized as the ability to read the same mathematical situation from different points of view choosing each time which of the involved variables should be mathematically interpreted as a parameter. The characterization and relevance of second-order covariation still deserve to be deepened through further research.

From a mathemagic trick to number bases: using cryptography and the software WIMS to stimulate algebraic thinking in primary school

Marina Cazzola[1] and Valentina Grazian[1]

[1]Università degli Studi di Milano – Bicocca, Milano, Italy;
marina.cazzola@unimib.it, valentina.grazian@unimib.it

Keywords: Primary school mathematics, algebraic thinking, educational software.

Introduction

Kieran (2004) suggests that early algebraic thinking is linked to problem solving, modeling, working with generalizable patterns, justifying and proving, making predictions and conjectures, analyzing relationships, and identifying structure. Many studies reveal that algebraic thinking can be developed at an early stage, as long as it is stimulated by appropriate interventions by the teachers (e.g. Blanton & Kaput, 2005). Indeed, the application of student-active methodologies plays a fundamental role in the teaching process, especially in mathematics, as described by Schoenfeld (1992). In this view, our first aim of research is to provide support to improve teachers' practice toward engaging pupils in algebraic activities. We aim to achieve this goal by designing and sharing ready to use materials, which are realizing a *problem-solving approach* and involve modern technologies. The resulting effect on students' learning is our second aim of research: to examine if this type of instruction truly affects the pupils' capacity for justifying and proving.

We present an activity based on the modern cryptography technique of Hamming codes for error correction that is built around a magic trick and is supported by the software WIMS (WWW Interactive Multipurpose Server, e.g., see Cazzola, et al., 2020). The various tasks involved push the students into a learning path that can be described in short as follows:

- Participation in the magic trick
- Question: "How does it work?" (*problem solving, predictions and conjectures*)
- First analysis of the trick (*analyzing relationships and identifying structure)*
- Sharing of observations (*justifying and proving*)
- Conclusion (*generalizations*)
- Bridge to the study of number bases.

The last step is an added value of our activity: students approach a typical algebraic topic associating it to a fun and intriguing game, strengthening their motivation to learn about it. A detailed description of the experience can be found in (Cazzola & Grazian, 2021).

Description of the activity

The game we present is called "7 questions and 1 lie". A volunteer is asked to think about a number from 0 to 15 and to answer 7 yes/no questions about it, with the chance to lie only once. Looking at the answers, the mathemagician will be able to guess not only the mysterious number, but also if there was a lie and the question it corresponds to. Once the pupils' attention is caught, the real work starts, leading the students to find an answer to the obvious question "how does it work?".

The solution involves the use of a particular scheme (Figure 1) containing 7 numbered circles. Each circle corresponds to the question with the associated number and the instruction is to blacken it if the answer is “yes” and to leave it blank otherwise.

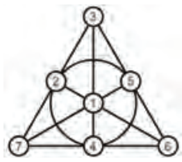

Figure 1: Scheme to solve the “7 question and 1 lie” magic trick

The analysis of the patterns will reveal the solution. Also, if we impose that a blackened circle corresponds to 1 and a blank one corresponds to 0, once the lies are detected and the coloring is fixed, the expression of the mysterious number in base 2 is given by the sequence of 0’s and 1’s given by the first 4 circles. This unusual approach to the study of number bases captures students’ attention and motivates the pupils in discovering more about this algebraic topic. Our activity can be presented using pen and paper only but becomes even more interesting if supported by its digital version, which we elaborated using the software WIMS. The dedicated WIMS page contains the magic trick, a step-by-step solution and a series of games aimed at practicing the description of numbers using different number bases.

Our experience

We presented the activity to four classes of 8-9 years old Italian students, for a total of 78 pupils, in Spring 2021. We conducted classroom observations and collected written students’ feedbacks. During the activity we recognized that pupils were actively engaged and carried out various examples of algebraic reasoning (especially in the form of making and motivating conjectures). This encourages us to further explore this approach and to deepen our investigation on its effects on pupils’ argumentation abilities. Furthermore, we could observe that pupils and teachers reacted enthusiastically to the tasks, strengthening our belief that this kind of proposal can also contribute to the diffusion of problem-solving and student-centered methodologies in primary school education.

Potential semiotic synergy in *TouchTimes* multiplication

Sean Chorney and Nathalie Sinclair

Simon Fraser University, Faculty of Education, Canada; sean_chorney@sfu.ca; nathsinc@sfu.ca

Abstract: Inspired by the notion of synergy, the sharing of signs between tangible and digital artefacts, we explore signs created by students that emerge through their use of TouchTimes (TT), a multitouch iPad application. We use Peirce to study the tripartite function of the signs (symbol, icon, index) available, as a way to study potential synergies in TT, and how they compare to signs found in other visual models of multiplication.

Keywords: Multiplication, visual representations, TouchTimes, synergy, semiotics, multitouch.

Introduction

Figure 1 shows a drawing made by a grade three (9-year-old) student who had been asked to draw what it would look like to solve the following problem using the multitouch application *TouchTimes* (TT) (Jackiw & Sinclair, 2019): “A bunch of buttons fell on the floor. Nick gathered them in heaps of eight buttons. He made five heaps. How many buttons are there?” We wanted to use this drawing to motivate our interest in exploring the nature and status of visual images used in the teaching and learning of multiplication. The drawing has familiar aspects to it, such as the unit-of-units (of circles) drawn on the right, which can be found in Davydovian (1992) representations of multiplication. It also contains unusual elements, such as the fingers on the left or the two-part structure, with the vertical line down the middle. The left side illustrates the original unit of 8, which is produced in TT by pressing eight fingers on the screen (even though there are ten on the drawing!). And the right side shows the symbolic expression as well as the unit (large lasso) of 5 units of 8 circles.

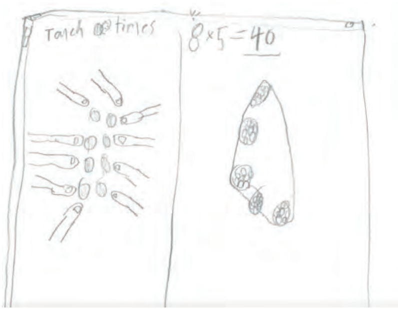

Figure 1: Student drawing of 8 × 5

The complexity of this drawing and its relation to the dynamic, tangible tool prompted us to wonder how it relates to commonly-used visual images of multiplication. Given the multiple ways there are of conceptualising multiplication, and the semiotic differences between them, we are interested in exploring how the use of TT might support the kind of *synergy* described by Mariotti and Montone (2020). We show that the material nature of Peirce’s indexical signs helps explain this synergy.

Visual models and representations of multiplication

Multiplication is a challenging concept for learners and researchers have advocated for the use of visual models or representations (Davydov, 1992). Kosko (2020) uses multiplicative scheme theory to argue that the development of multiplicative reasoning in children moves from counting by ones to conceiving of conceptual multiplicative representations. He argues that visual conceptual multiplicative representations can promote or limit engagement in multiplicative reasoning. However, there are a variety of ways to conceive of multiplication and each representation will stress some elements over others.

Maffia and Mariotti (2018) distinguish two models of whole number multiplication, the repeated-sum model and the array model, which are represented, respectively, in Figure 2a and 2b. They show how different properties of multiplication can be justified using each model. They also acknowledge that while the former model is pervasive in school mathematics, it has limitations, and that many researchers have argued for increased use of the latter model—particularly to support students' understanding of multiplication as a binary operation (in contrast to the unary operation of addition).

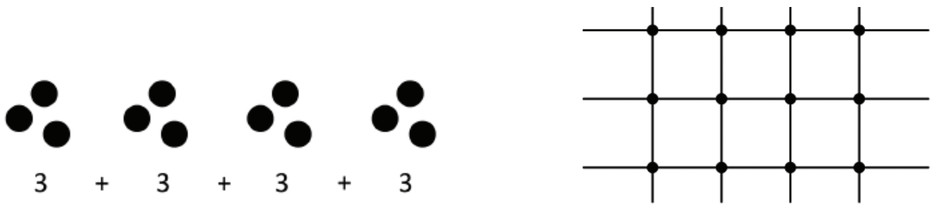

Figure 2: (a) Repeated sum model; (b) Array model (in Maffia & Mariotti (2018))

For example, Clark and Kamii (1996) use the image shown in Figure 3a to contrast additive and multiplicative thinking. While the top representation draws on the repeated sum model, the bottom one highlights the two levels of inclusion involved in multiplicative thinking—both the horizontal one and the vertical one. Looking at the vertical component of the representation, there is a *many-to-one* relation expressed by the three arrows between the bottom row and the middle one; each of the three single points is moved to the next level where it is conceived of as a single unit. Boulet (1998) reformats the Clark and Kamii representation using a Davydovian approach (Figure 3b). Davydov bases multiplication in measurement so that multiplication is related to a transfer of units. According to Davydov (1992), unitization is when "a person purposely alters a unit of count" (p. 10). The horizontal encasing that was visually expressed in Clark and Kamii is absent. This focuses attention to the many-to-one relation, or, in Davydovian terms, unitising: three becomes one.

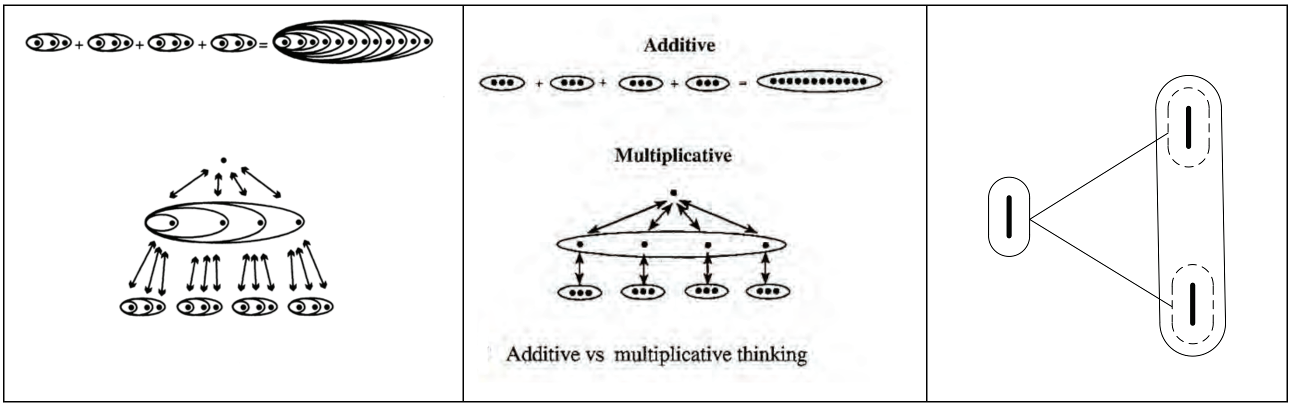

Figure 3: (a) The inclusive model; (b) The unitising model; (c) The splitting model

Confrey's (1994) splitting model (Figure 3c) depicts an original unit, which is then "split" to create duplicate versions of itself simultaneously, which contrasts with the sequential repetition of repeated sum model. The splitting model highlights a *one-to-many* relation in addition to equal grouping.

Finally, Vergnaud (1988) proposes a t-table (Figure 4) as a way of highlighting the four quantities involved in multiplication. He distinguishes two relationships: scalar and functional. The scalar relationship (vertical) is the ratio between two values of a variable: for example, the ratio between the number of cars is 5 : 1, which is the same as the ratio between the number of tires 20 : 4. The functional relationship (horizontal) is the ratio between two values of two distinct variables. For example, the functional relationship between the number of cars and the number of tires is 4.

The number of cars	The number of tires
1	4
5	x

Figure 4: The t-table functional, quarternary model of multiplication

While each of the authors cited above argues for the advantages of their model, we are interested in the question of how these various models might be complementary—if they each emphasise different aspects of multiplications and if student flexibility is valued, then surely exposure to multiple models if desirable. However, little research has focused on how students handle these different models.

Theoretical Framing

We adopt a semiotic approach drawing on the work of Peirce, who argues that understanding is based in signs. He distinguished three types of signs (icon, index, symbol) which differ in terms of the nature of the relationship between the signified and the signifier. Icons operate according to likeness or resemblance between the signifier and the signified. If iconic signs become conventional codes within particular cultures, they may become symbols, which have an arbitrary relationship with that to which they refer, as is the case for most spoken language as well as numbers and signs such as + and –. Figure 2a combines symbols (such as '3') and icons (the discs that resemble objects such as tokens). In Figure 2b, there are iconic elements in that the lines and intersections resemble either a rectangle or a cartesian coordinate system, but for some people, the image operates more like a symbol, if there is no resemblance apprehended. Indices are quite different from the other two in emphasizing the material link between signifier and signified.

Unlike icons and symbols, indexical signs are bound to the context in important ways—they "show something about things, on account of their being physically connected with them" (Peirce, 1894/1998, p. 5). As in the case of smoke billowing from a chimney indicating that the fireplace is in use, the smoke *indexes* the fire. The index is a sign that is materially linked or coupled to "its object". According to Peirce (1932), an index

> refers to its object not so much because of any similarity or analogy with it, (…) as because it is in dynamical (including spatial) connection both with the individual object, on the one hand, and with the senses or memory of the person for whom it serves as a sign, on the other. (2.305)

Verbal indexical signs perform this link to context very effectively, for instance, terms like "this" or "that" or even pronouns like "she", are meaningful only in relation to a given context. The arrows in Figures 3a and 3b act as indices in that they materially couple the three dots to the single dot; they are not similar to the transfer, but they index it. Similarly, the dotted lines in Figure 3c index a transformation of the object from one that has been split (copied) to one that belongs to the product.

Drawing on the Theory of Semiotic Mediation (Bartolini Bussi & Mariotti, 2008), Mariotti and Montone (2020) use the notion of *synergy* to refer to the common signs that emerge from students' interactions with different artefacts, which are related to the same mathematical concept. In their study, Mariotti and Montone had students translate and reflect a concave quadrilateral, first with paper and pins which fold and anchor, followed by a similar activity in a dynamic geometry environment. Mariotti and Montone argue that in the sharing of two artefacts, the new meanings emerging from the two artefacts synergistically interweave with each other to "reach the meanings that were intended" (p. 118).

We are interested in the synergy that occurs within the use of one single artefact, TT, in which there are signs that can be associated with different conceptual models of multiplication. This was exemplified in Figure 1, which shows the double unitising of the circles *as well as* the fivefold 'copying' of the 8 circles on the left. We would like to understand how this kind of synergy can arise and hypothesise that this can be done by studying the types of signs (in Peirce's typology) produced in TT. In other words, in order to identify opportunities for synergy, we analyse the TT environment in terms of its different signs, looking to see how they might relate to the different representations described in the previous section.

TouchTimes: A brief introduction

When first opened, TT is divided in half by a vertical line (Figure 5a). Whichever side of the screen is first touched by the finger(s) of the user's hand, results in a different coloured disc (termed a 'pip') appearing beneath each finger and the numeral corresponding to the number of visible pips being displayed at the top of the screen (Figure 5b). The numeral adjusts instantly when fingers are added or removed, whether temporally in sequence or simultaneously, and represents the multiplicand. In order to preserve each pip (that otherwise vanish), the finger(s) must maintain continuous screen contact. When a user taps on the other side of the line with her second hand, bundles of pips (called 'pods') appear with each contact (Figure 5c). The number of pods is the multiplier and each pod contains a duplicate of the pip configuration, matching both the relative locations created by the pips and the colours of those pips (Figure 5d). When pods are created, a second numeral also appears, separated from the first by the multiplication sign ('×'). If the user presses the array icon on the top right corner of the screen, the pips rearrange themselves into rows and the pods into columns.

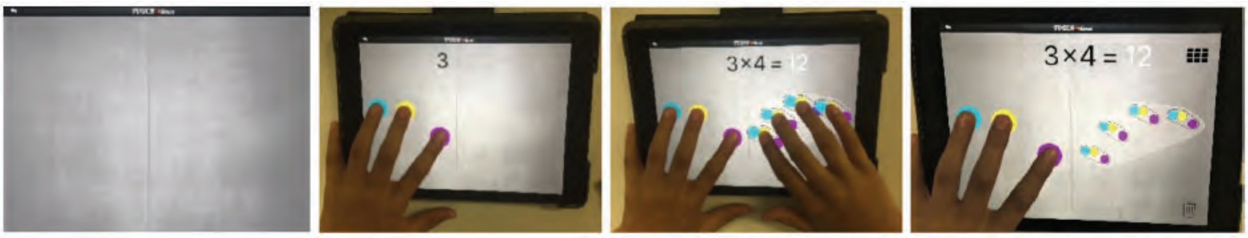

Figure 5 (a) The initial screen of TT; (b) Three fingers placed on the left; (c) Four fingers placed on the right; (d) Lifting the four fingers to see the unit of pods

Although TT provides a tangible, dynamic environment for creating multiplicative relations, and therefore differs significantly form the static representations shown above, it also aims to highlight certain aspects of multiplication and provides multiple opportunities for making different signs. The design of TT draws extensively from Davydov's (1992) model, with the first action being the creation of a unit, and the second action between the creation of a unit of units. Practically, this means a reversal of the repeated sum model since the unit size comes first—and therefore, we would read Figure 5d as 'three, four times' rather than as 'three groups of four', which is how the expression 3 × 4 is described in most North American classrooms. The array icon transforms the unit-of-units display into an array, which turns the repeated sum representation into a unit by unit array.

In addition to emphasizing *unitising*, TT also emphasizes the *splitting* idea in the sense that the 'copies' (literally, multi-plying) are produced simultaneously (pod-fingers touch the screen all-at-once). There is also the one-to-many relation that is emphasized when a pip finger is lifted or pressed since a change in pip on the left produces a change in each and every one of the pods on the right—we refer to this as a *spreading* idea. Finally, multiplication in TT is expressed as a *co-varying* operation between pips and pods (embodied by the use of two hands), with either quantity being dynamically changeable and visibly affecting the other.

In terms of *embedding*, the sequence needed to produce a multiplicative statement is shown in Figure 6. These four steps parallel the quarternary aspect of Vergnaud's description of multiplication (see also Askew, 2018). That is, there are four numbers involved in multiplication. In the first step, there is the determination of the number of pips, this is a variable amount, that is, it can change (at any time). The second step is to see those pips as a unit, or a pod ("1"). This idea is expressed in TT by embedding the pips by a border. The third step determines the number of pods, this is also variable. And the final step is to see these multiple pods as a unit, the product. Again, the four numbers are the number of pips, one pod, the number of pods, and one product.

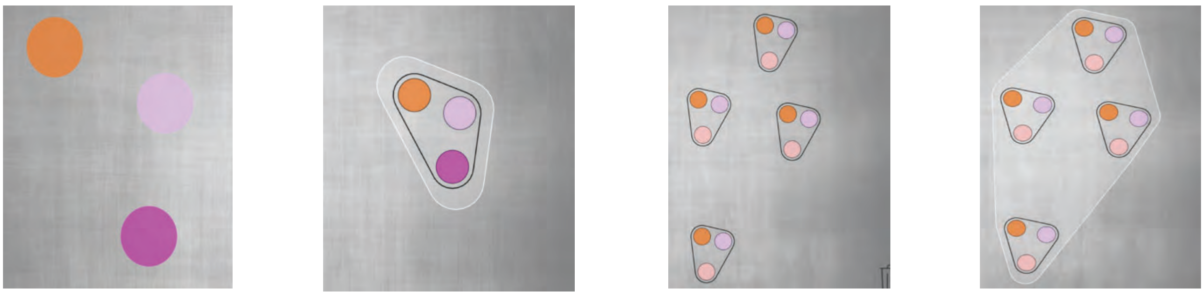

Figure 6 (a) Three pips; (b) A unit of three pips (a pod); (c) Four pods; (d) A unit of four pods (a product)

A semiotic analysis of TT

In terms of the signs at play in TT, there are numerous similarities and differences with the models we have described above, as well as significant polysemy. Some similarities include the use of circular (points, discs) signs to represent objects; the use of encircling to represent sets of objects; and, the combination of number and operation symbols with icons and indices. TT differs significantly from the other representations in three ways: (1) the use of colour; (2) the tangibility—the representations are seen *and* touched; and, (3) the temporality.

Colour is used to emphasise the idea of copying found in the splitting model, when three differently coloured pips created on one side of the screen are replicated on the other. Colour thus enriches the iconicity of 'object to the split'. Groups or units can therefore differ internally, unlike with the circular discs, repeated sum or the dots of the unitizing models. While the number of pods indexes the functional relationships of Vergnaud, colour indexes the scalar relationship (1 : 3). Figure 7 shows two drawings made by grade three (9-year-old) students in response to the button question (see introduction). These students had used TT during one class period and the teacher proposed the button question in order to see whether the students could connect a more traditional multiplication problem with their experiences using TT. We use these drawings simply to exemplify how TT signs might be re-used by learners. In Figure 7a, colour is used to index the split of the original unit into 5 pods.

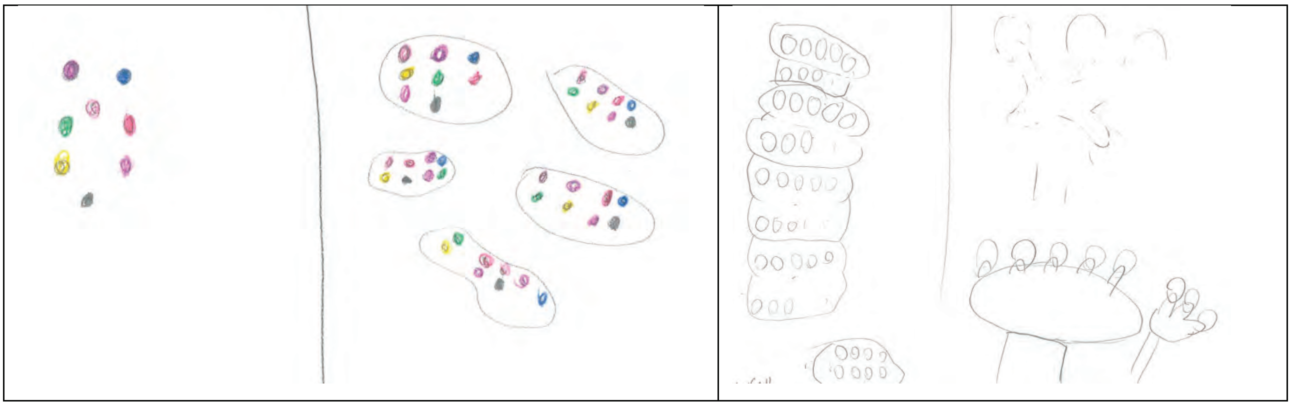

Figure 7 (a) Coloured pips; (b) 5 pods and 8 fingers

Unlike the iconic status of the circles in the repeated sum and the unitizing models, the coloured discs in TT have an indexical quality since they literally index the touch of fingers. In addition, the colour and the shape of the pods serve to index the placement of the pip-fingers. Colour and shape thus perform the same indexical function as the arrows in Figure 3a and 3b, but through different signs. The drawing of the hand in place of the pips on the right side of Figure 7b signifies the indexical relation between the use of one's fingers and the internal make-up of the pods drawn on the left. Similarly, as mentioned above, the splitting model uses a dotted line to index the double nature of the split element as both a copy of the original and as a part of the product. The encircling of the pod on its own and then of the pods altogether seems to have a similar indexical function.

The temporal aspect of TT introduces yet other difference. For example, if one focuses only on the final product, as in the image shown in Figure 5d, the meanings of the signs are different from those produced by the sequence shown in Figures 5a, 5b, 5c. The right-hand side of Figure 5d resembles the repeated sum image shown in Figure 2a and, indeed, could be seen iconically as four groups of three. But in the temporal production of the multiplicative expression, the unit of 3 is produced first, and then copied four times, so that the sign includes both the image on the left *and* the image on the right—it functions indexically as a trace of the finger touches.

There are two other aspects of temporality that functions in tandem and both involve the potential action of fingers. First, the potential to lift or press a pip-finger functions as an index in that it literally "shows something about things", which is that changing the number of pips will change each and every pod—which is the one-to-many idea that is represented in Figure 8a and aligns with Boulet's model. In prior research (Bakos & Pimm, 2020), the repeated lifting and pressing of fingers has been described as "dancing" (because of the simultaneous rhythmic change of all of the pods at once), and is a common mode of interaction for learners. In this dynamic dancing gesture, attention is drawn to a fundamental element of multiplication, that of spreading. Spreading is articulated in the work of Confrey (1994) who first proposed an alternate multiplicative metaphor based on children's facility with the action of splitting. Dancing draws attention to the horizontal embedding of Clark and Kamii, which hints towards the general since the iterative pattern of the embedding can be easily extended. This possibility of horizontal variation emphasises both the horizontality and verticality of multiplication as a reference transformation.

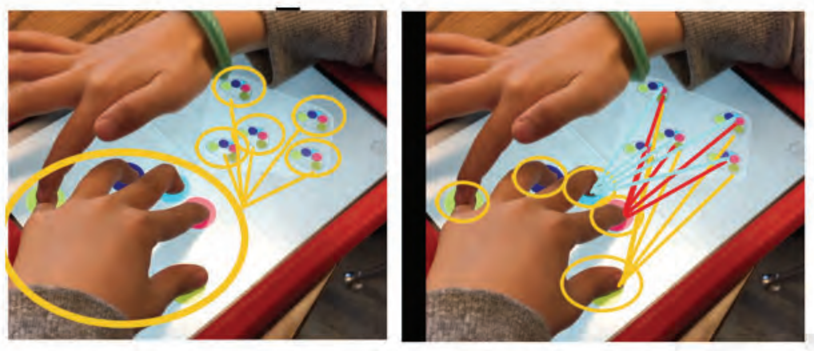

Figure 8: (a) Focus on pods; (b) Focus on pips

The second aspect of temporality is the potential to remove or add any pod (by lifting or pressing a pod-finger) which shows that changing the number of pods will change the product. This is the many-to-one idea represented in Figure 8b, which aligns with Clark and Kamii. Figure 8 highlights an additional polysemic aspect at play in TT.

Our analysis shows the different ways in which TT shares signs with other representations, even though these are quite distinct kinds of artefacts from one another. Focusing on the signs created helps explain how TT might function as an environment that promotes semiotic synergy. In addition, the temporality and tangibility of TT elicit more indexical signs, in lieu of iconic ones, which establishes a dynamic connection between the object and "the senses or memory of the person for whom it serves as a sign", to re-quote Peirce.

Conclusion

In this paper, we have analysed different visual representations of multiplication (which draw on different mathematical models of multiplication) that have been discussed in the research literature, including the repeated-sum model, the array model, the unisiting model and the splitting model. Our goal was to identify the different aspects of multiplication emphasised in these representations so that we could compare them semiotically to *TouchTimes* and also explore the potential for semiotic synergy found within TT. Our analysis revealed that the signs in TT are polysemic, indexical and multiple. While this might lead to conceptual confusion (see Izsák & Beckmann, 2019), we argued that it increased the potential for synergy. The three drawings offered in the paper suggest that students can in fact work with the multiple meanings, and can choose to use some more explicitly than others. The presence of the hands in two of the drawings strengthens our hypothesis that the greater indexicality of TT signs can better support embodied understandings of multiplication.

[2] University of Macerata, Department of Education, Italy; george.santi@unimc.it

In this paper, using Radford's Theory of Objectification, we analyze 2 students' learning activity that show how the features of the drawing robot (GGbot) affect student's sensuous cognition, forging their theoretical perception for the learning of geometry.

Keywords: Eye as a theoretician, GGbot, geometry, theory of objectification, sensuous cognition.

Introduction

Digital technologies open new possibilities in the teaching and learning of mathematics. In line with the theory of objectification (TO), we conceive learning as the student's sensuous encounter with systems of thinking and action that have been historically and culturally constituted (Radford, 2021). In this paper, we analyze the role of the drawing robot GGBot (abbreviation of GREATGeometryBot) in the learning of geometry in primary school. We report an exploratory study carried out with grade 3 students performing an activity that involved the use of the GGBot in the solution of geometrical tasks. The aim of the contribution is to understand the impact of the GGBot in transforming the individual's perception (which here we intend being visual, tactile, kinesthetic, and imaginative) in the learning of geometry.

Conceptual framework

The TO, embedded in sociocultural perspectives, stems from a profound intertwining between culture and the individuals' activity. Culture is an intrinsic component of mathematical thinking and learning, and activity is the ontological category of the TO as it realizes the consubstantiality between individuals and their culture. In the stance of the TO, mathematical thinking and learning are not processes confined in the mind but they are intertwined with individuals' social activity. Signs and artefacts play an important role, beyond the role of something that stands for something else or as mediators of activity. In the TO, they are considered an integral part of human thinking and human activity (Radford, 2021). The issue of learning is rooted in the dialectics between the individual and their culture. Learning is a movement pushed by the intrinsic differential between the individual and cultural knowledge. In fact, in attending to knowledge the student has to cope with something that in the beginning is different from him, an alterity that challenges, resists and opposes him. Learning is the process that erases such a difference to make sense of cultural knowledge and transform it into something familiar that allows new forms of action, thinking, imagination and feeling. In order to reduce the distance between the individual and cultural knowledge, activity as a specific human endeavor is required on the part of the student. Radford (2021) conceives learning as a social process of becoming aware of cultural-historical systems of thinking and doing, through our bodily, sensory, and artefactual semiotic activity. We remark that, according to the TO, signs and artifacts are constitutive of the activity that leads students to notice mathematical knowledge. They are bearers of an embodied intelligence and culturally endowed with specific patterns of activity that individuals use in their meaning-making processes and to carry out their actions (Radford, 2021). The outcome of the learning process is the encounter with mathematical (cultural) objects and their transformation into objects of consciousness. From this standpoint, learning has a strong phenomenological nature where noticing occurs in an enlarged notion of mind and consciousness, termed by the TO sensuous cognition, that includes not only ideal and mental features but also embodied ones such as perception, feelings, and kinesthetic activity. In light of the dialectic-materialist approach underpinning the TO, the basic tenet behind the notion of sensuous cognition is that the body, the senses, and the objects of sensation are not a priori entities but mutually transformed by cultural-historical activity entangled with the use of signs and artefacts. The relations of mind and body to the world are historical intertwines with material and ideational culture, and our senses change and develop along with the changes of the cultural-historical dimension (Radford, 2021). From the standpoint of sensuous cognition, human perception is, in the words of Wartofsky (1984, p. 865), “a cultural artefact shaped by our own historically changing practices”. In this regard, perception deploys cultural forms of seeing, touching, hearing etc. that characterize our relation with the world. Within sensuous cognition, the issue of learning is identified with the manner in which perception is transformed into a theoretical cultural form of perception, in progressively noticing and endowing with meaning cultural-historical systems of thinking and doing. How do students change their perception from “spontaneous” forms of attending to objects to a mathematical and theoretical one? To answer this question, we must consider learning as a “domestication of the eye” (Radford, 2021), a long process that allows students, in cultural-historical activity intertwined with the use of signs and artifacts, to transform the eye (and other senses) into sophisticated theoretical organs able to notice and make sense of certain things in mathematical manners - for example recognizing numerosity, algebraic structures, geometric invariants etc. We remark the co-variational nature of sensuous cognition in that learning processes entail a transformation of perception along with the transformation of the perceived cultural object into an object of consciousness. We underline the multimodality entailed with the “domestication of the eye”, both in the various sensorial channels and the richness of signs and artefacts interwoven with cultural-historical activity involved in the transformation of perception (Radford, 2021).

In this framework, we aim to analyze the impact of the GGBot, with its artifactual and semiotic features, which combine the well-known strengths and opportunities offered by the modern visual programming language with those of Papert’s original robotic drawing-turtle (Papert, 1980). The GGBot is composed of two wheels, a marker-holder at each end, where one can insert markers to let GGBot draw (Figure 1a), and SNAP!, the visual programming language used to provide commands to the GGBot. We show some of the available commands in Figure 1b, and we refer to Baccaglini-Frank and colleagues (2020) for more details on how the GGBot works.

a)  b) 

Figure 1: a) view of the GGbot; b) SNAP! Commands list

This contribution focuses on the dialectical movement between primary school students, geometrical knowledge and cultural-historical activity that pivots around the use of GGBot as they learn geometry. More precisely, the present study aims at answering the following research question: how does the GGBot with its related multimodal artifactual and semiotic features (the physical robot, the SNAP! commands, movement, drawing, gesturing, natural language) affect students' sensuous cognition? That is, how does the GGBot "domesticate the eye" (seeing, touching, kinesthetic activity, imagination) for the learning of geometrical figures in primary school?

Methodology, data and analysis

We consider data collected during one session of a sequence of three that was conducted by Anna Baccaglini-Frank (Baccaglini-Frank & Mariotti, in press). Each session lasted a fixed time-frame and involved one class of grade 3 students, the classroom teacher, and the researcher. The students were asked to carry out various types of tasks. First, a technical exploration of the GGBot guided by questions is conducted. Then, students continued working in pairs and they were asked to use SNAP! to code the movement of the GGBot that would lead it to draw with the marker a certain given figure (figure-to-code tasks). The students were involved in another type of task as well, a collective task where they could answer in turn. Starting with a given SNAP! code, they were asked to predict the GGBot's movement and, consequently, foresee the trace that the marker would have left on the paper (code-to-figure tasks). Given the potentialities of predictive tasks in providing insight into the learning process in geometry (Miragliotta, 2020), in this paper, we focus on the code-to-figure tasks. We consider some video recorded sequences where a group of students are predicting the GGBot's drawing outcome of a given code displayed on the projector (Figure 2a). For the reader's convenience, we show in Figure 2b the commands explanation and the expected figure drawn by the GGBot according to the code alongside (what is shown in Figure 2b was not projected nor shared with students during the experiment).

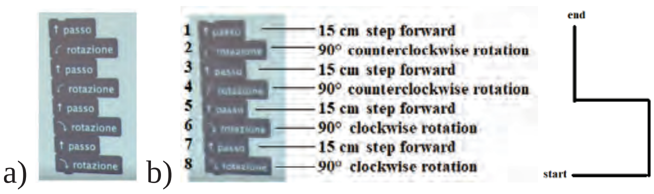

Figure 2: a) SNAP! Commands list (projected); b) Commands explanations and the expected figure

We remark that with the code-to-figure predictive task, students are asked to manage three separate, but connected, passages that entail theoretical forms of seeing, touching, movement and imagination. The first goes from the given code to the prediction of the GGBot movement in their imaginary dimension; the second, from the imagined movement to the prediction of the figure that such movement would trace on the paper; the third, from the imagined trace to its external outcome shared with the use of words, gestures, and drawings. The analysis of the nodes of such a chain of passages allow us to understand how the students' sensuous cognition evolves in the interplays with GGBot features. Our analysis focus is on the mutual transformation of perception and mathematical objects in activities whose outcome is the "domestication of the eye". We consider variables, specific to the task at stake, concerning perception, signs and artifacts, and geometric knowledge: in regard to perception, seeing, touching, movement and imagination; with respect to signs and artifacts, gestures, drawings, natural language and SNAP! commands; in regards to knowledge we focus on the egocentric and allocentric system of references (SoR) – whose involvement in similar activities is well documented in the literature (e.g. Baccaglini-Frank et el., 2014) - the notion of angle and the (mis)matching between the drawing of the figure resulting from the GGBot movement and the one primary school students would have performed using paper, pencil and possibly a ruler. We remark that in the code-to-figure task the GGBot is not physically present as in the figure-to-code ones. Nevertheless, the GGBot, in relation to the previous activities, is present in the imaginative perception as students coordinate gestures, natural language, drawings, and SNAP! commands.

Data and their analysis. The students, the researcher and the teacher are arranged in a circle around a big piece of paper on the floor where there are some drawings of previous activities (familiarization with the robot's functionality and figure-to-code task to draw a square). We focus on 2 students (Angela and Vanessa) and the following tables contain excerpts of the transcription of the video recording significant of the three passages described above (code to imagined movement, imagined movement to imagined figure and imagined figure to external shared the figure). In order to be faithful to the synchronicity in the use of signs and artifacts, we present the data in three columns: one for the gestures and non-verbal signs, the second for the utterances, and the third for the drawings (in Table 1, the drawings are just for the reader's convenience since Angela traced the figure with a finger on the paper). In the transcription: R stands for the researcher, and we numbered the lines using the same number to indicate simultaneity. In the analysis we enumerate both the transcript line (TL) and the SNAP! command line (SL, see Figure 2b).

Angela, who traces the figure with her finger on the paper		
Gestures and non-verbal signs	**Utterances**	**Drawings**
[1] Angela points her index finger on a white area of the paper and then she traces a first segment in the horizontal direction (according to her egocentric SoR) towards her right 	[1] R: like that	[1] [2] Angela goes on with a second segment in the vertical direction (according to her egocentric SoR) moving away from herself and articulating the movement in two steps		[2] 	[3] Angela: ehm	
[4] Angela traces a third segment in the horizontal direction (according to her egocentric SoR) towards her left. This segment is shorter than the first two.		[4] [5] Angela traces a fourth segment in the horizontal direction (according to her egocentric SoR) towards her right. This segment is shorter than the first two as well.		[5] 
[6] Angela traces a fifth segment in the vertical direction (according to her egocentric SoR) moving away from herself. Then, she stops moving and gazes at R.		[6] 
[7] Angela gazes at her finger on the paper		

[8] Angela moves horizontally her finger right and left various times	[8] Angela: and like…	[8-9] 	[9] Angela: and like so and so…	
[10] R points her finger towards Angela	[10] R: So it is an excellent idea. It is a sort of stair, did you see?	

Table 1: Angela

Analysis. Angela traces correctly with her finger the first three segments of the figure (TL 1-4 that correspond to her interpretation of the SL from 1 to 5). When reaching the 6 SL, she is not able to correctly handle the change of direction in the rotation. Therefore, she interprets the change in the direction of the rotation as a reverse direction along the same segment (TL 5). At the 7SL, Angela traces with her finger the vertical segment (TL 6). Then, the last command puzzles her even more and she goes back and forth with her finger (TL 8-9). In her activity, Angela resorts only to gestures and the SNAP! commands. She is able to notice in her imaginative perception the corresponding movement of the GGBot related to the first 3 segments of the figure. Nevertheless, when it comes to the third rotation, her perception is not able to grasp the angle of the figure as it is conveyed by the movement of the GGBot. The coordination of gestures and the SNAP! icons requires a transformation of imaginative perception to notice the angle of the figure in terms of step and rotation of the GGBot and not as the portion of the plane delimited by the two half-lines (i.e. the two sides of the figure). Furthermore, it requires a transformation of imaginative perception able to consider also the connection between egocentric (Angela's) and allocentric (GGBot's) SoR that does not emerge in the use of pencil and paper. Her perception does not encompass the change of direction in the rotation due to both the new way of encountering the angle of the figure as a rotation of the GGBot and the conflict between the egocentric and allocentric SoR. The back-and-forth gesturing along the side of the figure (TL 8-9) and the global absence of structured natural language are tokens of Angela's blurred perception and her struggle in "domesticating the eye" to transform her perception of the angle with respect to the one she learnt before. The process of "domestication of the eye" does not make the necessary leap to handle both the angle of the figure and the SoR, thus missing in the imaginative perception the expected figure drawn by the GGBot corresponding to the SNAP! commands.

Vanessa, who draws the figure on the paper with the marker		
Gestures and non-verbal signs	Utterances	Drawings
	[61] Vanessa: So before she (Vanessa is referring to a classmate's answer in a previous figure-to-code task) did a square, ok? [62] R: ok	
[63] Vanessa draws on the paper a line in the vertical direction (according to her egocentric SoR) moving away from herself.	[63] Vanessa: So, he took a step forward, no?	[63] 
[64] Vanessa draws on the paper a line in the horizontal direction (according to her egocentric SoR) towards her right	[64] Vanessa: a rotation	[64] [65] Vanessa separates the marker from the paper and starts to oscillate over the second segment	[65] Vanessa: then another, a ...another step forward, so the rotation…	
[66] Vanessa continues to oscillate repeatedly over the second segment	[66] Vanessa: yes well, the, the step forward	
[67] Vanessa draws a third short segment in the vertical direction (according to her egocentric SoR) towards herself	[67] Vanessa: a rotation	[67] [68] Vanessa draws out the line towards herself	[68] Vanessa: and then after the rotation again a step forward	[68] [69] Vanessa draws on the paper a line in the horizontal direction (according to her egocentric SoR) towards her right	[69] Vanessa: then he put the rotation the opposite way, and so like this	[69] [70] Vanessa draws quickly another two lines	[70] Vanessa: and like this	[70] 
Table 2: Vanessa

Analysis. For Vanessa the conflict starts since the beginning, when she is managing the second SL (TL 64). After she has drawn the first segment, she explicitly links the word rotation with the drawing of the second perpendicular segment. After that, in TL 65, Vanessa should go a step forward with the marker but she is puzzled about where to go due to the previous interpretation of the rotation. Indeed, drawing another step forward in her situation would have resulted in a drawing with a “side doubled” ,i.e., two strokes of the marker (instead of a step, a rotation and then another step). Vanessa’s confusion is highlighted by her oscillating the marker over the second segment and uttering “then another, a ...another step forward, so the rotation…” and “yes well, the, the step forward” (TL 65-66). Vanessa is confused because she lives in a conflict between the two ways in which the notion of angle co-emerges with her sensuous act: the angle as the part of the plane between two half-lines and the angle as the rotation of the GGBot. The gesturing with the marker and the utterances described above, testify such a conflict; she is able to draw the consecutive segments, but, when trying to relate them with the SNAP! commands, she is at odds with what she is doing. In TL 67, Vanessa is managing the second rotation of the 4th SL: she avoids the conflict linking the word rotation with a little portion of a perpendicular segment that she extends synchronously with the words “then after the rotation again a step forward” (TL 68). Vanessa’s use of natural language is always assertive and explicit: she uses words to scan the imagined movement and the resulting trace. Her coordinated use of natural language and the drawing with the marker (TL 67-68) shows in an evident and interesting way the “domestication of the eye” related to the angle and her struggle to erase the differential between her previous form of noticing and the new (GGBot’s) one that is challenging, resisting, and opposing her. We observe Vanessa’s difficulty in fully accomplishing the domestication of her sensuous cognition to “see” angles with the “eyes” of the GGBot. Vanessa handles the coordination of the egocentric and allocentric SoR in the direction of the steps, in fact she always says “forward” as if she were in the SoR of the GGBot. However, she is not able to coordinate the two SoR when it comes to the rotations. She systematically shifts the left with the right and vice versa. Notwithstanding the difficulties in coping with the angle and the two SoR, Vanessa arrives at a drawing consistent, apart from the inversions of left and right rotations, with the SNAP! commands and the ensuing movement of the GGBot. This testifies a first transformation of her geometrical perception to conceive of figures both as theoretically perceived in drawings with pencil and paper and in the entanglement between the SNAP! commands and the ensuing movement of the GGBot in terms of steps and rotations. The coordinated use of the marker to draw and as a pointer, natural language and the SNAP! commands allows a transformation of Vanessa's multimodal perception made of seeing, touching, movement and imagination to encompass new ways of noticing the SoR (egocentric and allocentric), the angle of the figure (resulting from steps and rotations), and the geometric figure (in the interplay between SNAP! commands and the imagined movement of the GGBot). Despite her struggle in coping with new ways of attending to the angle and the SoR, Vanessa's "domestication of the eye" allowed her to connect the two meanings of the figure, the one conveyed via the GGbot and SNAP! and the previous one conveyed via drawings and paper and pencil. Thus, Vanessa testifies in her learning process the mutual transformation of perception and the mathematical object.

Discussion and conclusion

Data show how the encounter of geometrical objects using the GGBot involves a complex intertwining of signs and artifacts (icons, gesturing, natural language, material objects), perception, and geometric knowledge. The analysis of Angela and Vanessa, exposed to code-to-figure tasks, allows us to delineate how the use of GGBot resists and opposes our two students in their process of "domestication of the eye". In previous activities without the GGBot, students' sensuous cognition had been carried out with material objects, rulers, gestures, natural language etc., on which they had direct perceptual and sensorimotor control. Furthermore, perception took place in their egocentric SoR. The introduction of the GGBot strongly transforms students' perception in new cultural and theoretical modes of attending to geometrical objects. Metaphorically speaking, students have to think, perceive, move and "feel" as if they were the GGBot. In the code-to-figure task, pupils do not have direct control on the robot, and they have to establish, in sensuous cognition, a relation between the SNAP! code, the resulting movement of the robot and the geometrical figure that it would have traced. Since the code-to-figure is a predictive task, this happens in their imaginative perception without the physical presence of the robot but forged by the use of gestures, natural language and the sensorimotor activity, inherited by the previous tasks with it. The code-to-figure task suggests to what extent the students' perception has been theoretically domesticated according to the ideal and material characteristics pivoting around the use of the GGBot, to embrace new and richer encounters with geometric knowledge.

Answer to the research question. From a geometrical point of view, above all, students have to handle different SoR (egocentric and allocentric) and angles conceived as a rotation. The predictive code-to-figure task shows that the introduction of the GGBot, with its correlates of signs and artifacts, requires a "domestication of the eye". The transformation of perception is hindered by the conflict between an already theoretically domesticated eye - which encounters a geometric figure in a single SoR, in terms of segments and angles perceived as portions of a plane between two half-lines - and the new GGBot's theoretical eye - which encounters a geometric figure as something constructed in terms of steps and rotations, and the intertwining of the egocentric (student) and allocentric (GGBot)

SoR. In regard to the features of sensuous cognition, on the one hand the introduction of GGBot requires the students to "see" theoretically the figure as a recomposition of the SNAP! commands and the corresponding steps and rotations of the robot perceived visually and kinesthetically. On the other hand, in previous activities with paper and pencil, the students theoretically "see" the geometric figure as successive segments with different orientations perceived visually and kinesthetically as they trace on the paper. Concerning the task under scrutiny, we highlighted, in connection to the deepest conflicts lived by the students, that their "domestication of the eye" does not flow smoothly. The mutual transformation of perception and the geometric objects emerging from the activity with the GGBot establishes a distance between the individual and knowledge, which is perceived as an alterity. The "domestication of the eye" is the long process of learning that allows the student to erase such a distance, and further studies are needed to deepen the process of domestication of the eye in activity involving the GGBot. We hope that our work can suggest possible future research directions.

Acknowledgment

The GGBot is an invention of Eric Frank and Anna Baccaglini-Frank; with a patent number 102019000018254; it is produced by GREATRobotics Srl. The SNAP! commands are developed by Alessandro Norfo under the collaboration with ASPHI onlus within the PerContare Project, co-funded by the Fondazione per la Scuola della Compagnia di San Paolo di Torino.

Representations as site of the tension between abstract and concrete in mathematical practice: University students at work with a spirograph

Francesca Ferrara and Giulia Ferrari

Università degli Studi di Torino, Italy

francesca.ferrara@unito.it, giulia.ferrari@unito.it

In this paper, we propose to study representations as site of encounter with the lively tension between abstract and concrete in mathematical practice. In so doing, we question visions of practice as a sequence of moves towards abstraction that see mathematical concepts as fixed and disembodied, detached from the physical, and learning in terms of developmental trajectories. Beyond a tendency to reduce abstract and concrete to a dualism conceiving of more of one as less of the other, we are more interested in what learners do and how this mobilises practice as a flow of activity across abstract and concrete. We offer the case of some university students working with a spirograph to experiment with this approach to mathematical practice.

Keywords: Mathematical practice, abstract, concrete, representation, spirograph.

Introduction.

The relevance of representations has been studied in mathematics education research from different points of view. For example, Meira (2002) has looked at mathematical representations as notations-in-use, pointing out that pure referential views of signs and meanings may not give enough emphasis to notational systems as mediational tools that can trigger and sustain mathematical activity. Other studies have investigated how the production of representations by learners does not only support cognition and communication but also transforms the very way that mathematical activity evolves (e.g., Hall, 1996; Nunes, 1997). In this paper, we are interested in this transformative character of the activity within the mathematics classroom, especially when tools are used in practice and allow learners to create and work with representations of mathematical objects. Tools have the potential to transform the teaching and learning of mathematics (see Hoyles, 2018). The ways in which the bodily and the kinaesthetic are involved in interaction with the tool extend the horizon of possibilities that learners come to entertain (Nemirovsky & Ferrara, 2009), and a growing body of research considers notions of embodiment and perceptuo-motor engagement in mathematics to characterise them (Nemirovsky et al., 2013; de Freitas & Sinclair, 2014). Additionally, mathematical activity can be conceptualised as *involving* and *evolving* concepts, showing the role of body and movement in learning mathematics (de Freitas & Ferrara, 2015). We build on these considerations to investigate two main aspects that we see as central in the study of mathematical practice with tools: on the one side, how tools change mathematical practices as tool use constantly reconfigures the activity; on the other side, the ways that tools always demand the body and mobilise mathematics in unexpected ways. We will argue that representations and diagrams are at the core of both aspects as the site of encounter of abstract and concrete in mathematics. We examine these two aspects through the specific case of doing mathematics with a spirograph. The spirograph was invented by a mathematician but it is usually known as a classic toy for children to create diagrams, beautiful drawings that might resemble mandala or recall images of flowers. The mathematics of the spirograph is quite sophisticated and related to the number of radially symmetric curves that can be made using the tool (Ippolito, 1999). Among the many types of spirograph available nowadays, we consider a very simple spirograph that consists of a couple of plastic ring gears with teeth on the inside of their circumferences and three different-sized pinion gears (or gearwheels) with holes in various positions, which are used to insert a pen and draw (Figure 1a). The class of curves that can be traced rotating the pinion gears inside the ring gears enters that of hypocycloids (an example is shown in Figure 1b). In this report, we draw attention to the mathematical practice of a class of university students that have used this spirograph to examine the mathematics out of the obtainable diagrams. Rather than attending to practice in terms of what the students *can achieve*, we shift focus to what the students *do*, and how this engenders and renders what *is produced* in practice, mainly attending to diagrammatic activity.

Mathematical practice and the tension between abstract and concrete.

Learning mathematics is often conceptualised as a progression or movement from the concrete to the abstract. This progression amounts to a gradual passage from physical acts and senses to the more fixed and disembodied (ideal) mathematical concepts. In this taken-for-granted idea of school mathematics, the concrete is left behind, often delineating a clear cut between the physical and the conceptual and a directed trajectory for learning. Mathematical practice is thus mainly conceived of as the steps and acts of acquiring concepts and attaining abstract knowledge. Despite their prescriptive habit, traditional images for the attainment of abstraction have been questioned in the literature. More complex pictures have been offered: for example, by troubling the divide of concrete and abstract as properties of entities rather than as relationships between persons and things (e.g., Wilensky, 1991), and by introducing diverse kinds of concrete knowledge (Clements, 2000) or ‘hybrid’ notions of situated abstraction (Noss et al., 2002) and abstraction in context (Hershkowitz et al., 2001). These studies have in common a tentative discourse on ways in which something can be abstract or concrete for someone in relation to practice, while challenging the idea of whether mathematical abstractions can always be separated from the context of their construction or application. However, they maintain a vision of teaching and learning processes as tending towards the achievement of abstraction. In a similar vein, the nature of expertise has also been a subject of concern, with expert knowledge in mathematics (and science) as commonly described as formal and abstract. Coles and Sinclair (2018) have more recently critiqued assumptions about developmental paths to abstraction and have rather stressed a relational view of abstract and concrete, which challenges what is meaningful in learning mathematics. Whatever approach we take, the tension between abstract and concrete is pervasive in the doing of mathematics. Following Noss and colleagues (2002), "precisely because mathematical activity is anchored in the artefacts and discourses of the practice, it is recontextualized in ways that sometimes make it difficult to recognize at all" (p. 227). In another work (Nemirovsky et al., 2020), we address the notion of abstraction detaching it from a vision bounded to the dualism abstract-concrete, according to which more of one is simply conceived of as less of the other. Analysing three students at work with a graphing motion sensor, we show how, in the practice with the tool, it is possible to sketch a distinct path for the attainment of abstraction, which involves navigating a surplus of sensible qualities. In this paper, in line with such a non-dualistic perspective on abstraction, we look at the specific work with the representations to shed light onto the ways in which the students (inter)act with mathematical concepts through material activity. In so doing, we want to stress the contextual nature of mathematical practice that emerges from activity within the classroom, instead of reducing it to a sequence of moves toward abstraction. Accordingly, we want to *rethink* mathematical practice as a way of encountering or sustaining the relational dynamics of abstract and concrete in mathematics.

We turn to the French mathematician and philosopher of mathematics G. Châtelet, who has drawn attention to the notion of the virtual as a powerful way of overcoming the so slippery relationship of abstract and concrete and the split of the physical and the mathematical (Châtelet, 1993/2000). Châtelet discusses how the mathematical has a physical aspect to it, by analysing the mathematical practice of scholars in the history of mathematics and physics. The concept of the virtual is that which allows us to reconceive of the mathematical and the physical together, challenging visions that typically associate mathematical thinking to the mind and leave out the body. For Châtelet, the virtual is in the physical world, and its coupling with the actual is at the hearth of the emergence of new mathematical ideas. It pertains to the mobility and indeterminacy at the source of all actions and is mobilised and actualised through activity: the moves, the gestures, the diagrams, and their interplays are those which awake the virtual or potential multiplicities that are implicit in any material surface, and open room for inventiveness in the mathematics classroom (de Freitas & Sinclair, 2014; Sinclair et al., 2013). Briefly speaking, the virtual has to do with all the potential, future alterations of the world, rather than mirroring it as we see it. Borrowing from these ideas, instead of aiming for a clear cut between abstract and concrete in mathematical practice and conceiving of learning as the pursuit of abstraction, we intend to study the *flow*, or movement, of activity across abstract and concrete. We strive to do so in relation to the use of the spirograph, considered as a mathematical instrument (Nemirovsky et al., 2013) that engages kinaesthetically the students' bodies in the creation of mathematical curves. In this context, we look at moves, gestures, diagrams, and their interplays (processes of actualising the virtual) to see how the mathematical activity develops and changes.

Context and method.

The mathematical activity we consider in this paper was carried out in the context of a university mathematics education course attended by a group of 30 university students at the first or second year of their master's degree in mathematics. The activity engaged the class during a regular lesson of the course. The students were divided into groups of 5 people and each group worked for about 2 hours on written tasks to be faced using the spirograph. The tasks aimed at guiding the students to explore the tool and one main idea the students had to play with is that with the spirograph one always draws closed curves. This fact is explainable through elementary concepts of number theory, which allow to model the functioning of the tool depending on the ratio between the numbers of teeth of the chosen ring-wheel combination. With the spirograph used in our activity it is possible to combine six couples (R, W), where R and W indicate the numbers of teeth in the ring gear and in the gearwheel respectively. The mathematical relationships of Table 1 capture the number of 'petals' or 'tips' of the curve created by a specific combination of gears and the number of turns that the wheel covers along the ring to close the curve (lcm: lower common multiple). In Figure 1b we observe 5 petals, drawn with the couple (105, 63): indeed, lcm (105, 63)/63 = 315/63 = 5. Variations on the choice of the hole for the pen modify other characteristics of the curves, like the petals' curvature. For the sake of space, we do not expand our considerations further, but more mathematics can be explored with the spirograph.

Table 1: Some mathematical relationships at play with the spirograph

(R, W)	Number of petals = lcm (R, W)/W	Number of turns = lcm (R, W)/R

The first author was the teacher of the course, and both the authors designed together the tasks and took part in the activity as active observers. Each group was filmed by one author or a research collaborator with a mobile camera for the entire duration of the activity, and all the written productions of the groups were collected. The video and the written protocols constitute the data source of our study. We adopt a micro-ethnographic method (Streeck & Mehus, 2005) to focus our investigation on the students' interactions with the instrument and the corresponding representations.

For this paper, we focus on the work of one group of five students, who have thoroughly explored most of the mathematical ideas, to exemplify the dynamics of abstract and concrete in their activity with the spirograph and how it arises from the students' productive engagement with the instrument and the emerging representations. We point out two main elements which, we believe, speak directly to the lively tension between abstract and concrete in this context: (1) expectations about the 'future' of the curve and (2) interplay between composition and decomposition of gear motions. In the next sections, we first present two episodes and then briefly discuss them.

First episode.

The students (named S1, S2, S3, S4 and S5; three females and two males, Figure 3d) are seated around a table and have at disposal a spirograph, the written worksheet, and blank sheets of paper. We highlight some moments within the first 5 minutes of interaction. Student S3 reads the given description of the spirograph, and the group focuses on the task of describing *what can* be obtained using the tool. The combination of gears (105, 52), randomly selected and used by one student, S2, produces a first diagram (Figure 2a).

The students explore the physical situation: S2 draws moving the pen quite slowly, while his mates carefully gaze closely at him. In several turns, the dialogue develops as follows:

S1: Hm, but it never closes. [Figure 2a]
S2: Perhaps, we don't know.
S3: Well, come on! Go on then (everybody laughs). [S2 accelerates increasing the rotation speed and, after few seconds, removes the pinion gear, stops from drawing, and changes the combination to create another diagram. The student then produces a new diagram, which instead is completed in few turns, using the couple (96, 36). Figure 2b]

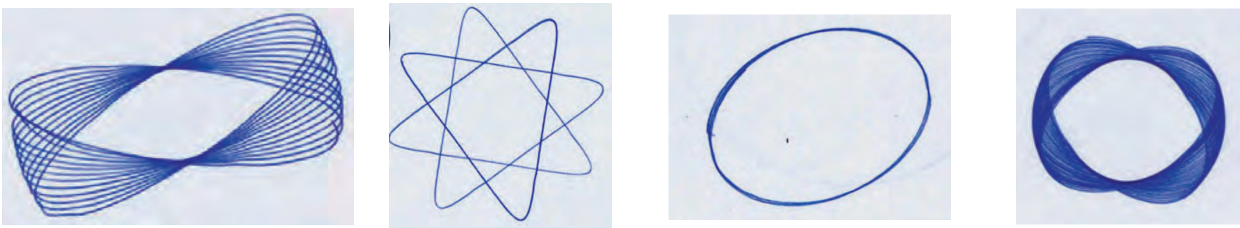
S2: So, it can close.

S3: Try with the most inner [hole], like where the spiral begins, but I don’t know (to S2). [S2 returns to the initial combination (105, 52), but changes the hole: after nearly four complete rotations around the ring gear, he stops. Figure 2c]

S3: Always an ellipse. [S2 changes the hole again, maintaining the same couple of gears]. Anyway, a fixed ellipse always occurs. [Several trials are made, then S2 creates a new diagram. Figure 2d]

S1: Ah, no, we had to go on (laughs).

For 2 more minutes, the students draw diagrams exploring the change of the hole while using the same couple of gears. Then, they start to discuss a collective answer for the task.



a b c d

Figure 2: Four diagrams created by the students within the first 5 minutes of work

Second episode.

After 5 more minutes, the students still discuss how to describe what they have created:

S2: It’s the orbit of a, a satellite, that is, an epicycle (draws circles repeatedly with the pen) isn’t it? That is, it turns around itself, around a…

S3: Yes, after all it’s like the orbit of a planet. [The girls focus again on the written, S2 starts drawing with the spirograph]

S4: What were you telling about the orbit (to S2)?

S2: The orbit of a satellite (mimes inverted commas).

S4: This (points to one of the curves on paper)?

S2: All of them. [S3: Yes]. That is, they rotate around a centre and around themselves, more or less (sketches a new diagram. Figure 3a). That is, for me, we could obtain this thing. [S4 laughs]. Yes! That is, this is rotating around itself and around a centre, and it’s the orbit, in the sense, hm, of the moon around the sun, here there’s the earth (points to the inner circle of Figure 3a, one gear is positioned onto the diagram) and it’s this one, and this one rotates around itself (moves the gear from the diagram and makes it rotate around itself).

S3: Try to go very slow (to S2) and let’s see what happens […] that is, when you turn, let’s go slowly, so that we can see when this [the wheel] has done a turn on itself, and what’s been drawn meanwhile. [S2 marks the point where the pinion gear is tangent to the ring gear. He slowly begins to draw and stops the pen when the mark is touching the ring again. Figure 3b]

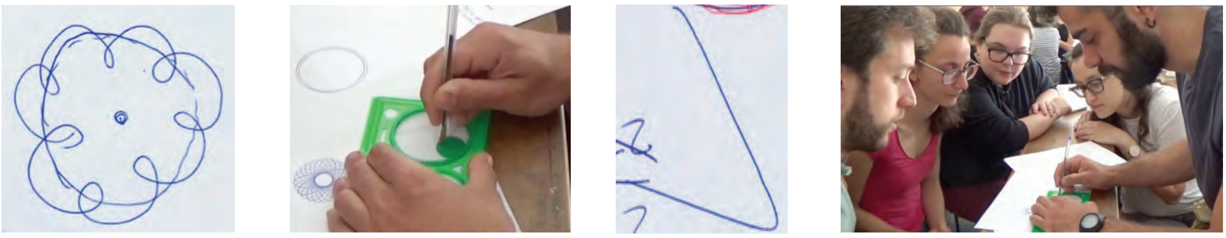
S2: This is a complete turn on itself (points to the drawn curve segment. Figure 3c).

S4: That doesn’t give us any information. [S3 and S1 giggle, while agreeing]

S2: But, if we decompose it (moves the gearwheel to the side), if we had a complete turn on itself (makes the gearwheel turning on itself) without composing it with the other motion (mimes a rotation with the pen over the ring gear), we will have a circumference. If this (points to the wheel) turns on itself…

S3-S4: Yes, but we’ve to consider it must turn around…

S2: Yes, yes (nods), but, I mean, what I was saying is that, well, it turns around itself and does a circle (draws a circle around the gearwheel). Turns around this, a point (points the pen in the middle of the ring gear), well, and it does a circle (draws a circle inside the ring gear). The composition of these two circles gives you, well, of these two motions (points to both the drawn circles).



a b c d

Figure 3: Four moments of the group work in the second episode

Discussion and conclusion.

In the first episode, the students use the spirograph to draw and discuss their expectations about the behaviour of the curves they are (partially or completely) creating. In the initial moment, right after few turns of the pinion gear, the possibility of a 'never-ending going on' intuitively reflects the possibility of non-closure of the curve in the diagram (a delicate, crucial point of the mathematical modelling of the instrument). The trial with a different combination of gears makes a different possibility emerge, that of a closed curve (Figure 2b). The new diagram embeds the end of the drawing movement and suggests it as a possible future also for the first curve, so that the students return to the initial combination of gears but changing the hole for the pen. The recognition of a seemingly elliptical shape (Figure 2c) and the association of a known curve with the "always" possible curve implicates that the students change the hole again, involving the creation of a new curve which do no longer resemble an ellipse. At this point, the possibility for the first curve to close and for the movement to arrive at an end is brought forth again, even beyond the material act of drawing. The iterative nature of the movement that creates the initial diagram, together with the time needed to close it, suggests a possibility for the movement to be repeated unlimitedly. The need of continuing the movement is therefore mapped onto the possible future(s) of the curve. We see how the tension between abstract and concrete is at play in the diagrams as possibilities of movement or possibilities of mathematical creation are encountered by the students and emerge out of the interaction with different combinations of gears or holes. Activity is reconfigured each time these possibilities are changed. The first episode is full of mathematical expectations that emerge from the physical movement, the combination/coordination of the gears and the material activity with them. This deeply explorative phase is characterised by a flow across *what is there* and *what might be*.

In the second episode, once a description must be produced, a new, more explanatory phase begins, in which the students attempt to make sense of the instrument by composing and decomposing its parts and the drawing movements. This happens by shifting attention to the fact that two movements occur simultaneously, each along a circular trajectory: that of the gearwheel along the ring gear, and that of the gearwheel on itself. The students closely observe this behaviour by moving slowly, so that they can decompose the curve "in the making", relating it to the internal gear's rotations. This is done to better unfold the previous reference by S2 to the planet/satellite dynamics, which pointed out that none of the two movements can be thought without the other. We see how the change in pace gives the students a different feeling for the curve, helping them crystallize how movements partake in the creation of the diagram. In line with Châtelet's vision of diagrams as site for contractions and expansions to be realised, in this brief excerpt, the diagrammatic activity with the tool unfolds through the ways in which the students use, reimagine, and rethink the tool, the curve and the composed movements. We have tracked three aspects of the work with the representations: the need of slowing down, the interpretation in terms of planets and satellites, the decomposition of parts that cannot be separated. We can see how these aspects speak directly to the lively dynamics of abstract and concrete that make mathematical practice entangled with the materiality of the tool and inseparable from the fleeting perception of movement. They express the expansions and contractions proposed by Châtelet, capturing the ways in which the students navigate the surplus of sensible qualities that arise in the experience of/with the instrument, and by shifting the activity towards the mathematics of the spirograph, they come to constitute mathematics as experience. Mathematical activity is imbued with possible futures and changes inextricably as it is intertwined with the kinaesthetic and the bodily. The diagrams that emerge are not static characters of the activity but generative of doubts, conjectures, and new meanings.

In this paper, we have offered a non-prescriptive and non-static vision of mathematical practice. We attended to practice as a way to encounter or sustain the tension between abstract and concrete and we focused on its contextual nature and what the students do, rather than what they can achieve. In this dynamic vision, diagrams operate as a locus of practicing and the abstract/concrete relationship. Drawing on Châtelet, we can say that the practice of mathematics is not of mathematics that *can* be practiced, but of mathematics that is *really* in the process of being practiced. Knowledge is of course potential in mathematics, but above all it actualizes itself there. We therefore recognize the complex nature of learning and the way that knowledge emerges from practice and material activity. Diagrams, representations, are intensive sites of actualization(s). Further research is necessary to investigate whether this approach to practice can open the ground for studying the tension between abstract and concrete in other contexts.

Grouping passengers: A microgenetic case study of a struggling student's representational strategies for quotitive division

Carla Finesilver

King's College London, UK; carla.finesilver@kcl.ac.uk

This paper focuses on the arithmetical understandings and behaviours of one fourteen-year old student with a history of very low attainment in mathematics, as she worked on a sequence of scenario-based quotitive division (grouping) tasks with individually-tailored verbal and visuospatial support. The student's independent and co-created visuospatial representations of arithmetical structures, along with verbal comments, were analysed qualitatively using a multimodal microgenetic approach. This paper uses selected illustrative examples to discuss certain arithmetical-representational changes (e.g. employment of pictorial, iconic and symbolic elements), some of the particular difficulties that may be experienced by students with impaired memory for arithmetical relationships and procedures, and potential compensatory strategies. It is intended to stand as a companion piece to the case study presented at the previous CERME TWG24 (Finesilver, 2019).

Keywords: Visuospatial representation, multiplicative thinking, numeracy, low attainment, special education.

Introduction

I encountered Wendy during a larger project investigating low-attaining students' representational strategies for multiplicative structures. Attending a typical inner London secondary school, she turned fourteen during the study; however, her capacities for and approaches to quantitative reasoning were atypical for her age group. Her particular stage of arithmetical thinking (struggling with the move from additive to multiplicative reasoning) has been of particular interest to researchers, and both her strong aversion to division (at least, when presented in traditional symbolic notation) and over-reliance on counting-based strategies, are well-known phenomena. She was very positively disposed to the problem-solving interviews, maintaining excellent focus, and was keen to try new things and experiment with diverse strategies. Furthermore, as she demonstrated good verbal comprehension and would say when she did not understand, I took the opportunity to engage her in some detailed discussions about the tasks she worked on, including how and why her arithmetical strategies worked, which she enjoyed and welcomed. These several factors provided an excellent opportunity for microanalytic case study: to examine this individual's arithmetical-representational strategies in fine detail, and note any changes taking place. Thus, I focused on an arithmetical concept with which the participant was insecure (division), building from activity in which she was comfortable (counting and addition), within scenario tasks that she could work on without peer pressure or artificial time limits. This paper presents and discusses some brief but illuminative excerpts from my work with her.

Theoretical background

There is a strong tradition of research into various aspects of early numeracy, such as counting-based arithmetical strategies, taking place in naturalistic teaching/learning environments. Those which focus on children's own representations of number are often quasi-ethnographic in nature, where (usually very young) children are observed in their mark-making (e.g. Atkinson, 1992), and their representations analysed for ‘emergent’ mathematics. Key to this body of work is that it focuses on children’s own, often non-standard, representational strategies; this is in the pedagogical tradition of “de-centring” (Donaldson, 1978), i.e. to shift from an adult perspective and imagine what a scenario, phrase or object might mean to a child.

While the details and exact terminology can vary, in psychological research paradigms some kind of representational progression is also generally assumed, moving from the most intuitive models of arithmetical relationships with one-to-one correspondence, through pictorial and/or iconic forms that may include one mark standing for a number $\neq 1$ and/or starting to incorporate abstract symbols, to eventual full formal symbolic notation (e.g. in the Enactive-Iconic-Symbolic modes of Bruner (1973)). The development of mathematical concepts has also been linked to increasing awareness of pattern and structure (Mulligan, 2011). The capability to make connections between multiple mathematical representations is important for a learner’s developing conceptual thinking (e.g. Ainsworth, 2006), and in particular representational flexibility for problem solving (Acevedo Nistal et al., 2009).

Nunes and Bryant (1996), among many others stretching all the way back to Piaget, suggest that to understand multiplication/division represents a significant qualitative change in children's thinking (compared to addition/subtraction) – and so is deserving of particular attention. Regarding the increased complexity, Anghileri (1997) points out that a counting strategy in a multiplication or division task requires three distinct counts: the number in each set, the number of sets, and the total number of items. The second of these – enumerating sets rather than units – may be particularly unintuitive for some. Notwithstanding, Carpenter et al.'s (1993) study of kindergarten students (i.e. age 5-6, with <1 year of formal schooling) demonstrated that they could carry out a wider range of division tasks, with greater success, than had formerly been realised – provided the tasks were presented in the form of scenarios which could be directly modelled. Furthermore, they argued that many older students abandon their fundamentally sound problem-solving approaches for the mechanical application of formal arithmetic procedures, and would make fewer errors if they applied some of the intuitive modelling skills of their younger counterparts.

Given this, it is appropriate to combine a subject focus of early division with an analytical focus on informal, nonstandard representational strategies that grow out of intuitive models. Although tasks involving grouping passengers in vehicles are not as common in division research as the sharing tasks featured in the companion paper, Finesilver (2019), they are a highly imaginable scenario for learners, and rely on the fundamental schema of one enclosure with multiple items inside (Nutbrown, 2011).

Much prior research has analysed visuospatial representations via simple taxonomies, organising them into broad categories. Here an alternative approach is used: comparing and contrasting students’ changing representations via a multi-aspect qualitative analytical framework (Finesilver, 2022).

Research questions

1. What arithmetical-representational strategies does the student use in division tasks?
2. What do the strategies tell us about their particular weaknesses and capabilities?
3. How do the arithmetical-representational strategies change over time and interaction?

Methods

The dataset for this study is taken from three (of five) 1:1 problem-solving interviews, each lasting 45 minutes, carried out by the author. Sessions 1-2 focused on other types of multiplication- and division-based activity (e.g. Finesilver, 2019); a significant proportion of this student's time in Sessions 3-5 was spent on the 'grouping' tasks described here. It employs microgenetic methods, which were developed for the study of the transition processes of cognitive development (Siegler & Crowley, 1991). They have been widely used in studies of children's arithmetical strategies and particularly in case studies of individuals with difficulties in mathematics (e.g. Fletcher et al., 1998).

Wendy had been described in a past Educational Psychologist's report as having dyslexia, leading to significant difficulties with numeracy, memory, organisation, and sequencing skills. These descriptions seemed fair at the time I was working with her. However, the report also contained the judgement that she "lacks the ability to retain and process academic subjects that require logical thinking, analysis, sequencing, rationalising and accuracy"; this is an example of the kind of dismissive labelling of certain atypically-progressing students as predetermined future, as well as past, academic failures, which I have criticised (e.g. in Finesilver et al., in press). Her Wechsler Individual Achievement Test (WIAT-II) scores at age 11 had been in the 2^{nd} percentile for numerical operations, and the 0.5^{th} percentile for mathematical reasoning. Like the quote above, these standardised test scores do not at all predict or encompass the nonstandard mathematical reasoning I describe below. Wendy was well aware of the importance placed by the education system on the memorisation of 'times tables', and of her own long-term failure to do so ("even with constant review and revision", according to records), which had left her, unsurprisingly, with a very low opinion of her own mathematical abilities, but she did not radiate overall low self-esteem.

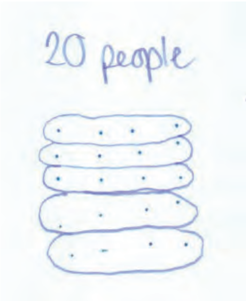
Unlike some other students in the larger study, Wendy's counting and addition were secure and reliable, and due to her growing enthusiasm I had to devise increasingly challenging tasks in situ to adapt to her progress. In each session, Wendy was set a series of quotitive divisions expressed via the scenario of a given number of passengers to be allocated to a given type of vehicle, with the required number of vehicles to be calculated. The quantities used were two- or three-digit dividends and one- or two-digit divisors, chosen in situ, depending on her arithmetical-representational functioning that day and in previous sessions. As Wendy was barely ever able to recall more than a few number relationships either from long-term memory or from previous tasks, I selected the divisors for their ease of repeated addition or step-counting, and re-used certain more familiar number patterns.

All sessions were audio recorded and all markings on paper collated. All markings in purple ink are by the researcher. Each task attempt was qualitatively analysed using a framework for visuospatial arithmetical-representational strategies across multiple semi-independent aspects of display, calculation and interaction. These were used for systematic description of representational elements and forms (*media*, *mode(s)*, *resemblance*, *spatial structuring*, *motion*, *unitcountability*, *enumeration*, *consistency*, *completeness*), evaluation (*strategic soundness*, *execution errors*), and noting teacher-student interactions (*verbal* and *visuospatial prompts*) – see Finesilver (2022). Particular attention was paid to any attempts where change in one or more of the aspects was observed; these were considered microgenetic 'snapshots'.

Selected data

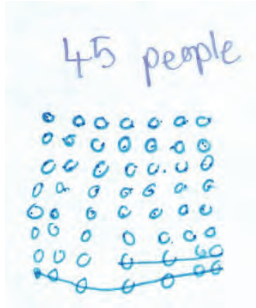
Due to restrictions of space, only a small sample of data may be reproduced in these proceedings; more are included (with verbal transcripts and fuller commentary) in the accompanying presentation. These three subsets of images are selected and grouped to illustrate particular points of interest with respect to arithmetical-representational strategies for quotitive division.

Subset 1: Working with array-structured unitcountable representations

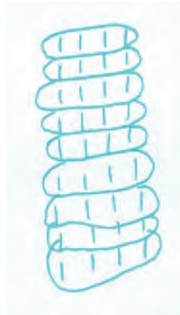


a. 20 people in 4-seater taxis

b. 32 people in 4-seater taxis



c. 45 people in 7-seater taxis

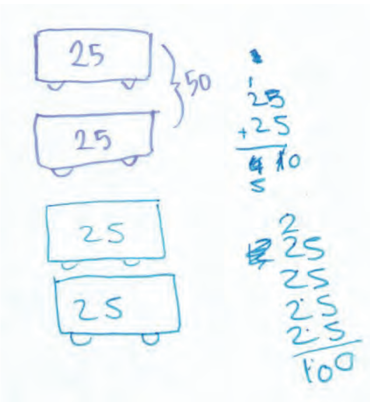


d. 36 people in 4-seater taxis

Figure 1a-d: Selection of unit arrays and array-container blends used in passenger tasks

When we first started work on quotitive division, Wendy struggled to calculate the number of 4-seater taxis required for 20 people (Figure 4a). She drew 20 dots, as always, arrayed neatly in rows, but was then unsure whether rows or columns represented taxis. I demonstrated the option of using containing rings as an additional structuring element. Figures 1b-d show various ways she experimented with spatial structuring in arrays and *array-container blends* (Finesilver, 2017) in subsequent tasks. These are all *unitcountable* in the sense that each represented unit (cube, tally mark, etc.) = 1, and enumeration of the total could be achieved by direct unitary counting (i.e. counting them *in ones*).

Subset 2: Working with number containers for scenario tasks, some with decorative elements



a. 45 then 96 people in 25-seater coaches

b. 343 people in 50-seater coaches

c. 612 people in 200-seater planes

Figure 2a-c: Selection of number containers used in more challenging passenger tasks

When we started working with larger numbers, Wendy was keen to try representational strategies that made sense to her within the scenario but did not involve drawing hundreds of unit marks. I demonstrated the option of building additively to the required total, which she adopted and used successfully in several subsequent tasks, spatially structuring the addends in *number containers* (Finesilver, 2017). The task represented in Figure 2c led to a conversation about the 'left over' 12 people. There was some tension between Wendy's awareness of the conventions of school maths tasks, and concern with the practicalities of the numbers in this scenario and, amused by the thought of a mostly empty plane, insisted the fourth should be "a smaller one" (which she did not draw).

Subset 3: Working with number containers for bare tasks, introducing narrative elements

In my final meeting with Wendy, encouraged by her success with various scenario tasks, I tried setting her a bare division (i.e. no scenario). Her first comment was "Something tells me it's going to have two zeros on the end of it" (indicating a misremembered rote 'trick' for multiplication) followed by blankness. I suggested we might imagine them as 180 people being put in 20-seater coaches: once the task had been 'made real' via a minimal bit of narrative, and again using number containers, she was able to complete this and similar tasks. She would picture a line of parked vehicles and a crowd of tourists grouping themselves tidily to fill them, and was particularly pleased by the option to take some unfriendly symbols of calculation and turn them into a scenario that could be imagined and represented in a way that she could comfortably work with.

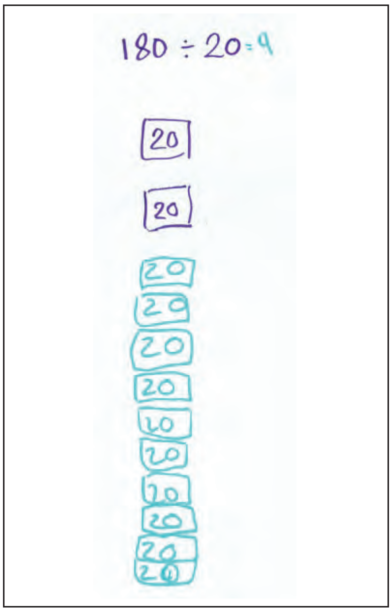


Figure 3: Number containers in a bare task

Discussion

What representational and arithmetical strategies does the student use?

Wendy showed a strong continuous preference for working with pen and paper over the concrete materials which were also available. She employed two main representational-arithmetical strategies, one unitcountable (all units individually represented, arranged in spatially-structured patterns, enumerated by group-counting) and one non-unitcountable (a written number representing each group, organised spatially in one dimension, enumerated by step-counting or addition). The first, which she introduced independently, was used for smaller quantities and the second, which I initially introduced but she readily adopted, for larger – although there would likely be an overlap of magnitudes where either might be chosen.

What do the strategies tell us about their particular weaknesses and capabilities?

Wendy wished to obtain answers she was confident were correct, with what she considered a reasonable expenditure of time and effort, and the strategies she used reflect this. In general her representations were highly mathematically functional, drawing and/or writing the minimum content which enabled task success. I see this as evidence of logical and meta-strategic ability, and a very sensible attempt to work around, and make the most of, her limited computational skills, minimal recall of number facts and relationships, and tendency to lose her place in multi-stage calculations.

Wendy produced 2D array representations quickly, confidently, and accurately. While this initial heavy reliance on unitcountable representations was a weakness, her use of this representation type also highlighted important and useful strengths in creating, recognising, and utilising structured visual patterns. Observation of her interactions with dot arrays demonstrated informal, non-declarative awareness of multiplicative structures, enhanced by the rhythmic nature of her counting. Wendy's flexibility in terms of willingness to experiment with and vary arithmetical-representational aspects can be considered itself a valuable component of metarepresentational competence.

Of particular note is Wendy's continued strong preference for scenario tasks over bare ones, even when they were obviously unrealistic. While her sensible comments about the comparative expense of different sizes of taxi and aeroplane demonstrate a real-world awareness of money and pricing that is often considered an important part of being 'numerate', this tendency to cling to the scenario aspect of the calculations could also indicate an unwillingness to engage in abstraction, and demonstrates a profound need for something extra-mathematical to grasp and cling on to. Numerical relationships, by themselves meaningless, were given meaning when they became numbers of people (etc.). This finding would be no surprise to a teacher of very young children, who has heard many exasperated students ask "Three? But three what?" (for example), but this strength of attachment to imagining numbers of things may be surprising in a secondary school student.

How do the arithmetical-representational strategies change over time and interaction?

The main observed progression was Wendy's capacity for tackling divisions involving increasingly large quantities. Repeated successes and gradual increases maintained the momentum of her confidence, allowing her to forget for a time her dislike/fear of division and negative self-beliefs about her ability to work with larger numbers.

Wendy had started these interviews secure in her purely iconic dot array representations for partitive division (having used them in the previous Sessions 1-2). Although it took some time for her to see that it could be equally useful for quotitive division (and multiplication), once grasped, this was added to her strategic toolkit. Although not addressed directly here, the triple function of unitcountable arrays has implications for deepening the understanding of the relationship between multiplication and division, and the commutative principle. Array-container blends provided a significant bridge between quantities engaged with as iconic units in spatial arrangements, and as numeric symbols. Enclosing equal groups of dots in rings visually transformed the groups so the most salient 'building blocks' were now a set of contained equal groups rather than individual units; visually, these containers became the new 'units'. This was vital for the significant cognitive leap of replacing a container with a number of dots inside it by a container with a number symbol inside it.

Wendy learned to use a building-up, additive strategy for quotitive divisions represented with non-unitcountable number containers. She sometimes chose to continue using drawings alongside symbolic calculation, but inconsistently – this makes their continuing purpose cause for speculation. Wendy did not doodle, and otherwise showed little inclination for decorational drawing, so I suggest that in longer, multi-stage tasks, when she was struggling to focus or experiencing doubt, the drawn element served as reminder and/or for affective support. The tactic of taking an offputting bare task and making it comprehensible (or, perhaps, 'realising' or 'concretising' it) through a familiar scenario was both helpful (in that she was successful in more arithmetically challenging tasks) and appealing.

Concluding comments

A microgenetic level of analysis of this student's arithmetical struggles illuminates certain specific ways of conceptualising and carrying out division-based tasks which may be unexpected and go unrecognised in classrooms. It also demonstrates the possibility of significant improvement which is unlikely to be picked up in standardised diagnostic testing, and has pedagogical implications. Is there evidence that Wendy was not just adopting and developing alternative representational strategies that were more amenable to her than those she had previously encountered, but also moving towards more successful symbolic thinking in arithmetic? Yes. Her mathematical journey was a slow and complicated one, with end point unknown, but this short section of it shows substantive changes.

While there may have been some progress since psychological assessment, Wendy was still performing poorly in her regular school mathematics classroom, and there was a huge discrepancy between these formal judgements made on Wendy's abilities and potential, and her clever maximisation of cognitive resources as captured in microgenetic observation. With the traditional strategies that rely on memorisation of facts and procedures unworkable for her individual pattern of neurodivergent characteristics, she analysed tasks to work out alternative strategies relying instead on sequence, pattern, visualisation, and a realistic self-assessment of the level of arithmetic she could reliably manage (counting and addition). She showed great interest in the numerical structures underlying arithmetical processes, and in suggestions for their use in solving different types of tasks. These self- or co-created strategies of which she had 'ownership' must stand a chance of being remembered better than those which had for most of her school life been ineffectively rote-taught. While Wendy is a single case with an individual pattern of mathematical strengths, weaknesses and strategies, other struggling students will share many of these experiences and traits, although each in their own individual pattern; certainly there are many who are labelled too easily by both teachers and researchers as 'low attaining'. And likewise, their self-belief will likely be low, and their strategic arithmetical-representational creativity dormant, undervalued and unencouraged.

Wendy's actions were not of a child who "lacks the ability to retain and process academic subjects that require logical thinking, analysis, sequencing, rationalising and accuracy". However, it took focused individual investigation and a flexible mixture of informal assessment, tuition elements, and discussion to gain a fair picture of the nature of her mathematical thinking (and this in one small area of the syllabus). If one accepted the statements in her diagnostic report at face value, to expend this time and effort on her would seem irrational. That kind of utilitarian philosophy is one of the factors leading to neurodivergent and learning disabled students being limited from reaching their potential in mathematics. Instead of dismissing learners like Wendy for their failure to perform in the expected ways, their unexpected ways of working mathematically should be valued – they have much to teach us.

Learning mathematics with media - representing, representations and representation transfer processes

Tobias Huhmann[2] and Chantal Müller[1]

University of Education Weingarten, Faculty of Didactics of Mathematics, Weingarten, Germany; huhmann@ph-weingarten.de[2]; mueller04@ph-weingarten.de[1]

With digital media, the possibilities of representation have developed fast: in terms of temporal and local availability and in terms of manipulation, dynamization, representation-networking and -synchronicity. They open up an expanded new spectrum of representation-transfer, in which representations, levels of representation and associated processes of representation-transfer must be identified, analyzed as well as researched and evaluated from a mathematic educational perspective. Which cognitive demands are thus placed on learners and which are supported or replaced by media? The goal for research and teaching is a "specific sensitivity for media (use) in (mathematics) education", so that analogue and digital media are analyzed in a potential-oriented way in order to orchestrate them for better teaching and learning.

Keywords: Mathematical concepts, learning with analogue and digital representations, transfer of representations, cognitive demands.

Theoretical Framework.

The learners' own transfer of representation is an essential indicator to develop understanding in the process of learning mathematics (Wittmann, 1981). Representation transfer processes are always required when at least two representations are given. They have to be compared on one or between different levels of representation – the levels acting, iconic, symbolic (see Bruner, 1971). A representation transfer is also required when a new representation has to be constructed based on a given representation. In both cases, given elements of one representation have to be related to given or to be constructed elements of another representation. In these transfer processes, a self-acting, active-discovering engagement with mathematics is central (Krauthausen, 2018; Kühnel, 1954; Winter, 1989, 2016; Wittmann, 1981). A purposeful use of different representations can create learning opportunities to explore relationships between representations and to recognize basic structures (Kuhnke, 2013). The significance of representing, representations, and representation transfer processes is emphasized in national and international curricula and standards as one of the main "general" process-related competencies to be developed in mathematics education (DIPF, 2021; KMK, 2005; Midgett & Eddins, 2021; NCTM, 2000). Representing and representations pursue two basic intentions. In *representing* the focus is *on doing*, on *externalizing one's own thinking* for communication with oneself and with others. Representing for oneself takes place in order to relieve and support one's own thinking processes through what is (visually) represented, in order to orient oneself in one's own thinking and to shape the further thinking process. Between one's own thinking and representing, processes of exploration and analysis are carried out in the context of mathematical discovery and reasoning through processes of ordering, sorting, and structuring (Aebli, 1980; Freudenthal, 1973). Representing for others is done to communicate one's own thoughts through what is (visually) represented. It also helps to explain where words are missing for oneself and for others. The (visual) information can support to get into exchange with others, to communicate about one's own thoughts and to justify findings about relationships and regularities with the help of what is represented (Duval, 2006). *Representations* serve for the process of representing *as a tool to present one's own perceptions and ideas externally*. So, the intention of representations is to document information which is volatile (Huhmann, 2013; Wollring, 2006). According to Bruner (1971), knowledge and thus also representations through which knowledge is expressed can be assigned to the three levels – acting, iconic, symbolic. In summary, these areas, representing, representations, and representation transfer processes lead to comprehension-oriented learning and are an indicator of understanding. In the following we will use the term *TripleR* for these three areas.

With digital media, possibilities of TripleR evolved enormously. Thereby we see a development in terms of temporal and local availabilities as well as in terms of manipulation, dynamization, representation-networking and synchronicity. These new possibilities open up new possibilities of interaction in learning mathematics with media and how teaching-learning processes can be designed (KMK, 2012). Therefore potentials of digital media must first be identified, as well as whether and how these potentials of digital media unfold in the reality of teaching as an added value for learning. Thereby, the question arises, which cognitive demands are supported or replaced by digital media or are still placed on learners by learning mathematics?

Research Desideratum.

Based on the models of knowledge acquisition and representation (Bruner, 1971; Piaget, 1972), further models can be found for identifying and analyzing representation possibilities and representation transfer processes. Lesh et al. (1987) focus in their model on different analogue representation forms and associated representation transfers. The model is extended by a technological form of representation by Johnson (2018), with which digital media, which appeared in many forms e.g., manipulable and moveable pictures, are basically covered. Further distinctions and specific features of representations with digital media as well as learning with these digital representations remain out of consideration. The model of multiple external representations according to Ladel (2009) is based on Bruner's (1971) model and levels of representation - enactive, iconic, symbolic. It focuses on elaborated representation possibilities with digital and analogue media. However, it does not focus on the identification and analysis of representation transfer processes. Overall, the models listed here do not take into account which (cognitive) demands are placed on learners by analogue and digital media during representing, learning with representations, and representation transfer processes, or which are replaced by media. In summary, we see a research desideratum in the model-theoretical identification and analysis of TripleR in learning with analogue and digital media. For teaching and learning we ask – how different media with their different cognitive demands and with possibly different analogue-digital components can be brought into connection with each other with regard to TripleR – and how this can be identified and made visible?

The Representation-Transfer-Spectrum.

Based on the models of Piaget (1972) and Bruner (1971) as well as on the extended new representation possibilities offered by digital media, we have developed an extended model as a representation transfer spectrum as you can see in Figure 1. With this model we want to identify, analyze, and evaluate from a mathematics educational point of view learning in terms of perceiving and acting with analogue and digital media:

1. *Identify*: In which levels are representing, the representations and the representation transfer processes located?
2. *Analyze*: Which cognitive demands are associated with representing, the representations and the representation transfer processes? Which cognitive demands are placed on learners and which are supported or replaced by media?
3. *Evaluate*: Which representing, representations and representation transfer processes are suited from a mathematic educational perspective?

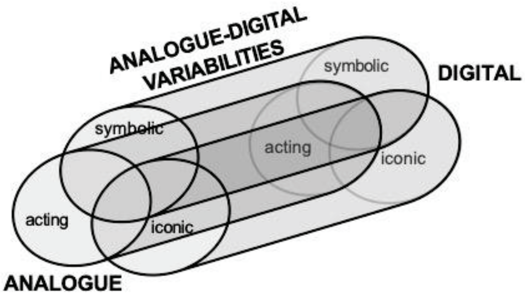

Figure 1: Representation-Transfer-Spectrum (Huhmann & Müller, in press)

Learning objects and associated activities can be located in their representations in the analogue area, digital area or analogue-digital area. Within these areas, a further assignment to the different levels of representation takes place. Between these levels we see no hierarchic arrangement. The focus in this paper is on the reciprocal transfer processes of representations within and between these levels of representation. Build on the levels of representation according to Bruner (1971), the intersections of the levels of representation are new elements of the model. We include these intersections under the term *levels of representation* because representations cannot always be assigned to just one level. If representations contain elements from different levels e.g., iconic elements (depictions) and at the same time symbolic elements (descriptions) (Schnotz & Bannert, 2003), they are to be placed in the corresponding intersection.

Analogue area: The characteristics of the three levels – acting, iconic, symbolic correspond to the known levels from Bruner. If actions are verbally accompanied, verbal expressions are supported by gestures, or symbolic representations are used to act, we identify these as representations of the acting-symbolic level. Representations that contain both depictions and descriptions (e.g. tables, diagrams, function graphs) belong to the iconic-symbolic level. Actions with *inherently unchangeable depictions* are located in the acting-iconic intersection. These can be ordering, sorting and comparing processes of images. Actions such as ordering, sorting and comparing processes with iconic-symbolic images are assigned to the acting-iconic-symbolic intersection.

Digital area: The model extension by the digital area is identical to the analogue area in its structure, but it differs in specific characteristics. On the acting level, there is the fundamental characteristic of the *manipulability of objects of action*. However, these are no longer haptically tangible and movable. Objects are manipulated and moved merely by wiping and tapping movements. Objects that are digitally represented as *inherently unchangeable images* are assigned to the iconic level. Objects that are represented as audio or written text in a symbolic way in the digital area are assigned to the symbolic level. The acting-iconic intersection covers both the user's own digital actions with inherently unchangeable images and representations of digital actions in the form of animations and movies based on images. The acting-symbolic intersection covers the user's own creating, manipulating, and acting with symbolic representations. This involves audio texts and written texts that can be accessed, duplicated, and combined with digital media. The iconic-symbolic intersection covers inherently unchangeable representations that include both depictions and descriptions. The acting-iconic-symbolic intersection covers the user's own actions with manipulable representations as well as representations of digital actions in the form of animations and videos that contain both depictions and descriptions.

Analogue-Digital area: The analogue-digital area forms a spectrum between the analogue and the digital area. This area is to be explored with regard to the representations of learning objects and activities in terms of their characteristics and possibilities. This involves the identification and analysis of analogue-digital variabilities - in the sense of variable portions closer to the analogue or digital areas as well as with variable focal points in or between the three diameters of the respective areas. In this area, augmented reality and virtual reality applications, among others, are to be considered in a future-oriented manner.

With regard to the digital and analogue-digital area, there is an urgent need for research into these areas, the possible representations of the learning objects, and the suitability of the representation-transfer-spectrum to identify, analyze and evaluate from a mathematic educational perspective.

Representation transfer processes become visible in this model by connecting the activities located on the representation levels with arrows, so that the transfer from an initial representation, which is given to learners, to a final representation, which learners are supposed to construct independently or relate both given ones, is recognizable. Representations become visible by dots in the levels.

Example.

The activity *Architect and Bricklayer* (Thöne & Spiegel, 2003) is an example to demonstrate the use of the representation-transfer-spectrum: Learner 1 builds a cube building with cubes and describes it verbally to learner 2. Without seeing the cube building, learner 2 must build a cube building based on the description from learner 1. Afterwards, both cube buildings are compared with each other. The following description of this learning activity includes the implementation of the complementary use of the app *Cubes (Klötzchen)* (Etzold, 2015).

	The task *Build a cube building with 8 cubes* is presented to learners by the teacher on a *symbolic* level verbally or in writing.

<table>
<tr><td></td><td>Based on this task, learners build a cube building as a 3D model using the app Cubes. From the originally symbolic presented task, the learners have to perform a transfer of representation to the action level in the digital area.</td></tr>
<tr><td></td><td>The cube building build in 3D by using the app is now used by the learners to describe it verbally. At this point, the learners perform a representation transfer from the action level in the digital area to the symbolic level in the analogue area.</td></tr>
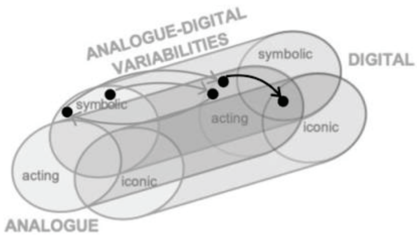
<tr><td></td><td>This verbal description now serves other learners as a starting point for rebuilding the cube building on their own tablet using the app. Here, too, the learners transfer the representation from the symbolic level in the analogue area to the action level in the digital area.</td></tr>
<tr><td>


</td><td>The two cube buildings of the learners need to be compared with each other. There are different ways to do this.

Both cube buildings are displayed in the 3D view on both tablets and compared with each other. Since both cube buildings can be manipulated in this representation, i.e. single virtual cubes could change places, the process of checking the results takes place at the acting level in the digital area.

It would also be conceivable for the learners to use the construction plan, which is created automatically and synchronously by the app Cubes, to check the results.

For example, both construction plans can be compared with each other. The result verification is now in the intersection acting-iconic-symbolic, in the digital area. However, the following aspect should be emphasized here: The intermodal transfer from the 3D view to the construction plan, from the digital-acting to the digital-acting-iconic-symbolic level, does not have to be performed by the learners themselves, it is taken over by the digital medium.</td></tr>
</table>

Table 1: Transfer of Representation in the Representation-Transfer-Spectrum (Huhmann & Müller, in press)

Findings and perspectives.

The Representation-Transfer-Spectrum is a theoretical model that is in a developmental state and needs further research. According to the example above, we consider it to be suited to identify representations and representation (transfer) processes. The activity *Architect and Bricklayer* served here as an example to demonstrate the use of the Representation-Transfer-Spectrum. First, we identified the TripleRs related to this activity in the model to make visible which forms of representation exist at which levels of representation and which representation transfer processes are demanded. Through this, possibilities of action and affordances, (Gibson, 1977) that means possibilities of action implicit in the medium, become visible. Second, we analyzed which representation transfer processes are performed by the learners and which are taken over by the digital medium. Third, we now would have to evaluate the representations and representation transfer processes from a mathematics educational perspective so that different media for this learning object can be orchestrated for lesson planning.

For *lesson planning*, it may thus serve as a model of thinking and analysis to make design decisions. The overall goal for teaching is a purposeful use and orchestration of different media for learning. From a *research* perspective, the representation transfer spectrum may serve as a model of thinking and analysis for characterizing applications: For applications that have been developed and are in the process of being developed. For exploring applications in terms of how learners use and proceed with them. All in all, it may serve for further development of analogue and digital representation possibilities and design decisions for applications. A main question is which manipulation *possibilities* are implemented in the application and which manipulation *realities* can be identified during individual task processes with the application? With the help of the model, *possibilities* and *realities* of use are to be identified and made visible. Therefore, the goal of this model is to characterize learning objects and their use in the context of digital media with regard to (new) forms of representation, (new) levels of representation and (new) representation transfer processes as well as (new) combination possibilities of representation.

The associated goal for research and teaching is a *"specific sensitivity for media (use) in mathematics education"*, so that analogue and digital media are analyzed in a potential-oriented manner in order to orchestrate them for better teaching and learning. Last but not least, the future-oriented question is which significance the representation-transfer-spectrum can have as a model of thinking and analysis in connection with learning with analogue and digital media, also in other educational disciplines.

Solving arithmetic word problems: representation as a tool for thinking

Giulia Lisarelli[1] and Federica Poli[2]

[1]University of Pisa, Italy; giulia.lisarelli@dm.unipi.it

[2]The English International School of Padua, Italy; f.poli@eisp.it

In this paper we report on two tasks that are part of a didactic sequence on arithmetic word problems and we discuss some episodes that happened in one experimental grade 7 class. Our main goals are to gain insights into the role of representation for students in problem solving and to investigate whether a specific task design can contribute to making representation become a tool for thinking. Preliminary results show that students tend to use representation for communicating their answer, but they can be guided in the process of transition towards the use of representation for reasoning about the problem and its resolution.

Keywords: Word problems, mathematical discussion, psychological tool, representation, task design.

Introduction

In this study, we address the question that is at the heart of the ongoing debate and research in Mathematics Education: "How can teachers support learners' representational and meta-representational competences?" and, in order to do so, we focus in particular on representations in the context of word problem solving. The use of representations in problem solving processes has been highlighted as an important issue in the mathematics education literature (e.g., Arcavi, 2003). Representations can take on different roles in problem solving: tools used for finding a solution to the problem; means of validating and convincing of the result obtained; narrative tools used to communicate and present findings to other people. Van Essen and Hamaker (1990) claim that by translating a word problem into a picture, students are brought to pay attention to the relationships in the problem. This is particularly important in our case because we consider the class of word problems, in which the relationships between the quantities involved are known, but not the numerical values of those quantities that have to be found.

There is a huge body of research documenting students' difficulties with arithmetic word problems (e.g., Verschaffel et al., 2000) and algebra word problems (e.g., Clement, 1982). To understand these problems, students have to interpret the semantic context, using their prior knowledge, and construct a representation that allows them to figure out how to search for a solution. For this reason, different forms of representation come into play and the graphic scheme produced by students to visualize and simplify the problem plays a central role in the resolution process, also activating their meta-representational competences (Ott, 2020). There are some contexts and studies where a representation is provided explicitly by the teacher. For example, Singapore has adopted a unique approach to support students in word problem solving: the model method (Ng & Lee, 2009). Students in Singapore are taught to represent known and unknown quantities using rectangular bars that specify quantitative relationships amongst data in word problems. In contrast, we asked ourselves how teachers could support students in becoming aware of the importance of making a representation, so that it is the product of their own cognitive processes, and not something provided explicitly by the teacher. In this paper we present two tasks that are part of a didactic sequence on arithmetic word problem solving through representations and we discuss the methodological and design choices made to promote students' use of *representations for thinking*.

Theoretical framework

In line with the Vygotskian socio-cultural perspective (Vygotskij, 1978), we believe that social interactions and the use of artifacts and signs are of central importance in teaching-learning processes. Social interactions, specific teacher's interventions as in the orchestration of Mathematical Discussion (Bartolini Bussi, 1996), and an accurate task design with proper principles (Gravemeijer & Cobb, 2013), can promote the production of collective signs, the awareness of the meanings of different signs and their evolution towards mathematical meanings. Moreover, thanks to the cultural mediation conducted by the teacher, students acquire the technical tools developed by previous generations and, through the complex process of *internalisation*, a tool can become a *psychological tool* that will shape new meanings (Vygotskij, 1978).

For this study we are interested in the central role that representation can play in problem solving, participating in the construction of mathematical meanings and in the development of cognitive processes. In order for this to happen, however, the semiotic mediation carried out by the teacher is important because it supports the transition from signs (i.e., representation) with a communicative function to signs as psychological tools that are, therefore, generators of intellectual functions (Bartolini Bussi & Mariotti, 2008).

Research questions

The investigation presented in this paper is guided by two closely related research questions: What is the role of representation for students in arithmetic word problem solving processes? How can task design contribute to making representation become a psychological tool for students?

Methods and participants

The activities we report on in this paper are part of a didactic sequence on problem solving, developed within a larger research project in which the authors of the paper were involved. The general aim of this project is designing and experimenting inclusive mathematical activities for middle school, following a design-based approach (Gravemeijer & Cobb, 2013). Specifically, a group of teachers and researchers worked closely together in the design of a didactic sequence that has been implemented in several grade 7 classes in Italy (students aged 11-12), during the school year 2020/21. We considered arithmetic word problems in which the relationships between the given quantities are known but not the numerical values of these quantities, that are sought for. The sequence is divided into 4 phases characterized by the type of relationship existing between data (Table 1).

All the experimentations of the didactic sequence have been conducted by the regular teacher, without the presence of researchers or other teachers in the classroom. The collected data consists of excerpts taken from the students' workbooks and transcripts of short interventions by students during the whole class discussion, which the teacher took note of or, when possible, recorded with a microphone, and then translated into English. Therefore, the discussions were orchestrated by the teacher, who left room for the students by asking a few stimulating questions, according to the task's objectives. These objectives were previously identified with the researchers and teachers involved in the project.

Table 1: Overview of the didactic sequence on arithmetic word problems

Phase	Type of relationship between data in the problems	Example
1.	"Integer multiple" and sum known	The sum of two numbers is 96. One number is three times the other. Find the two numbers.
2.	"Integer multiple" and difference known	A number is five times another number and their difference is 528. Find the two numbers.
3.	"Exceeds by" and sum/difference known	The sum of two numbers is 174. One number is 3 more than twice the other. Find the two numbers.
4.	"Fractional multiple" and sum/difference known	The sum of three numbers is 180. The first is 4/9 of the second and the third is 7/9 of the second. Find the three numbers.

In this paper we focus on the first two tasks in phase 1 of the didactic sequence, that are shown in Figures 1 and 2.

First task

The first task consists of students working individually on the resolution of the problem (Figure 1), and then they are asked to engage in a mathematical discussion orchestrated by the teacher.

Solve the problem and explain your reasoning with the help

of a representation (e.g., drawing, diagram, scheme, ...).

"The sum of two numbers is 96. One number is three times the other. Find the two numbers."

Figure 1: First task

Second task

The task consists of students working individually on the attempt to interpret Bernardo's reasoning and apply it to solve the problem (Figure 2). Then, they are asked to engage in a mathematical discussion orchestrated by the teacher.

"The sum of two numbers is 4710. One number is five times the other. Find the two numbers."

This is a picture of the workbook of a student, Bernardo, who tried to solve the problem but stopped. Help Bernardo to move forward!

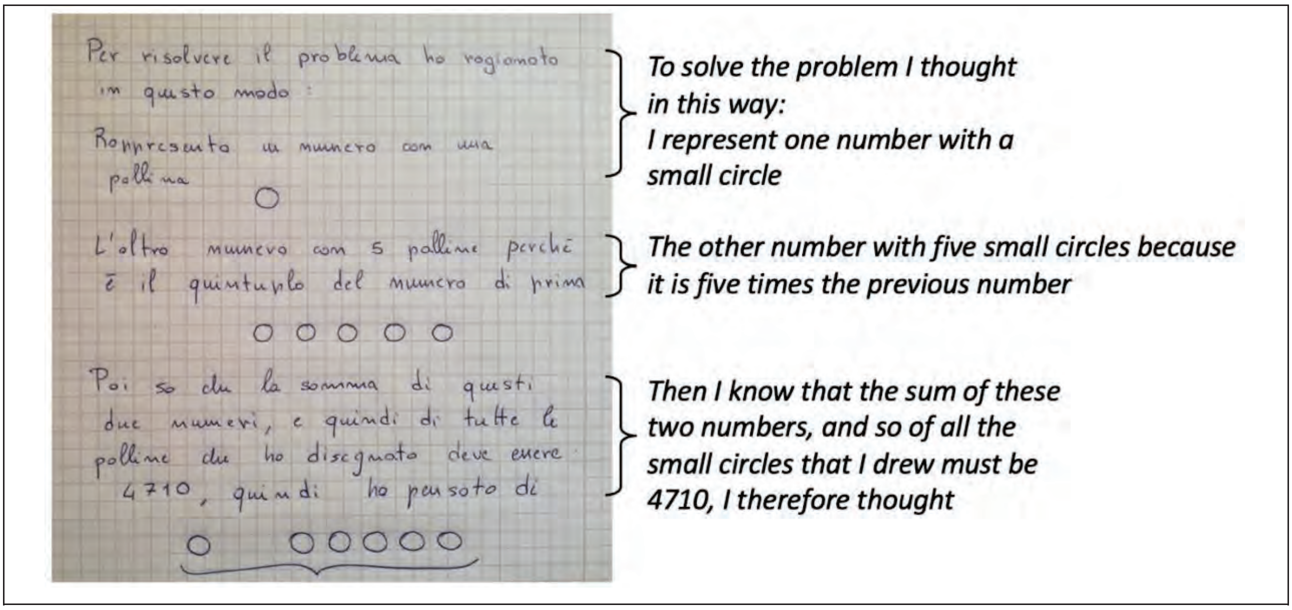

Figure 2: Second task

In the following section we report on the task design made by the group of teachers and researchers involved in the project, both a priori and during the implementation of the didactic sequence, between one lesson and the next, based on students’ reactions. Moreover, we discuss some preliminary results, showing data from one of the experimental classes that has been chosen as a representative example. That class was considered to be representative because it allows us to show the general dynamics of what happened in all the experimental classes, in a quite short time span to be reported on in this paper. Overall, very similar mathematical discussions and students’ reactions came up in the different classes during the didactic sequence.

The class had not previously dealt with this type of arithmetic word problems, not even in geometry, and they had not yet approached equations. Additionally, the teacher had never discussed with the students what the different roles of representation in problem solving might be. Students in this class are used to taking part in mathematical discussions, explaining their reasoning and argumentation. The observation and analysis of signs produced by the students, in their workbook and during mathematical discussions, make it possible to gain insights into the role of representation in their resolution processes of the proposed problems. For answering the second research question, we investigate whether something changes in students’ use of representation in problem solving, in relation to a specific task design.

Discussion of the tasks and preliminary results

The first task (Figure 1) is designed with the aim of observing the different solutions proposed by students, the type of representations they suggest and how they use them. In the task some possible representations are given in brackets because, having never done similar work before, the teacher expected that the term “representation” might not be completely understood by the students and so planned with the researchers to give them some examples of possible signs. After the time for individual work, about 20-30 minutes, students are asked to explain their reasoning to the classmates. In this way, during the discussion the teacher can gather information about the role of representation, whether for students it is a tool for communicating to the teacher the problem answer, that has been found only with calculation, or a tool for thinking about the problem itself.

In the experimental class, we observed that most students made the representation a posteriori (after finding a numerical solution to the problem), following the teacher's request to explain their reasoning or, more explicitly, to use a representation themselves. Indeed, as can be seen in Figure 3, the numerical values of the involved quantities, that is the solution, already appear in the proposed representations. Many students' strategy for solving the problem was to proceed by trial and error, starting with two numbers that partially satisfy the given conditions (e.g., whose sum was 96) and then modifying them so that they also satisfy the other conditions (e.g., one was also three times the other). A few students drew 96 circles, while most calculated the half of 96 but then failed to explain why this strategy worked. These representations are almost never generalized, because they refer to the specific problem and do not represent in general the two given relationships, i.e., "sum" and "three times". Therefore, most of them could not be used for representing a similar arithmetic word problem having the same relationship between data but different numbers. A possible exception is the last screenshot in Figure 3, in which the student used four circles, each accompanied by the letter *n*.

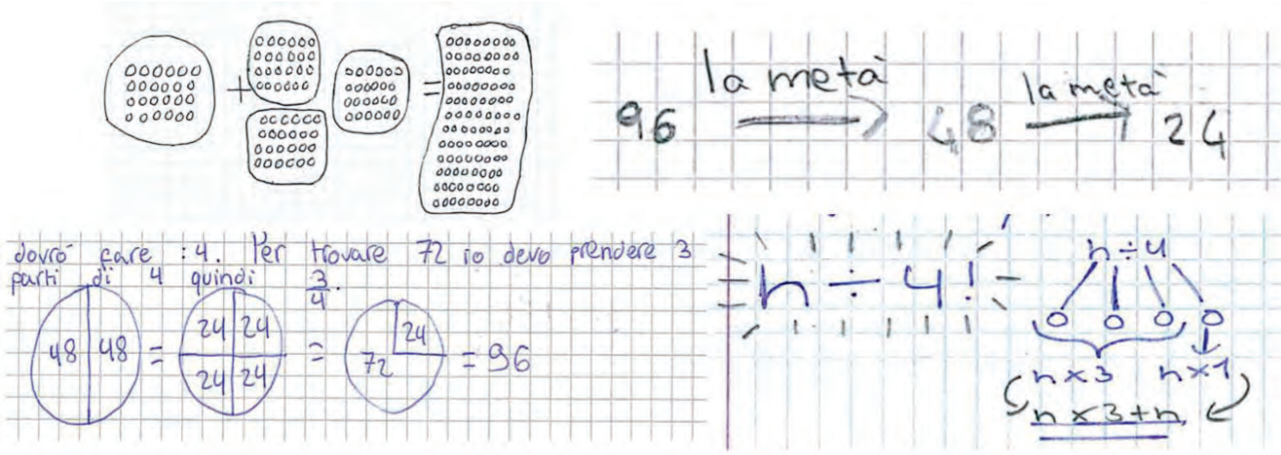

Figure 3: Examples of representations proposed by the students in the first task

In light of what emerged from the discussion of the first task in the experimental class, the group of teachers and researchers realized that these signs were used by students merely as tools for communicating the procedure followed or, simply, for pleasing the teacher's request of making a representation and accomplishing the task. As a result of the teacher becoming aware of this signs' utilization, the second task (Figure 2) is designed to support a transition in the role of representation towards possible tool for supporting students' reasoning in arithmetic word problem solving.

The main idea behind the second task design is to create a dialectic in which the representation is partly created by the students and partly provided by the teacher. Specifically, it is based on a ploy that consists of showing the workbook of a (imaginary) student, Bernardo, who makes a representation using circles for solving an arithmetic word problem that is very similar to that given in the first task. We note that in this class the choice of circles, rather than squares or rectangles or other, came from a student's idea (Figure 3) accepted by the students as the most functional because circles are easy and quick to draw; upon which the teacher worked in continuity.

In this task, to prevent students from trying to solve the arithmetic word problem without paying attention to Bernardo's solution, they are asked to help him (and to do that they need to figure out his reasoning). Indeed, in this type of tasks, the teacher must take care of the devolution of the problem (Zan, 2007): what is the problem that students must solve? The possible options are:

1. Solve the arithmetic word problem, then find the two numbers;
2. Try to understand how Bernardo reasoned;
3. Help Bernardo to complete the solution to the problem, based on the reasoning followed up to that point.

In order for students to put themselves in Bernardo's shoes and enter into his reasoning, which is based on the use of small circles, it is important that they try to exploit this representation. Therefore, in this task students are asked to solve the problem in the third formulation, i.e., to help Bernardo complete the solution. After the time for individual work, about 20-30 minutes, the teacher orchestrates the mathematical discussion, prompting it through questions like: What is this student reasoning? Do you think that the representation with small circles drawn by Bernardo can be useful for finding a solution to the problem? If yes, in what way and if not, why?

In the experimental class, this problem proved to be quite difficult because many students thought they had to divide 4710 by 5 instead of 6. For example, this is an excerpt from a student's workbook:

First of all I found this to be quite a difficult problem, but with Bernardo's scheme it was much easier to solve. When his reasoning stopped the last thing that was on the paper was the diagram with the 6 circles and the curly bracket, which I saw as an addition because the first circle, alone, was the normal number and the other five circles were five times the number so all the six circles with the curly bracket below (which puts them together, i.e. adds them up), and under the curly bracket there will be the number 4710 because it is the result of the sum, as the problem says.

As this student wrote, Bernardo's representation has been helpful to understand why the sum 4710 should be divided by 6, a number not explicitly available in the text of the problem. This was not the only case, for example another student matched each part of the representation with a part of the text of the problem and then completed the solution by exploiting Bernardo's reasoning (Figure 4):

In my opinion, what Bernardo did is very useful for finding the solution to the problem. This is because he translated the sentence "one number is five times the other" by drawing the circles. He represented "a number" with a circle and since the other number is "five times the other" he said that five times the circle is the other number. I wrote the rest of what Bernardo did like this:

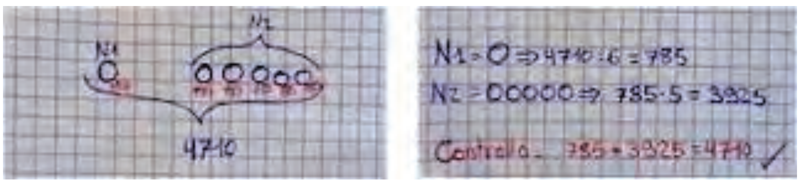

Figure 4: How a student exploited the representation with small circles in the second task

Therefore, students' attempt to follow Bernardo's reasoning, based on the use of circles, to complete the solution to the problem, helped them give meaning to the problem itself. At the end of the whole classroom discussion, they seemed to have grasped the usefulness of the representation proposed by Bernardo that can be used to find out what calculations to do. For example, a student participated in the discussion observing that for them the time for representation usually came after the time for calculation, whereas Bernardo seems to have swapped this order:

In my opinion Bernardo's reasoning was to reason first and then to do the calculation, even though I usually do the calculation first and then the reasoning to explain how I came to solve it.

The teacher highlighted this observation, repeating it aloud, believing that it could be a key element to promote for all students the a priori construction of representations for thinking about the problem.

Conclusion and implications

In this paper we reported on two tasks taken from a didactic sequence on arithmetic word problems and discussed some episodes that happened in one of the experimental classes. The first task is aimed at eliciting different proposals for possible representations from students and their preliminary considerations and ideas on the use of a representation in problem solving processes. In line with the literature on arithmetic word problems, students found some difficulties in solving the problem proposed. We also observed that the representation did not prove to be a useful tool for them to find a solution strategy, but it was used for showing and communicating their answer to the teacher and classmates. Having this in mind, the second task is designed to mediate the process of *internalisation* that may transform the representation into a *psychological tool*. In our experience, this task has been crucial in changing the role of representation for students, because it made them gain awareness of the effectiveness of representation as a possible tool for thinking in problem solving. To achieve this shift towards the representation as a psychological tool for students, the teacher's role in designing the task, within the group of researchers and teachers, and in orchestrating the whole class discussions was fundamental. Indeed, after the second task, in the later phases of the didactic sequence, most of the students started to use the representation with small circles to solve this type of problems, and we think that a number of factors contributed to this success. First of all, the representation with small circles was not provided explicitly by the teacher, but it was the result of a dialectic process. In addition, students were asked to help Bernardo to complete the solution, based on his reasoning that was not centered on calculations. Finally, during the mathematical discussions the teacher repeatedly drew students' attention to the fact that a "good" representation is generalized, i.e., it allows them to solve different problems of the same type. For instance, in our case it could be always possible to use a small circle to represent an unknown quantity, regardless of context, and then representing the other data of the problem through a set of small circles, whose number depends on the relationship given in the text.

A relevant didactical implication of this study is that, in our opinion, it is possible to support learners' representational and meta-representational competences through careful design and methodological choices made by the teacher. The presented didactic sequence on arithmetic word problems is an example of task design in which students acquire the technical tools that, through a process of *internalisation*, become *psychological tools* for them. This is an exploratory study and the results are still at a preliminary and local level, however, we hope that the conclusions we arrived at can inspire the work of teachers and researchers who share with us the assumption that using a representation as a tool for thinking when solving arithmetical problems is of fundamental importance.

Acknowledgment

Optimization without calculus: What benefits might using physics-based visualizations in the classroom bring?

Jakub Michal

Charles University, Prague, Czech Republic; cjakub@email.cz

Keywords: Optimization, experimentation, physical representations, methods of problem solving.

Introduction

A lot of questions which are at the core of optimization problems are already asked by both primary (age 6 – 15) and secondary (age 15 – 19) school pupils. Nevertheless, it is only quite late (if at all) that the answers to these questions are provided. This is because in the Czech curriculum optimization is taught mainly after derivatives. This sudden appearance of new type of problem causes many obstacles in pupils' understanding. To avoid this, a series of optimization problems and methods, usable at either primary or secondary school, was collected from the history of optimization. One of the methods identified is based around using physical representations.

A series of semi-structured interviews based around this visual method was conducted. The main focus of interviews was to analyze the way pupils react to uncommon and novel methods of problem solving. I sought to find out if physical representations could be suitable for classrooms and to find what advantages and disadvantages such demonstrations might bring for both pupil and teacher.

Theoretical background

Many problems from the field of optimization were solved using parallels with the physical world. For instance, *Heron's problem* was solved by observing the way light beams travel (Rojo & Bloch, 2018) or *Snell's law*, from physics, was used to solve the *brachistochrone problem* by Bernoulli (Tikhomirov, 1986). This approach is not as common today, as it lacks rigor and generality (Polya, 1954). Levi (2009) states that mathematics and physics are so intertwined that one without the other is deprived. Levi (2009) also considers mechanics to be geometry focused on touch and movement. These two elements add extra benefits which geometry otherwise lacks. Using physical experiments allows pupils to perceive the problem with other senses, which leads to multisensory learning.

Methods

For the research, a series of interviews was conducted. Interviews were in form of a dialog between participant and researcher (myself), as I wanted to observe the way the pupil worked with manipulatives. The length of interviews varied from 30 minutes to one hour depending on the pupil's ideas, focus, and will to go on. The research sample consisted of 8 primary and 9 secondary school pupils. Pupils from primary school were selected based upon their positive attitude towards the subject and their skills in mathematics and physics. Pupils from secondary school were volunteers willing to participate in the research. Tasks selected for the interviews were picked based upon two criteria. First, the problems had to be clear enough for both primary and secondary school pupils to understand, and second, the experiments via which the problems were solved had to be real-life performable (not merely thought experiments). The first problem discussed was *Steiner's* *problem*. Pupils were to use the soap films to find the *Toricelli point* and its properties (Courant & Robbins, 1996). A special contraption consisting of two transparent rectangular plates connected to each other by three columns was used. This contraption was submerged into soap water and taken out. Between the plates and the columns, soap films were formed. When looked at from above, we saw a perfect 2D representation of the shortest path with the *Toricelli point* as an intersection of three soap films. The second approach used three weights of the same weight and three pieces of string of arbitrary length. The strings were tied together and the other end was attached to the weights. Three pulleys were needed as well. After we hung the contraption on the system of the pulleys (which formed a triangle) the weights would eventually find a state of equilibrium and would not move anymore. The position of the knot which tied all three strings together represented the *Toricelli point* (Levi, 2009).

Results

It was difficult for pupils to work with manipulatives on their own. They often gave up quickly and had to be guided through the experiment. Their guesses were based solely on visual impressions that the point (intersection of strings/films) is a center of gravity, inscribed or circumscribed circle etc. Pupils mostly abstracted from the physical world and looked at the results as if they were only 2D representations on paper. They saw films and strings as lines and ignored weights, gravity or energy necessary for understanding. After pupils understood the meaning behind the experiments, they were fascinated by the fact that it works. That was an important moment, as the pupils themselves were motivated to look for explanation. Both experiments awoke curiosity in pupils as they asked “why” and “how”. After initial struggle, pupils considered the explanations to be easy and playful. From that I assume this kind of experimentation could be powerful in the classroom as it makes the problems accessible for younger children and motivates them to learn. Several misconceptions in the children’s understanding were revealed as well that might otherwise remain hidden. This suggests the experiments could serve as a diagnostic tool for teachers.

From figural to theoretical control (and back): a first proposal for framing the interplay between different controls

Elisa Miragliotta[1] and Carlotta Soldano[2]

[1]University of Pavia, Italy; elisa.miragliotta@unipv.it

[2]University of Torino, Italy; carlotta.soldano@unito.it

Grounding on Fischbein's studies, our work is intended to deeply investigate the systems of control which influence the dialectic between the figural and the conceptual component of figural concepts. We propose a first attempt for characterizing the systems of control by introducing a fine-grained distinction between three dimensions: visual, spatial, and theoretical. This theoretical frame is used for analyzing some excerpts from a case study which involve graduated students in Mathematics, while solving a geometrical task concerning the reciprocal position and the intersection point of cube diagonals. Through the analyses of these excerpts, we show evidence of the three types of control and of their interplay. Finally, theoretical and educational implications of the study are discussed.

Keywords: Figural concepts, systems of control, theoretical control, geometrical reasoning, cube diagonals.

Introduction

Research in mathematics education has developed theoretical constructs, useful for interpreting students' conception of geometric objects and its evolution while learning geometry. A fundamental contribution in this direction was given by the inspiring work of Efraim Fischbein, whose psychological point of view on geometrical objects had a huge impact on many subsequent studies. Starting from a strong assumption on the multifaceted psychological nature of geometrical objects which shares both figural and theoretical aspects, *geometrical reasoning* is interpreted in terms of dialectic between these different aspects and respective *systems of control* (Fischbein, 1993, p. 151). Broadly speaking, the systems of control seem to be involved in recalling and transforming the figural or the theoretical aspects of geometrical objects. They are activated during the geometric reasoning hence they have not to be considered as a specific phase of the problem-solving process. Despite the central role of these controls in geometrical reasoning is recognized (e.g. Mariotti, 1992; Mariotti & Baccaglini-Frank, 2018), a precise description of them and of their possible interplay still remains opaque. Nevertheless, shedding light onto the construct of control will provide a new insight into the solver's geometrical reasoning and consequently inform the design of educational interventions for overcoming student's difficulties.

In this paper, we intend to turn on a spotlight on Fischbein's construct of *control* as a fundamental element of geometrical reasoning. More precisely, we intend to theoretically elaborate on the notion of controls and on their possible synergy. According to this general aim, we propose a frame based on Fischbein and Mariotti's works related to the topics of figural concepts and controls for analyzing different types of control activated by students while solving geometrical tasks.

Theoretical framework and research aim

Fischbein's *Theory of figural concepts*

Building on the *Theory of figural concepts* (Fischbein, 1993), we consider geometrical objects as having a dual nature. More precisely, when people use or refer to geometrical objects, they are thinking in terms of *figural concepts*, that are mental entities which simultaneously possess both *conceptual* and *figural* components. Figural concepts "reflect spatial properties (shape, position, magnitude), and at the same time, possess conceptual qualities - like ideality, abstractness, generality, perfection" (Fischbein, 1993, p. 143). In principle, the two components are strongly intertwined and blended. However, more often the conceptual and the figural components remain under the influence of the respective *system of control*. Indeed, the figural component is influenced by the Gestalt theory of perception or graphical constraints; on the other hand, the conceptual components may be affected by logical fallacies. Following Fischbein, Mariotti (1992) has described the different intervention of the two systems of control as follows.

> The figural control system suggests transforming the drawing, moving (translating, rotating, reflecting, ...) the pieces, changing their places [...] But, only the conceptual control system can affirm the possibility and the correctness of this procedure. (Mariotti, 1992, p. 15)

Moreover, the conceptual control allows the solver to cope with the fact that the same geometrical object can play different roles or have different theoretical properties within the same geometrical configuration (Mariotti, 1995). For example, in a rectangle a diagonal can be conceived also as the hypotenuse of a right triangle, depending on the solver's aims. In this description of the conceptual control both spatial and theoretical elements are involved, but each of them contributes differently to the geometrical reasoning. Indeed, the mastery in managing the spatial aspects allows the solver to see the same object as part of other ones, while the domain of theoretical aspects allows the solver to put these objects in relation to their mathematical description (Mariotti & Baccaglini-Frank, 2018).

Grounding for a characterization of *controls*

In light of the brief literature review discussed above, the construct of *control* echoes the Saada-Robert's (1989) *control function* which concerns organizing knowledge based on the conditions of the given situation and the Vinner's (1997) *control mechanism*, which allows the solvers to dominate, more or less consciously, their spontaneous associative reaction to a given stimulus. However, broadly speaking, although Fischbein has theorized the role that the two systems of control might play in geometrical reasoning, he does not provide an operative definition of them, so that a researcher could observe and study these controls in the geometrical reasoning of an actual solver. A first attempt in this direction was made by Mariotti and Baccaglini-Frank (2018) who provide a definition of a kind of control that is strongly intertwined with the reference mathematical theory within which the geometrical reasoning is carrying on (in this case, the Euclidean geometry). *Theoretical control* is defined as the act of "mentally imposing on a figure theoretical elements that are coherent in the theory of Euclidean geometry" (Mariotti & Baccaglini-Frank, 2018, p. 156).

Moreover, Fischbein considers both shape and position together as parts of the figural component. However, according to the most recent finding in cognitive psychology, there is a distinction to be made in the processing of the *spatial* (e.g., position of an object in space) and *visual* (e.g., color, shape, texture) attributes of an object that is perceived or mentally manipulated. This distinction is corroborated by evidence that two different neuronal pathways are involved in processing spatial and visual information, respectively the "where" and the "what" pathway (Anderson, 2015). For instance, considering a *rectangle* we can refer to the global appearance of the shape which answers to the "what" question about the object, otherwise we can refer to the mutual position of its parts which answers more likely to a "where" question. Furthermore, from a developmental point of view, the spatial aspects play a fundamental role in the personal construction of the conceptual component of a figural concept. Indeed, at the beginning, geometry relies on a natural organization of space that gives a contribution to the conceptual components (Mariotti & Fischbein, 1997). So, within the domain of geometrical reasoning and in order to consider the psychological perspective – in line with the very first Fischbein's declared intention – a solver might exercise a control upon the visual aspects and/or upon the spatial aspects. So, besides *theoretical control*, we will consider and make a distinction between *spatial control* and *visual control*. For example, in the case of the figural concept of rectangle, students might focus on its "rectangularity", since they has experienced the rectangular shape of physical objects (visual control); they might zoom into the shape and focus on the diagonals as part of the rectangle (spatial control); finally, they can recall some other figural concepts that are consistent with the rectangle, such as the right angles or the parallelogram as a more general case of quadrilateral (theoretical control).

In light of the theoretical framework presented here, this exploratory study intends to problematize and shed light onto *systems of control* which intervene in geometrical reasoning in order to pave the way to an operative definition of them which can be shared within the community of researchers in mathematics education.

Methods

The present study is focused on a case study involving 18 master students in mathematics of the University of Turin. The selection of a sample of expert solvers was driven by the hypothesis that these students might possess well harmonized figural concepts. In this paper we focus on the "cube diagonals problem", which was solved by the involved students in groups of three. Each group spent around 30 minutes in solving the task. Data was collected in December 2019 and consists of students' written productions and video-recordings of three groups-work.

Data are analyzed focusing on instances of *visual*, *spatial*, and *theoretical control*. More precisely the control is coded as *visual* when a figural concept is recalled through drawings, gestures or words which describe its global appearance (e.g. showing through a gesture or drawing a triangle; determining the congruence of two triangles according to the figural resemblance of the whole shapes); the control is *spatial* when figural concepts are conceived within a physical reference frame or zoom in/out movements are produced within the considered figural concept (e.g. focusing on right triangles inside the rectangle; among these two, focusing on the triangle "on the right"); the control is *theoretical* when figural concepts are introduced in a way that is coherent with the Euclidean geometry (e.g. justifying the congruence between right triangles inside rectangles by considering the congruence criteria of triangles; identifying a triangle focusing on the three points that generate it).

The cube diagonals problem

The given task is a reformulation of a geometric problem described by Mariotti (2005): "*Determine if the diagonals of a cube meet and if they meet perpendicularly*".

As observed by Mariotti (2005), despite the cube being a familiar polyhedron, students' mistakes in solving this task are common. In order to see whether diagonals are perpendicular or not, it is necessary to conceive them as diagonals of rectangles made by an opposite pair of cube's edges and an opposite pair of cube's diagonal faces. Since diagonals of these rectangles are not perpendicular to each other, the answer is negative. Moreover, in a rectangle, the intersection point of diagonals and their respective midpoints coincide. This further observation supports the unicity of the intersection point of cube diagonals. In the following section we will report the analysis of some excerpts of the video-recording of groups-work. We will refer to them as group A, B, and C.

Data analysis

The first extract is taken from group C. Before starting to solve the problem students share in the group their conjecture: diagonals meet in the "center" of the cube. The word "center" suggests that the figure is conceived within a physical reference frame and that the students are zooming inside the cube, hence that they activate a *spatial control*. Then, students make a drawing of a cube (Figure 1a) and confirm that diagonals meet by activating the *visual control*. Looking at the drawing Ellen says that she is imagining planes made by pairs of cube diagonals. With these words, Ellen starts introducing *theoretical* elements in the figure. The following extract is taken some minutes after her observation:

Ellen: But sorry if you think of these as squares, but placed obliquely, the diagonals are those of the square and they meet and are perpendicular *(mimicking the perimeter of the square and the diagonals with her pen, see Figure 1b)* … That is, if you think of the plane that passes through CE and BG *(gesture with the palm of the hand, see Figure 1c),* these two *(mimicking the diagonals with the pen)* are the diagonals of the square that I construct like this *(with the finger she links the extreme points of the diagonals, mimicking the perimeter of the square)* and meet and are perpendicular.

Richard: It is not a square!

Ellen: You are right, it's a rectangle!

(a)  (b)  (c) 
Figure 1: The drawings and gestures performed by Ellen during the resolution of the given task

Ellen is imaging "squares placed obliquely" which lay on planes that pass through diagonals. The activated control is *spatial* because she conceives planes in a physical reference frame which allows her to see them obliquely and because she made a zoom-in movement from the cube to some of its elements. The activated control is also *theoretical* when the plane is introduced from diagonals CE and BG; Ellen makes a mistake in the identification of the quadrilaterals generated by imaging to link the extreme points of cube diagonals: activating a *visual control* she visualizes squares instead of rectangles. Possibly Ellen's thoughts are driven by the automatic association (Vinner, 1997) which relates the same geometric object in different dimensions (cube in 3D space to square in 2D plane). From this incorrect information, a wrong conclusion is driven ("[cube diagonals] meet and are perpendicular") by activating a control that looks like a *theoretical control* but in fact involves some inconsistent elements.

The following extract shows the discussion on the same geometrical objects (planes inside the cube, type of quadrilateral obtained and relative position between diagonals), taken from group A:

Brian: Eh I'm seeing them... this side here *(pointing to an edge of the cube, see Figure 2a)* and this side here *(pointing the "opposite" edge)* detach a plane *(pointing the diagonals of faces, see Figure 2b)*. A plane where ... this side [measures] 1, this [side] is square root of 2 *(pointing and writing, see Figure 2c)*. It's a rectangle, right?

Red: It looks like a square to me, but in fact...Yes, [sides] detach a rectangle, the diagonals of a rectangle are not orthogonal.

(a) (b) (c)

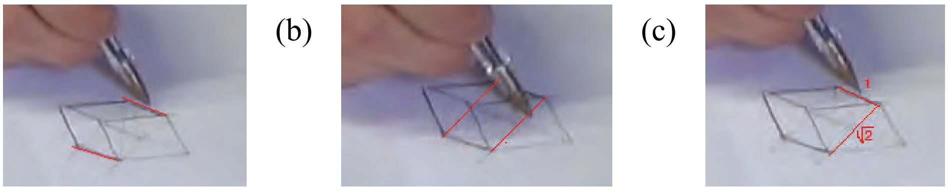

Figure 2: The gestures performed by Brian during the resolution of the given task

In planes recognition, Brian activates a *spatial* and *theoretical control*: the first one allows him to see planes inside the cube with a zoom-in movement ("I'm seeing them"), while the second one allows him to construct them theoretically from cube "sides" ("this side here and this side here detach a plane"). Rectangles inside planes are identified partially by sides' measures, hence activating the *theoretical control* ("his side [measures] 1, this [side] is square root of 2") and partially by observing the shape of the drawing which allows him to discard the parallelogram configuration, hence activating the *visual control*. The concomitance of the *visual* and *theoretical control* might explain the uncertainty expressed by the final question mark on the identification of the quadrilateral nature. Red's words show the predominance of *theoretical control* over the *visual control*: even if visually the quadrilateral "looks like a square", the theoretical elements introduced by Brian allows him to affirm that it is a rectangle. Finally, the conclusion that "the diagonals of a rectangle are not orthogonal" is driven under *theoretical control*.

The following extract is taken from Group B:

Beth: If you cut it in this way (*mimicking the rectangle perimeter with the pencil, see Figure 3a*).

Lucas: Oh, I also thought about these here (*mimicking an X with the pencil, see Figure 3b*).

Beth: These are the diagonals of a rectangle.

Lucas: Yes, exactly they are the diagonals of a rectangle and they meet.

Beth: But not perpendicularly.

Lucas: Diagonals of a rectangle meet perpendicularly (*making the gesture in Figure 3c*), yes always. […] No! (*Lucas draws the rectangle in Figure 3d while Beth draws two intersecting segments on her worksheet*). This drawing shows a counterexample.

Beth and Lucas, activating a *visual* and *spatial control*, introduce a rectangle and its diagonals as figural elements in the drawing (Figure 3a-b). Then, activating a *theoretical control*, Beth identifies the cube diagonals as rectangle diagonals (“These are the diagonals of a rectangle”) and deduces their non-perpendicularity (“But not perpendicularly”). Lucas, activating mainly a *visual control* shown in his arms gestures (Figure 3c), reaches the opposite conclusion (“Diagonals of a rectangle meet perpendicularly”) and then change his mind supported by the produced drawing (Figure 3d).

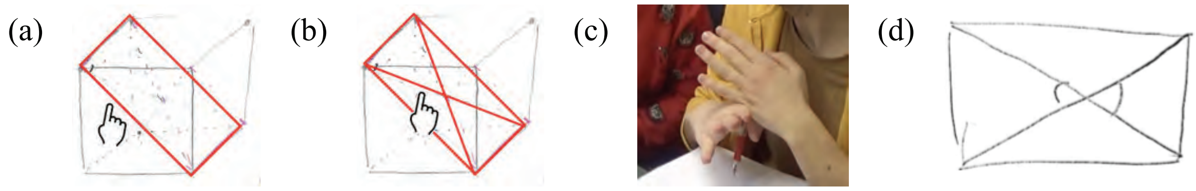

Figure 3: The drawings and gestures performed by Group B during the resolution of the given task

While solving the problem, all the three groups discuss the unicity of the intersection point of diagonals. Group C establishes the unicity of the point activating a *visual* and *spatial control* but failed in showing it with a *theoretical control*. Visually they show in the drawing that all four diagonals meet in the same point and spatially they conceive changing pairs of diagonals in which each pair has a diagonal in common with the previous considered pair. However, since they do not observe that the meeting point is the midpoint of diagonals, they are not able to justify theoretically why the meeting point does not change. Although they try to activate theoretical control by attempting to formalize the relationship between the diagonals, they finally get lost in their reasoning mainly because they have lost the visual and spatial counterparts in this sort of blind formalization.

Instead, Group A and B observe the property firstly activating a *visual* and *spatial control* and then activating the *theoretical control*. The following extract is taken from Group A, and shows the attempts made by students to answer their own question: “Taking the other planes then, their pairs of diagonals of the other two meet at the same point where these two ones meet here?”.

Nick: Yeees... I would say that these two also meet and that the point is the same. Definitely!
Ellen: But yes, it is certainly that because these two *(referring to a pair of diagonals)* meet in the middle, let's say, and also these other two *(referring to another pair of diagonals)* in the middle, both from one sense and from the other, so it is the same point.
Nick: This is the midpoint. Take another plane…
Ellen: Yes, yes...
Nick: You find another point, that is the midpoint then...
Ellen: And therefore it is unique.

The excerpt shows a motion in the activated control from *visual* to *spatial* to *theoretical*. Nick’s first sentence, introduced by the conditional tense (“I would say that...”), suggests that what he states (“the point is the same”) does not come from his theoretical knowledge but could be the result of a visual clue made activating the *visual control*. Moreover, the *spatial control* is intertwined with the *visual* control, since the sameness of the point is reached by zooming in and out between the point and the diagonals (“these two”) and back. The conclusion of his statement with the expression “definitely” seems an anticipation of the *theoretical control* activated afterward. Ellen’s observation “[diagonals] meet in the middle [...] from one sense and from the other” suggests the introduction of different viewpoints on the cube diagonals, hence the activation of a *spatial control*. Also the word “middle” suggests the spatial idea. Nick gives a theoretical status to the different viewpoints, speaking about different planes and to the "middle" point, speaking about "midpoint". Through Nick's words, Ellen's *spatial control* evolves in *theoretical control,* guiding Ellen to the conclusion of midpoint unicity.

Conclusion

In this study we have presented a first attempt for clarifying and operationalizing the controls that might come into play in geometrical reasoning of expert solvers. From the theoretical point of view we have combined the traditional literature in mathematics education on the figural concept (Fischbein, 1993) and the more recent findings in cognitive psychology on the visual and spatial aspects of imagery (Anderson, 2015). In this sense, we propose three different dimensions of control: *visual*, *spatial*, and *theoretical control*. Data analysis shows how this tripartite structure allows us to gain a deep insight into the complex observation of cognitive processes which involve the solver's use of control. In particular, we can observe the different contributions of the spatial and theoretical aspects that were originally encapsulated into the conceptual control.

The analysis shows that, during the discussion of reciprocal positions between cube diagonals, all groups activate *conceptual control* by introducing planes and quadrilaterals with a zoom-in inside the cube conceived within a physical reference. At the same time all groups activate a *figural control* since these planes and quadrilaterals are drawn or described through words and gestures. Distinguishing just between the conceptual and the figural control, all analyzed solutions seem similar to each other, showing harmonized figural and conceptual components of figural concepts involved. However, by introducing *visual, spatial,* and *theoretical control* important differences emerge: Ellen (group C) and Beth's (group B) controls are characterized by a predominance of *visual* and *spatial* over *theoretical*, while Brian's controls (group A) are characterized by a predominance of *theoretical* and *spatial* over *visual*. The predominance of *visual* and *spatial* over *theoretical* leads Ellen to make mistakes in the quadrilateral identification. Differently, the *theoretical control* activated by Brian allows him to conceive the quadrilateral not only from its shape but also from the property of congruence between opposite sides, leading to correct quadrilateral identification. Building on data analyses, we can sketch a preliminary model of the mutual interactions between systems of control: using Fischbein's terminology and imagining the three different dimensions of control in a continuum spectrum from *visual control* to *theoretical control* passing through *spatial control*, the solver's *figural control* might range from the visual to the spatial control and the *conceptual control* might ranges from the spatial to the theoretical control. Ellen and Beth's controls are located mainly at the visual and spatial region of the spectrum (predominance of figural over conceptual) while Brian control is located mainly at the spatial and theoretical region of the spectrum (predominance of conceptual over figural). This continuous spectrum model represents a new hypothesis to be tested and explored in further research.

The finer lens through which we are looking at controls, allow not only to better locate one's control on this spectrum but also to analyze control movements in group dynamics between visual, spatial, and theoretical. For example in group C, Ellen's visual/spatial control moves to a theoretical control thanks to Richard's intervention. In group B, Beth's theoretical control moves to visual thanks to Lucas's intervention. Also in group A we can observe controls' movements in Red's words thanks to Brian's observations. However not always these movements appear in group-works, this is the case of group C while discussing the unicity of the intersection point, remaining anchored in the theoretical control which cannot evolve due to absence of spatial and visual control activation. Moreover, by definition, theoretical control is always consistent with the reference mathematical theory; however, Ellen's first excerpt shows how students might manifest a discontinuous theoretical control, that is a control which might look like a theoretical control, but which in fact contains some inconsistency. Borrowing Vinner's (1997) terminology we might call it *pseudo-theoretical* control. So, further research could investigate what determine the distance or the closeness of the instances of control manifested by an actual solver to the sought-after theoretical control. From an educational point of view, a teacher aware of all the dimensions of control could be more receptive in observing a lack in the theoretical, spatial, or visual components or in their dialectic and consequently can intervene properly supporting students' geometrical reasoning development.

Although we cannot draw any general conclusions because we still have analyzed few data, the excerpts offered seem to support our interpretation of control as a complex structure that can be manifested in different interacting dimensions. We hope that considerations emerging from this paper can draw the attention of our community of researchers on the necessity and opportunity to further elaborate on Fischbein's inspiring notion of control.

Did you know you can draw a huge number of infinite heights? The students' realization tree of the heights of a triangle

Elisa Miragliotta[1] and Giulia Lisarelli[2]

[1]University of Pavia, Italy; elisa.miragliotta@unipv.it

[2]University of Pisa, Italy; giulia.lisarelli@dm.unipi.it

In this paper we report on the analyses of the mathematical discourse of 7th-grade students about the solution of a task on the recognition of the heights of a triangle. Our aim is to describe through the commognitive lens the realizations that appear in the mathematical discourse of the classroom and to observe possible interactions between them. For this purpose, we construct and compare the expected and the actual students' realization trees, showing the richness of the realizations addressed by the participants in the mathematical discourse.

Keywords: Realization tree, commognition, heights, triangle.

Introduction

A wide literature in mathematics education has documented students' difficulties in drawing and recognizing the heights of a triangle and has highlighted that the most common difficulties are related to obtuse triangles and right triangles (Hershkowitz, 1989; Mariotti, 1995). Among the several reasons for explaining these difficulties, there is the influence of specific representations of the height, that are presented at school, and which become so popular and widespread that they are considered the concept itself by many students (Hershkowitz, 1989). In particular, at least in the Italian context, at the end of primary school students' idea of "height of a polygon" is strongly related to stereotyped representations of it and this is often the result of a univocal definition of height (Sbaragli, 2017).

Based on this scenario, and on the assumption that the notion of height is involved in many important mathematical results that students will face during their learning experiences, this study investigates the effects of a didactical approach for introducing students to the notion of heights of a triangle based on the presentation of multiple characterizations and representations. The effects are described in terms of the features of the height of a triangle, with respect to one side, that have become part of the classroom discourse.

Theoretical framework and research questions

We adopt Sfard's commognitive lens (2008) according to which discourse and its development are analyzed on their own, as main objects of research rather than as means to explore other constructs. We share the underlying assumption of this theory that thinking is not ontologically different from communicating and learning is a way of changing one's discourse. Commognition describes mathematical discourse as involving continuous transitions between *signifiers* that are "words or symbols that function as nouns in utterances" (Sfard, 2008, p. 154) and their *realizations* that are "perceptually accessible object[s] that may be operated upon" for producing narratives about the signifiers (Sfard, 2008, p. 154). These terms are used to emphasize that nothing is "there" to be represented, since mathematical objects are discursive objects. Moreover, some signifiers are more commonly used than others, but there is no one signifier that represents the object. This hierarchical role of realizations can be visually represented through *realization trees* (Sfard, 2008). In this study, we are interested in the classroom discourse on the heights of a triangle. The construction of the students' realization tree allows us to gain insights into its growth and richness as resulted from a didactical sequence, thus, giving information on the formation of the mathematical object "height of a triangle" in students' discourse. Usually when students deal with a new signifier, they use different realizations separately; the conscious reference to the same signifier by using many different realizations is a learning achievement which is the result of a *saming* process (Sfard, 2008).

One of the main elements characterizing the mathematical discourse are *narratives*, i.e. statements (written or spoken) formulated as descriptions of objects, relationships between objects or processes, which are subject to possible approval or rejection. The shared narratives of a classroom are those that are considered true; they may be different from those accepted by the scientific community. Moreover, mathematical discourse involves a consistent use of *routines*, i.e. specific repetitive patterns (Lavie et al., 2019) and of *visual mediators*, i.e. objects of symbolic, iconic, gestural nature to which we refer (Nachlieli & Tabach, 2012). For example, in geometry, the drawing of a figure can be a visual mediator in both paper-and-pencil and dynamic geometry environments.

In light of this theoretical lens, the research questions guiding our investigation are: (a) What realizations of the signifier *height of a triangle* can be identified in students' discourse? (b) Are there interactions between different realizations? If so, when do they occur?

Methodology

The data we present are collected in a 7th-grade class, during a video recorded lesson on the recognition of the heights of a triangle. The students were introduced to the mathematical object *height* through different possible realizations. In particular, two main realizations were proposed by the teacher, who was participating in a larger project aimed at designing and experimenting inclusive mathematical activities at middle school. We describe these two realizations as follows:

T1) *Segment perpendicular to a side, or to its extension, passing through the vertex not contained in that side (opposite).* It was discussed with students that this realization can be realized in two ways: as a segment drawn from the vertex (*T1-a*) or from the side (*T1-b*). The teacher also promoted the construction of heights using both physical (ruler and set square) and digital (*GeoGebra*) artifacts.

T2) *Height of the strip in which the triangle is inscribed.* This realization addresses the height of a triangle in terms of the height of the strip into which the polygon can be inscribed. A strip is determined by two parallel lines: one line contains a side of the triangle and the other the vertex that does not belong to the chosen side.

These two realizations are chosen because *T1* is very familiar among students at the end of primary school and it is largely proposed in school textbooks at different levels; on the contrary, *T2* was intentionally introduced for the first time by the teacher because it lays the foundation for looking at the length of the height as the class of congruent segments and for overcoming the common difficulty consisting in placing the height outside an obtuse triangle.

In this study we focus on a 1-hour lesson, conducted by the second author of the paper with the regular mathematics teacher. Students are given a task (Figure 1), involving an obtuse triangle.

Observe the figure.
Are all the four dotted segments heights of the triangle?
Explain why.

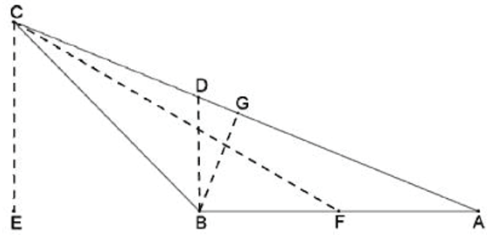

Figure 1: The heights recognition task

The task is designed for triggering the students' discussion on the four dotted segments. In order to answer the question, students have to argue why each of them can or cannot be a height of the given triangle. The explanations will inform us on the realizations that the class has developed until then.

The *a priori* realization tree

Building on Weingarden and colleagues' (2019) elaborations, the theoretical realization tree (Figure 2) is *a priori* constructed according to all the possible realizations of the height that students, who were exposed to specific geometrical activities on the height of a triangle, might refer to.

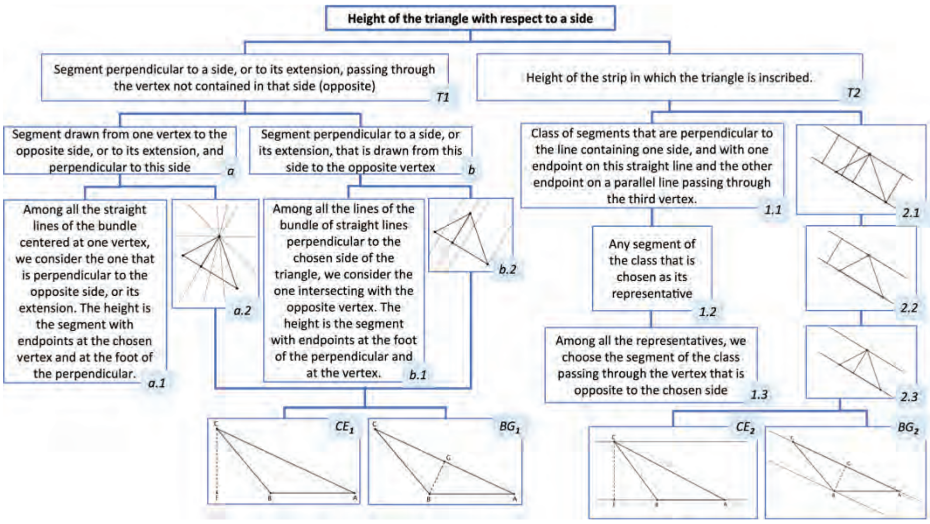

Figure 2: The a priori realization tree of the signifier *height of the triangle with respect to a side*

The tree has the root in the signifier "height of the triangle with respect to a side". From this root, two main branches with T1-realizations (on the left) and T2-realizations (on the right) develop; each branch contains both verbal and visual realizations. At the first level under the root, there are the main realizations that are explicitly used during the geometrical activities.

Focusing on the left side of the tree, the node at the first level splits into two branches (*a* and *b*). At this level the realizations (*a.1, a.2, b.1, b.2*) maintain some traces of the construction rituals. *T1-a* realizations characterize the height by starting from all the straight lines passing through a vertex and choosing the line that perpendicularly intersects the straight line upon which the side of the triangle lies; the second extreme of the height is reached in this way. Within the tree, we reported these realizations by referring to the bundle of straight lines centered in a vertex of the triangle. In these realizations the starting point is the chosen vertex. *T1-b* realizations characterize the height by starting from all the straight lines perpendicular to the side of the triangle and choosing the line that passes through the non-consecutive vertex. Within the tree, we reported these realizations by referring to the bundle of straight lines perpendicular to the chosen side of the triangle. In these realizations the starting point is the chosen side.

Focusing on the right side of the tree, starting from a realization with many heights (*1.1*, *2.1*), following the branch we can reach a realization where only one height passing through a vertex is considered (*1.3*, *2.3*). The coexistence of these different realizations in a student's tree presumes that a *saming* process was accomplished, as for the expert mathematicians.

The leaves at the lower level make explicit the realizations of the heights with respect to the given task. Although they are visualized only as visual realizations, since the given drawing provides the student with a common visual mediator, we use them also for verbal realizations such as "*CE*" or "*BG*" which make sense only coupled with the given drawing.

How the analyses were conducted

Data were cyclically analyzed, passing through several rounds of analyses. The preliminary step is the transcription of the classroom discussion by reporting all the components of students' discourse, i.e. verbal utterances, drawings, gestures. Working on this transcription, the first round is aimed at identifying the instances of realizations – labeled using a progressive number in square brackets – within the students' discourse. For example, an utterance as "*if you put the ruler on BA, you have also the height CE*" is coded as a verbal realization of the height with respect to the side *AB*.

The second round focuses on these instances of realization. The analysis aims at identifying the type of realization that students refer to. In particular, the coding is conducted according to the closeness of students' discourse with one of the descriptions of the height as a T1 or T2 realization. For example, a statement such as "*it is a height because it goes to the opposite vertex*" is coded as a verbal T1-realization of the segment traced from the side to the vertex, and the reference to the movement towards the opposite vertex allows us to label it as a T1-b realization. The closeness is also established according to the inferences of the researcher who knows the endorsed narratives developed by the class during the previous activities. For example, the expression "Paolo's method" is coded as a T2-realization because it was developed by the students for shortly referring to the ritual of drawing the heights inside the strip. This round allows us to qualitatively describe the characteristics of each realization and therefore provides useful information for answering the first research question.

These two rounds of analyses are fundamental for gathering the essential information on the realizations to be exploited for the construction of the actual realization tree. For the subsequent round, we start from an empty structure of the a priori realization tree; we read again the labeled transcription for filling the leaves with the corresponding realizations. For example, since the first instance of realization emerges in Alessio's discourse and it is coded as T1-b, we write "*[1]Alessio"* in the leaf named *b* (Figure 3). The unexpected realizations are included as new leaves with the label *NEW*. After this round of analyses we obtain a new tool for observing at a glance how the realizations were spread during the discussion. Moreover, this round allows us to observe which realizations of the height have become part of the classroom discourse and which not yet. The progressive numbers coupled with the name of the students allow us to keep track of the temporal development of the realizations during the lesson and of the students who participated in the mathematical discourse. The actual realization tree provides us with a tool for observing the possible interactions among different realizations, and therefore for answering the second research question.

Preliminary findings: the realization tree as a tool for analyses

The actual realization tree (Figure 3) highlights that there are some empty leaves for the expected realizations that are not addressed by students and new leaves for unexpected realizations that emerged within the classroom discourse.

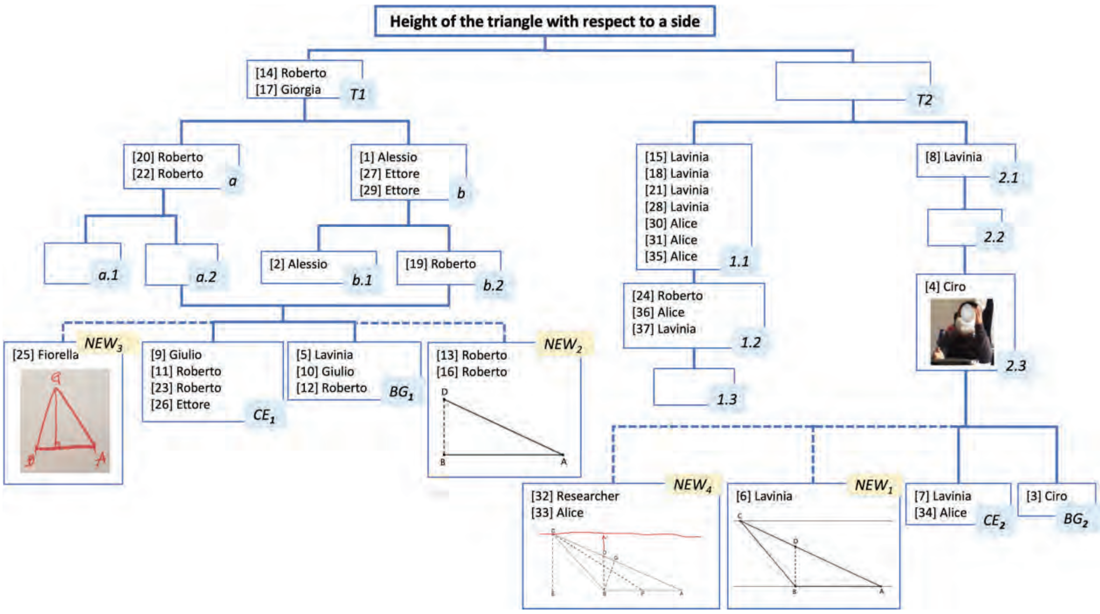

Figure 3: The classroom realization tree of the signifier *height of the triangle with respect to a side*

Comparing the a priori and the actual realization trees

As regards the expected realizations that are not addressed by students, we notice the bundle of straight lines centered in a vertex of the triangle. Although students refer to realizations of height that are drawn from the vertex towards the side of the triangle ([20], [22]), in their discourse we do not find elements that suggest the choice of the perpendicular line among the many passing through the vertex. This aspect can be justified by frequent references to the construction ritual through ruler and set square. Among the T1-realizations, this ritual shifts much of the students' focus toward realizations that implicitly make use of the bundle of parallel lines ([2], [19]); in this way, the perpendicularity is embedded into the use of the set square. Among the T2-realizations, the empty leaf in Figure 3 shows that there are no explicit references to the strip in which the triangle is inscribed. Rather, the students' discourse seems to be linked to the construction ritual, that is Paolo's method, which involves a line parallel to the side in focus.

As regards the unexpected realizations, there are leaves (see *NEW* in Figure 3) which report on the discourse on segments different from *CE* as realizations of the height for the side *AB*, and realizations which refer to triangles different from *ABC*. In the former case, students' discourse is focused on the segment *BD*, after that Lavinia triggers the attention on it ([6]) as a possible T2-realization of the height. Then she adds further details ([15]):

Lavinia: If you put the ruler on the segment AB, okay, are you with me? And then you take the set square. You start drawing some heights and BD is one of those.

Roberto accepts, to some extent, Lavinia's idea of considering *BD* as a height, but he addresses a different triangle ([16]):

Roberto: I think you're looking at a hidden triangle ABD and you think BD is a height.

Claims like this lead us to include another leaf in the actual tree (see *New*$_2$ Figure 3). This is a T1-realization since Roberto's discourse does not contain any reference to the strip.

The last new T2-realization is introduced by Alice who proposes a refined version of Lavinia's realization of the height. Alice starts describing how to draw a height for *AB* which passes through point *B* ([31]); the researcher supports her description by adding new visual elements on the visual mediator, which is shared with the whole classroom. Comparing the new realization with the segment *BD*, Alice explains why *BD* is not a suitable realization of height for *AB* ([33]):

Alice: Therefore, BD cannot be a height, because it has to reach at least... the intersection.

Building on Anita and Lavinia's discourse, students consider the possibility of having more than one height for *AB* and continue arguing on these T2-realizations.

Another unexpected realization is the one proposed by Fiorella. She considers another triangle, *ABG,* and shares her drawing with the classmates (see *New*$_3$ Figure 3). In particular, Fiorella uses this new visual mediator to justify the possibility for *BD* to be accepted as a realization of height, and in line with Roberto's discourse she stresses the need to change the reference triangle. However, she disagrees with Roberto concerning the choice of such a triangle.

Moving from T1 to T2 realizations

By looking at the progressive numbering of the labels in the realization tree (Figure 3) it is possible to observe the distribution of T1 and T2 realizations within the classroom discourse. Generally speaking, each student seems to be tied to a certain type of realization. Indeed, during the entire lesson some students, as Alessio, Roberto, and Giulio, focus on T1-realizations while other students, as Lavinia and Ciro, focus on T2-realizations. Although most of the students remain anchored in a certain type of realization and they do not spontaneously move back and forth between different types of realizations, we can notice that when Roberto moves from the T1 branch to the T2 ([23], [24]) some other students start reporting on T2-realizations in their discourse. Therefore, the global classroom discourse goes through a shift from T1 to T2 realizations. This shift in discourse develops around the segment *BD*. Lavinia claims that *BD* is a height, addressing T2-realizations ([15]). She refers to the use of the set square, describing the construction ritual for drawing "several heights" (T2-realization). She does not speak about moving the set square in order to trace the only segment that intercepts the vertex of the triangle. On the other hand, other students argue that *BD* is not a height, bringing arguments based on T1-realizations. In this respect, the exchange between Lavinia and Roberto is very interesting:

Lavinia: So BA is the segment. Did you know you can draw a huge number of infinite heights?
Roberto: But if they don't go to the opposite vertex...
Lavinia: But that doesn't matter! They don't have to go!

The turning point occurs when Roberto changes perspective and switches from the left to the right side of the tree, that is, when a T2-realization of height enters his discourse ([24]). This shift is shown in the tree: between [23] and [24] Roberto changes side. The corresponding discourse is:

Roberto: Do you know how to make a height? You have to put a ruler and a set square, from the opposite vertex you have to draw a line to the opposite side or to its extension, that's what the EC side is for.

Roberto: If you really want to make a height here [he points at a position on AB], at least you have to use Paolo's method.

The reference to "Paolo's method" seems to be key in shifting the attention of the class towards T2-realizations. Indeed, after Roberto's intervention there are many references to T2-realizations: [28], [30], [31], [32], [33], [34], [35], [36], [37].

At this point Roberto tries to convince Lavinia that in order for the segment *BD* to be a height it lacks an important feature: the point *D* does not intercept the strip.

Roberto: Oh thanks [*sarcastic tone*], but then DB is not a height if it doesn't reach there.

The first realizations of height in his discourse involve a segment with endpoints at one vertex and at the opposite side of the triangle, so his interventions are all placed in the left branch of the realization tree. Then Roberto seems to include in his tree, through a *saming* process, also segments not passing through any vertex of the triangle, and this happens when he starts participating in Lavinia's discourse.

The transition from T1 to T2 realizations seems to play a fundamental role in the classroom discourse. By remaining anchored to only T1-realizations of height, students fail to convince Lavinia that *BD* is not acceptable. When the focus of Roberto's discourse shifts to T2-realizations also the other students become participants in Lavinia's discourse and begin to use the same words and visual mediators. Finally, the classroom discourse finds a synthesis in the realization constructed by the researcher under the students' guidance (see New_4 Figure 3).

Conclusion

The analyses of the classroom discourse allow us to conclude that students spontaneously refer to both T1 and T2 realizations of height. By looking at the realization tree (Figure 3) it is possible to grasp the richness of the classroom discourse, involving different realizations of height: students refer to most of the expected realizations and they also introduce new ones. Each student remains essentially tied to one type of realization; therefore, we do not observe in their discourse interactions between T1 and T2 realizations. However, we can notice how the interaction is promoted by the attempt to match two discourses on two different realizations. This is evident in the discussion between Roberto and Lavinia, who refer to a T1 and a T2-realization of the height, respectively, while they are searching for a shared narrative about *BD*. The interaction becomes necessary for them to participate in the same discourse and Roberto plays a key role in moving from a T1 towards a T2-realization. In this way, he succeeds in finding a common ground with Lavinia and also in involving the whole classroom in the discourse. In particular, the "use of the set square" and "Paolo's method" are shared narratives referring to rituals that have been culturally constructed by the classroom and they are linked to both T1 and T2-realizations.

Comparing the two realization trees, we can claim that students include in their discourse most of the expected realizations. From the educational point of view, this is relevant since the richness of the realization tree seems to be a marker of the effectiveness of an unconventional – but in line with the solid findings of the research in mathematics education – introduction to the height of a polygon which explicitly works on different realizations. From the theoretical point of view, the study presents a first attempt of using realization trees as tools for *a priori* and *a posteriori* analysis of the classroom discourse in the domain of geometry, where the visual mediator (i.e. the drawing) has a specific and prominent role (Mariotti, 1995). In this perspective, the classroom realization tree needs further elaboration to become a more effective tool in terms of reporting on the students' discourse behind the construction of the tree and the role of the teacher's intervention in supporting such a discourse.

Although this is an exploratory study and the findings are quite local, we hope that considerations emerging from this paper can provide educators and researchers with food for thought, in particular concerning the didactical value of promoting a widespread use of many different realizations for the same signifier as a means for triggering the students' participation into mathematical discourse.

Acknowledgment

We are deeply endowed to Anna Baccaglini-Frank for having pointed us in this direction of research. Moreover, we wish to warmly thank the teacher, Federica Poli, for carrying out and documenting the activities, and all the students involved in this study.

Representing mathematical induction in proving processes

Bernardo Nannini

University of Florence, Department of Mathematics and Computer Science, Italy; bernardo.nannini@unifi.it

Using a multimodal semiotic perspective, I investigate the production and use of signs in expert (doctoral) students involved in processes of constructing argumentations and proof by mathematical induction. Focusing on their speech, written inscriptions, and gestures, different categories of signs, related to mathematical induction, are identified and analysed. In this paper I show some paradigmatic examples of these signs.

Keywords: Mathematical induction, proving processes, semiotic bundle, gestures.

Introduction

Semiotic offers an interesting perspective for research in mathematics education, providing a window through which to observe and investigate several teaching-learning processes. Recently the analysis of signs has been enriched including the study of gestures. This has involved different areas of research, as well as the studies on argumentation and proof. Arzarello and Sabena, for instance, bring empirical evidence that "gestures may also play specific roles in providing a logical structure to argumentation" (2014, p. 99). Similarly, Krause observes that the gestures' production "may support the collective act of reasoning […]. It makes traceable how the argument was organized as logical inference" (2015, p.1432). Along the same line, Sabena, registers that the use of gestures "support[s] the students in structuring the entire argumentation at a global level" (2018, p. 556). The study presented in this paper is part of wider research, conducted with a semiotic perspective, on proving by mathematical induction processes of post-graduate, undergraduate and secondary school students.

The proving scheme of Mathematical Induction (MI) is, at the same time, important and useful for a mathematician, interesting from a logical point of view, but also extremely problematic from a didactic perspective. The difficulties involved can be observed across different levels of education, from secondary school students (Fischbein & Engels, 1989), to master's students in mathematics (Carotenuto et al., 2018). A problematic aspect for students is related to its justification, i.e. why, given a predicate P on the natural numbers, we can conclude that $\forall n \in \mathbb{N}$, P(n), by proving the base case P(0) and the inductive step $\forall n \in \mathbb{N}$, P(n)$\rightarrow$P(n+1). Ernest (1984) affirms:

> Many students encountering the method of proof by induction wonder why this rather complex and seemingly arbitrary principle is adopted […] [It] is neither self evident nor a generalisation of previous more elementary experience. (p. 183).

Generally, a non-formal justification is that MI works as a "cascade" of infinite syllogisms (Poincaré, 1906, p. 9): from P(0) and P(0)$\rightarrow$P(1) it follows P(1); from P(1) and P(1)$\rightarrow$P(2) it follows P(2), and so on. Often, to provide an intuitive explanation for MI, teachers and textbooks describe it by using some images (for some examples, see Ernest, 1984). Perhaps one of the most known is the falling dominos analogy: given an infinite line of dominos (i.e. the whole set $\mathbb{N}$), by the fact that the first one is knocked over (i.e. the base case) and the fact that each couple of consecutive dominos is at the right distance so that if one domino falls, it will knock over the consecutive one (i.e. the inductive step), we can conclude that every domino after the first one in the line will fall (i.e. $\forall n \in \mathbb{N}$, P(n)).

Images (or, more generally, signs) like the cascade of syllogisms or the falling dominos, are often used by teachers and textbooks to introduce and describe MI to students. On the other side, similar signs might also be produced and used by subjects involved in proving by induction activities. In this paper, I focus on this second aspect, analysing the signs produced and used by students with experience of proving by induction during the resolution of problems which potentially involve MI.

Theoretical framework

A multimodal semiotic perspective

In order to take into consideration a wide spectrum of signs, in this study I adopt a multimodal semiotic perspective. Arzarello (2006) considers all the different kinds of sings involved in teaching and learning processes (verbal language, mathematical symbols, diagrams, sketches, gazes, gestures, etc.) as an inseparable unit. He defines a *semiotic bundle* as a dynamic structure composed by different *semiotic sets* together with the relationships between them. Within this perspective, a sign may have different components depending on the semiotic sets involved in it. For instance, a subject's spoken utterance with a simultaneous gesture, referring to a certain written inscription, can be seen as a unique sign made by three components (speech, gesture, and inscription).

Linking and iteration signs

Using this multimodal perspective, in a previous study (Antonini & Nannini, 2021), we analysed the semiotic bundle consisting of three semiotic sets (speech, written inscriptions and gestures) in some post-graduate students' processes involved in the generation of a conjecture and of a proof by MI. As a result, we identified two particular categories of signs which seem to play an important role in these processes:

- *Linking signs*: Signs produced or used to refer to two or more entities (objects, mathematical objects, problems, situations, etc.) and to their relationships, where these entities are seen in connection with two consecutive natural numbers.
- *Iteration signs:* Signs that refer to iteration, or that are composed by a repetition (in time or in space) of linking signs, or that refer to a repetition of them.

To give an example of linking and iterations signs we can interpret from a semiotic point of view the above-described image of the falling dominos. The whole image (either pictured or verbally described) is a rather complex sign composed by several other signs. Of those, one is the image of two dominos, one of each falling, potentially falling, or already fallen onto the other one. Out of the analogy this sign represents two propositions, P(n*) and P(n*+1), for which the truth of the first one implies the truth of the second one (i.e., an instance of the inductive step). This is an example of linking sign. Moreover, the whole line of dominos (fallen, falling, or standing), representing the infinite syllogisms obtained by base case and inductive step, is a repetition of linking signs and, globally, can be interpreted as an iteration sign.

In this paper I report on an explorative and qualitative study focusing on linking and iteration signs in post-graduate students' processes involved in problem solving activities. The study investigates the different characteristics that linking and iteration signs can have during the problem resolution process, aiming at a possible classification of them.

Methods

The study is based on interviews in which expert students were asked to solve some problems and then to speak about mathematical induction. Participants were 4 doctoral students in Mathematics. They were interviewed individually for approximately 80 minutes each. They were not aware of the focus of the study. Collected data consist of audio-video recordings and of the written inscriptions produced by the students. In this paper I will refer to the following two problems.

The chessboard problem: *"Consider a $2^n x 2^n$ chessboard. What is the maximum number of squares which can be tiled with L-shaped pieces composed of 3 squares each?"*. The solution, which can be proved by MI on n, is that it is possible to tile the entire $2^n x 2^n$ chessboard except for one square.

The false coin problem: "N identical coins are given. One of these, however, is false and it weighs less than the others. There is a traditional weighing scale at our disposition. What is, in function of N, the minimum number of weighings necessary to determine the false coin?". A partial solution for the problem is that, if $N=3^m$, then with m weightings it is possible to determine the false coin. Again, this can be proved by MI.

Preliminary findings

A classification for linking and iteration signs

With the analysis of the semiotic bundle produced and used by the students during the interviews, it was possible to identify three different categories of linking and iteration signs:

- Linking and iteration signs produced or used to refer to the (mathematical or not) objects described in the problem's text (functions, variables, chessboards, tiles, coins, etc.), to their properties, or to their mutual relationships. For these, I use the term *Ground-level* signs.
- Linking and iteration signs produced or used to refer to the proving scheme of mathematical induction itself, to its logical structure or to the justification of its validity. For these, I use the term *Meta-level* signs.
- Linking and iteration signs that could be seen simultaneously as ground and meta-level signs. This happens when a single component or different components of the same sign refer both to some objects of the problem and to mathematical induction itself. For this intermediate category, I use the term *Hybrid-level* signs.

In the following pages I will present some paradigmatic examples of these categories of signs. The students' names are pseudonyms. In the transcripts, with (*italics*) I describe gestures or inscriptions in the moment when they are made.

Ground-level signs

Lorenzo, in this part of the interview, is dealing with the false coin problem. After reading the text he claims to remember the solution of a similar problem in which nine weights are given, all identical except for one which is lighter. Lorenzo describes the solution of this second problem:

1 Lorenzo: In this case the game was: you split in three groups, then three coins, first group, three coins, second group, three coins, third group *(he writes ‘9’ on the sheet, then he draws three arrows starting from it and pointing to the right, he then writes ‘3’ at the end of each arrow and, finally, ‘1st’, ‘2nd’, and ‘3rd’, Figure 1a)*. Then you say: we take two groups, we weigh them and since there are three possible results, that are one is lighter, the other is lighter, or even, I can determine in which group the lighter one is. Then I iterate the procedure on the others.

Later on, Lorenzo tries to generalise the just described solution for a group of n coins:

2 Lorenzo: So, the reasoning would be… n coins, I split in three groups (*he draws a point and three lines starting from it and pointing down on the sheet*), I select one of them with one weighing, I split in other three groups, (*he draws a second point at the end of a line and then three other lines starting from this new point*), I select one of them with another weighing (*again, he draws a third point at the end of a new line and then three other lines from this. At this point he has drawn a mathematical tree, Figure 1b*).

In the first part of the excerpt (line 1), when describing the solution of the problem for a group of nine coins, Lorenzo produces a sign (the inscription in Figure 1a, together with his speech) which represents how the group of 9 coins is linked to three groups of 3 coins each, namely a linking sign. With this sign, Lorenzo represents the first step of the solution of the problem (to divide the group in three subgroups and to determine which one contains the false coins). Afterwards (line 2), Lorenzo describes a possible strategy to solve the general problem, and to do this he draws an inscription which is composed by the repetition of the previous linking sign, this time without any indication to the number of coins (Figure 1b). This is an iteration sign and allows him to describe the iterative solution of the problem.

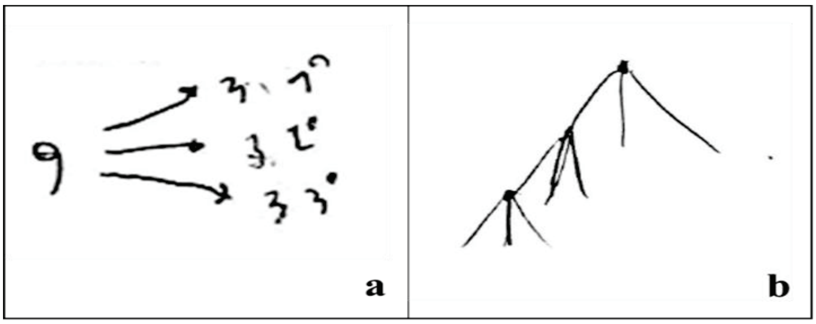

Figure 1: Lorenzo’s inscriptions in line 1, Figure a, and in line 2, Figure b

In the remaining part of the interview related to this problem, Lorenzo explores the mathematical tree that he drew in order to find, in function of n, its height (which corresponds to the number of weightings necessary to determine the false coin). Both the just presented linking and iteration signs are ground-level signs because they refer to different groups of coins and the relationships between them.

Meta-level signs

Guido, at the end of the interview, says to be convinced of the validity of MI as a proving scheme. Then he justifies his answer.

1	Guido:	You do the base case, which is true, and you verify it (*he puts the right hand in front of him at the level of the table, touching his leg with the four fingers, Figure 2a*).
2	Guido:	Then (*he makes two consecutive arc-shaped gestures rotating the right hand in the air keeping thumb and pointing finger at a constant distance and moving the hand from left to right, Figures 2b/c*) the inductive step (*he repeats the previous gestures a second time*) guarantees that it is always true (*he moves rapidly the right hand starting from his leg to an up-right direction in the air, Figures 2d/e*).

Guido's speech alone does not seem to provide a justification for the validity of MI. He only says that after the case base is proved true (line 1), the inductive step assures the truth of the proposition for every natural number (line 2). However, if we look at his gestures, we notice that his discourse is enriched by other semantic elements. The base case is represented by a point on Guido's leg, which he touches with his right hand (Figure 2a). Before saying "the inductive step", Guido makes a rather complex gesture: he moves his right hand in the air from left to right and simultaneously he rotates it twice, keeping thumb and pointing finger at a constant distance, forming two arcs (Figures 2b/c). He then repeats the same gesture while saying "the inductive step".

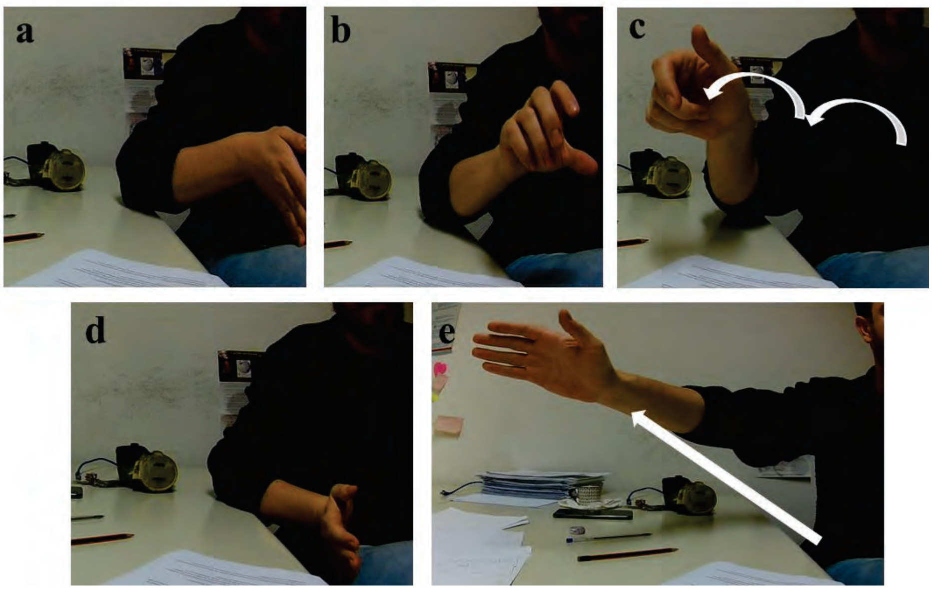

Figure 2: Guido's gestures. In Figure a, it is showed the "case base gesture", in Figures b/c the "inductive step gesture", and in Figures d/e the final gesture of line 2. The white arrows summarise the gestures' trajectories

These gestures are interesting because with them Guido seems to represent the inductive step itself as a series of arcs in the air. Each arc-gesture could indicate, metaphorically, the link between two cases of the proposition to be proved by induction (the implication $P(n)\rightarrow P(n+1)$). These are examples of meta-level linking signs. Finally, while saying "it is always true", Guido performs a new gesture which is a composition of the previous ones, but now more rapid and contracted: He starts touching his leg (as when he was referring to the base case), and then he moves fast to an up-right direction in the air. This time the hand moves in a straight line without shaping any arcs (Figures 2d/e). With this gesture he seems to describe the whole iteration which, starting from the base case and by successively applying the inductive step, allows to conclude the truth of P(n) for all the natural numbers greater than the base. This is an example of a meta-level iteration sign.

Hybrid-level signs

Silvio, in this part of the interview, is dealing with the chessboard problem. Until this moment he has explored the problem, finding that for the chessboards corresponding to n=0, n=1, and n=2, it is possible to create a tessellation which leaves out only one little square and he has conjectured that the same thing is possible for every $2^n x 2^n$ chessboard. Then he has observed that a $2^n x 2^n$ chessboard is composed by four $2^{n-1} x 2^{n-1}$ chessboards. This seems to suggest to him a possible solving strategy:

1	Silvio:	I think that one could do something like by induction (*keeping the pen in his right hand, he rapidly draws some circles in the air, Figures 3a/b).*
2	Silvio:	Because, since in the case zero I have only one little square and it remains out (*with the pen he touches the sheet where he previously wrote* ‘n=0→0 tiles’, *Figure 3c*),
3	Silvio:	then, let’s say, in a sequential way this little square will always remain out (*with the pointing finger of his right hand, he draws some circles in the air whilst moving up his hand, Figures 3d/e*).

In the remaining part of the interview related to this problem, Silvio tries to construct a proof by MI for his conjecture.

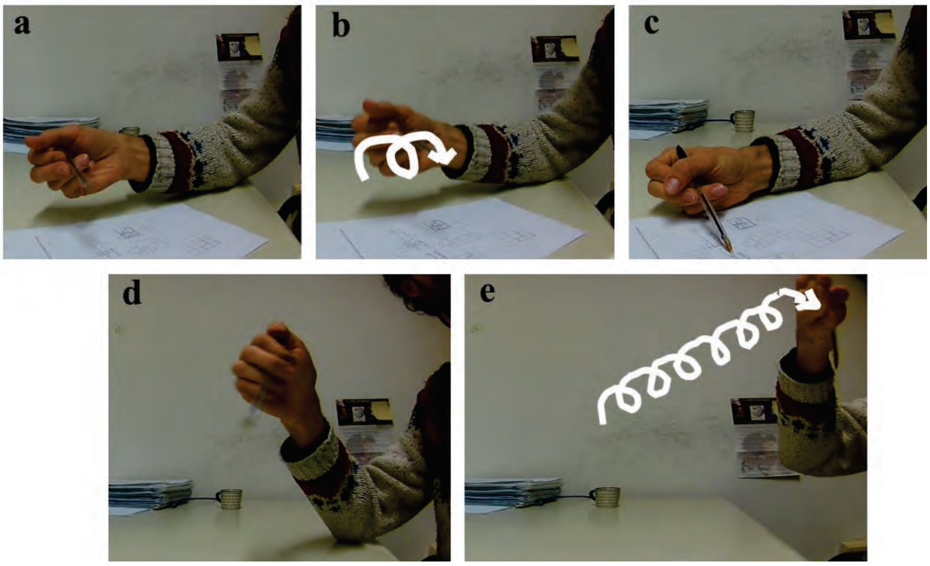

Figure 3: Silvio’s gestures. In Figures a/b it is showed the gesture of line 1, in Figure c the gesture of line 2, and in Figures d/e the gesture of line 3. The white arrows summarise the gestures’ trajectories

The analysis of this excerpt reveals the presence of a hybrid-level sign. Firstly, Silvio claims that a possible solution could be obtained doing “something like by induction” (line 1). Whilst saying this, he makes a gesture which seems to refer to the iterative structure of induction itself (Figures 3a/b). Considering the bundle (his utterance together with the gesture) we can interpret this as a meta-level iteration sign. In lines 2-3, Silvio clarifies what he meant with “something like induction”. He says that the chessboard corresponding to n=0 is composed only by one little square which thus cannot be tiled. Then he says that from this, “in a sequential way”, it could be possible to show that the little square will remain out of the tessellation for all the bigger chessboards as well. In describing this strategy, Silvio is apparently using his previous observation of the fact that it is possible to construct a $2^n x 2^n$ chessboard with four $2^{n-1} x 2^{n-1}$ chessboards. Silvio’s discourse contains elements which refer to some objects of the problem (“this little square will always remain out”), showing that with his speech he is referring to chessboards and tessellations. However, observing the whole semiotic bundle, we can see that he is also referring to the structure of the solving strategy itself. He firstly touches the sheet where the inscription for the 1x1 chessboard is, which he calls the “case zero” (Figure 3c). Then, while saying “in a sequential way”, he draws several circles in the air whilst moving up the hand (Figures 3d/e). Note that now there is not any reference to chessboards or tessellations. This gesture, in fact, seems to repeat the “something like by induction” gesture previously made in line 1, but now it is longer (both in time and space). If we consider the whole movement of his right hand (Figures 3c/d/e), we can see it starting from the sheet, concretely touching with the pen the inscriptions which refer to the chessboards, and then moving up, drawing a sort of helix in the air, as representing the iterative structure of the reasoning by induction itself. This is an iteration signs which starts as a ground-level sign and then becomes a meta-level sign. This is therefore an example of a hybrid-level sign.

Concluding remarks

In the first two excerpts, I showed some examples of linking and iteration signs, both ground and meta-level. These two categories of signs apparently involve different aspects of the problem solving and proving processes. The ground-level signs seem to have an important role in the resolution of the problem, allowing the subject to recognise that it could be solved with an iterative procedure. The meta-level signs, instead, are related to the description of the logical structure of a generic proof by MI. We can in fact observe that the first two excerpts were taken from two very different moments of the interviews. Lorenzo’s example, through which some ground-level signs were shown, is part of his initial exploration of the false coin problem. On the other side, Guido’s excerpt, containing some examples of meta-level signs, refers to the final part of his interview in which, after having solved some problems (some of those by induction), he is explaining why he is convinced of the validity of MI. However, as the third excerpt has shown, it was also possible to observe some meta-level signs in other phases of the interviews, in particular during the exploration of a problem as well. When Silvio produces the meta-level iteration sign, in fact, he is still exploring the chessboard problem, and he has not found a way to tessellate a chessboard using the tessellation of the previous chessboard (a sort of inductive step). Nevertheless, he recognises a parallelism between his possible iterative solution to the problem and the proving scheme of MI. When this happens, he produces a hybrid-level sign: an iteration sign referring both to some problem’s proper elements (ground-level), and to the structure of MI itself (meta-level). The production of these signs highlights a crucial moment in Silvio’s problem solving process. In this moment, in fact, Silvio seems to see in his own argumentation the structure of a proof by MI (he says “something like by induction”). Subsequently, in fact, he decides to prove by MI his conjecture. In other terms, the presence of these signs seems to reveal a continuity between the process of generation of the conjecture and the subsequent construction of a proof for it. It could be interesting to further investigate this last aspect within the framework of the Cognitive Unity (Boero et al.,1996), focusing on the role of hybrid-level and meta-level signs in the transition between the argumentation supporting a conjecture and a subsequent proof by MI. Further research is also necessary to investigate the production and use of linking and iteration signs (either ground, meta, or hybrid-level) in less expert students.

Diagrammatic activity and communicating about it in individual learning support: Patterns and dealing with errors

Barbara Ott[1] and Annika M. Wille[2]

[1]St. Gallen University of Teacher Education, Switzerland; barbara.ott@phsg.ch

[2]University of Klagenfurt, Austria; annika.wille@aau.at

Diagrammatic activity and communicating about it in different representational systems is essential for mathematical discourse. Therefore, it is also of great importance for individual mathematical support. So far, little is known about how teachers conduct such discourses with children. By analyzing the diagrammatic activities and the communication about them with an analyzing method developed for this purpose, patterns of diagrammatic activity and communicating about it can be elaborated. The example of an individual learning support between a preservice teacher and a second grade student who work in the representational systems of natural numbers and the field of twenty is presented. It shows that these patterns can be supportive in dealing with errors.

Keywords: Individual learning support, diagrammatic activity, mathematical discourses, arithmetics.

Individual learning support as increasing participation in mathematical discourse

When learning mathematics, not all students achieve the teaching goals through joint teaching in the class. These students need individual learning support. Individual learning support can be understood as "support of individual […] learners by a person with more expertise in building knowledge or acquiring competences to solve a task or a problem with a view to the learners' future independent mastering of analogous tasks and problems" (Krammer, 2009, p. 89; translated by the authors). This understanding of the term is closely related to Vygosky's concept of the zone of proximal development (Vygotsky, 1978). In this and in concepts based on it (e.g. Rogoff, 1990), the importance of the social and thus of interaction for cognitive development is emphasized. According to Sfard (2001), learning mathematics can thus be understood as a cultural practice. Thus, learners do not encounter mathematics per se, but a cultural practice that is understood as mathematical by members of that culture (see also Tiedemann, 2012). In this sense, learning mathematics means being able to participate increasingly confidently in discourse that is considered mathematical by experts (Sfard, 2001). Interaction with experts is essential for this. In such an interactionist view of learning (Krummheuer, 1992), mathematical support can be understood "as a specific process of interaction […] that is successively established [by adult and child] through a mutually interrelated interpretation and action" (Tiedemann, 2012, p. 49f.; translated by the authors). According to Dörfler (2006), "progressive participation in the social practice of diagrammatic activities" can be seen as typical of mathematical discourse and mathematical cultural practice (p. 213; translated by the authors). Thus, individual learning support in mathematics means that learners gain expertise in diagrammatic activities and can thus participate in mathematical discourse. Tiedemann (2012) was able to identify general patterns of interaction between parents and children in early mathematical education. However, there is a lack of research on what such interaction patterns and routines look like in individual learning support, especially with regard to diagrammatic activities.

Diagrammatic activity and communicating about it

Diagrams, understood in the sense of the American philosopher Charles Sanders Peirce (1839-1914), are seen in this paper as objects of mathematical activity. In this sense, diagrams are signs with a relational character that belong to a representational system (Dörfler, 2006). The representational system determines how diagrams are created and how they are operated or experimented with. For students, each representational system is its own learning content, as is each direction in moving between different representational systems. In what follows, activities with diagrams that are specified by a representational system are referred to as diagrammatic activities (Wille, 2020). Gestures can also be part of a diagram as quasi-materialized inscriptions (Huth, 2020) and likewise be part of diagrammatic activities. It should be noted that a diagram can be interpreted as such if a corresponding representational system is known (Wille, 2020). That is, no diagram is in itself a diagram. It requires interpretation as one. Activities with diagrams such as experimenting or observing can help clarify, structure, and coordinate thought processes (Hoffmann, 2007). In addition, diagrammatic activities can give rise to mathematical concepts and understanding (Dörfler, 2006). In this way, diagrams themselves become the subject of reasoning processes. Another essential part of mathematical activity is communication about it (Dörfler, 2006). Communication about diagrams and diagrammatic activity involves both linguistic and gestural utterances. Communication about diagrammatic activity enables the use of denotations for diagrams that belong to different representational systems, and it also enables interpretations of diagrammatic thinking (Wille, 2020).

For learning processes, it is crucial that students do not just do something, but that their attention is drawn to the crucial aspects through communication (Gaidoschik, 2016). It is often reported that teachers have few professional discourses with the learners and do not pay much attention to the learning processes of the students in the dialogues, but rather often dominate the classroom discussion (Krammer, 2009; Begehr, 2006). Consequently, it is necessary to already qualify preservice teachers to conduct such professional discourses with learners. However, there is a lack of research on how diagrammatic activities and communication about them intertwine in individual learning support between a preservice teacher and a student.

Research interest

The research focuses on situations of individual learning support between a preservice teacher and a student in grade 1 or 2. It addresses the question of how diagrammatic activity and the communication about it intertwine in individual learning support. Since support is most evident when learners have particular difficulties or make an error, special attention is paid to how diagrammatic activity and the communication about it intertwine in such situations.

Setting

At the St. Gallen University of Teacher Education, preservice teachers provide one-on-one support to first and second grade children as part of an elective course. In the spring semester, one pre-service teacher supports one child per week for about 30 minutes. A seminar at the university accompanies the support sessions, which in particular are recorded on video. In the individual learning support, the preservice teachers make use of support activities that were developed in the MALKA project (Wehren-Müller et al., 2018). The goal of individual learning support is to enable students to solve arithmetic tasks without counting strategies, because a solidification of initial counting strategies can lead to difficulties in learning mathematics (Scherer & Moser Opitz, 2010). Due to this, it is necessary for students to develop sustainable ideas about numbers and operations (Häsel-Weide, 2016). To achieve this, learners should be supported in perceiving and determining the cardinality of a quantity through structural subitizing (Schöner & Benz, 2018). This can be practiced especially on structured materials, such as the field of twenty (Häsel-Weide, 2016; Scherer & Moser Opitz, 2010). The representational systems that are essential for structural subitizing in the individual learning support analyzed here are the field of twenty and the natural numbers.

Method

The analysis takes place in several steps. In a first step, an interaction analysis is carried out to reconstruct the interaction processes in detail (Krummheuer & Naujok, 1999). In a second step, the diagrammatic activity and the communication about it is analyzed. For this purpose, an analysis method developed by Wille (2020) for imagined dialogues was adapted for interactions in the two representation systems, the field of twenty and the natural numbers (Ott & Wille, 2021). An analysis sheet for the whole episode is filled in according to the following rules:

- If a *diagram* is used in a turn, a *filled circle* is set in the column of the corresponding representational system. If *communication about* diagrams is used, a *dashed circle line* is set. If both take place, both are noted together. A star is used if an activity cannot be interpreted as a diagram or communicating about it.
- The filled circles or dashed circle lines are connected to each other by *solid lines* if a connection is made by *diagrammatic activities*. The line is *dashed* when the connection is made by *communicating about diagrams*. If both occur, both are noted together.
- If, in a turn, *diagrams of different representational systems correspond* with each other, they are connected by an *arrow*. The direction of the arrow indicates which representational system is used as the starting point.
- If *diagrams that have already occurred once occur again in exactly the same way*, they are connected by *two narrow lines*.
- Communication that cannot be assigned to either one or the other representation system is noted as “others”.

In the following, the results of the analysis of diagrammatic activity and the communication about it of one preservice teacher and one child will be presented. Activities of the preservice teacher are noted in red, activities of the child in blue.

Results

In the following, we will first show some patterns that become visible in the analysis sheet. Afterwards, the handling of errors will be described. The scenes shown in the following are taken from two support episodes between the preservice teacher Mr. Wehrle, who is in the fifth semester of six semesters, and Samira, who is a student at the beginning of the second grade. Mr. Wehrle and Samira work on a structural subitizing task, in which the number of chips in different arrangements on the field of twenty are to be determined (Scherer & Moser Opitz, 2010) (see Figure 1a and 1b). They work with chips and with strips of five on the field of twenty. In the transcript, the field of twenty is numbered as shown in Figure 1c. The transcripts were originally in German and were more detailed.

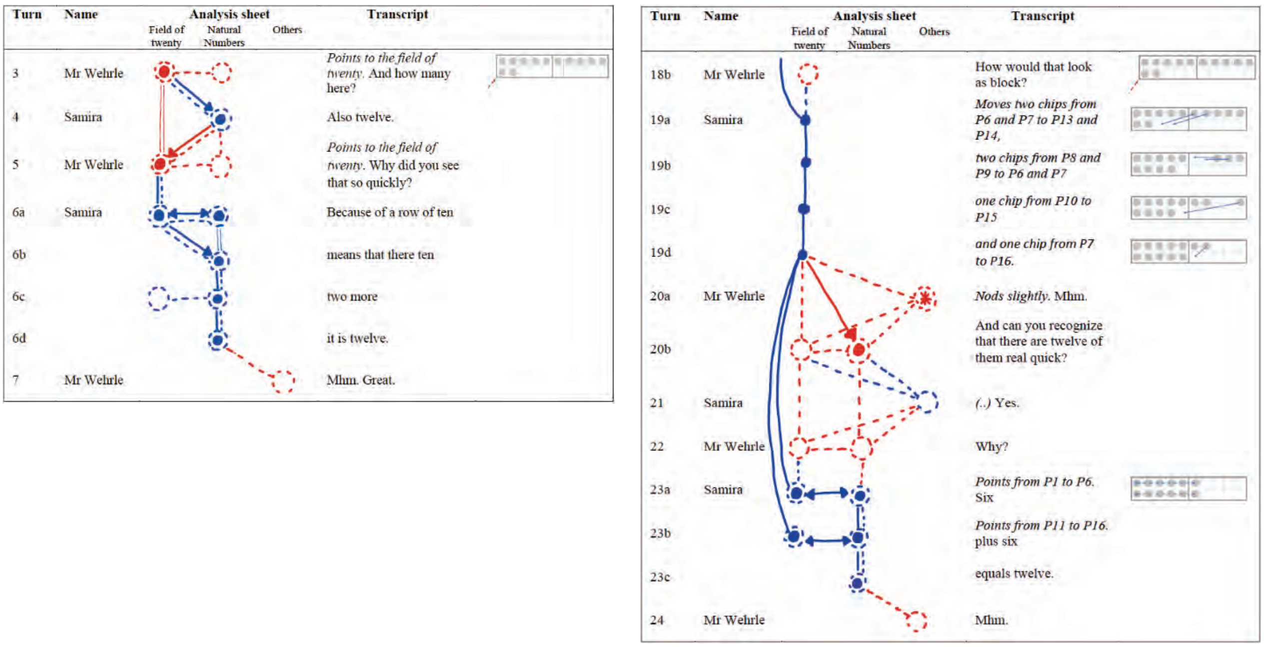
a b c

Figure 1: Field of twenty, (a) row arrangement (b) block arrangement (c) numbering in the transcript

Samira initially has difficulty determining numbers by structural subitizing when they are arranged in a block (see Figure 1b), especially with odd numbers. She becomes increasingly confident in this, but she repeatedly makes errors in determining odd numbers.

Patterns

The analysis sheets show some patterns in the interaction regarding diagrammatic activities and communicating about them. The two selected scenes from episodes 1 and 2 (see Figure 2 and 3) exemplify these patterns.



a b

Figure 2: Analysis sheets and transcripts, (a) episode 1, scene 1 (b) episode 2, scene 3

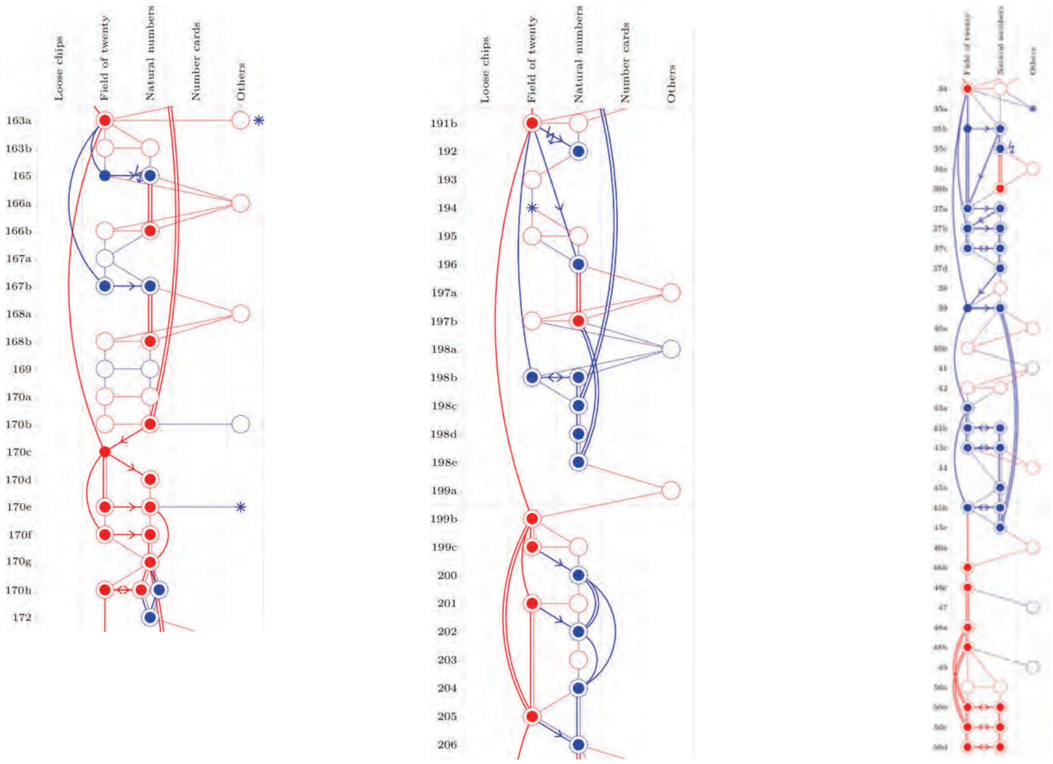
- Mr. Wehrle sets the tasks for Samira often in such a way that both representational systems are linked at least by communicating about a diagram (see Turn 3 and 5 in Figure 2a; Turn 20b in Figure 2b). Samira then also combines both representational systems in her answers (see Turn 6a in Figure 2a; Turn 23a, b in Figure 2b) by using diagrams in both representational systems.
- Mr. Wehrle promts Samira repeatedly to switch back and forth between the representational systems. To this end, he himself switches between the representational systems. He adapts this to the respective situation. If Samira's answer is only in the natural numbers, he switches to the field of twenty (see Turn 4–5 in Figure 2a). If her answer is only in the field of twenty,

he switches to the natural numbers (see Turn 19d–20b in Figur 2b). Therefore, he uses corresponding diagrams to the ones Samira used in the other representational system.

- Diagrams are mainly used by Samira. She also mainly carries out the diagrammatic activities. Mr. Wehrle encourages these according to the principle of minimal help (Aebli, 1998). The impulse to communicate about diagrams usually comes from Mr. Wehrle. He almost always communicates via the diagrams he uses.

Dealing with errors

If a content-related error has occurred during the task processing, a correction is needed. Samira repeatedly makes errors in determining odd numbers that are arranged in a block. In the analysis sheets, errors are indicated with a flash. Figure 3 shows three analysis sheets for error situations.



a b c

Figure 3: Analysis sheets of error situations, (a) episode 1, scene 13 (b) episode 1, scene 15 (c) episode 2, scene 5

In episode 1, scene 13 (Figure 3a), Samira determines an incorrect number and corrects herself when Mr. Wehrle asks where she sees this number (T. 164–168a). He then asks her, how she got the correct number and Samira reports that she counted (T. 168–170a). Now Mr. Wehrle becomes diagrammatically active himself to correct the error by referring to a known procedure and carrying it out himself. In doing so, he always connects the two sign systems with each other and communicates via each diagram. He thus demonstrates to Samira the possibility of non-counting number determination by way of example. Samira participates by agreeing and taking over the diagrammatic activity at the end:

170b Mr. Wehrle: You had a great trick at twelve earlier.
170c *Pushes the chip from P17 to P18.*

170d At twelve you said
170e here are six. *Points from P1 to P6.* <

170f And here are six. *Points from P11 to P16.* <<
170g Equals twelve.
170h *Pushes the chip back from P18 to P17.*
And then <<< only plus one.
171a Samira: < Yes.
171b << *Nods.*
171c <<< One.
172 Samira: Equals thirteen.

In episode 1, scene 15 (Figure 3b), Samira determines an incorrect number, too. With Mr. Wehrle's advice to look carefully and count the top row, she is able to give the correct number (T. 191–196). When asked how she figured it out, she refers to the previous number and states that there is now one more chip (T. 197b–198e). She is mainly diagrammatically active in the natural numbers. Mr. Wehrle then works with her to determine the number by structural subitizing, always combining both representational systems. He takes the field of twenty as the starting point and encourages Samira to switch between the sign systems. He takes over the diagrammatic activities at the field of twenty:

199b Mr. Wehrle: And have a look. *Puts two chips on P8 and P19.*

199c *Points along the top row of chips.* If you now count this row up here. How many are there?
200 Samira: *(4 sec.)* Eight.
201 Mr. Wehrle: *Covers the chip on P19.* How many are there then in the bottom row up to here? *Points to P18.*
202 Samira: Eight.
203 Mr. Wehrle: Equals
204 Samira: Sixteen.
205 Mr. Wehrle: *Uncovers the chip on P19.* And this one.

206 Samira: Seventeen.

In episode 2, scene 5 (Figure 3c), again, Samira determines an incorrect number (T. 34–35). When asked why there are this number of chips, Samira now becomes diagrammatically active. She uses both representational systems flexibly, switches back and forth between them and can identify her answer as incorrect and name the correct number:

37a Samira: *Points from P1 to P8.* I counted here, that—it's eight.
37b *Points from P11 to P17.* But there, it can't be eight.

37c *Points to P18.* Because there should be one more.
37d So, it is not sixteen.
38 Mr. Wehrle: *(..)* But?
39 Samira: *(10 sec.) Makes slight nodding movements with the head.* Fifteen.

Mr. Wehrle asks her not to count the number. Thereupon Samira again becomes diagrammatically active. Again, she uses both representational systems flexibly, switching back and forth between them. Now, however, she is proceeding in a very orderly manner:

43a Samira: *(.)* For example. *Pushes the chip from P8 away next to the field of twenty.*
43b Now there are *(.)* seven. *Slight circular movement via P6, P7, P8, P9.*
43c Plus seven.
44 Mr. Wehrle: Mhm.

45a Samira: Equals fourteen,
45b and one more *Pushes the chip back to P8.*
45c equals fifteen

Mr. Wehrle repeats this approach and enriches it with terms such as “doubling” (T. 46–49).

Overall, development can be seen: while Mr. Wehrle initially demonstrates a non-counting strategy, he increasingly takes a step back and challenges Samira to diagrammatic activities. Conversely, Samira is initially strongly focused on the natural numbers. Increasingly, she connects them with the field of twenty and finally becomes independently active in both representational systems in order to correct her error. While Samira initially has to be prompted to communicate about the diagrams and the diagrammatic activity, in scene 5 (episode 2) she does this on her own and uses it to think aloud.

Conclusions and limitations

By analyzing the diagrammatic activity and communicating about it in individual support episodes as a whole, patterns and developments become apparent. In the individual learning support presented here, for example, these patterns can be seen in the fact that Samira was repeatedly encouraged to switch between the two representational systems and to connect them. In this way, Samira can increasingly participate in the mathematical practice of diagrammatic activities (Dörfler, 2006). Mr. Wehrle uses the diagrams of different representional systems, mainly of the field of twenty and the natural numbers, as the subject of the reasoning and communication processes (Dörfler, 2006). In doing so, he encourages Samira to explore and interpret these diagrams. This interaction leads to Samira being able to clarify and structure and her thought processes (Hoffmann, 2007). Especially when dealing with errors, this becomes evident: Samira is finally able to engage in a mathematical discourse for error correction using diagrammatic activity and communicating about. In doing so, she applies elements of the patterns that were previously established between her and Mr. Wehrle.

This study has some limitations up to this point. Since only one situation of individual learning support was initially considered, it is yet unclear whether such a pattern also leads to a similar result in other situations and whether success might be found in other patterns of interaction. In future research, individual learning support of different preservice teachers will be compared in order to obtain insights into teacher training in this area in the long run.

Bar-model introduction in late primary school

Belén Palop del Río[1] and Juan José Santaengracia [2]

[1]Universidad de Valladolid, Segovia, Spain; belen.palop@uva.es

[2] Universidad de Valladolid, Segovia, Spain; juanjosesantaengracia@gmail.com

The Singapore bar-model has recently arrived in many Spanish classrooms, where it has been identified as an effective modelling tool for problem-solving in primary schools. This model introduces a pictorial approach prior to the abstract symbolic resolution. Schools usually change over to this scheme by introducing it in grade 1 (6/7 years old) and progressing yearly with the children. In this study we perform a pre-post analysis of 71 fifth graders. An experimental group of 16 children were introduced to the Singapore bar-model, while the control group, the remaining 55 children, solved the exact same set of problems using their usual symbolic-only approach. Our results show statistically significant improvements in the performance of the experimental and the control groups in the cognitive domains of "knowing" and "applying" as well as in the content domain of geometry.

Keywords: Problem solving, mathematics education, Singapore bar-model, classroom research.

Introduction

Problem-solving is one of the key aspects in mathematical education and maybe one of the most difficult skills to teach. Many students and many teachers struggle with this issue, where solutions come from a complex mixture of creativity and pattern-recognition. Teaching mathematical modelling literature agrees on problem-solving being some cycle (Perrenet & Zwaneveld, 2012) where reality is transformed into a mathematical model whose mathematical solution is found and, later, transformed back into reality.

According to DeWindt-King and Goldin (2003) "a representation is any configuration (of characters, images, concrete objects, etc.) that can denote, symbolize or, otherwise "represent" something else" (p. 2). The representation of the problem data can be a way to emphasize, understand and link the most important information, so that practice can be seen as a useful tool for the students in problem solving (Heagarty & Kozhevnikov, 1999). The scientific community agrees that representing data is useful for improving performance in problem solving, although there is no single way to represent data. The works of Fagnant and Vlassis (2013) and Heagarty and Kozhevnikov, (1999) show several ways, focusing mostly on the schematic representations. Appropriate representation has positive effects on children's performance, which reinforces the importance of working on this content from an early age (Uesaka et al., 2007).

Spanish tradition tends to rely only on the symbolic representation of mathematical models, and other types of representations are hard to find in classrooms and/or textbooks. Among teachers and students, the usual scheme is known as the "*Datos-Operación-Solución*" scheme (which translates as "data-operations-solution"*, DOS,* from now on). Under this scheme, children are asked to organize problem-solving in the three steps shown in practice in Figure 1. First, they write down "Data" and all numerical data that appears in the problem statement, usually with units. Then, children have to perform the needed calculations (*Operations*). Finally, in the *Solution* block, they write down a full sentence stating the result back in the context of the problem.

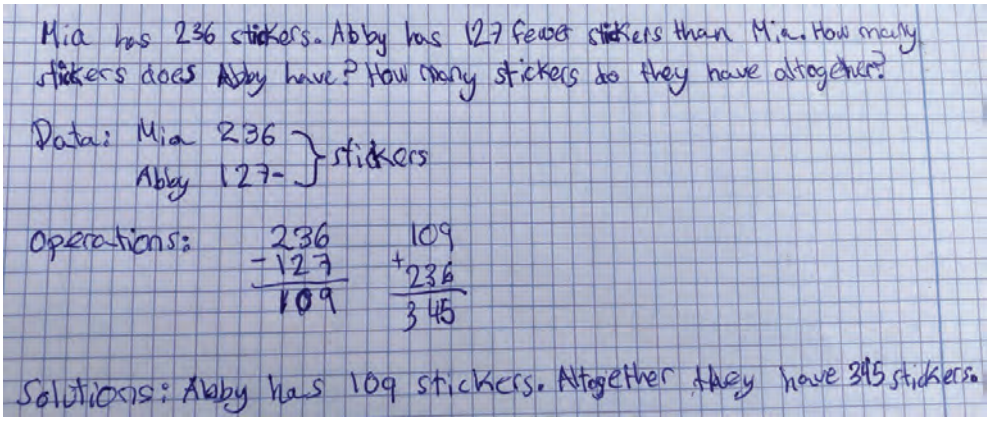

Figure 1: DOS-Scheme implemented by an 11-year-old from a bilingual school (English & Spanish)

It was in the 1980s when Singapore brought in the idea of modeling quantities and their relationships with bars, avoiding the more abstract symbolic-only approach and giving students a pictorial way to represent a problem's mathematical model. According to Blum and Leiss (2005) modelling cycle, shown in Figure 2, BMM allows the students to obtain a model of the situation prior to the mathematizing step. This approach clearly contrasts with the DOS, which moves directly towards the mathematical work without performing any modelling.

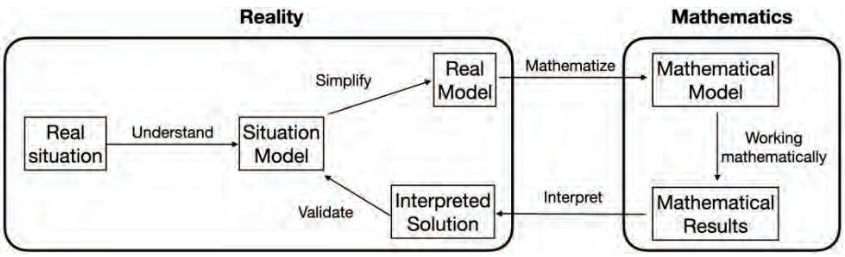

Figure 2: Blum and Leiss modelling cycle

The bar method model (BMM from now on) uses as a fundamental mainstay the concept of the "bar", which is a pictorial diagram that allows the organization of the abstract information, converting it into understandable data (Walker, 2005). Using this method, it is possible to represent data from arithmetic and algebraic problems (word problems), which not only allows us to transform abstract words and concepts into pictorial representations, but also helps to understand and analyze the problem itself (Yeap, 2011). According to Kho (1987) and Kho et al. (2009), once the students have been able to represent the data using the bars, they are much more likely to understand the situation and, therefore, to solve the problem.

Since its introduction in Singapore, the BMM has been a centerpiece in mathematics, beginning in the first grade of primary education. According to Ng and Lee (2009), in the first two years, they usually work through pictorial representations of known objects, to encourage students to have specific references to the data. Subsequently, the concept of the "bar" is introduced, with which they continue to work throughout their school years. Many Spanish schools have started to use Singapore's textbooks. Usually, the method is introduced in grade 1 and progresses with the children as they advance in their schooling years. In those schools, older kids are thus taught with the DOS scheme while their younger schoolmates are introduced to this pictorial representation. This situation leads to the main research question for this study: Can grade 5 students, who have only been taught to use abstract symbolic modelling, also benefit from the introduction of BMM?

Methodology

This research follows a pre-test/post-test design. This study has been carried out in a middle-sized school in Segovia, Spain. All 76 fifth grade students have participated in it, though 5 of them have not been included since they are identified as special-education students. The remaining 71 children are divided into 4 classrooms, each one lead by a different math teacher. Three of the classrooms (55 students) have been assigned as the control group, and the remaining one (16 students) has acted as our experimental group, since their teacher was looking for new approaches to problem-solving methods, given the difficulties their students had on this topic.

The intervention was carried out as follows: For over a month, daily, both experimental and control groups solved the same two problem inventories consisting of a total of 53 word-problems, all able to be solved with the help of BMM. It is important to remark that these children have never been exposed to pictorial models before our interventions. The control group worked with their usual DOS scheme. The word-problem inventory was agreed upon by the four classroom teachers and divided into three sections: additive structure with natural numbers, additive structure with decimal numbers and, finally, multiplicative structures and fractions (that were also represented with bars). With respect to TIMSS' content-domain classification, all the problems fall in the group *numbers*, while regarding cognitive domains, 49% classify as *applying*, 17% as *reasoning*, and 34% as *knowing*.

The first sessions for the experimental group were entirely dedicated to the pictorial representation of the problem statement, introducing BMM by example. In the first two sessions, all questions were removed from the problems' statements to avoid the mechanical use of DOS scheme by the students. Only when students got used to modelling the situation with bars and could pose and answer several questions from their drawn bar-model were the original questions to the problems reintroduced.

To assess the effectiveness of the intervention we used two similar sets of questions released from TIMSS (2011) as pre-test and post-test. The first set had already been configured and tested in the Spanish context in Fraile's PhD (2017) while the second was designed to match this one with a similar weight (shown in Table 1) in both content domains (numbers, data display and geometric shapes and measures) and cognitive domains (applying, reasoning, and knowing).

Table 1: Total number and percentage of the questions in each domain for the pre- and post-tests

	Date	Question content domain			Question cognitive domain		
		Numbers	Data	Geometry	Applying	Reasoning	Knowing
Pre-test	28/04/2020	7 (63%)	2 (18%)	2 (18%)	4 (36%)	4 (36%)	3 (27%)
Post-test	08/06/2020	9 (60%)	4 (27%)	2 (13%)	5 (33%)	5 (33%)	5 (33%)

Among all the questions in the pre-test, three of them threw up unexpected results and were reintroduced to better understand the children's motivations for their answers, redesigning them as diagnostic questions, where incorrect responses allow the teacher to understand where the mistakes may be (Wylie & William, 2006).

Analysis

Students' answers analysis has been carried out using R software. We start by comparing problem solving skills before our intervention between the experimental and control groups, according to their results on the pre-test. The results shown in Table 2 may suggest some bias in favor of the experimental group, but the chi-square test p-value is 0.82, showing no significant differences between the number of correct answers in both groups.

Table 2: Post-test average results in a 0-10 scale for each group in the studied domains. In brackets, pre-test average results and difference between both measurements.

	Student's content domain			Student's cognitive domain		
	Numbers	Data	Geometry	Applying	Reasoning	Knowing
Experimental	8.1 (5.7+2.4)	9.0 (6.9+2.1)	7.2 (6.6+0.7)	8.2 (7.8+0.4)	8.1 (5.6+2.5)	8.0 (4.4+3.6)
Control	5.9 (4.6+1.3)	8.0 (6.9+1.1)	2.6 (4.7-2.2)	5.6 (6.3-0.7)	6.9 (5.3+1.6)	5.4 (2.9+2.5)

The results suggest better problem-solving skills in the experimental group, as well as an improvement of this group after the intervention. Six repeated measurement Anovas were performed to determine statistically significant differences between both groups. These results are shown in Table 3.

Table 3: Anovas' summary for the differences between both groups

Student's content domain			Student's cognitive domain		
Numbers	Data	Geometry	Applying	Reasoning	Knowing
$F(1,69)=8.055$ $p<0.1$ (.)	$F(1,69)=0.737$ $p=0.39$	$F(1,69)=13.72$ $p<0.001$ (***)	$F(1,69)=11.2$ $p<0.01$ (**)	$F(1,69)=1.572$ $p=0.21$	$F(1,69)=10.71$ $p<0.01$ (**)

From the data shown in Table 2, the only significant difference in content domain has been in geometry, with an average difference of 2.9 points between groups due to the worse results in the post-test for the control group. In numbers and in data the differences have been smaller, with 1.1 and 1 average points respectively, only significant to a 90% for the data domain. With respect to cognitive domains, two out of the three categories have had a significant increase for the experimental group showing p-values in the Anova tests below 0.01.

As mentioned before, three questions in the pre-test were introduced in the post-test. Let us start our analysis with the following question (TIMSS Ref.M051091) that falls into the content domain “numbers” and the cognitive domain “knowing”.

Figure 3: Question TIMSS Ref.M051091 that was included (in Spanish) in the pre-test

Which fraction is not equal to the others?

A.1/2 B. 4/8 C. 2/4 D. 2/8

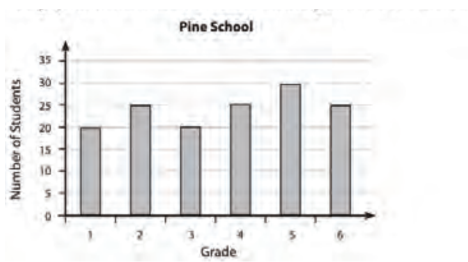
The pre- and post-test results of our fifth graders are shown in Table 4. No significant differences between experimental and control groups have been found in the answers of both groups in the pre-test (Chi-square test p-value=0.18) nor in the proportion of correct answers (Binomial test p-value=0.06). After consultation with teachers and students we understood that “not equal” might be ambiguous for the children. In the post-test we used the unambiguous term “not equivalent” obtaining a non-statistically significant 14% increase in the correct answers. Experimental and control groups differ in favor of the experimental group in the post-test (Chi-square test p-value=0.02; Binomial test p-value=0.004) where 94% of the children in the experimental group can answer correctly.

Table 4: Comparison between pre- and post-test in exp. and cont. groups in M051091 question

	Pre-test					Post-test				
	A	B	C	**D**	Other	A	B	C	**D**	Other
Cont.	21 (38%)	5 (9%)	3 (5%)	**21 (38%)**	5 (9%)	16 (29%)	3 (5%)	3 (5%)	**27 (49%)**	6 (11%)
Exp.	2 (13%)	2 (13%)	0 (0%)	**11 (69%)**	1 (6%)	0 (0%)	1 (6%)	0 (0%)	**15 (94%)**	0 (0%)

The second question that was reevaluated is shown in Figure 4. TIMSS provides the four answers A. 20, B. 25, C. 30 and **D. 35**. Trying to improve its usage as a diagnostic question, we changed the solutions to **A. 35**, B. 7 (number of empty gaps in the graph), C. 180 (6 grades times 30 students) and D. 145 (students represented in the graph). A remark on Fraile’s PhD annotations (Fraile, 2017, p.110) suggested one might further modify in the post-test the answer B. 7 to B’. 30, which was a common mistake, probably due to 30 being the only numerical data in the exercise.

Figure 4: Second question (TIMSS Ref.M051117) that was included (in Spanish) in the pre-test



In the Pine School there is room in each grade for 30 students. How many more students could be in the school?

A. 20

B. 25

C. 30

D. 35

Due to the changes in the test answers, we only analyze the proportion of correct answers. Table 5 shows a higher success rate in the post-test of the experimental group, with 75% of correct answers, with respect to the 44% of the control group but also an increase in the mistakes towards the new option B'.30. The binomial test for the two groups p-value of 0.108, with no statistical significance.

Table 5: Comparison between pre- and post-test in exp. and cont. groups in M051117 question

	Pre-test					Post-test				
	A	B	C	D	Other	**A**	B'	C	D	Other
Cont.	**26 (47%)**	0 (0%)	18 (33%)	6 (11%)	5 (9%)	**24 (44%)**	8 (15%)	11 (20%)	10 (18%)	5 (9%)
Exp.	**8 (50%)**	1 (6%)	6 (38%)	1 (6%)	0 (0%)	**12 (75%)**	2 (13%)	3 (19%)	1 (6%)	0 (0%)

The last question that was reevaluated (see Figure 5) deals also with basic facts about fractions and falls also in the content domain "numbers" and the cognitive domain "knowing". It is an open question where students are asked to write their own answer.

Figure 5: Question TIMSS Ref.M041299 that was included (in Spanish) in the pre-test

Tom ate $\frac{1}{2}$ of a cake, and Jane ate $\frac{1}{4}$ of the cake. How much of the cake did they eat altogether?

TIMSS suggests 2/6 as a common mistake, resulting from adding the two numerators and the two denominators. Our analysis of the pre-test showed that 1/6 is also a common answer. Table 6 shows the results for **3/4** (or equivalent) answers, 2/6, 1/6, other answers and blanks for both tests. No statistically significant differences are found between pre- and post-tests for any of the two groups, but, again, the experimental group obtains a higher rate of correct answers in the post-test compared to the control group, throwing a p-value of 0.064 in the Binomial test.

Table 6: Comparison between pre- and post-test in exp. and cont. groups in M041299 question

	Pre-test					Post-test				
	3/4	2/6	1/6	Blank	Other	3/4	2/6	1/6	Blank	Other
Cont.	15 (27%)	9 (16%)	7 (13%)	3 (5%)	21 (38%)	18 (33%)	8 (15%)	2 (4%)	5 (9%)	22 (40%)
Exp.	6 (38%)	3 (19%)	0 (0%)	1 (6%)	6 (38%)	9 (56%)	2 (13%)	1 (6%)	0 (0%)	4 (25%)

Conclusions

Not surprisingly, both experimental and control groups have benefited on average from the systematic work in problem-solving. A deeper analysis shows that there are three domains in which we have found significant differences between groups at 95% significance-level. With respect to content domain, significant differences have only been found in the geometry block, while the numbers block, throws a p-value only below 0.1. Regarding cognitive domains, "applying" and "knowing" show a statistically significant difference in favor of the experimental group, consistent with the fact that these blocks have been the focus of 83% of the intervention.

The international success average of fourth graders in question M051091 assessing the concept of equivalent fractions is 44%, while Spanish students obtain a much lower rate of 30%. One academic year later, our fifth graders are close to the international average with a slight difference (not statistically significant) in favor of the experimental group and a 45% average success rate. After the intervention, where bars were used to represent fractions, there is a non-statistically significant increase in the results of both groups which now shows a much clearer difference in the experimental group, where only one student misses this question. The differences between groups in the post-test are statistically significant and prove a better grasp of the basic facts of fractions for this group.

The international success average for fourth graders in Question M051117 where they are asked to read and interpret data from a graph is 54%, while Spanish students obtain a lower rate of 50%. In the pre-test there are nearly no differences between the two groups, with C. 180 being the most common wrong answer. The average success for this question is 48% in the pre-test. Option B was replaced by 30 respondents in the post-test, where 14% of the children chose this modified answer (only one chose number 7 in the first version), a clear sign of a better choice for a diagnostic question.

The international success average for fourth graders in Question M041299 where they are asked to add fractions 1/2 and 1/4 is 23% showing, again, Spanish students a much lower rate of 14%. In the pre-test, our fifth graders obtained a better result on average of 30%, with no significant differences between groups. After the intervention, the percentage of correct answers for the control group is 33% and 56% for the experimental group, without statistical significance.

According to the literature, BMM can help children's problem-solving skills when it is taught in the early years. This study suggests that the positive effects of this approach can be attained even as late as 5th grade and that further analysis and interventions should be tested to better understand how it affects the different cognitive domains and to establish with elder children (or even adults) if the opportunity window to improve problem-solving skills with the use of BMM ever closes.

Acknowledgments

The authors want to thank the experimental-group classroom teacher, Amaya Delgado, for her never ending enthusiasm and the control-group teachers for their support and patience. We also appreciate all the support from Arántzazu Fraile, who shared with us the raw-data and dozens of files from her PhD thesis, which served as a guide and constant reference.

Solving geometric problems: Squaring in motion using manipulatives, measurement of long-term effects

Daniele Pasquazi[1,2]

[1] LSS B. Touschek, Grottaferrata, Italy

[2]Tor Vergata University, Department of Mathematics, Rome, Italy; pasquazi@mat.uniroma2.it

Neurophysiological studies have shown that our motor system plays a fundamental role in the scaffolding of our cognitive system. Taking these findings into account, we have designed and produced manipulatives that reproduce geometric figures. Through them, we can amplify our perception of the relationships between different elements. We believe that repeated interactions with the manipulatives generate the ability to imagine similar movements on drawn figures. An example is "squaring in motion", through which a given figure is transformed into an equivalent rectangle. We verified, through a quantitative study involving preadolescents (12-14 years old), the long-term effectiveness of the use of manipulatives on problem solving.

Keywords: Perception, movement, insight, productive thinking, Leonardo da Vinci.

Introduction

Problem solving is a very important aspect of mathematics education. This is already underlined by the NCTM since 2000 and, specifically in Italy, by the 2012 Italian National Guidelines for Instruction concerning the curriculum for pre-school and "first cycle", i.e. 6-14 education. Taking into account the distinction between exercise and problem (Duncker & Lees, 1945), "l'impressione che, proprio in matematica, si chieda ai nostri studenti di attivare essenzialmente processi riproduttivi, risolvendo esercizi, piuttosto che processi produttivi, risolvendo problemi" ("the impression is that, precisely in mathematics, our students are asked essentially to activate reproductive processes, solving exercises, rather than productive processes, solving problems", Di Martino, 2017, p.24 translation by the author). Furthermore, the identification of automated algorithmic processes to solve problems, especially if introduced too early, can clog original sources of insight (Freudenthal, 1983).

In this context we refer to the search for effective strategies to solve problems concerning the equivalence between surfaces. We want to concentrate exclusively on the study of the figures related to them. This is why every problem always has a figure: according to Duval (1995), "the usefulness of geometrical figures in the resolution of a problem of geometry is beyond doubt. They provide an intuitive presentation of all constituent relations of a geometrical situation" (p.143). Therefore, we would like to emphasize how important it is to be able to extract as much information as possible from a geometric figure and, through this, elaborate a solution strategy. In accordance with Kanizsa (1973), we believe that this depends mainly on an appropriate development of geometric perception.

In this paper we propose an innovative way of amplifying geometric perception that has produced immediate results in solving geometric problems and whose effects also appear to be long-lasting.

Theoretical background

Our study is supported by some neurophysiological aspects. One of these concerns the neuronal activations that occur during the observation of an object or picture. There are currently no specific studies on the encoding of geometric figures. However, we can assume that their encoding at a neuronal level is similar to that of words, for which many studies have been conducted. A hypothesized model (Dehaene et al., 2005) verified experimentally by Vinckier et al. (2007) allows us to understand that during word reading, neuronal activation takes place starting from the occipital cortex for the encoding of the most elementary components of the letters, up to the inferior temporal cortex for the encoding of more complex forms like letters and whole words. From studies on macaques (Tamura & Tanaka, 2001), whose brains are very similar to those of humans, we know that at the top of this hierarchy is a single neuron that encodes an entire word. The process does not essentially change if, instead of reading, we are looking at an object. The power of these activations depends on the frequency with which that image is seen and the way it is habitually viewed, i.e., orientation, angle of view, etc. The organization of our perception is undoubtedly influenced by these activations. Frequently seen shapes are more easily recognized than less frequently seen ones. We realize that when we study a complex figure, the shapes we have seen most often are recognized most quickly. As for the others, we must make an extra effort to be able to see beyond what immediately appeared to us. This reorganization of the elements of a figure can lead to sudden *insight*: this is precisely the term coined by Köhler (1921/2018). In this way, *productive thinking* is manifested, using Wertheimer's term (1959), which is necessary to effectively understand the relations contained in a figure of any kind of problem.

To support our study, we wanted to consider another neurophysiological aspect concerning the neuronal activations that occur during interaction with objects such as *artificial manipulatives*, as defined by Bartolini Bussi and Martignone (2020). These are concrete artifacts specifically designed for educational activities. It is well known that the way we grasp an object depends on the series of attempts that we have previously made. The most effective was chosen for our purpose. Through studies on primates (Rizzolatti, Luppino & Matelli, 1998) and humans (Culham et al., 2003), we know that every time we grasp a specific object, first the neurons in the parietal cortex and then those in the premotor cortex are activated to perform a visuomotor transformation. The observed physical properties of an object (shape, orientation, size, etc.) are transformed into the correct hand configuration for grasping it. Moreover, and this is really remarkable, these neurons are not only activated when the individual's hand interacts with the object, but also when s/he simply observes the object (Chao & Martin, 2000) or even remembers the interaction with it (Jeannerod & Decety, 1995).

Finally, two very important complementary studies allow us to highlight the direct interaction between the motor system and perception. The first argues that the previous perception of a bar influences the way we grasp it later (Craighero, 1996). At the same time, grasping a bar actually amplifies its perception (Craighero, 1999). It is as if to say: perception influences action, which in turn influences perception.

Aims of our research and methodology

In this study we have been concerned with finding strategies for solving geometric problems whose text is accompanied by a related figure. We have focused on the concept of equivalence between polygons and curvilinear figures that can be deduced from an appropriate movement that transforms one figure into another. This, as will be shown later, is not a very simple task for students. To overcome this difficulty, we have reproduced geometric figures by means of manipulatives so that, through interaction with them, these transformations can actually be realized.

We know that repeated interactions with objects such as manipulatives stimulate the communication of different neuronal circuits. If we assume that these circuits are also reactivated when studying a geometric figure of the same type as the one simulated by the materials, we hope that the same movements previously performed on the manipulatives will be imagined on the figure. We believe that this amplification of geometric perceptual abilities will motivate students to rely on them more and more when studying a figure. Furthermore, the cortical areas activated using the manipulatives are in addition to those typically involved during the study of geometry. This involvement of a greater number of neuronal circuits should foster the retrieval of mathematical facts and therefore it is also hoped that what is learned through these motor activities will persist much longer than traditional learning.

We wanted to test the validity of these hypotheses by involving lower secondary school students (grade 7, age 12-14) in a quantitative study. Our research aims were:

a) to measure the effectiveness of manipulatives that simulate geometric figures. That is, we aimed to test whether they are able to generate the ability to imagine the same movements when studying a drawn geometric figure. In this research we dealt with geometric problems already provided with the figure. The object of these problems was the calculation of the area of polygonal and curved figures and the verification of equivalences between different figures,
b) to verify whether the effects of using manipulatives persist over time.

The research design used presents some peculiarities both for the type of variables that were to be measured and because the psychometric survey was carried out in schools during curricular hours (see Pasquazi, 2020 for more details). The study was divided into 6 phases: design of the Pre-test (Phase 1), validation of the Pre-test (Phase 2), administration of the Pre-test (Phase 3), the treatments (Phase 4), administration of the second test called Post-test 1 (Phase 5), and the administration of the third test called Post-test 2 (Phase 6).

Initially (Phase 1), we designed a new test consisting of 16 items to be completed in one hour (the time of a lesson) because, given the aims of our research, there was no suitable one. Of course, it was considered that the topics covered in the test items were already known to the students before our study. We show, as an example, a test item planned for this study dedicated to a type of polygon that differs slightly from a known figure (Wertheimer, 1959): *calculate the area of the surface* Q (Figure 1a). The students had to provide two open-ended answers: in *sub-answers* A they had to describe the solving strategy they used to arrive at the solution. The answers were assessed according to the following criteria. A value of 1 was assigned if dynamic aspects resulting from the study of the figure were used to determine a solution strategy. These answers called *dynamic answers*. In the example shown, the solution strategy that exploits the dynamic aspects is provided when equality is established between the projection and the hole, which leads us to imagine moving the projection until it occupies the entire hole. The equality between the protrusion and the hole is undoubtedly evoked by the shape of Q which resembles that of a rectangle, a figure well known to students and therefore "recognized" by our visual system. Otherwise a value of 0 (zero) is assigned if the answer is missing or is present but is not a dynamic answer. In general, for designed items, when the answer is not dynamic, a lot of calculation is required. In the example considered, if we did not recognize the proximity of Q to a rectangle, we would be forced to calculate the areas of the various polygons into which the figure is divided and then add them up. The answers to the questions in the respective items were to be reported in *sub-answers* B: 0 (zero) was given if the answer was wrong or missing, 1 if the answer was correct. For example, sub-answers A in Figures 1b and 1c will be given a value of 1 because it has been recognized that Q is equivalent to a rectangle (at least that is what it looks like in Figure 1b); the score given to sub-answer B, on the other hand, is 0 in the first case (because the calculation of the area of the rectangle is wrong) and 1 in the second.

Subsequently (Phase 2), the designed test was validated by seventy-four students of an institute. By calculating the *point-biserial correlation coefficient* of each item, the *Cronbach alpha coefficient* (α) was obtained (Pelosi & Sandifer, 2003). The latter was used to measure the reliability and coherence of the test. Conventionally, tests with an $\alpha > 0.70$ are considered acceptable.

Once the validation of the test was completed, the experimental phase began, involving eighty-seven students of the same age from two further institutions (different from the one involved in the validation). The students were divided into two homogeneous groups called *experimental group* and *control group*. The experimental phase started with the administration of the validated test, called *Pre-test,* to the students of both groups (Phase 3). The aim of this test was to find out whether or not the students manifested dynamic aspects in their solving approach and what effect this approach had on the correctness of their answers. We emphasize that the administrators, after giving the appropriate instructions, no longer interacted with the students during the test.

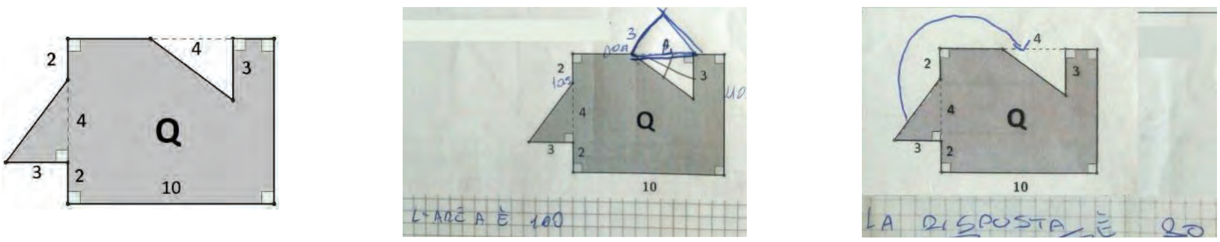

Figure 1: (a) figure associated to an item, (b) and (c) item responses examples

Phase 4 presents a special feature of the research design. Effective treatments were carried out in both the experimental and control group (one meeting per week for a total of three meetings of two hours each). Since there was already an idea of what the results of the Pre-test might be, the treatments aimed at stimulating the perception of dynamic aspects deduced from the observation of the figures. This should have improved the students' performance in answering the test items.

I will show an example of a treatment performed to produce effective resolution strategies related to the test item shown above. Treatment is inspired by the figures of Leonardo da Vinci found in the *Codex Atlanticus*. He performed a lot of squaring of parts of circles and curvilinear figures like the one shown in Figure 2a. His intuitive approach emerges from the captions of the figures, which provide real didactic indications such as the following: "la cosa che si muove acquista tanto di spazio, quanto ella ne lascia" ("what moves acquires as much space as it leaves", folio 505 recto, translation by the author).

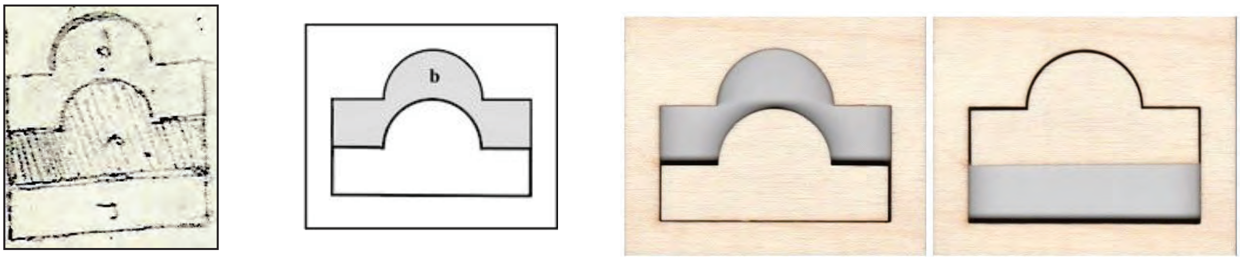

Figure 2: (a) detail of folio 505 recto, *Codex Atlanticus*, (b) figure to an associated problem, (c) manipulatives inspired by the figure of Leonardo

Students in both groups are given the same problem. In the example we want to describe, the task was to measure the area of surface **b** (Figure 2b). Students mostly work in pairs, free to speculate on what they observe, to check, correct themselves if necessary, and then to try a different strategy. Teachers intervened and made suggestions only when students asked for help. Students in both groups were stimulated to formulate and, at the same time, test the validity of their hypotheses. However, the students in the experimental group could use appropriate manipulatives, whereas those in the control group could only draw on their notebooks.

We would now like to briefly describe the manipulatives used by the students in the experimental group. These consist of two elements: a *base* and a *mobile figure* (Figure 2c). By reading the task and looking at the drawing (Figure 2b), students understand how to use the manipulatives appropriately. It is interesting to observe, from the students' actions and statements, the influence of the use of the manipulatives on the perception of geometric properties and how the progressive discovery of these properties guides, in turn, the use of the manipulatives. Initially, the students move the mobile figure at random. Then, as a result of these movements, they understand that all figures obtained from the difference between the base and the moving figure are equivalent. It is evident that the students' eyes light up when mobile figure reaches the opposite position to the starting one. The insight came in: they realize that the difference between the base and the moving figure is now a known surface, i.e. a rectangle. The association between the initial and final difference surface makes the solution obvious. We call *equivalence in motion* this kind of equivalence obtained by movement. Since it is always possible to square a rectangle (Proposition II.14 of Euclid's Elements), it is legitimate to speak of *squaring in motion*.

The answer shown in Figure 1c given by a student in Post-test 2 shows a solution strategy based on squaring in motion that leads to a correct answer. Considering the two right angles on the left in the polygon shown in the Figure 1, we can see that their sides would join if we imagine extending them. This observation contributes to Q evoking a rectangle. The presence of the arrow shows that the student has imagined the movement of the triangle-shaped protrusion in the identical hole. In the Pre-test (Phase 3), the same student had given an unclear and incorrect answer (Figure 1b). The dynamic aspects, if they were present in his mind, had not been effectively exposed.

To test the effectiveness of the treatments, a new test (Phase 5) called *Post-test 1* was immediately administered to the students in both groups. The structure of the Post-test 1 was identical to the previous one, while the questions asked were similar (but not the same). For a separate comparison of the data obtained on Pre-test and Post-test 1 the *Paired Samples t-Test* was used.

In the following six months there was no further interaction with the students involved in the experiment. In order to check whether the effectiveness of the treatments was still detectable at the end of this period, the students were administered *Post-test* 2 (Phase 6), the same as the Pre-test. The administration of a new test long after the previous one is another peculiarity of the research design used in this quantitative study. The data from Post-test 2 were also compared with those from Post-test 1 by means of the Paired Samples t-Test.

Results

In this section we would like to briefly report the main results obtained in the individual phases of the quantitative study. In the validation (Phase 2) of the designed test, for sub-responses A we obtained $\alpha = 0.81$ while, for sub-responses B, $\alpha = 0.88$, thus indicating, in both cases, a very high reliability of the test which motivated us to use it in the next experimental phase.

The analysis of the results of the Pre-test administered in Phase 3 shows, as expected, that there are no substantial differences between the groups. The experimental group obtained an average score of 7.50 (SD 3.76) for sub-answers A and a average score of 7.2 (SD 4.15) for sub-answers B, while control group obtained an average score of 6.12 (SD 4.48) for sub- answers A and an average score of 7.98 (SD 4.50) for sub-answers B. The analysis of the results obtained leads us to conclude that the majority of students in both groups do not prefer to give dynamic answers. Furthermore, the performance concerning the correctness of the answers is also quite unsatisfactory.

In order to verify the effect of the treatments carried out in Phase 4, Post-test 1 was administered a few days later to the students of both groups (Phase 5). The Paired Samples t-Test indicates that the difference between the two averages obtained in Post-test 1 and Pre-test for sub-answers A ($\Delta M = 2.405$, $SD = 3.357$) and for sub-answers B ($\Delta M = 1.595$, $SD = 2.905$), found in the experimental group, are both statistically significant with $t = 4.642$ and $t = 3.558$ respectively and, again for both, p(2-tailed) $< .001$. Similarly, for the control group, the same differences for sub-answers A ($\Delta M = 3.186$, $SD = 3{,}561$) and for sub-answers B ($\Delta M = 1.209$, $SD = 2.739$) were also statistically significant with $t = 5.867$ and $t = 2.895$ respectively and, again for both, p(2 tails) $< .001$. The results therefore indicate that the treatments motivated more students in both groups to provide dynamic answers to the items. As a result, the number of correct answers increased.

After the administration of Post-test 2 (Phase 6), we compared the data obtained between Post-test 2 and Post-test 1 using the Paired Samples t-Test again. In the experimental group alone, the difference between the two averages obtained in Post-test 2 and Post-test 1 for both sub-answers A ($\Delta M = 1.381$, $SD = 4.066$) and sub-answers B ($\Delta M = 1.357$, $SD = 4.119$) were statistically significant with $t = 2.201$ and p(2code) $= .033$ and with $t = 2.135$, and p(2code) $= .039$, respectively.

Thus, the number of students in the experimental group who solve the items by means of dynamic answers increases further. An increase can also be seen in the number of correct answers. In the control group, on the other side, the difference between the two averages obtained in Post-test 2 and Post-test 1 for both sub-answers A ($\Delta M = -0.558$, $SD = 2.914$) and sub-answers B ($\Delta M = 0.116$, $SD = 2.480$) with $t = -1.256$ and $p(2\text{code}) = .22$ and with $t = 0.307$, and $p(2\text{code}) = .76$, respectively, were not statistically significant. This means that there is no substantial difference between sub-answers A and sub-answers B in the two tests for the control group.

Conclusions

In this paper, we have described how to find strategies for solving geometric problems concerning the equivalence of surfaces. We have focused on the ability to provide dynamic answers characterized by the ability to imagine appropriate movements that allow us to transform an irregular figure into an equivalent rectangle. We called this type of transformation "squaring in motion". This strategy has been developed through the use of manipulatives that simulate geometric figures. These allow us to concretely perform continuous movements and visualize equivalences between figures of different shapes.

The effectiveness of the manipulatives presented in this article was verified in a quantitative study involving preadolescents. The latter initially showed that they were unable to imagine movements on the figures of the geometric problems. This had a negative effect on the correctness of the answers. After treatments based on the use of appropriate manipulatives, the students immediately showed an increased ability to solve the problems by providing dynamic answers. Moreover, these abilities were still found six months after the end of the activities. We verified that all these results are statistically significant, telling us that the use of manipulatives can make very important contributions to mathematical learning. However, further investigations on the effectiveness of manipulatives are needed. In particular, we would like to understand why the use of manipulatives did not contribute to the solution strategies for some test items.

Connecting representations for understanding probabilities requires unfolding concepts in meaning-related language

Monika Post [1] and Susanne Prediger [1,2]

It is well known that multiple representations can enhance students' conceptual understanding, but only if (potentially superficial) translation activities are deepened by making the connections explicit. But what exactly does that mean? In our qualitative analysis of a design experiment with two twelfth graders from vocational school on conditional probabilities, we show that explicating connections between multiple representations requires processes of unfolding a highly compacted concept into its concept elements (in our case, part, whole and part-whole-relationship) and articulating them in a decontextualized meaning-related language. By this, we intend to contribute to the research identifying conditions of success for working with multiple representations also for high school students.

Keywords: Connecting multiple representations, explicating connections, unfolding.

Introduction.

It is generally acknowledged that multiple representations can enhance students' conceptual understanding of abstract mathematical concepts (Duval, 2006; Lesh, 1979), but access to multiple representations can be challenging for some students (Ainsworth, 2006; Goldin & Shteingold, 2001). That is why empirical research tried to identify conditions of success under which the use of multiple representations can really contribute to developing conceptual understanding. One identified condition is that representations are not only juxtaposed, but really connected by making the connections explicit (Marshall et al., 2010; Renkl et al., 2013). So far, limited research explored what exactly that means, and how it applies beyond arithmetic and functions, also for probabilities.

Multiple representations have been shown to be relevant also for high school mathematics topics such as conditional probabilities, for which many studies report that visual representations can enhance performance (Böcherer-Linder & Eichler, 2017), e.g. for the conceptual challenge to distinguish conditional probabilities $P(A/B)$ from joint probabilities $P(A \cap B)$ (Binder et al., 2020):

(I) What is the probability that a boy does not play game A?

(II) What is the probability that a teenager is a boy and does not play game A?

An expert can directly assign the correct probability type: conditional and joint probability and translate the questions into a symbolic expression or a visual model. *But what do students need to develop this conceptual understanding of situation types while connecting the statements into visual models or symbolic representations?* In this paper, this research question is pursued within a conceptual framework that combines semiotic processes with epistemic processes, as we present in the first section. The design experiments are conducted in design research methodology and analyzed qualitatively with methods introduced in the second section before the analysis is presented and discussed.

Theoretical background: Semiotic and epistemic processes for developing understanding for conditional probability.

Semiotic processes between multiple representations.

According to the translation models (Lesh, 1979; Duval, 2006), students can develop conceptual understanding by translating between different representations (*e.g., symbolic representation*, *visual models*, *technical language*, *contextual language*). For the case of conditional probabilities, the area model has proven as accessible visual model (Böcherer-Linder & Eichler, 2017) to capture the underlying part-of-part-structure (Leuders & Loibl, submitted), yet most research refers to information processing from *given texts*, not to students' processes of developing conceptual understanding.

In order to overcome well-documented challenges while dealing with multiple representations (Goldin & Shteingold, 2001; Ainsworth, 2006), researchers pointed out that beyond unconsciously *switching* between representations, conscious *translating* activities are crucial (Lesh, 1979, called conversion by Duval, 2006) as well as *explicitly explaining the connections* (Duval, 2006; Marshall et al., 2010). Thus, translating and explaining are connecting processes with a high degree of consciousness about the connection whereas switching involves often low awareness about the change. For clearly explicating how multiple representations are connected, a *meaning-related language* is required to talk about the mathematical structures involved (Pöhler & Prediger, 2015) and how the concept elements occur on the other representation (Renkl et al., 2013). We distinguish contextual language (which can also convey meanings) from a more specific meaning-related language that is decontextualized and suited to *explicate* the *more general structure* behind the part-whole-relationships. In Figure 1, we list the involved representations and distinguish four semiotic processes according to the increasing degree of integration of representations (Post & Prediger, submitted).

Semiotic processes for dealing with multiple representations

Figure 1: Multiple representations and semiotic processes between representations

Epistemic processes for understanding concepts by unfolding into concept elements.

To characterize students’ development of conceptual understanding, we will draw upon a second perspective, namely an epistemic perspective from cognitive psychology focusing the epistemic processes of students’ mental constructions of new conceptual entities (Aebli, 1981; Drollinger-Vetter, 2011). In this epistemic perspective, learning of concepts is characterized by working with refined concept elements that students have to construct, relate to each other and then to *compact* them into new conceptual entities (ibid.). Characteristic for deep understanding of these new conceptual entities is that they can be *unfolded* back into the contained concept elements.

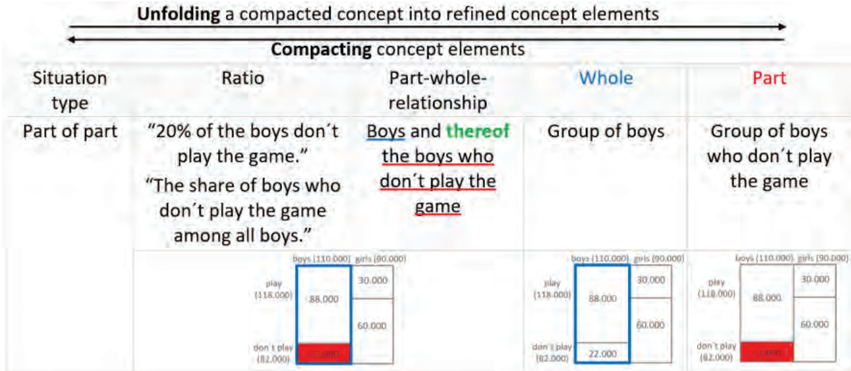

Figure 2: Unfolding and compacting processes for topic-specific concept elements (vertical structure turned into horizontal structure for saving space, here)

Relevant concept elements for our topic-specific conceptual framework were theoretically and empirically identified and are presented in Figure 2. With a focus on statistical ratios, the conditional probability (Question I from above) can be verbalized as “The share of boys who don´t play the game among all boys.”. To differentiate from Question II (joint probability interpreted as “The share of all boys who don´t play the game among all”) these ratios can be conceptualized abstractly as part of different wholes, what we refer to as *situation types*. Question I is a part of a part, whereas Question II corresponds to a part of a whole. Ratio or rather situation types can be unfolded into underlying *concept elements*, namely the *parts*, the *wholes* and the *part-whole-relationships*. For unfolding the ratio, grasping the underlying part-of-part- structure (Leuders & Loibl, submitted) is crucial.

Conceptual framework.

For exploring our research question, we locally integrate the epistemic perspective into our conceptual framework of semiotic processes in Figure 3.

Semiotic processes for dealing with multiple representations

no connection switching - - - translating —— explaining connections ====

Unfolding a compacted concept into refined concept elements / **Compacting** concept elements

	Given text GT	Contextual language CL	Meaning-related language ML	Visual model VM	Technical language TL	Symbolic representation SR
Situation type						
Ratio						
Part-whole-relationship						
Whole						
Part						

Figure 3: Conceptual framework: Navigation space for semiotic and epistemic processes

This allows us to refine the research question: *What concept elements do students address in their pathways of explaining connections between multiple representations for highly compacted conditional probability concepts?* The conceptual framework allows us to trace students' pathways and show how connecting representations requires the unfolding into concept elements.

Method.

Methods of data collection. This case study is part of a larger design research project with two goals, (1) to design learning arrangements and (2) qualitatively investigate learnings processes with the aim of developing local theories on teaching and learning processes (Gravemeijer & Cobb, 2006). In the larger project, design experiments were conducted in seven whole classes (in total n = 150 students) with their regular mathematics teachers. Between the whole class lessons, the first author conducted design experiments with pairs of students to deeply capture their thinking processes. Design experiments were video-recorded and partly transcribed. In this paper, we analyze the transcript of a design experiment with Katja and Justyna from Grade 12 (selected because their intense discussion reveals insights into typical processes found in several cases), restricted to the research question above.

Methods for qualitative data analysis. In order to investigate how semiotic and unfolding/compacting processes interplay, a three-step procedure was conducted: In Step 1, teacher's and student's utterances were coded according to the *concept elements* and *representations* addressed and located in the navigation space of our analytic framework (Figure 3). For analytical clarity and reliability, representations were only coded when references were articulated (e.g., naming the area, quotation from the statement) or gestured, or if the teacher or task demanded it. In Step 2, the *semiotic processes* of relating representations were coded according to their degrees of integrations. In Step 3, the vertical movements up and down were characterized as *conceptual compacting and unfolding processes* and marked in the navigation space by vertical arrows.

Empirical insights into Katja's and Justyna's processes.

In the whole class design experiment sessions, the two girls had already dealt with complex statistical information on parts of different wholes and the area model to visualize part-whole-relationships: For highly compacted statements, students discussed the underlying mathematical structure by explicating the unfolded concept elements whole, part and part-whole-relationship and connecting relevant representations (similar to Post & Prediger, submitted). The teacher had already guided the process of compacting the typical situations into three situation types according to the underlying structure of the statements, called part-of-part-statement, joint statement and simple statement.

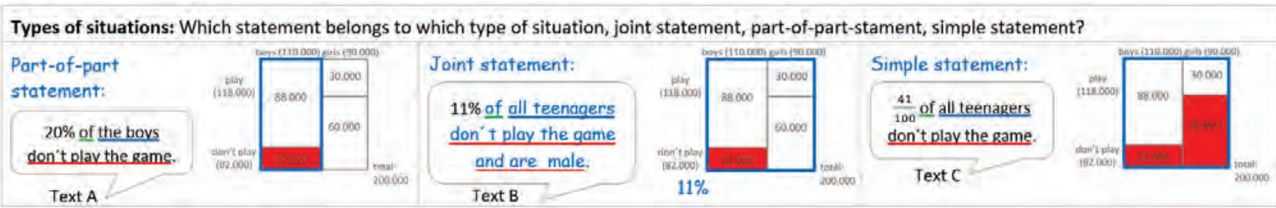

Figure 4: Students' solution for translating compacted situation types to visual model and given text

In the intermediate design experiment in laboratory setting, the design experiment leader went back to the critical step in the learning pathway, connecting highly compacted situation types to visual models and typical given texts. Figure 4 shows their worksheet (translated from German original, blue type marks handwriting, underlining and shaded areas as in original). The students already discussed the given texts by correcting numbers, completing the missing text and coloring in the statements and the area model. The transcript starts when the design experiment (DE) leader pushes them to progress from the successful translating process from texts to visual model to giving titles (Turn 1/2) and explaining these compacted concepts by their explicit comparison (from Turn 3 on).

1	DE leader:	You have got to know these three types of statements. What is this? And this? And this? [*points at the 3 given texts*]	
2	Katja:	That is the simple statement [*falsely points at part-to-part-statement in Text A*]. No, not true, that is the simple [*points at simple statement in Text C*], that is part-of-part [*points at Text A*] and then, that is the combined [*points at Text B; DE writes down titles*].	**2 Situation type** Translate: ML – GT
3	DE leader:	[…] Why? […] What is the difference?	
4	Katja:	Do you want to start?	
5	Justyna:	Um, I cannot explain. Ok, joint is just?	
…		[*hesitates and stumbles, teacher encourages her*]	
12a	Justyna:	Ok, well, here, it is only about the boys who do not play [*unclear on what text she points*] and for the joint, there is one more thing, namely [*2 sec. break*]	**12a Part (Text AB)** Translate: GT – CL
12b		Um, yeah, the boys also take part. But this, there the boys become even more relevant? Thus, these, all persons asked.	**12b Whole (Texts B)** Translate: GT – CL
13	DE leader:	Um, and when you look at the picture again. These are those, aren't they? [*points at the shaded area models*]	
14	Justyna:	Yeah.	
15	DE leader:	This would be part-of-part, this is the joint [*notes titles*]. What exactly, what is the big difference that comes to your eye?	
16	Justyna:	That the persons asked have changed.	**16 Whole (AB)** Switch: CL - - $VM_{A/B}$
…			
25	DE leader:	[*to Katja*] Do you have an idea how to explain it differently?	
26a	Katja:	Um, part-of-part	**26a Situation type** No connection: ML
26b		refers to the subgroup of the whole. And thereof, the other part is the subgroup of the subgroup.	**26b P-W-Relation** No connection: ML
27	DE leader:	Show us, where you are	
28	Justyna:	Oh my god!	
29a	Katja:	Ok, for part-of-part, it refers, it is here, the subgroup, ok, this here, 	**29a Situation type** No connection: ML
29b		the whole [*circles around the left half of the area model*] is the subgroup of the complete, out of the complete persons asked [*circles around the whole area*].	**29b Whole** Translate: VM – ML – ML – CL
29c		And the subgroup is then, um, actually, a part of the part [*circles around the lower left part, then the whole left part*], hence, of the part of the complete.  	**29c P-W-Relation** Explain connection: ML = VM
30	Justyna:	Yes, but said quite complicatedly, no?	
31	Katja:	Yes, though, I understand it [*laughs*].	

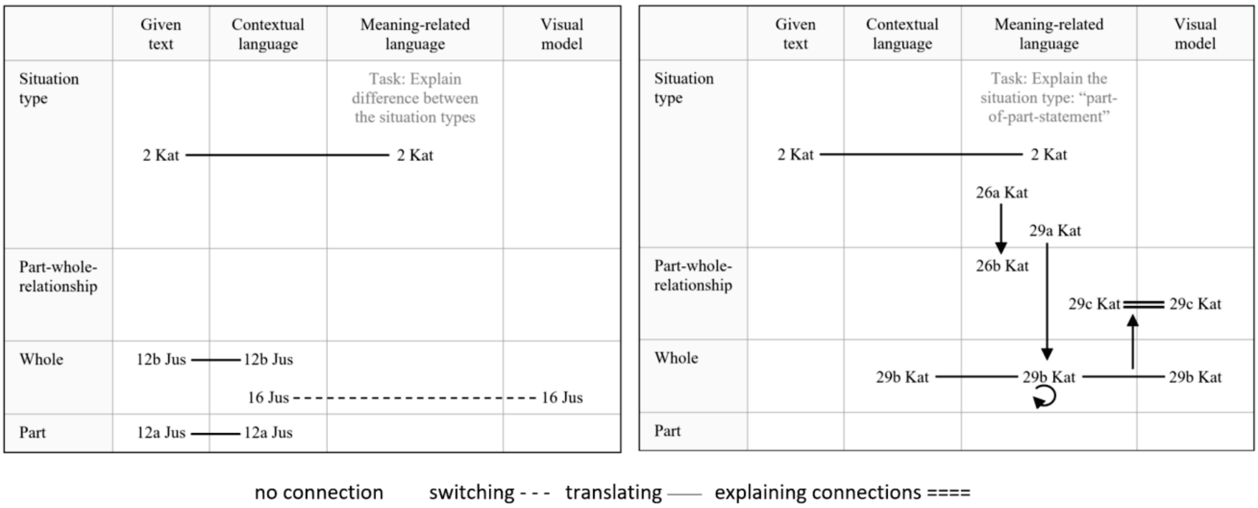

Figure 5: Justyna's and Katja's pathways in the navigation space

In Turn 1, the DE leader asks the girls to assign the given texts (GT) to the situation types (expressed in structural meaning-related language, ML), Katja immediately translates the highly compacted meaning-related notions to the given texts (Turn 2; Translating: ML − GT), yet without explaining her decisions. When the DE leader elicits further explanations (Turn 3), Justyna stumbles (Turn 5-11). Repeatedly encouraged, she starts explaining the connection by unfolding the texts into the part and the whole, and translates both elements into contextual language (Turn 12 ab, Translating: GT − CL), but without explicitly articulating the structure of part and whole. Even when the teachers guides her to comparing the wholes in area model A and B, she unconsciously switches to contextual language ("the persons asked", Turn 16), without explicitly articulating that this is the whole. She keeps on feeling uncomfortable with her explanation and does not even pick up the structural meaning-related language offered by the DE leader in the non-printed Turns 17-24, so the clarification stocks.

In Turn 26, Katja starts her explanation of the meaning of the highly compacted concept "part-of-part statement" and verbalizes the underlying part-whole-relationship in a perfect decontextualized meaning-related language (Turn 26a,b; No connection: ML). In order to strengthen the accessibility of her explanation (for Justyna), DE leader invites Katja to refer to the visual model when continuing the explanation. Katja again starts from the highly compacted concept and addresses the whole (unfolding) by translating between the area model (encircling left half of the area model) and the decontextualized meaning-related language. Moreover, she translates *within* the meaning-related language for expressing the specific character of the whole, before translating to contextual language ("the whole is the subgroup of the complete, out of the complete persons asked", Turn 29b: VM − ML − ML − CL). In Turn 29c, she does not refer separately to the part, but addresses the part-whole-relationship in decontextualized meaning-related language and encircles simultaneously first the lower left rectangle then the left half of the area model. In this way, she explains the connection between the meaning-related language and the area model for the part-whole-relationship (Turn 29c: ML = VM).

For comparing Justyna's and Katja's pathways in the navigation space in Figure 5, the graphical summary makes visible typical phenomena that we could identify also in other cases:

- Both girls do not only switch unconsciously between representations, they connect representations by *translating* or *explaining* with high degree of consciousness.

- Both try to explain the compacted concepts such as “part-of-part-statement” by unfolding some inherent concept elements, part, whole, and part-whole-relationship, and connecting further representations as the visual model or meaning-related language. Whereas a translation can be conducted on each level of compaction, the explanation of connections between these representations always requires the unfolding into more refined concept elements (Renkl et al., 2013).
- Although Justyna works with part and whole separately, she does not have the language to articulate the mathematical structure behind it, so her explanations get stuck. The translations into contextual language alone is not sufficient for her to explain the connection.
- In contrast, Katja successfully unfolds the highly compacts situation types in the texts to the whole, the part, but also to the part-whole-relationship. When she explains the connection between representations, she uses structural decontextualized meaning-related language that allows her to explicitly articulate the structures and the part-whole-relationship that Justyna felt unable to express.

In this way, Katja masters better than Justyna to explicate the connection between these representations in more depth, and to go the way back upwards to the compacted concepts.

Discussion and Outlook.

In this paper, we brought together two theoretical perspectives formerly treated as separate, semiotic processes for dealing with multiple representations (Lesh, 1979; Ainsworth, 2006; Renkl. et al., 2013) and epistemic processes of compacting concepts in conceptual development (Aebli, 1981) or unfolding them back into its constituent concept elements. This act of networking perspectives allowed us to study how two girls deal with multiple representations for complicated concepts such as situation types of conditional or joint probability. When the students’ semiotic processes are disentangled with respect to the concept elements they refer to, we understand better how dealing with representations is connected to epistemic processes of compacting and unfolding concepts.

The qualitative analysis reveals that at the level of compacted concepts, it seems not possible to explain the connection in more depth beyond stating the correspondence of the compacted concepts. For being able to explain the connection more explicitly, the compacted concept must be unfolded into its concept elements, and multiple connections need to be explained, for the part, for the whole and the part-whole-relationship. In this way, the conceptual framework of the navigation space can provide an insightful tool to disentangle what exactly it means that the complex meanings of multiple representations must be negotiated in classrooms (Marshall et al., 2010). Although the vague idea of connecting representations is often mentioned in practical contexts, we will need much more investigations within our conceptual framework to disentangle the complexities of what this entails exactly (Post & Prediger, submitted).

So far, these first empirical findings have to be interpreted with respect to their methodological limitations. Specific limitations are (1) the small sample size, and (2) the restriction to one specific topic and one particular task. In future research, the investigations need to be extended to other tasks and topics to investigate in how far the identified intertwinement of semiotic and epistemic processes cuts across different mathematical topics.

Changes and rigors in systems of mathematical representations within gifted children's problem-solving process

Sebastian Schorcht

Technische Universität Dresden, Germany; sebastian.schorcht@tu-dresden.de

The paper shows how two gifted primary school children use rules of an individual system of mathematical representations during a problem-solving task. From a research perspective, transformations within and between various representations lead to new mathematical insights and is fundamental for mathematical experiences. But which processes of using mathematical representations do primary school children go through within problem-solving? What happens descriptively before a new mathematical insight in context of representations? For this purpose, two children (3rd grade, 9 years old) were confronted with a mathematical problem-solving task. The case of Fred and Mark shows how they develop the means of representation themselves before a new mathematical insight.

Keywords: Representation, problem solving, gifted, enrichment.

Theoretical Framework

Within a semiotic-pragmatic approach to explaining how mathematicians get new insights, Hoffmann (2005, p. 149; Translation by Schorcht) describes the interplay between representations and representational changes:

> Playing with representations and their [...] transformations are essential to make those associations possible, that we need in order to be able to tap into ideas and conjectures for possible solutions […].

In this quote, he describes how transformations of mathematical representations lead to associations, which in turn allow mathematical insights. Transformations of representations seem to be necessary for mathematical insights. Accordingly, successful problem-solving depends on the ability to transform between representations flexibly. These transformations are one characteristic skill of mathematical gifted children (Käpnick, 1998; Benölken, 2015; Assmus & Fritzlar 2018), who are mostly successful in problem-solving. In order to observe mathematical problem-solving with respect to transformations of representations, the analysis of the problem-solving behavior of mathematically gifted students is particularly suitable. Since this transformation performance is an attribute of mathematical giftedness, transformation processes should be well analyzable in a setting with mathematically gifted children. The resulting choices for the setting are discussed in more detail in the section Methods.

Transformations within or between modes of external representations are grounded on Bruner's (1966) model of different representations of knowledge, which is mostly extended by different researchers (Lesh, Post, & Behr, 1987; Prediger & Wessel, 2011). For the analysis, the semiotic-pragmatic approach will be used, to understand the interplay between these "modes" of representations and new mathematical insights. Representations will be understood as diagrams in the sense of Dörfler (2014, p. 5; Translation by Schorcht): Diagrams contains "inscriptions with a well-defined structure, specified by relationships between parts […], together with rules for reshaping, transforming […] etc." Dörfler understands inscriptions primarily as signs without a visible relation or system of representation. Decompositions and transformations will be possible, if rules of representation are included. Relationships between parts of inscriptions can be transformed, including reference to a rule of the used system of representation.

Dörfler (2014), referring back to Peirce (1976), embeds the actions on diagrams in *diagrammatic reasoning*. Diagrammatic reasoning involves the construction of diagrams: the *creation of a rule-based set of related inscriptions*. Diagrammatic reasoning also involves *performing experiments on the diagrams*: this means transformations, compositions, combinations or decompositions, such as adding, removing or restructuring representations. According to Dörfler (2014), and in special degree also Hoffmann (2004), *observing and recording the experimental results* is a necessary part of diagrammatic reasoning:

> It is not sufficient, thus, that we perform our experiments with diagrams quasi blindly, like a machine. Although a computer might perform experiments quite better than human beings, the essential point of realizing the limits of a selected representational system is self-reflection: *observing what we are doing* when performing an experiment. (Hoffmann, 2004, p. 301; Italic by Hoffmann)

Transformations of representations, such as reshaping, compositions and decompositions of diagrams within certain rules in a system of representation, enable associations that lead to mathematical insights. Through these transformations of representations, new insights become associable for mathematicians by self-reflection on the process. Hoffmann (2004) assumes two possible ways to evolve the diagrammatic reasoning within a certain problem:

> The interesting point, now, is the question *how to get something new* from observing the outcome of diagrammatization. I want to distinguish two possibilities. On the one hand, there is the process of uncovering new *implications* of constructions within a *given* system of representation, and on the other hand, there is the process of *developing the means of representation themselves*. (Hoffmann, 2004, p. 299; Italic by Hoffmann)

In focus on learning mathematics the following research question emerges:

(1) Which processes of self-reflection on diagrammatizations of representations do primary school children use within problem-solving from the first inscription to a subjectively identified mathematical solution?

The paper will briefly show an outline on this research question. In the following, the methodological conditions are clarified and categories for a qualitative content analysis (Mayring, 2008) are deductively determined from the theory just described.

Methods

The survey is affiliated to the project "Mathe für Cracks" (Math for cracks) at Justus-Liebig-University Giessen. The project is an enrichment program for students (3rd to 8th grade; 8 to 14 years old), who are particularly interested in mathematics. Most participants are tested for giftedness while the program accepts children whose interest is mathematics as well. This is due to the origin of the participants, who come through the "Deutsche Gesellschaft für das hochbegabte Kind" (German Society for the Highly Gifted Child) and partly also from "Mensa". For membership in "Mensa" association, the children must be tested. Insights into these test results or the procedure of the tests do not take place for data protection reasons. All participants must present a teacher recommendation in order to participate in the course. Consequently, these are particularly high-achieving students, some of whom have also been tested through their own membership of clubs. In cooperation with "Deutsche Gesellschaft für das hochbegabte Kind" (German Society for the Highly Gifted Child), Mathematikum Giessen and Mathematik-Zentrum Wetzlar, the program provides 40 places for primary school children (8 to 11 years old) and 50 places for secondary school children (10 to 14 years old). "Mathe für Cracks" cooperates with one third of primary and secondary schools in Hesse (State of Germany). Since studies with mathematically gifted children, such as Käpnick (1998) or Assmus and Fritzlar (2018), show that the changes in representation is a characteristic of mathematical giftedness, the framework "Mathe für Cracks" is particularly suitable for recording transformations of representations before new mathematical insights.

The pilot study contains video recordings from 13 interviews with 18 children: 8 children worked individually and 10 children worked together in sets of two. Working on problems alone resulted in not externalizing internal processes or interpretations. Only in collaboration and communication with others did internal processes become visible. Therefore, the setting was adapted in the last 5 interviews. The children operate in these last 5 interviews together with their pencil on one given paper. This was intended to increase the collaboration rate between the two children. 9 settings took place with an accompanying interviewer (7 single interviews and 2 group interview), while 4 settings were only provided with an introductory interviewer (1 single interview and 3 group interview). The setting was changed during the pilot study because the interviewers had too much influence on the students' solving behavior. The children tried to guess a solution via gestures of affirmation instead of solving the problem through mathematical reasoning. For this reason, an accompanying interviewer was not used in the final 4 interviews with 7 children. As Goos and Galbraith (1996) also discussed, working in teams is best suited to avoid influences of the interviewing environment and incomplete and inconsistent verbalizations. For this reason, thinking aloud, interrupting interview questions, or retrospective questions were neglected during the last interviews in the pilot study. One geometric (5 interviews) and one number theory problem-solving task (8 interviews) were provided to the participants. The paper will be focused on the following number theory task:

> A palindrome number can be read forwards and backwards. For example, 1221 and 808 are palindrome numbers. Neighbor palindrome numbers are located next to each other on the number line (for example 121 and 131). Which differences are possible between two neighbor palindrome numbers?

As shown in the student's solution at Figure 1, one good idea to solve this problem is to write down some palindrome numbers in order. By arranging neighbor palindrome numbers, the difference between the numbers can be found. In 6 pupils' solutions are lists of the possible differences as well (circled numbers in Figure 1). These knowledge stores are results of experiments on diagrams.

Distances between two neighbor palindrome numbers are 2, all powers of ten and all powers of ten multiplied by 11.

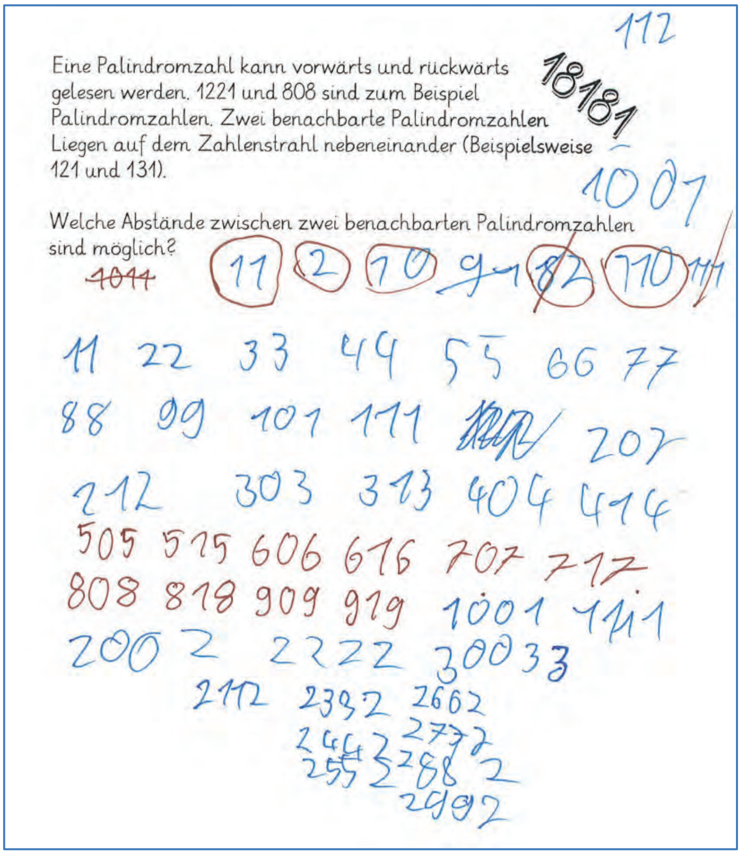

Figure 1: Given task and solution by Fred and Mark (9 years old).

Beside these products of diagramatization, there are transcripts of video recordings. These transcripts were analyzed by qualitative content analysis (Mayring, 2008) with coding categories developed deductively. The coding category *diagrammatization* contains four subcategories:

- *constructing an icon or a diagram*,
- *experimenting upon this icon or diagram*,
- *observing the result of experiments* and
- *determining in general formulae*.

If the children start to use the pencil to make a drawing, this section was coded with *constructing an icon or a diagram*. If the relations were transformed in a new representation, it is an *experimenting upon this icon or diagram*. After an experiment, the *observing the result of experiments* could be identified verbally. *Determining in general formulae* is coded if the results of the experiments for all examples are verified.

The coding category *new mathematical insights* contains two subcategories:

- *uncovering new implications of constructions within a given system*,
- *developing the means of representation themselves.*

Uncovering new implications of constructions within a given system was encoded when students followed the given rules within an experiment or transformation, naming relations that were not included in the previous representation. *Developing the means of representation themselves* was coded when students changed the meaning of the representation by adapting new rules.

In the following, the case study of Fred and Mark is analyzed in order to show the self-reflection process during problem solving and before a new mathematical insight (in the sense of Hoffmann).

Analysis

Mark and Fred (9 years old), who face the palindrome number task, *construct a diagram* by noting the palindrome numbers from 11 to 111. They use representations such as 112 to communicate and negotiate the rules of their own system of representation. They *experiment with the diagram* to identify differences and *observe the results of experiments* by circling the differences. In the following, they note the palindrome numbers from 202 to 919, but only those with 0 and 1 in the hundreds place. After that, 1001 and 1111 follow. By *uncovering new implications of constructions within a given system*, they correctly note all palindrome numbers between 2002 and 3003 (Figure 1). In the following, two moments will be considered in more detail: First, at the moment of establishing a rule to create the diagram, and second at the moment of a new mathematical insight:

In the first case, Mark and Fred are into the process of diagrammatic reasoning. They design a list with all palindrome numbers. To do this, they start at 11 and continue through two-digit multiples of 11 until they reach 101 and 111. From this moment on (line B039 in the transcript below), they discuss different ways of continuing the sequence to satisfy the rule "A palindrome number can be read forwards and backwards" within the given system of natural numbers. Among the numbers discussed are 112, 122 and 220 but these are not included in the list of palindrome numbers (B039 to B053 and B058). Fred and Mark *develop the means of representation themselves.* The rule for construction of palindrome numbers is extended to the rule "same digit in the hundreds place value and ones place value". They construct 202, 212 (B054, B059 to B061):

B039	Fred:	No hundred and twelve is not
B040	Mark:	But there is the one twice
B041	Fred:	Yes, but that means nothing. Look! <<writes separately on the sheet 112>> One, one, two - read backward would be two hundred and eleven
B042	Mark:	True!
B043	Fred:	and that's another one and then the next one is one hundred [twen]-two
B044	Mark:	[twen]
B045	Fred:	Yes, one hundred twenty-two.
B046	Mark:	Noo!
B047	Fred:	Or, yes, yes, yes! Um, because the rest doesn't work.
B048	Teacher:	<<leaves his place>>
B049	Fred:	One hundred and twenty-two <<writes 122>>
B050	Mark:	Yes, but then we now have two hundred, um
B051	Fred:	uhhh, true true true

B052	Mark:	[two hundred and twenty-one] read backwards
B053	Fred:	Oh yes! <<crosses out 122>>
B054	Mark:	So, it does not work. Now it's two hundred and two.
B055	Fred:	Yes, so um
B056	Mark:	Now two hundred and two comes here. <<taps his pencil to the right of the crossed-out 122>>
B057	Fred:	But two hundred, uh, right, the rest does not work. <<writes 202>>
B058	Mark:	Exactly, and then two hundred and twenty.
B059	Fred:	Two hundred and twelve.
B060	Mark:	Right, two hundred and twelve is correct.
B061	Fred:	<<writes 212>> and then three[hundred and three].
B062	Mark:	[hundred and THREE]! <<nods once>>
B063	Fred:	<<writes 303>>
B064	Mark:	We've got it now, right?

Constructing 303 after 212 suggests another rule that both share nonverbally but consensually (B062 to B064). In the following Fred and Mark construct only palindromes with 0 or 1 in the tens place value. An uncommunicated rule might be: "There is 0 or 1 between the largest and smallest place value". Consequently, the digits of the hundreds place value and ones place value are increased by one in the following and noted with 0 or 1 at the tens place value. Fred and Mark construct 313, 404, 414, 505 to 919. Following the rule, that the first and last digit of the number must have the same digit, they construct 1001 and 1111. After Fred notes 2002 and 2222, he compares the representation of four-digit numbers with that of three-digit numbers and stops the further construction of palindrome numbers (B154 to B160). In doing so, he makes a new mathematical insight and disproves the previously nonverbal rule (B162). Digits other than 0 and 1 can be entered in the middle place value. This considerably expands the representation of the palindrome number list. He is *uncovering new implications of constructions within a given system*:

B154	Fred:	Has actually only one zero more than here the two numbers <<points with the pen to 202 and 212>>. Wait, thousand one hundred, there is still one, we can best <<writes 2112>>, ehm, let's note it down according to the size. Here <<points with the pen to 1001 and 1111>> there is also another one (unintelligible), it doesn't work here!
B155	Mark:	<<looks at the task sheet>> (mumbles unintelligibly)
B156	Fred:	Wait! <<points with the pen to the lowest written line>>
B157	Mark:	Truue, true.
B158	Fred:	Paliadrome, <<shakes head>> ahh, no idea. So, it must be <<writes 3003>> three thousand three <<writes 3 and traces the number several times>>.
B159	Mark:	Three thousand three.
B160	Fred:	Hm, moment, I just thought about it for a moment. Then three thousand, there's that possibility again. Three
B161	Teacher:	Can I see what you're doing?
B162	Fred:	Ahh so, here there are still more possibilities <<points with the pen at 2222>>. The whole like here, the whole can make nevertheless also still with the three. There are still thousands

> of possibilities. But we can simply leave that in the small, because that is still the same distances. <<looks at the task sheet>> Namely one hundred and eleven, <<points with the pencil to 2112>> here, these are always, so these are one hundred and eleven again, I'll write under here again briefly the others that work <<writes 2332, 2442, 2552, 2662, 2772, 2882 and 2992>>.

Discussion

Which processes of self-reflection on diagrammatizations of external representations do Fred and Mark use within their problem-solving process? Mathematical insights become possible for them by developing rules within their given system. Palindrome numbers consist of digits whose value is equal in power at the largest and smallest place value, at the second largest and second smallest place value, at the third largest and third smallest place value, and so on. The relation between the digits of a palindrome number Fred and Mark try to capture in a diagram. To do this, they discuss rules for constructing their diagram, which lines up palindrome numbers ordinally. To begin, they start with 11 and correctly continue the series of palindrome numbers to 111. Fred then constructs the number 112 in line B041 to see if it can be read forward and backward. In addressing the construction of the diagram, they also test 122 (B049). 220 is checked mentally (B056). Both develop the means of representation themselves by establishing the rules for constructing their diagram. However, setting the rule "There is 0 or 1 between the largest and smallest place value" to construct the diagram is no longer viable for the task after a certain moment. By the unspoken rule, Fred constructs 1001, 1111, and 2002. He also constructs 2222. Then, in conversation, Fred reflects on his construction by comparing the four-digit numbers 2002 and 2222 with the already constructed three-digit numbers 202 and 212 (B154 to B160). This self-reflection leads to a change in the rule of their representation system. Fred discovers that between 2002 and 2222 the palindrome number 2112 can be formed. In self-reflection, Fred uncovers new implications of constructions within their system. He changes his own rule for constructing the diagram and independently forms a new rule. With this rule he can form new palindrome numbers and thus correctly notates all palindromes between 2002 and 3003.

Conclusions

This one example shows that Hoffmann's idea of self-reflection processes for constructing one's own diagrams for new mathematical insights are also relevant for children. In this case study, one can see particularly well how the self-reflection of the construction of the diagram leads to new mathematical insights. Continuing the diagram of 1001 and 1111 with 2002 and 2222, both children see a new relation that was not visible before. In the comparison of the four-digit numbers, with the three-digit numbers 202 and 212, Fred can uncover a new implication via self-reflection. Both change the set of rules for creating the palindrome list. The question now arises whether this development of rules is typical for new mathematical insights? Do the new insights always manifest themselves in this way in children's problem-solving processes? How can children be encouraged to develop their rules? Is there a way to descriptively capture the timing of children's mathematical insights? Further work on this topic will follow.

Students’ Perception of Change in Graphs: An Eye-tracking Study

Aylin Thomaneck[1], Maike Vollstedt[1] and Maike Schindler[2]

[1]University of Bremen, Germany, thomaneck@uni-bremen.de, vollstedt@math.uni-bremen.de

[2]University of Cologne, Germany, maike.schindler@uni-koeln.de

Changes and dependencies of two different quantities are characteristics of functional relationships, which are often visualized in graphs. Hence, for graph interpretation it is necessary to perceive and interpret change. This paper focuses on how students perceive change in graphs. Since eye tracking is a promising research tool to approach thinking processes, we conducted an exploratory case study with two participants: We used eye tracking and stimulated recall interviews to examine this method’s potential for studying individual processes in perceiving change in graphs. From the observed eye movements and given interpretations, we were able to illustrate that students’ individual approaches in perceiving change in graphs can be related to different levels of covariational reasoning.

Keywords: Eye tracking, eye movements, functions, graphs, covariational reasoning.

Introduction.

Graphs, which are one of the external representations of functions, are pervasive in our lives and therefore also an important topic for mathematics education since they represent functional contexts (Friel et al., 2001). However, the meaning of a graph is not immediately apparent (e.g., Freedman & Shah, 2002). To understand data, represented in graphs, it is important to be able to interpret graphs and especially to perceive the relationship between the values of two quantities.

Some studies have already been conducted on how students reason when working with two different quantities, focusing on how they change in relation to one another. Research focuses, for instance, on different kinds of covariational reasoning (Johnson, 2015). Yet, how students proceed when interpreting empirical graphs and their change is investigated only to a limited extent. Knowledge on this can help to improve the learning and teaching of graph interpretation and in particular of covariational reasoning. To shed light on graph interpretation processes, eye tracking (ET) appears to be a promising research tool. Since ET has—to the best of our knowledge—not yet been used to study students’ empirical graph interpretation, we first want to investigate the method’s potential itself: whether it is possible to draw conclusions from eye movements of students interpreting graphs and to infer students’ approaches of perceiving change in graphs. We first ask a methodological research question RQ1: *Is it possible to infer students’ perception of change in graphs from their eye movements and given interpretations?* If it turns out that such inferences are possible, it is of interest to approach the empirical research question RQ2: *What approaches do the participants use when perceiving change in graphs and what levels of covariational reasoning does this reveal?*

Theoretical Framework.

Graph interpretation and covariational thinking in mathematics education.

Graphs play an important role in everyday life, as they are used, for example, in order to visualize the development of stock market prices, temperature curves, or training processes. Due to this high applicability for real-world phenomena, and because graphs represent also inner-mathematical functional relationships suitably, graphs are central contents in mathematics education. Graphs do not reveal their meaning immediately, which is a general characteristic of mathematical objects, as Duval (2006) describes:

> Mathematical objects, in contrast to phenomena of astronomy, physics, chemistry, biology, etc., are never accessible by perception or by instruments (microscopes, telescopes, measurement apparatus). The only way to have access to them and deal with them is using signs and semiotic representations. (p. 107)

Data visualized in graphs must be understood by inferring their interrelationships, their background, and meaning. To meet these demands, it is crucial for pupils "to identify certain types of changes and dependencies, which are part of common events in the real world, as well as to become familiar with their representations" (Eisenmann, 2009, pp. 73–74). Numerous studies revealed that students may have difficulties dealing with representations of functions and that certain types of errors are common due to a lack of covariation understanding (e.g., iconic interpretations, interval/point confusion, slope/height confusion) (Leinhardt et al., 1990). Working with functions requires dealing with two different quantities, focusing on how these quantities change in relation to one another. Thompson and Carlson (2017) emphasize that students' need to develop an appropriate idea of the relationship between values of two quantities in their work with functions. They argue that "variational and covariational reasoning are fundamental to students' mathematical development" (p. 423). Since the graphs used in our study always consider changes in two quantities (time/distance covered and velocity, or time and filling level), we restrict ourselves to covariational reasoning in this paper. Thompson and Carlson (2017) distinguish six major levels of covariational reasoning, which show a continuum of students' conceptions of covariation: *no coordination, precoordination of values, gross coordination of values, coordination of values, chunky continuous covariation, smooth continuous covariation* (p. 441). The first four levels can be considered as preliminary stages of conceptualizing covariation. Students whose covariational reasoning can be classified in the two highest levels perceive actual covariation, as only then the change in one quantity affects changes in the other quantity. Therefore, our study focuses on chunky and smooth continuous covariation, since we intend to describe students' covariational reasoning when describing change in empirical graphs. In general, *continuous covariation* involves the perception of change in one variable simultaneously with changes in another variable. More specifically, in a *chunky* continuous covariation, the changes are perceived in intervals with a fixed, but not necessarily the same, size. The focus is on the values *at the end* of each interval and how they change as compared to the end of the following interval. In contrast, in a *smooth* continuous covariation the change is perceived as increasing or decreasing. The focus is on how the values change *within* an interval.

Some studies have already investigated how changes and covariation in functions are identified and understood (e.g., Johnson, 2015). Yet, it has hardly been explored how change is perceived in the interpretation of graphs and in how far covariational reasoning is involved. These processes of interpreting graphs and perceiving change within them are complex and may differ between individuals, so that ET appears to be a promising method to investigate these processes on a micro-level. We believe that with the help of eye movements, cognitive processes in the interpretation of graphs and in particular the perception of change in graphs as well as students' approaches and use of covariational reasoning may be inferred: This is why we investigate the use of ET and its potential for this purpose in this paper.

Eye tracking in mathematics education research.

ET describes the capturing of person's eye movements, which can be visualized in a video of participants' field of view, with a wandering dot indicating the gaze. Studies on eye movements have considerably increased over the last years (König et al., 2016). In a mental-oriented view of ET, which we also adopt for our study, ET studies are used to infer cognitive processes from eye movements, i.e., "to use eye movements as a window to cognition" (König et al., 2016, p. 2). The prerequisite for this is the eye mind hypothesis (EMH). The EMH presumes a close relationship between what persons fixate on and what they process (Schindler & Lilienthal, 2019). However, it has been revealed that this assumption cannot easily be taken for granted in mathematics education. For example, Schindler and Lilienthal (2019) found that there are instances in which eye movements cannot easily be mapped to cognitive processes and that even if this is possible, the interpretation of eye movements is often ambiguous. Therefore, they call for domain-specific theories for the interpretation of eye movements. One domain in which ET has rarely been used is graph interpretation. Nevertheless, ET seems to be beneficial for studying students' graph interpretation: Strohmaier et al. (2020) emphasize that ET lends itself to the use of visualizations of mathematical objects since the work with visualizations requires persons to process visualized information with multiple gazes. To investigate the potential of ET for the analysis of graph interpretation processes, we conducted the study that is presented in this paper: It explores the potential of ET for analyzing graph interpretation and perception of change in particular. In addition, we will empirically focus on how change in graphs is perceived by students and on if and how eye movements can be used to infer students' covariational reasoning.

Method.

Sample, task design, and setting.

In our exploratory study, we analyzed eye movements of two university students during graph interpretation tasks, who volunteered to be participants for our study. They were told that they will participate in a study on functions at secondary level. The participants, Gerrit (age 21; engineering and management student with a focus on production engineering; high affinity for mathematics) and Elias (age 28; a teacher student for German and history; low affinity for mathematics) were selected because they have different profiles in terms of their professional background and mathematics affinity. Further, they were not familiar with empirical graphs so that they might show interesting approaches to interpret them. In addition, being university students, they could probably express rich information about their cognitive processes in the interviews.

This paper presents an excerpt from a larger study that examined participants' eye movements while interpreting graphs in different situational contexts (see Figure 1 for two examples) as inspired by the Shell Centre for Mathematical Education (1985)). Each unit consisted of five analogous tasks with different demands. The focus in this paper is on the first task, which asked the students to describe the change in the graph (see Figure 1). The tasks were presented on a screen. There was no time restriction for working on the tasks. The study took place in a quiet room with the participant and the first author of the paper administrating the tasks. The participants sat on a firm chair in front of a table where the monitor was located. Before the questions and the graph were presented, the students were familiarized with the situational context and the graph by presenting them with a digital task sheet on the monitor showing the graph and an introductory text about the situational context.

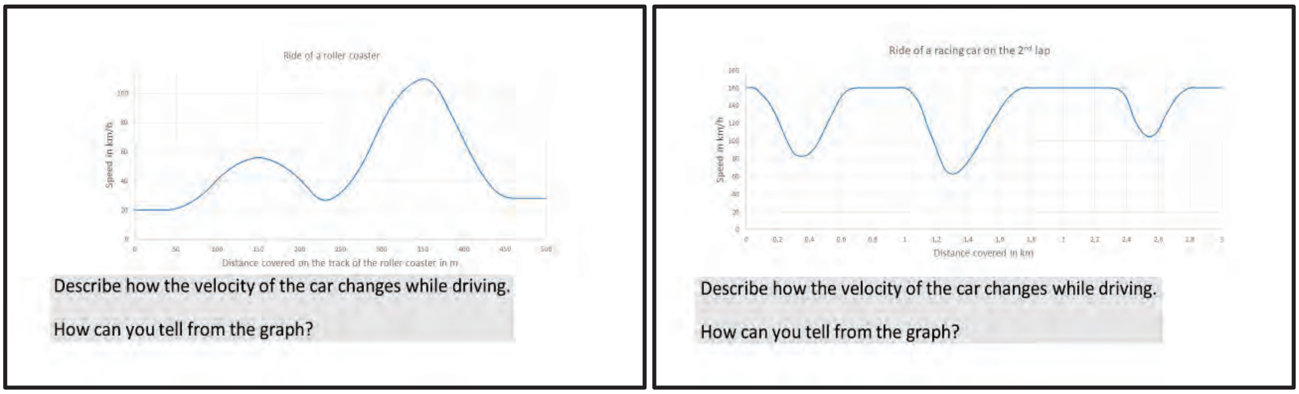

Figure 1: Examples of Task 1 (translated to English)

Eye tracker and ET data.

For data collection we used a wearable eye tracker: Tobii Pro Glasses 2 (50 Hz, binocular, infrared, 45 g, built-in microphone). The tasks were presented on a 24" screen (60 Hz, viewing distance: 60 cm). First, a single-point calibration procedure was performed. Under ideal conditions, gaze estimation is 0.62° (Tobii Pro, 2017). In our study, the accuracy was 1.1° on average, which corresponds to 1.15 cm in the screen. This inaccuracy was taken into account in the task design and data interpretation. Before solving the tasks, Gerrit and Elias passed an additional 9-point calibration verification so that we could later check the measurement's accuracy. Since we wanted to study students' interpretation process and especially their perception of the change in graphs, we considered all eye movements relevant and decided to analyze raw data (Holmqvist & Andersson, 2017), i.e., eye movements as displayed in gaze-overlaid videos.

Stimulated recall interview based on gaze-overlaid video.

In our study, we combined ET with stimulated recall interviews (SRIs) using gaze-overlaid videos, similar to Schindler and Lilienthal (2019) since ET has not been used so far to investigate student's perception of change and therefore it is still unclear how to interpret the eye movements in this context. Stimulated recall is a technique that "gives participants a chance to view themselves in action as a means to help them recall their thoughts of events as they occurred" (Nguyen et al., 2013, p. 2). We used gaze-overlaid videos as stimulus in our study, in which the participants can watch their eye movements as a wandering dot. They were supplemented with students' utterances during task processing. Gaze-overlaid videos represent a strong stimulus because they make eye movements visible, which are usually not conscious (Stickler & Shi, 2017). Thus, it is particularly important to keep the time span between the ET recordings and the SRI short. We therefore conducted the interviews directly, after only a short break for data transfer, so we can assume that they were still very much aware of their thoughts, which were then additionally recalled by the strong stimulus of visible eye movements as trigger. The participants had the possibility to stop the video themselves to explain their thoughts. In addition, the interviewer was able to pause the video and to invite the participants to express their thoughts. The participants wore ET glasses even during the SRI. Here we made use of the scene camera and the built-in microphone of the eye tracker to record the verbal utterances and gestures. This procedure was explained to the participants before data collection.

Data analysis.

To prepare the data analysis, the students' utterances while working on and answering the tasks were transcribed together with a description of the eye movements taking place during this process. In addition, the utterances of the interviewer and the interviewees in the SRI were transcribed. These elements were arranged in one document in neighboring columns to make visible what happened simultaneously and what the SRI refers to. Data analysis followed Schindler and Lilienthal (2019) since this approach is particularly suitable for domains in which ET has rarely been used before and where it is not yet clear how eye movements can be interpreted: The steps of qualitative content analysis (Mayring, 2014) were applied and—due to the explorative and descriptive nature of the research questions—categories were developed inductively. We distinguished between gaze categories that describe gaze patterns and interpretation categories that describe the cognitive processes associated with the respective gazes. Eye movements and cognitive processes, as described by the students in the SRIs, were then mapped for all data.

Results and Discussion.

Research Question 1: Feasibility of inferring students' perception of change in graphs.

Our methodological research question (RQ1) asked whether it is possible to infer students' perception of change in graphs from their eye movements. Results indicate that the participants were able to explain their eye movements in the SRI. Their utterances gave information about their cognitive processes while interpreting graphs and perceiving the change within them. This is the prerequisite, since we have as a basis only utterances and interpretations of the participants' eye movements. We cannot observe the cognitive processes directly, but can only get closer with the help of the participants' eye movements and interpretations. However, like Schindler and Lilienthal (2019) we found that a certain eye movement pattern could not always be clearly assigned to one cognitive process (see Table 1).

Nevertheless, conclusions about approaches can be drawn based on the eye movements that the participants used when perceiving change and interpreted in the SRI. For instance, we were able to observe certain eye movement patterns, consisting of different gazes, that were interpreted by the participants (e.g., following the course of the graph, jumping between a point on one axis and a point on the graph, looking on several different points on the graph in succession). These eye movements were used to perceive the change in the graphs to eventually be able to describe it in order to answer the task. The participants referred to these gaze sequences, which differed between them, in the SRI. Using this information, we were able to infer approaches when perceiving change in graphs.

Eye movement pattern (identified in the gaze-overlaid video)	Cognitive process (described by the student in the SRI)
The gaze follows the course of the graph	Grasp the graph (e.g., the course or properties) Grasp the situational context (e.g., thinking about driving curves with a racing car)
Fixations on turning points of graphs	Focus on prominent parts of the graph (e.g., turning points) Grasp the graph (e.g., the course or properties)

Table 1: Exemplary eye movements from task 1 and students' interpretation

Research Question 2: Students' perception of change and covariational reasoning

Our empirical research question (RQ2) addressed the approaches the participants use when perceiving change in graphs and whether levels of covariational reasoning can be revealed from this. As mentioned above, we were able to observe differences regarding the occurring eye movements between the two participants. Elias followed the course of the graph or a graph section with his gaze particularly often. Afterwards, he interpreted this mostly as trying to grasp the situational context and sometimes the graph (e.g., course or properties). Moreover, he often looked at several different points on the graph in succession. He explained that this eye movement pattern served the same intention (grasping the situational context or graph). Also, Elias used gestures to support his gaze, for example by following a section of the graph with his finger. This was never the case for Gerrit, who also used other eye movements particularly frequently. His gaze often jumped between a point on one of the axes and a point on the graph. He explained that he was reading a particular point or value from the graph. Sometimes he added that he used this to grasp the graph. In addition, he often looked at turning points of the graph. He interpreted this in the SRI as focusing on prominent parts of the graphs. These results indicate that Elias perceived the change in the graphs by looking at the graph and following it with his gaze and, in some instances, his fingers, or by making sense of it by looking at several different points. He explained the change of velocity of a racing car in a car race as follows.

Elias: The car starts. Probably, most likely enters a curve, therefore drives slower here, then comes out of the curve, drives faster again, drives a straight stretch, then drives a steep curve, so narrow, must brake very hard in any case. Then drives relatively quickly out of the curve again, then again a long stretch and then again a small curve. [utterance translated from German to English by first author]

It is clear from the utterance that he focuses on the change of velocity within the intervals, i.e. increasing or decreasing. This is characteristic for smooth continuous covariational reasoning.

Gerrit's perception of change was apparently different. He also said several times that he focused on prominent parts and read values there:

Gerrit: Ehm, so first the velocity decreases to 0.35 km. Then it increases again to the original 160 km/h from 600 m to 1 km. Then it drops again to about 60 km/h. And then increases again to 160 km/h after 1.3 kilometers. From 1.8 km to 2.3 km keeps that, eh the car its velocity. And then drops again to 105 km/h approximately at 2.5 km/h and then rises again to its original 160 km/h until 2.8 km and then keeps that until 3 km. [utterance translated from German to English by first author]

In this utterance, Gerrit defined intervals and read off a value for each endpoint of an interval in order to describe the change of velocity, what is typical for chunky continuous covariational reasoning. Yet, he did not disregard the change of the graph between two of such points: He described whether the graph increased, decreased, or was constant in the respective interval. This hints—at least to a certain extent—also at smooth covariational reasoning.

Discussion and outlook.

In this paper, we have illustrated that it is possible to interpret students' eye movements when interpreting graphs in order to obtain information about their perception of change in graphs. Our tentative results indicate that ET in combination with SRI seems to be a suitable method for studying the perception of graphs. In addition, we were able to infer different approaches regarding the perception of change and different levels of covariational reasoning for Elias and Gerrit. Our results provide evidence that certain eye movement patterns are typical of certain levels of covariational reasoning. For future research, it would be of interest, for instance, whether the relations found between Elias and Gerrit's gaze patterns and approaches can also be found for other individuals. Moreover, we only focused on smooth and chunky covariational reasoning, i.e. the two highest levels of covariational reasoning according to Thompson and Carlson (2017). Thus, it might be valuable to test and further sharpen the insights from this exploratory paper on a larger data set, and with middle school students to maybe find different approaches in interpreting the change in graphs and related levels of covariational reasoning and its preliminary stages. Besides, it should be examined what implications arise from our initial result. Elias, whose approach can be related to smooth covariational reasoning, for example, often referred to the situational contexts and related the change of velocity directly to the circumstances of the situational context (by saying that the car is driving a curve and therefore brakes, etc.). Whether there is a direct connection between the kind of covariational reasoning and the extent to which the situational context is referred to and how this affects the further interpretation of the graph remains to be studied. Even though our case study provided only a glimpse on these aspects, we think that it may be a first step towards investigating students' interpretation of graphs and in particular their perception of change in graphs using eye tracking.

Teachers’ practice and pupils’ representations in a Grade 3 class

Isabel Velez[1], Maria de Lurdes Serrazina [2] and João Pedro da Ponte [3]

[1] Instituto de Educação, Universidade de Lisboa, Lisboa, Portugal; velez@campus.ul.pt

[2]Escola Superior de Educação de Lisboa, Lisboa, Portugal; lurdess@eselx.ipl.pt

[3] Instituto de Educação, Universidade de Lisboa, Lisboa, Portugal; jpponte@ie.ulisboa.pt

In this paper we analyze a grade 3 teacher’s practice and how it relates with his pupils’ representations. We focus on teacher-pupils interaction in the classroom while pupils are solving a problem. We aim to understand how the teacher manages his pupils’ use and interpretation of representations. Data were collected through video and audio recording of lessons and later analyzed through content analysis. The results show that the teacher’s representations, actions and questioning types change according to the pupils’ activity and difficulties and that the whole class discussion is the teacher’s preferable moment for a more dynamic change of actions and questioning. That way, to promote his pupils’ use and understanding of representations, the teacher adapts his representations, actions and questioning types.

Keywords: Representations, elementary school teachers, teaching practices, teachers’ actions, questioning.

Introduction

A representation is a mental or physical construct that describes the characteristics of a concept and its relationships with other concepts (Tripathi, 2008). The way teachers deal with representations in their practice has a great influence in how pupils use and understand them (Stylianou, 2010). It is widely acknowledged that teachers must use different kinds of mathematical representation to promote pupils’ understanding of representations (NCTM, 2007; Tripathi, 2008). However, representations are connected to each other in different ways and that can promote several difficulties in the process of pupils’ understanding and learning of representations (Goldin, 2008). Knowing how teachers may use different representations is important to know if that is the source of pupils’ difficulties. Our aim in this study is to understand how a grade 3 teacher explores a task with his class, focusing our analysis on the way he manages to promote the use and interpretation of representations.

Teachers’ practice and representations

Pupils’ activity on a task is determined by the way that teachers explore it in the classroom, specifically the role that teachers assume, their actions and the questions that they ask (Swan, 2007). For Boaler (2003), the process of describing and analysing the practices of teachers is very complex considering that they result from the influence of different aspects like teachers’ knowledge, beliefs and prior experiences. She also states that besides describing teacher practices it is important to know how they are doing these practices, what decisions are they taking and what influences them. Thus, in the classroom, it is important to analyse teachers’ actions and how they are questioning their pupils. In their perspective, McDonough and Clarke (2003) suggest that in the classroom teachers should: (i) talk clearly to their pupils; (ii) explore adequate and challenging tasks with more than one possible solution; (iii) promote the establishment of connections with pupils’ previous knowledge; and (iv) explore learning opportunities that emerge in the classroom. These authors also refer to the importance of using different teaching approaches, materials and representations. Blosser (1975) identifies four question types: (i) managerial, to give operating instructions; (ii) rhetorical, to emphasize an idea; (iii) closed, when there is a limited number of right answers; and (iv) open, when there are several possible answers. In a similar way, for Mason (2000), there are three different main aims in teachers' questioning: (i) focusing, when the teacher questions seek to help pupils focus in detail, using a funneling effect; (ii) testing, in which the teacher analyses the pupils' activity, namely their comprehension, how they articulate ideas and make connections among them; and (iii) inquiring, when the teacher questions the pupils to understand what they are thinking.

Vergnaud (1987) refers to representations as crucial elements for teaching and learning mathematics. Accordingly, NCTM (2007) refers to representations as essential elements in upholding pupils' understanding of mathematical concepts, in mathematical communication, in argumentation and in suiting mathematics into realistic problems situations. Simultaneously, many authors have been categorizing representations in different types. For example, Bruner (1999) indicates that representations may be active, iconic or symbolic, Thomas et al. (2002) refer to pictorial, iconic and notational, and, more recently, Loc and Phuong (2019) indicate visual, symbolic, verbal, contextual and physical representations. It is important to acknowledge that understanding representations is a complex process because a representation may have several meanings and a meaning may have different representations (Goldin, 2008). Concurrently, Duval (2006) refers that for understanding the features of a mathematical object, we need to know how to make changes within a representation (treatment) or to convert it into another representation (conversion).

In the classroom, the role of teacher is crucial in helping pupils to understand and to use this intricate web of representations. In the past years some researchers have been studying teachers' practice regarding mathematical representations. For example, Webb et al. (2008) not only categorize representations as formal, informal and preformal but they also provide suggestions to teachers regarding how to help their pupils in interpreting and using representations. In the pupils' learning process, teacher's representations also have their own role. Bishop and Goffree (1986) indicate that teachers must encourage the establishment of connections among representations while promoting their interpretation. Stylianou (2010) develops these ideas indicating that representations play a crucial part of teachers' explanations as they provide new concepts, drawings regarding problem-solving processes, and create connections among concepts. She also states that a teacher may bring in new representations, connecting them to pupils' previous knowledge and, by doing this, the teacher supports pupils' learning of concepts, procedures and problem solving processes.

Methods

This paper is drawn from larger research about elementary school teachers' practices regarding mathematical representations. During the study, a working group composed of four grade 3 teachers got together in pre and post lesson sessions to analyze their practices and their pupils' work. In this paper, we will only present and analyze the interaction of one of these teachers, Ricardo (teacher and pupil names are pseudonyms), with his pupils, during one lesson. He is a young grade 3 teacher, from a school in the surroundings of Lisbon (where he has been for the past 2 years, since he started to teach). He has twenty pupils (8 to 10 years old) and they have been working together since grade 2. The pupils are used to solving problems as the one reported in this paper. However, the teachers thought that the problem would be interesting to explore with their classes, given their pupils' needs and difficulties in problem solving and in working with whole numbers. That way, we will analyze Ricardo's practices while exploring the following task in his classroom: "*The third graders are planning a field trip. They rent four buses that are fully booked. Each bus has 24 pupils. Knowing that for each group of 10 pupils there must be one teacher, how many children and adults are going in this field trip?*".

Data was gathered by video and audio recording during class observations. Pupils' written work was also collected. Data was analyzed through content analysis (Fiorentini e Lorenzato, 2006), according to the three moments of the lesson indicated by Ponte (2005): (i) introduction of the task, where negotiation of meaning may take place (Bishop & Goffree, 1986); (ii) pupils' autonomous work, individually, in pairs or groups); and (iii) whole class discussion. From the categorizations of Bruner (1999) and Thomas, Mulligan and Goldin (2002) we categorized representations as: active (handling objects or materials), pictorial (drawings really close to context); (iii) iconic (informal symbols – like dots and arrows – diagrams or schemes using different types of representations); verbal (words); and symbolic (mathematical symbols). Based on the framework of Ponte and Quaresma (2016), we defined a new table of analysis (Table 1). Here, we categorize teachers' actions regarding how they promote the understanding of representations, and we relate their actions with their pupils' activity. We assume that it is underlined the mutual influence between the pupils' activity and the teacher's actions. That is, pupils' activity affects teachers' actions and, in turn, teachers' actions promote pupils' activity.

Pupils' activity regarding representations	Teachers' actions
Choosing/Designing	Promoting the free choice of a representation Challenging to choose a different representation Guiding about an adequate representation Providing explicit suggestions or examples
Using	Challenging to use a representation Asking to interpret a representation Guiding about the use or interpretation of a representation Informing pupils about how to interpret or how to use a representation (In)validating a representation chosen by pupils
Transforming	Challenging to establish treatments, conversions and connections Guiding to establish connections Guiding to identify possible treatments and conversions Inform about treatments and conversions
Reflecting	Challenging to systematizations Leading to systematizations Informing about systematizations

Table 1: Teachers' actions in different moments of the pupils' activity

In table 1 there are four categories for pupils' activity, related to teachers' actions: (i) support the pupils' design or selection of a representation; (ii) promote the use or/and interpretation of a representation; (iii) promote the transformation of representations; and (iv) promote pupils' reflection about representations.

Regarding teachers' questioning, based on the general frameworks indicated by Blosser (1975) and Mason (2000) we considered three different types of questions, with some subtypes (table 2).

Type	Subtype	Examples
Focusing	Rhetorical	We saw this already, didn't we?
	Processual	Could you open your books on page 58? What if we look back into the task?
	Orienting	What if you sum it all?
Confirmation	Closed	How many will we have if you add 10?
	Open	Can we solve it in another way?
Inquiring	Open	Do you agree with your colleagues' answer? Why?

Table 2: Different types of teachers' questions

As we move from Focusing to Inquiring, questioning the questions' subtypes become more demanding for pupils and teachers as they enable the possibility of having different answers, strategies and representations.

Results

Introduction of the task

Ricardo reads the statement of the task and his pupils begin a whole group discussion as they try to solve it by using verbal representations. As the discussion gets really confusing, the teacher chooses to help them by informing the class how to interpret the statement of the task. He focuses on data that he finds most relevant ("You must find two different things. How many pupils and how many teachers are there?").

Pupils' autonomous work

While the class is working individually and autonomously, Ricardo notices that some pupils do not understand the statement of the task and he chooses to discuss it again with his class. One of the pupils, Mateus, states that there are 96 pupils. The teacher questions him through closed confirmation questions (How do you know that there are 96 pupils?" and the pupil answers correctly ("That's because it's 24 times 4!"). Additionally, Ricardo brings another representation to the discussion as he converts Mateus' verbal representations into an active representation, by using his own fingers (Twenty-four in one [finger/bus], plus twenty-four in another, and another one, and another! It's 96, isn't it?"). Although Mateus can explain his answer, he is struggling to find the number of adults.

That seems to happen because he’s referring to a real-world situation, as they’re field trip usually has one adult per bus (“There are four adults because each bus takes one adult!”). However, Vanessa opposes him by recalling the statement of the problem (“No! Each group of TEN must have one responsible adult!”).

While the pupils keep trying to solve the problem by using oral verbal representation, Ricardo pressures them to use written representations. When Ana, another pupil, answers “I am solving it! I am thinking about it!”, Ricardo tells her “You are thinking (…) but I want you to explain it here [in your notebook]! I don’t want you to tell me… I want you to show me!”. In saying this, he is not being critical or restrictive about using a specific representation. Much on the contrary, he is trying to promote the use of different types of representation and, at the same time, he seeks that the pupils convert mental representations into written ones. As some pupils are still trying to understand the statement of the problem, Ricardo uses an iconic representation to inform them about its interpretation (Figure 1).

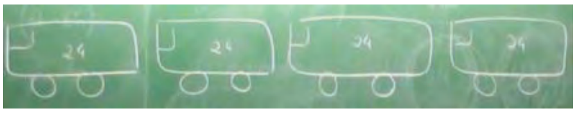

Figure 1: Iconic Representation (with pictorial and symbolic representations) used by the teacher

Whole group discussion

Ricardo transcribes to the board the iconic representation used by Jonas, another pupil, and he asks the pupil to explain it to his colleagues (Figure 2).

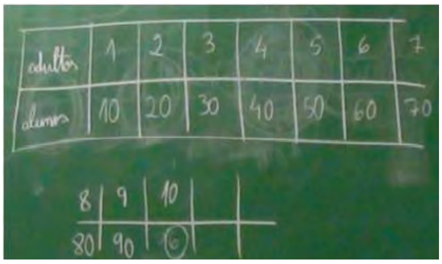

Figure 2: Iconic Representation (table with verbal and symbolic representations) used by Jonas and transcribed by the teacher

The teacher questions Jonas with rhetorical questions (“You did this, didn’t you?”, “For each group of ten pupils there is an adult, right?”), confirmation questions (“One adult… For how many pupils?”, “How did you fill this table?”). In this way, Ricardo almost completes the iconic representation, reaching the 90 pupils square. At this moment, there are six remaining pupils. At first, Ricardo decides to challenge his pupils to interpret Jonas’ representation, questioning them through inquiring questions (“Can I add one more adult?”, “Can we have ten adults?”). When he does this, he triggers a big discussion with two different opinions and several arguments. Most pupils agree that the right answer is nine adults while a few (like Jonas) argue that the right answer is ten adults. However, none of the pupils can give a proper explanation and Ricardo changes his actions and questioning type. This time, he gives some suggestions to interpret Jonas’ table through open confirmation questions (“What about the remaining six pupils? Are they staying at school?”) as he tries to relate to a real-world situation. Now, although pupils seem to notice that leaving behind six pupils it is not a fair thing to do, they still cannot justify the tenth adult. Once again, the teacher changes his actions and questioning type to help the pupils. On a third attempt, Ricardo informs the class about how they can interpret Jonas's table and he questions the pupils with rhetorical questions ("There must be one more adult, doesn't it?", "These six pupils are not going all by themselves, right?", "We need one more adult to go with them, OK?"). Despite Jonas's and Ricardo's explanations, some pupils are confused and they do not accept this solution because they have solved it in a different way. For those pupils the right answer is 96 pupils and 12 adults. Previously, during the teachers' working group session, teachers acknowledged that there could appear two different possible solutions (96 adults with 10 or 12 adults, depending on the assumption made about the requirement for adults accompanying children: is it in the buses or is it for the global group of children). As this task might have two different solutions, they thought that it would be the perfect opportunity to work this type of tasks with their classes. That way, Ricardo knows what is happening and he asks Mauro to present his solution to his colleagues (Figure 3).

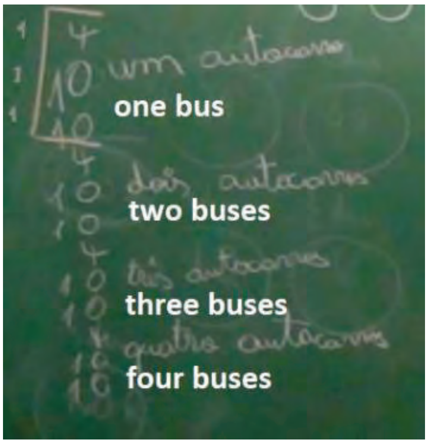

Figure 3: Iconic Representation (with verbal and symbolic representations) used by Mauro.

Mauro explains how he interpreted and used his representation ("There are 24 pupils in each bus… So… Ten pupils go with one teacher, another ten with another teacher and the four children left are going with another one!"). Ricardo informs the class about Mauro's explanation, focusing on the data that he found more relevant (he compares Jonas' and Mario's representations and strategies). For that, he questions the pupils through rhetorical questions ("Before, we add all the pupils to find the number of adults, wasn't it?"). After this, he asks again Mauro to explain his representation as he guides his pupils to establish connections between the two different iconic representations. He questions his class through closed confirmation questions ("How many adults here?"). Ricardo ends the whole group discussion by informing the pupils about the aspects that he found more relevant. That way, he talks about the differences and similarities of the two representations, reinforcing that both representations, strategies and solutions are correct.

Discussion

During the introduction of the task, Ricardo informs his class about the statement of the task, focusing on the information that he finds more relevant. For that purpose, he uses closed confirmation questions as he supervises the whole group discussion that occurs among pupils. Afterwards, during the pupils' autonomous work, the teacher asks the pupils to use and to interpret their own representations, guiding them to convert mental representations into written ones. Although he uses active and pictorial representations (included in the scheme of the buses – figure 1) to help the pupils to interpret the statement of the task, while they are working by themselves he promotes a free choice of representations. By doing this, Ricardo promotes his pupils' awareness of the importance of choosing an adequate representation (Thomas et al., 2002). The whole group discussion is the moment where Ricardo asks the pupils to explain to the class their own representations. For that purpose, he uses rhetorical and closed confirmation questions. Depending on the pupils' answers and difficulties, the teacher: (i) challenges the pupils to interpret a representation, questioning them with inquiring questions; (ii) suggests how to interpret a representation by using open confirmation questions; and (iii) informs the class about how to interpret a representation through closed confirming questions and/or rhetorical questions.

In the three moments of working on the task, Ricardo's actions tend to change according to the pupils' answers and difficulties. When pupils have less difficulties, Ricardo prioritizes actions with a higher level of cognitive demand (Figure 4). When and if pupils start having more difficulties, Ricardo changes his actions and questioning, decreasing its level of cognitive demand. That way, the more difficulties the pupils face, the lower level of cognitive demand his actions have.

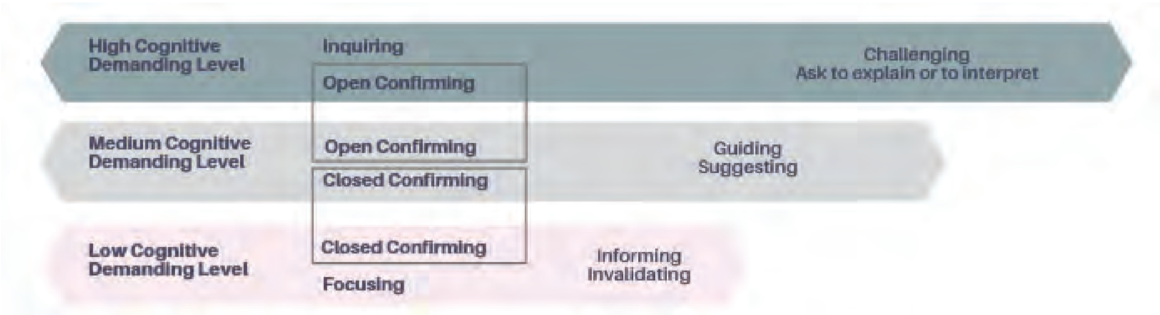

Figure 4: Interrelation teacher's actions and teacher's question

Conclusion

As Duval (2006) states, to understand the features of a mathematical object we need to know how to make treatments or conversions. Ricardo is aware of this as he, at the introduction of the task, informs the pupils about the conversion of the verbal representations (from the statement of the problem) into pictorial and active representations so they can understand it and choose an adequate representation to solve the problem. Additionally, during pupils' autonomous work, the teacher looks up for different representations. Later, during the whole class discussion those representations can be discussed, as the pupils present to their colleagues the two possible solutions for this task. By doing this, Ricardo provides the pupils the opportunity of establishing connections between the two different iconic representations (Bishop & Goffree, 1986). In this way, by using different types of actions, questioning and representations (not only from pupils but also his own), Ricardo strives to promote the pupils' understanding and the use of different representations. From here, in the future, it would be interesting to explore how the teacher's actions influence pupils' representations.

Introduction

The Thematic Working Group 25 "Inclusive Mathematics Education – Challenges for Students with Special Needs", established for CERME11 in 2019, was running for the second time at CERME12. The scope and focus of TWG25 covers research about special educational needs (SEN) and inclusion, in the intersection of mathematics education research and special education research. Since this scope is broad, the TWG-papers comprised grades 1-12, teacher professionalization and teacher education programs, types of inclusive settings in mathematics, concepts and models for instruction and subject matter didactics, special educational needs and child characteristics, and content related decisions for inclusive mathematics education.

During CERME12, TWG25 had 34 participants from 12 countries (Europe, also Brazil, Canada and the US) who presented 17 papers and 7 posters. The first session was spent on aims and objectives of this TWG and an exchange of overarching issues of the situation of SEN mathematics education in the different represented countries. In the following TWG-sessions, two up to four papers were presented each time, under an overarching theme. The three main fields were:

General papers, conceptual models, research review

Focus on teacher education, pre-service and in-service teachers

Focus on classroom, teaching and learning situations, different school levels

Moreover, poster authors were asked to identify the connection to papers in the initial session in order to include all participants. Posters were about inclusive education and collaborative instruction focusing on pre-service, general and special educators (Dibbs & Boyle) and their different roles (Scherer & Rolka). They also covered specific interventions for supporting students with difficulties in learning mathematics (Larmann & Ludwig), proposed a structure that should facilitate development of teaching materials for inclusive classrooms (Novotná & Moraová), presented ways of supporting special-needs children in the context of probability (Jaschke) and discussed diversity in relation to digitalization (Ludes-Adamy & Viermann), as well as affective and mediational suitability (Blanco et al.) in relation to a specific inclusive program.

In detail, the sessions were arranged according to the following thematic focal points:

Session 2: General papers, conceptual models, research review

This theme includes discussions of prior research regarding conceptual models as well as inclusive models for special educational needs in mathematics.

Helena Roos & Anette Bagger: Explicit instruction and special educational needs in mathematics in early school years

Marzia Garzetti, George Santi, Heidrun Demo & Giulia Tarini: The interplay between theory and practice in the development of a model for inclusive mathematics education

Karine Millon-Fauré, Patricia Marchand, Claire Guille-Biel Winder, Teresa Assude, Jeanne Koudogbo, Laurent Theis & Mathieu Thibault: Preventive support scheme for mathematics learning: possible ways to provide aid before and after the class session

Session 3: Focus on teacher education, pre-service and in-service teachers

This theme includes discussions of how framework conditions such as teacher education, specific teaching, cooperation between professions and steering documents influence inclusive mathematics teaching.

Tabea Knobbe, Christof Schreiber & Michaela Timberlake: Cooperation of mathematics teaching and special education – seminar concept and experiences

Jennifer Bertram & Petra Scherer: Pre-service teachers' beliefs and attitudes about teaching in inclusive mathematics settings

Michael Gaidoschik: "Individual Educational Plans" for "dyscalculic" students in primary schools of South Tyrol: A questionable law, poorly implied

May Ron Ezra & Esther S. Levenson: Perceptions of mathematical creativity among math teachers in special education classrooms

Session 4: Focus on classroom, teaching and learning situations, primary level

This theme includes discussions of specific interventions in the inclusive mathematics classroom to enhance learning of every student. The focus of research could be the learning environments, the students' learning processes, or teachers' acting.

Yola Koch: Working with objects of representation in practical contexts on length in inclusive classrooms

Uta Häsel-Weide & Marcus Nührenbörger: Inclusive math practices in primary school

Marie-Line Gardes, Céline Hugli, Jasinta Dewi, Ludivine Hanssen & Michel Deruaz: Evaluation of a computer-based learning program for students with mathematical learning difficulties

Carina Gander: "Counting with all children from the very beginning": One attempt to promote early arithmetical skills based on part-whole thinking

Session 5: Focus on classroom, teaching and learning situations, primary and lower secondary level

Also in this session, the papers and discussions focused on specific interventions in inclusive mathematics classrooms, with a special view on more advanced content such as problem solving or early algebra.

Raja Herold-Blasius & Benjamin Rott: Low-achieving secondary students learn mathematical problem solving – A longitudinal, qualitative video study

Ángeles Chico, Inmaculada Gómez & Nuria Climent: Problem-solving by students with Asperger's Syndrome

Ann-Kristin Tewes & Marcus Schütte: The mathematical support format reproduction

Francesca Gregorio: The role of examples in early algebra for students with mathematical learning difficulties

Session 6: Focus on classroom, teaching and learning situations

This theme includes discussions of how to create engagement in inclusive mathematics classrooms to enhance learning and participation of every student.

Amanda Queiroz Moura: Inclusive landscapes of investigation in mathematics classrooms with deaf and hearing students

Silvia Baccaro & Annalisa Cusi: A teaching methodology focused on the use of a videogame: analysis of the engagement of students with special educational needs

Introductory discussion – overarching issues of inclusion

Mathematics education needs to embrace the diversity that exists in mathematics classrooms to be able to meet every student. This implies that heterogeneity with respect to language, culture and abilities needs to be acknowledged (Bishop et al., 2015). This requires an accommodation in the mathematics classroom to enhance every student's learning. To be able to embrace the diversity and to meet the needs in a democratic education for all, where students with different languages, cultures, abilities and skills are educated together, inclusion is used as an overarching notion for support (Bishop et al., 2015). Though, often the notion of inclusion has been connected to special education rather than to a democratic education overall (Allan, 2012).

If we define the concept of inclusion in a *mathematics education* context, it implies to look for ways enabling us to meet the diversity in the teaching of *mathematics.* In Europe (and also around the globe) the way "inclusion in mathematics education" is defined and used is very different (Roos, 2019). Some countries and cultures connect inclusion very tightly to special education and disabilities, while others have moved towards meeting diversity on a more overarching level, connected to a democratic and equitable education. This also depends on the national governing documents. Even so, there are many challenges for inclusive education in school and research (Kollosche et al., 2019).

Mathematics education at every school is expected to create inclusive classrooms, with lessons where every student receives appropriate support and challenge. Here, the teachers' competences and those of other professionals are crucial. In turn, this puts pressure on the teacher education to be able to equip teachers for their mission regarding inclusive mathematics teaching (Krainer, 2015; Scherer, 2019). Although there exist big differences in different countries, the need of preparing both pre-service and in-service teachers for inclusive mathematics education is recognized in all countries. The discussions in TWG25 showed the need to recognize different strategies to support pre-service and in-service teachers' processes of inclusive mathematics teaching. If teachers are better prepared for teaching in inclusive classrooms and have models and methods to make it work, education can be able to meet and value diversity (Askew, 2015).

During many sessions in TWG25, both 2019 and 2022, the question of how we understand inclusive education in mathematics was discussed. What does "inclusive education" mean in different countries? What is the role of stakeholders in different countries? How do we apply inclusive education to different cultural and national settings, and what are sufficient strategies on organization, classroom and individual level? These questions are reflected upon in the overarching themes that emerged from the discussions of TWG25, and described below.

Overarching themes of TWG25

Research in the field of inclusive mathematics covers a wide range, and several trends in mathematics education were presented in the papers of TWG25. All papers focus on some aspects of mathematics teaching and learning in relation to SEN and deserve due attention. During the sessions, the following points were discussed, especially how they are linked with each other.

What do we understand as „inclusive maths education", which theoretical perspective do we have/propose?

Within TWG25, it was agreed that it is important to have a broader discussion about inclusion, also from a theoretical point of view. In addition to bringing *solutions*, it is important to ask *questions* about what inclusion means, about the (no) need of labels for students, about the characteristics of students with special needs and other aspects of research not intended to directly provide something applicable in the classroom, but with consequences on classroom practices. Without a focus on theory, it is not possible to have deep enough discussions and propose good enough solutions.

Inclusive mathematics education is a very complex field with manifold perspectives: Student perspective, teacher perspective, teacher training, etc. The question we should ask is who is it in the system that has special needs – the student, the teacher, the system of education?

It follows from the discussions in the TWG that truly "inclusive mathematics education" is such practice in which every pupil in the classroom is welcome regardless of knowledge, skills and background. One way of achieving it is by paying enough attention to the learning environment, to let pupils work together, collaborate, be active. *Participation* and *inclusion* are strictly connected. A way of achieving this is making suitable learning offers and preparing lessons allowing each pupil to be successful and experience the pleasure of achieving. We should look for ways of engaging all students in standards-based, inquiry-based instruction, but provide structures and support so that all pupils will be successful, without diminishing the cognitive demand of the tasks. No doubt that this is not easy to achieve, but it is what we should be aspiring to.

The challenge takes on additional facets when deafness and the lack of a common (sign) language make communication between hearing and deaf children as well as between deaf children and (mathematics) teachers who are not trained in sign language difficult or at times even impossible. In her contribution, Amanda Queiroz Moura pleads for the establishment of “inclusive landscapes of investigations” with the permanent engagement of sign language interpreters, who have the explicit task of facilitating communication also between hearing and deaf children while they work together on challenging problems. In the discussion, however, it was also questioned whether the “dogma” of joint learning of hearing and non-hearing children might not, under certain conditions, lead to a reduction of learning opportunities for the non-hearing, so that in this case *social participation* might happen at the expense of the *content-related participation* of deaf children.

Genuine inclusion always means both (Roos, 2014; Jung & Schütte, 2017) – and obviously requires a great deal of ressources in terms of competent teachers, time, but also technical aids, material, spatial requirements and the like. One important task for future research in inclusive mathematics education might be to provide a more solid empirical basis than we have at the moment for assessing the way in which those inclusive settings, which have been enacted in different nations based on pedagogical convictions and, in the end, *political decisions*, actually prove their worth for the *content-related participation* of children with different learning backgrounds.

What do we understand as „special-needs student“, what (if any) use is it to have „labels“ like „dyscalculic", how helpful/harmful are national laws/policies in that respect, (how) do we/can we have influence on such laws/policies?

Another subject of discussion was the issue of labelling. In many countries, diagnosing a special-needs child is a process that schools have to perform in order to be allowed to adapt the child’s program and start interventions. As a rule, such diagnoses follow a medical-psychological approach, with deficit-oriented definitions of “disorders” and clear cut-off criteria within standardized testing procedures. This seems to be particularly problematic in the case of “dyscalculia”, given the empirical evidence from mathematics education research that learning difficulties in mathematics may at least to some extent be explained by inadequate instruction (Gaidoschik, 2019), and in many other cases be traced back to insufficient fit between the teaching and the learning requirements of a single child. In such cases, it is not the child that suffers from a learning disability, but rather the school system from disability to offer the child a proper learning environment. Attributing “dyscalculia” may therefore result, on the one side, in maintaining such classroom practices that do no good to any child, and on the other side, in single children's learning difficulties being labelled as consequence of *their individual* dispositions (Gaidoschik et al., 2021).

Of course, under the given circumstances, only such a diagnosis may mean the possibility to have fewer pupils in classroom, a special teacher to cooperate, to give the pupil extra time in exams, to have an assistant for the child. Yet, if the label does not lead to *additional pedagogical resources* that could help to overcome the learning difficulties, it rather has the function to formalize the further treatment of a child defined as presumably permanently not able to learn mathematics at a “normal” level. In the following, this labelling may be very unpleasant for the child as they get an official stamp of not being ordinary, of being different from the others. In some cases, it may result in resignation, low aspirations, low self-confidence and low level of motivation. The discussion among the TWG participants showed that there is no simple answer to whether such labelling is the right step in inclusive education. While some argued that the label helps the teacher understand the pupil's needs but also may help the pupil gain self-confidence seeing that they do not perform badly because they would be "stupid", but because of a diagnosis that is not their fault, others argue that a truly inclusive classroom with truly inclusive practices is ready to support every learner whatever their special needs are.

Do we have best practices or proposals for such practices or open questions about how to get to best practices in teacher education for inclusive maths education with a view to collaboration of maths and special education teachers?

A lot of the discussions focused on good as well as bad practices in mathematics classrooms, existing and used in different countries. As Michael Gaidoschik pointed out in his paper, inclusive practices in many countries tend to be tied by demands of the authorities. The school has to create a formal document (which may have different forms in different countries) that defines the methods of work, the objectives, the needs, but all this is rigid and quite formal. In some countries this kind of document or plan is subject to work of the inspection more than what is actually happening in the classroom. This in no way supports good practices at schools. And, as follows from the discussion, research has a responsibility to not just accept what politicians do and how they act and define things, but to always be critical, especially when researching inclusive and special education.

The discussions also focused on collaboration between ordinary mathematics teachers and special teachers, which does not happen in all countries, and special teachers are still very rare in some of the countries. To put it shortly, mathematics teachers tend not to get sufficient training in care for special-needs children and special teachers, in general, do not seem to have sufficient training to understand problems in mathematics. Hence, special teachers need more training in mathematics and mathematics teacher more training in special education. Also the need of close collaboration between special and regular mathematics teachers was part of the discussions and is regarded as one of the topics that should be inquired in more detail in research and on the next CERME.

Following the discussions in TWG25, *collaboration* is at the base of inclusion. This does not refer only to pupil-teacher but also to teacher-teacher and also researcher-researcher as well as teacher-researcher collaboration, where mutual projects of special education and mathematics education will definitely bear fruit. Collaboration and knowledge-sharing between disciplines is what is needed. Effective co-teaching requires sustained professional development in which both (special and mathematics teacher) develop a shared understanding of mathematical development, curricular design and both the challenges and strengths of pupils with special needs. It also requires that teachers have adequate time to plan together. Teacher education programs need to foster collaboration between special education and mathematics education. In turn, research on the mathematical learning of students with disabilities must integrate neurodiversity into research design and implementation.

In the discussions it turned out that a lot of current research focuses on the pupil and his/her activity. However, it is the teacher whose everyday reality is teaching heterogeneous classes with pupils of very different skills and levels. They need to be paid a lot of research attention, looking for ways of helping them grow more self-confident and less anxious in classrooms. The question the research community should ask is “What training and support does the mathematics teacher need?”

Conclusion and further directions of TWG25

Reflecting on the research presented in TWG25 and on the discussions, diverse issues concerning inclusion in mathematics education and challenges for students with special needs in mathematics exist, and further research is needed. One major question is how to cope with the diversity of research directions and cultural as well as national and international differences. Still, it is interesting to see that even if there are very diverse issues concerning inclusion in mathematics education, there are similarities too, and this could be a chance for national and international exchange and cooperations. In our view, research topics should be better connected and, if possible, transferred. Research findings for specific mathematical topics in the sense of best practices should be reviewed for other topics or for similar topics on different school levels or grades. What are the relevant factors or design elements that work in inclusive classrooms? In what way can we consider both students’ perspective and teachers’ perspective? Also on the teacher education level, apart from specific studies with a detailed focus, the different phases of teacher education programs could be considered in a more general way: Understanding professional development of teachers as a life-long-learning process (e. g. Cedefop, 2015), findings with respect to pre-service teacher education programs should be reviewed for in-service teachers, and should be connected to programs for teacher educators. Mathematics programs for special education and programs for regular teacher education should be reviewed in more detail and checked for common objectives. Only in this way will the necessary cooperation in so called multiprofessional teams be ensured.

In summary, there seem to be opportunities to build a common ground regarding inclusive mathematics teaching and challenges for students with special needs. Looking forward to CERME13 the community has a challenge to build further on the work at CERME12 and build a common ground to address issues within the scope of TWG25.

A teaching methodology focused on the use of a videogame: analysis of the engagement of students with special educational needs

Silvia Baccaro and Annalisa Cusi

Sapienza University of Rome, Italy; silvia.baccaro@uniroma1.it; annalisa.cusi@uniroma1.it

In this paper we reflect on the effects of a methodology based on the use of a videogame in terms of engagement of students with special educational needs. By referring to theoretical lenses useful to characterize students' in-the-moment engagement, we analyse data collected within a teaching experiment conducted within mixed-abilities lower secondary school classes. The results of our analysis show a general positive trend in the evolution of students' engagement structures.

Keywords: Special educational needs, videogames, inclusion, structures of engagement.

Introduction

The research documented in this paper is part of a wider study on the use of videogames in fostering inclusion in the teaching-learning of mathematics at primary and lower secondary school level. Different studies highlighted the potentialities of the use of videogames in fostering inclusive processes for students with special needs (Durkin et al., 2013), highlighting the key-role of fundamental dynamics that these methodologies trigger, such as identification, gradualness and non-public failure (Gee, 2003). In the case in which the use of videogames supports mathematics teaching, fostering inclusion requires a careful design of the teaching methodologies with the aim of giving to all the students the opportunity to "experience mathematics in ways which make sense to them" (Scherer et al., 2016, p. 641). Research has shown, in particular, the key-role of fostering students' reflections on: (a) the mathematics embedded within the videogame (Jorgensen (Zevenbergen), 2015); (b) the skills they develop when they play (Gros, 2007); (c) their own difficulties and the possible ways to overcome them (Van Eck, 2015).

In tune with these ideas, we designed a teaching methodology which combines the use of a videogame with the activation of reflective practices developed by students at both individual, peer and collective level. In this paper, we reflect on the effects of this methodology in terms of students with special educational needs engagement, by focusing on data from a teaching experiment carried out with mixed-abilities classes of lower secondary school.

Context of the study and teaching methodology

The teaching experiment on which this paper is focused involved 93 students of 5 mixed-abilities lower secondary school classes (grades 6 and 7) and their mathematics teachers. Here, we analyse the case of 25 pupils with special educational needs (in the following, SEN) belonging to these classes.

Before presenting these students, it is important to share some information about the Italian tradition in terms of inclusion. In Italy, differential classes were abolished during the 1970s. The issue of SEN has become central since 2012, when the Ministry of Education introduced a specific regulation that identifies three main categories of students with SEN: (A) students with certified disabilities (sensory, motor or psychic); (B) students with specific developmental disorders (dyslexia, dyscalculia, dysgraphia, dysorthography, attention deficit hyperactivity disorder and limiting or borderline cognitive functioning); and (C) students within a condition of socio-economic, linguistic or cultural disadvantage. The regulation introduces, in particular, a series of benefits for students belonging to these categories, such as the creation of personalized didactical plans that include didactic strategies based on the students' needs and a list of didactic tools to be used to support the students.

21 students, among the 25 on which the study is focused, belong to these three categories: 2 students belong to category (A), 15 students belong to category (B), and 4 students belong to category (C). Other 4 students not belonging to these categories were included within this study, due to their poor performance and the difficulty faced by the teacher in involving them during mathematics lessons.

Table 1: An example of activity that students face within Matematica Superpiatta

Description of the activity "Prime numbers"	**Tools provided to students within the activity**
The activity is divided into 6 tasks of increasing difficulty. The goal of each task is to complete a sequence of integer numbers by inserting the missing numbers. Each number in the sandbox game is represented as a block that can be searched and picked up, placed, or created (crafted) according to some rules. Students can find only prime numbers in the game field. Not prime numbers have to be crafted as products of prime numbers through the tools provided in the game.	"Inventory": a place when the user can collect objects gathered in the game field. "Crafting table": a table where prime numbers can be inserted to craft other numbers as products of prime numbers. "Pick": when used on a block containing a number, the block disappears from the world, appearing in the user inventory. In case the picked block does not contain a prime number, it is "broken" into blocks containing the prime factors, which appear in the inventory.

As stated above, during the teaching experiment we implemented a teaching methodology that combines the use of a sandbox videogame, Matematica Superpiatta (www.matematicasuperpiatta.it) with the activation of students' reflective practices. Matematica Superpiatta (in the following, MS) was designed with the aim of realizing a learning environment within which students could face challenging mathematical activities by interacting with the different tools at disposal. Table 1 summarizes one of the activities that students face within MS ("Prime numbers"), which is aimed at making them reflect on the decomposition of numbers in prime factors. The teaching methodology combines individual interactions with the MS and collective metacognitive reflections on the strategies implemented during this interaction and on the mathematical knowledge on which these strategies are based.

Table 2: Questions from the reflective worksheet related to the activity "Prime numbers"

Questions from the worksheet	**Aims of the questions**
(a) Which of these numbers can you find in the field? Why? (list of numbers written under the question: 11, 14, 27, 31, 59, 75) (b) How do you find the useful numbers to be put in the crafting table?	Questions (a) and (b) are aimed at making students reflect on the mathematical knowledge on which the activity is focused and on the strategies that they adopted during the game.
(c) Does the game become easier or harder when you progress through the levels? Why? (d) What did you learn through this activity?	Questions (c) and (d) are aimed at making students reflect on their own experience of learning through the use of the videogame.

The teaching methodology is characterized by this sequence of phases: individual interaction with MS (phase 1); individual (phase 2) and small groups' (phase 3) reflections on the activities faced within MS; and collective discussions aimed at sharing and comparing ideas, enhancing the contribution of each student in the collective construction of meanings (phase 4). Specific reflecting worksheets have been designed to support students' metacognitive reflections during phases 2 and 3. Examples of questions from the reflecting worksheet proposed after students' individual interaction with the activity "Prime numbers" are presented in Table 2.

Research framework and research questions

Motivation plays a fundamental role, especially in the case of students with special needs and learning disabilities (Sideridis, 2009), since it has the potential to direct students' choice of taking part (or not) in mathematics activity. In the last years, research studies on the issue of motivation in mathematics suggested to shift the focus of the research on motivation in mathematics from the study of longer-term attitudes and beliefs toward the study of in-the-moment engagement (Middleton et al., 2017). *Engagement* is a multidimensional construct, which combines three interrelated components (Fredricks et al., 2004): *behavioral engagement,* which draws on the idea of participation; *emotional engagement,* which refers to students' affective reactions in the classroom; *cognitive engagement,* which incorporates "thoughtfulness and willingness to exert the effort necessary to comprehend complex ideas and master difficult skills" (Fredricks et al., 2004, p. 60).

To study and understand the specific nature of *mathematical engagement*, Goldin et al. (2011) introduce the term *engagement structure*, defined as:

> an idealization involving a characteristic motivating desire or goal, actions including social behaviors toward fulfilling the desire, supporting beliefs, self-talk, sequences of emotional states, meta-affect, strategies, and possible outcomes – a kind of behavioral/affective/social constellation situated in the person, becoming active in social contexts (Goldin et al., 2011, p. 548).

The key-role played by the design of teaching methodologies in structuring students' engagement have been stressed by Jansen (2019), who states that engagement is structured by the opportunities to do mathematics given to students and by students' way of taking up these opportunities to interact with the teachers and peers about mathematics. Goldin et al. (2011) identified 9 main categories of engagement structures: (1) *Get the job done*, related to students' desire of completing an assigned mathematical task correctly following given instructions; (2) *Look how smart I am*, related to the desire of impressing others or him/herself with his/her mathematical ability; (3) *Check this out*, related to the desire of obtaining a reward; (4) *I'm really into this*, related to the desire of experiencing the very activity of addressing a mathematical task with the need of understanding; (5) *Don't disrespect me*, related to the desire of meeting a perceived challenge to the student's dignity, status, or sense of self-respect; (6) *Stay out of trouble*, related to the desire of avoiding interactions that may lead to conflict or distress; (7) *It's not fair*, related to the desire of redressing a perceived inequity; (8) *Let me teach you*, related to the desire of helping another student; and (9) *Pseudo-engagement*, related to the desire of seeming to be engaged while avoiding genuine participation.

The aim of this paper is to reflect on the potentialities of the teaching methodology implemented during our teaching experiment in structuring students' with SEN engagement by providing them with opportunities to both do mathematics and reflect, with the teacher and their classmates, on their experience. The research questions related to this aim are: (1) How could the students' with SEN engagement, during the teaching experiment, be characterized at the behavioural, social, cognitive and affective level? (2) What are the main characteristics of the teaching methodology that structured this kind of engagement?

Research methodology

Middleton et al. (2017) stress on the importance of focusing on multiple methods to investigate students' engagement, combining different techniques, such as, for example, researcher's observations, students' self-reports and teachers' reports.

In tune with this idea, we collected different kind of data: students' written answers to the questions in the reflecting worksheets; videos of classroom discussions; data about students' individual interactions with the videogame (levels of the game that were faced, number of mistakes, number of attempts, …); students' answers to a questionnaire about their experience within the whole teaching experiment; teachers' answers to two different questionnaires proposed at the middle and at the end of the project; teachers' final interview aimed at making them reflect on their students' experiences.

In order to answer our research questions, we developed a qualitative analysis of the collected data that refer to the students who participated in the teaching experiment. For each student, the results of the analysis of each kind of data have been intertwined with the aim of highlighting clues of his/her engagement. Table 3 summarizes the data analysed to characterize each level of engagement.

Table 3: Data analysed to characterise each level of engagement

Level of engagement	Data that have been analysed
Behavioural engagement	- students' interventions during the classroom discussions that highlight their ways of taking part to the collective work that is developed; - students' ways of interacting with others (tone of their voice, kind of gestures they used…); - students' answers to the final questionnaire, in which they share how they perceive their participation within the classroom activity.
Affective engagement	- students' interventions during the collective discussions, answers to the reflecting worksheets and to the final questionnaire, through which they share their emotions toward mathematics and manifest their perceived competence in doing mathematics.
Cognitive engagement	- students' interventions during the classroom discussions that highlight their willingness of understanding and of contributing to the reflective practice developed at a collective level; - students' answers to the reflecting worksheets, in which they make explicit the mathematical reasons subtended to the strategies adopted during their interaction with the videogame.

The data collected through the questionnaires proposed to the teachers and their final interviews were analysed with the aim of confirming (or not) our interpretation of the other data. In particular, during the final interviews, teachers were explicitly asked to reflect about their students' engagement and about the role played by the methodology adopted during the teaching experiment in structuring students' engagement.

Data Analysis

In this section we present two examples of the analysis we performed. We chose to focus on two opposite cases: the case of Antonia, which testifies a positive evolution of the student's engagement throughout the teaching experiment; and the case of Giorgio, which highlights the role played by the student's difficulties in inhibiting his fruitful participation

Example 1: The case of Antonia

Antonia is a female student diagnosed with severe specific learning disorders (dyslexia and dyscalculia; category (B)). She has a problematic relationship with a very close and competing classmate, Elisabetta, who tends to impose herself on Antonia, blocking her attempts to participate in classroom activities and heightening her sense of insecurity. During the different phases of the educational project, Antonia's participation becomes active lesson by lesson.

This evolution of her engagement has been clearly highlighted at the behavioral level. In fact, during the pair activities and the classroom discussions, the tone of her voice and the gestures used to show her involvement in these activities highlight Antonia's ongoing overcoming of her sense of insecurity in interacting with others. Moreover, in different moments during the classroom discussions, Antonia intervenes without the need of the teacher's solicitation, differently from what usually happened in the past. In the final questionnaire, she declares that she was stimulated to participate in an active way when excerpts from her reflecting worksheets were displayed on the interactive whiteboard. This testifies the role played by the design of the classroom discussion (phase 4) in fostering Antonia's positive attitude toward her participation within the discussion itself. The analysis of classroom discussions has also shown that Antonia has become able to overcome the difficulties due to Elisabetta's presence, since she reacts with confidence to her interferences when she intervenes during the discussions. We hypothesize that playing alone with the videogame (phase 1) contributed to strengthen Antonia's self-esteem and the sense of self-efficacy, thanks to the gradualness of the tasks and to the possibility of managing time in an autonomous way.

It was possible to highlight a positive evolution even at the level of cognitive engagement, since Antonia's interventions during the classroom discussions are productive also in relation to the mathematical content, highlighting that she is able to effectively direct her attention at the issues on which the discussion is focused. Moreover, Antonia is able to autonomously complete all the levels of the videogame that the students were asked to face. In the individual reflection sheets (phase 2) and in the final collective discussion (phase 4) Antonia often refers to the videogame as a real concrete experience talking about "numbers that cannot be multiplied", referring to the crafting table. This testifies that: on one side, individually interacting with the videogame (phase 1) contributed to make Antonia's experience with mathematics less abstract; one the other side, working on the reflecting worksheets enabled Antonia to make the mathematics behind the game more explicit and to reflect on the reasons subtended to the effectiveness of the adopted strategies. These factors allowed Antonia to speak more confidently about mathematics during the classroom discussion.

At the level of affective engagement, Antonia's answers to the questions within the reflecting worksheets display her increased perceived competence, as it is testified by this excerpt, which highlights her self-confidence about the competencies she has developed in facing the different levels of the videogame: “The videogame becomes more difficult (level by level), starting from the easiest (levels) to enable us to learn. Since you get better, the game gets harder".

Our analysis highlights different structures characterizing Antonia’s engagement during the project. Although some of her answers show an engagement in tune with the structure “look how smart I am” (testified by Antonia’s declaration that she was proud that her answers were displayed on the IWB, making her protagonist of classroom discussions), we think that the prevailing structure is “I’m really into this”, since Antonia explicitly addresses the idea of learning in her reflections, displaying satisfaction about her increased mathematical understanding through the different levels of the videogame. Our interpretation of Antonia’s engagement has been confirmed by her teacher, who, during the interview, declares that she was positively impressed by the desire to interact that Antonia, usually very shy and insecure, displayed during classroom activities.

Example 2: The case of Giorgio

Giorgio is a male student diagnosed with severe specific learning disorders (dyslexia and dyscalculia; category (B)). He presents serious short-term working memory problems, logical-cognitive difficulties and a strong sense of frustration that often leads to conflicting relationships with peers, teachers and parents. During the different phases of the teaching experiment, Giorgio’s difficulties are so great that they prevent him from deeply and truly participating in the activity at different levels. At the level of behavioral engagement, Giorgio does not participate in the collective discussions, even when one of his classmates solicits his intervention to share some reflections about the phase of small group work. The inconsistency and lack of meaning that characterize Giorgio’s answers to the reflecting worksheet highlight also the difficulties faced by Giorgio in being engaged at the cognitive level. Moreover, the student declares, in his reflecting worksheet, that he felt lost during the activities, testifying the problems related to his engagement also at the affective level. A little evolution of his engagement could be observed only in the last part of the teaching experiment, when, after a collective discussion, Giorgio shows a better sense of perceived competence when answering to the final questionnaire, declaring that he has understood a little better and that he has overcome, albeit with great difficulty, the problems encountered when interacting with the videogame, displaying a more positive attitude towards the activity performed.

Our analysis highlights a main structure characterizing Giorgio's engagement during the teaching experiment, that is “Pseudo-engagement”. In fact, although Giorgio seemed busy when he individually worked on the reflecting worksheet, a sentence within his answers to the final questionnaire testifies that his aim was to pretend to be actively involved in the activities, rather than really reflecting on the mathematics problems he faced and on the possible strategies to face them: “In the worksheet I had no problems because it was enough to write something”. Our interpretation about Giorgio’s engagement has been confirmed by his teacher who, in both the first and second questionnaires and during the final interview declared to be worried about Giorgio’s situation.

Conclusion

In the previous section, we presented two examples of analysis of the data collected during our teaching experiment. The first example, the case of Antonia, testifies the effectiveness of our methodology in fostering the positive evolution of students’ engagement structures toward a structure characterized by students' desire of being involved in the collective construction of mathematical knowledge and of learning, which Goldin et al. (2011) indicate with "I'm really into this". The analysis of the data collected for most of the 25 students with SEN who participated in our teaching experiment has confirmed the positive trend highlighted in Antonia's case. In particular, we observed that most of the students showed a positive evolution of their engagement structures, even at the level of cognitive engagement. 20 of them, in fact, were able to autonomously complete all the activities within the videogame. Among them, 14 students proposed fruitful interventions during the classroom discussions in relation to the mathematical content under scrutiny and 11 students showed awareness of their progress by explicitly reflecting on the improvement of their cognitive engagement. These interpretations were confirmed by the teachers in the intermediate and final questionnaires and in the interview. In particular, teachers stressed on the greater participation that they observed in the case of the students with SEN involved in the study, declaring that they observed a widespread students' desire to interact positively and a sense of gratification, trust and security manifested by most of these students, together with a reduction of fear of making mistakes and a general fun in doing mathematics.

These results allow us to propose some reflections on the characteristics of the teaching methodology implemented during our teaching experiment that played a key-role in structuring students' engagement. In tune with other studies, the phase of individual interaction with MS (phase 1) favors a positive development of students' sense of self-efficacy. Working (individually and in small groups) on the reflecting worksheets (phases 2 and 3) supports students in making the mathematics behind the videogame explicit and in developing argumentative competences, enabling them to effectively contribute to the classroom discussion. Phase 4, in turns, contribute to the refinement of the reflections developed during phases 2 and 3, supporting students' development of awareness about the teaching-learning processes in which they are involved.

The structure "I'm really into this", the one displayed through the analysis of Antonia's data, emerged only in 4 cases. We think that this result shows that it is necessary to devote more time to the implementation of this kind of methodology (in particular, the phases devoted to the activation of reflective practices) in order to foster an engagement characterized by students' will to address the activities guided by a real need of understanding. Our analysis has also highlighted that in some cases (Giorgio and two other students), students tended to strive not to be noticed, adopting an avoidance behavior, or pretended to be involved even if they did not really address the mathematical content under scrutiny. In these cases, students' experience within the teaching experiment was not effective in fostering a positive evolution of the structures of their engagement. Our hypothesis is that, in the case of students like these, it is necessary to plan a targeted intervention to help them overcome the difficulties that prevent them from becoming deeply engaged in the activities. In the case of Giorgio, a first targeted intervention has been carried out, involving him in meetings with his teacher aimed at triggering and supporting his explicit reflections about his experience with the videogame and the other activities around which our teaching methodology is designed. This approach seems to be promising but further experimentation is needed. As a further step of our study, we will also collect further data, throughout a longer time span, with the aim of investigating if the positive trend highlighted by our analysis could be confirmed.

Pre-service teachers' beliefs and attitudes about teaching in inclusive mathematics settings

Jennifer Bertram and Petra Scherer

University of Duisburg-Essen, Faculty of Mathematics, Germany; jennifer.bertram@uni-due.de; petra.scherer@uni-due.de

Research on subject-matter specific programs for inclusive teacher education is still of great importance. Beyond concept development and research on cognitive development, pre-service teachers' beliefs and attitudes are of major interest. The paper reports first on the project ProViel ('Professionalisierung für Vielfalt' – 'professionalisation for diversity') and presents its aims and objectives. Afterwards, we focus on pre-service teachers' affective attitudes about teaching in inclusive mathematics settings before and after a course on learning mathematics with substantial learning environments, and compare the findings concerning inclusive teaching in mathematics and in other subjects. The results show that the pre-service teachers in average feel more optimistic and comfortable than pessimistic and uncomfortable while thinking about teaching mathematics in inclusive settings. This neutral to positive position hardly changed having completed the course.

Keywords: Pre-service teacher education, inclusive education, beliefs, attitudes.

Introduction

Coping with heterogeneity in inclusive settings requires specific competencies of teachers (cf. Scherer, 2019a). Teacher education has to prepare prospective teachers for these challenges, and research is needed especially for subject-matter specific programs. Several studies concentrate on conceptual and developmental work with relevant accompanying research. Apart from content-related objectives teacher education programs have to address pre-service teachers' adequate attitudes and beliefs towards inclusion. In connection with this, investigations of pre-service teachers' competencies and competence development as well as their attitudes and beliefs are of great interest. The following paper will focus on the latter one.

Beliefs and attitudes about inclusive mathematics

Knowledge about pre-service and in-service teachers' attitudes about inclusive (mathematics) teaching is of great interest because a successful implementation of inclusion seems to be dependent on teachers having positive attitudes about inclusion (e. g. Avramidis & Norwich, 2002; Ruberg & Porsch, 2017). There are also first hints concerning effects of positive attitudes about inclusion on important practices and strategies in inclusive teaching (cf. Forlin et al., 2011). Research on beliefs and attitudes about inclusion focuses, for example, on factors that might influence teachers' beliefs and attitudes about inclusion (e. g. Kunz et al., 2021; Ruberg & Porsch, 2017) or how these beliefs and attitudes can be captured via questionnaire (e. g. Ewing et al., 2018).

Traditionally, three components of attitudes can be distinguished: cognitive, affective and behavioral attitudes (Rosenberg & Hovland, 1960; Eagly & Chaiken, 2011), whereby attitudes are defined as "a psychological tendency that is expressed by evaluating a particular entity with some degree of favor or disfavor" (Eagly & Chaiken, 2011, p. 11). This tendency or, in terms of Rosenberg and Hovland

(1960), these predispositions, are not directly observable, but the types of response which seem to be indicators of attitudes can be distinguished along the three mentioned categories. While the cognitive and behavioral components of attitudes concentrate on thoughts about and people's actions with the attitude object, "the *affective* [emphasis from original] category consists of feelings or emotions that people have in relation to the attitude object" (Eagly & Chaiken, 2011, p. 10).

The affective component is comparatively less subject of research, although this component seems to be of special interest concerning inclusive teaching (Seifried, 2015). Studies which investigate this component often conceptualize affective attitudes through teacher feelings about the practice of inclusive education or concerns about it (Ewing et al., 2018) as well as teachers' positive expectations of inclusion (Seifried, 2015). First results show that teachers fear being overwhelmed by inclusion or that they might not meet every students' needs (Seifried, 2015). However, teachers also express positive expectations of inclusive education for all students, like their social interaction and learning from each other (Seifried, 2015).

Mostly, this previous research does not consider specific school subjects – a research gap we focused on within our project 'Mathematics Inclusive' (see next section). In different contexts the assumption comes up that it is more difficult to teach mathematics in inclusive settings than other subjects, for example, because of the specific structure of mathematics, but this can exactly be a starting point for individual and joint learning in mathematics for all students (cf. Seitz et al., 2020). Therefore, we are interested in pre-service teachers' affective attitudes about inclusive teaching especially in mathematics but also in comparison to other subjects.

The project 'Mathematics Inclusive' within the project ProViel

The project ProViel 'Professionalisierung für Vielfalt' ('Professionalisation for Diversity'; https://www.uni-due.de/proviel/) at the University of Duisburg-Essen is funded by the Federal Ministry of Education within the frame of a program for teacher education (1st phase: 2016–2019; 2nd phase: 2019–2023). Numerous university departments are involved to ensure the development of a coherent conceptual program for teacher education. One field of action is 'Diversity & Inclusion', and several sub-projects might cover the wide facets and dimensions in this field (cf. Bishop et al., 2015; Good & Brophy, 2008). One of the sub-projects, 'Mathematics Inclusive', aims at implementing subject-specific concepts and modules for inclusive mathematics education, following a design-based research approach (Scherer, 2019b).

The developmental work firstly concentrated on the course 'Learning Mathematics with Substantial Learning Environments (SLEs)' (3rd year, BA-program for primary mathematics). The didactical concept of working with SLEs, and by this realizing a natural differentiation is in line with a constructivist understanding of teaching and learning, and has been proved to be suitable for heterogeneous learning groups in primary mathematics (cf. Krauthausen & Scherer, 2013; Scherer & Krauthausen, 2010). The course lays theoretical foundations with respect to SLEs and natural differentiation and gives examples for planning SLEs as well as analyses of concrete lessons. Moreover, the pre-service teachers have to plan clinical interviews for a chosen SLE, carry out these interviews in school and analyze the interviews according to selected focal points.

The design process for this course started in 2016, and the first course has been running during the winter semester 2016/17, followed by the three repetitions during the winter semesters 2017/18, 2018/19, and 2019/20. All courses were evaluated, and data collection comprised questionnaires (pre-post-design), selected interviews, as well as field notes. The following section will report some former results with respect to pre-service teachers' pre-experiences and competence development with respect to inclusive mathematics. After that the research question focused in this paper as well as the used methods for investigating pre-service teachers' affective attitudes will be reported.

Previous results

For data collection with respect to pre-service teachers' individual pre-experiences with inclusive mathematics an open item "*Which experiences have you made so far with inclusion in mathematics instruction?"* was used within an extensive questionnaire (see also section research question and methods). Written comments showed that only about 50 % of the pre-service teachers have made school-related-experiences whereas the others had no experiences, made experiences out of school or in other fields (see Scherer, 2019a). In many cases, specific experiences for mathematics were related to *differentiated learning offers* and forms of *inner* or *outer differentiation*. Experiences that are of great importance for the course concept 'Learning Mathematics with SLEs', as the pre-service teachers' experiences and classroom observations represent a quite different teaching concept than the university course (Scherer, 2019a).

Moreover, for measuring pre-service teachers' competence development the post-test included six items for a retrospective self-assessment (cf. Nimon et al., 2011). At the end of the course, participants had to rate their competencies 'before the course' and 'today'. These items were designed according to the curriculum objectives focusing on substantial learning environments, clinical interviews and analyses of students' thinking and learning processes. The pre-service teachers had to rate their competencies for these three aspects on the one hand in general, on the other hand concerning the relevance for inclusive mathematics. The differences of the retrospective self-assessment before/after the course showed high significances with all items (for all items $p < .001$; Cohens $d > 0.8$; for detailed analysis see Scherer, 2021). Looking at all items, the results show important developments of pre-service teachers' competencies and beliefs. With regard to the pre-experiences of the majority that differ from the course conception (Scherer, 2019a), these findings are of great importance.

Research question and methods

Beyond central research questions with respect to course design and pre-service teachers' competence development (cf. Scherer, 2019b; 2021), this paper will focus on the following research question:

> Which changes of pre-service teachers' attitudes and beliefs can be identified after they had completed a course that addresses inclusive mathematics?

To answer the research question, a standardized questionnaire was used in a pre-post-design, filled in by about 240 participants. The questionnaire contains items concerning attitudes and beliefs with respect to inclusion and inclusive mathematics (cf. Meyer, 2011), and one of the questions was, if and how pre-service teachers' attitudes and beliefs changed after completing the course. A bipolar scale with five pairs of adjectives (by Meyer, 2011) was used that allows the pre-service teachers to rate how they feel about teaching in inclusive mathematics settings (Figure 1). The participants did answer this question before and after the course with respect to inclusive mathematics teaching, as well as on how they feel about teaching in inclusive settings in other subjects than mathematics.

How do you feel about the thought of teaching MATHEMATICS in an inclusive class? Please mark the box (1 = very anxious to 7 = very relaxed) that describes your feelings best.								
	1	2	3	4	5	6	7	
anxious	O	O	O	O	O	O	O	relaxed
helpless	O	O	O	O	O	O	O	self-confident
burdened	O	O	O	O	O	O	O	unburdened
pessimistic	O	O	O	O	O	O	O	optimistic
uncomfortable	O	O	O	O	O	O	O	comfortable

Figure 1: Question for capturing pre-service teachers' affective attitudes

Results

Pre-service teachers' affective attitudes can be described as follows: They feel neither anxious or relaxed, helpless or self-confident and burdened or unburdened, as they answered in average with a neutral position between the opposite pairs (Table 1).

Table 1: Pre-service teachers' affective attitudes about teaching mathematics in inclusive settings (1 = very anxious and 7 = very relaxed; N = 241)

	1	2	3	4	5	6	7	mean
anxious/relaxed	2 %	5 %	16 %	32 %	27 %	17 %	2 %	4.37
helpless/self-confident	2 %	10 %	19 %	30 %	24 %	13 %	2 %	4.12
burdened/unburdened	3 %	12 %	31 %	27 %	14 %	11 %	2 %	3.79
pessimistic/optimistic	2 %	3 %	8 %	17 %	27 %	29 %	14 %	5.10
uncomfortable/comfortable	1 %	1 %	5 %	29 %	29 %	22 %	11 %	4.96

However, in average they feel more optimistic and comfortable than pessimistic and uncomfortable while thinking about teaching mathematics in inclusive settings. Although it seems as if pre-service teachers feel quite neutral to positive about inclusive mathematics teaching, there are also more than just a few pre-service teachers who seem to be burdened (46 %). This facet of affective attitudes is also the most negatively one in Meyer's (2011) study. The in-service teachers, asked in that study, answered quite similar, with feeling burdened (67 %). Maybe teachers in their everyday practice face the challenges of inclusive mathematics teaching even more than pre-service teachers, as the percentage of teachers being burdened is even higher than the percentage of pre-service teachers feeling burdened. Additionally, pre-service teachers seem to feel more positive than the in-service teachers in Meyer's study did concerning the other facets of affective attitudes.

With respect to our research question (see section research question and methods), we figured out that pre-service teachers' affective attitudes hardly changed over the semester, having completed the SLE-course. In average, at the end of the semester they still feel neutral to positive about teaching mathematics in inclusive settings (Table 2). However, our analysis showed one significant result for the pre-post-comparison in the opposite pair pessimistic/optimistic. Participants still feel optimistic about teaching mathematics in inclusive settings but significantly less optimistic than before the course. Possibly, the pre-service teachers experienced challenges within the course while working with the pupils they did not experience before, which made them feel less optimistic than before.

Table 2: Pre-service teachers' affective attitudes about teaching mathematics in inclusive settings after the course (1 = very anxious and 7 = very relaxed; N = 240 to 241[1]; *p < 0.05)

	1	2	3	4	5	6	7	mean
anxious/relaxed	1 %	6 %	20 %	34 %	26 %	11 %	3 %	4.23
helpless/self-confident	2 %	6 %	17 %	34 %	27 %	12 %	3 %	4.26
burdened/unburdened	3 %	12 %	30 %	29 %	17 %	7 %	2 %	3.72
pessimistic/optimistic	1 %	2 %	10 %	24 %	27 %	25 %	11 %	4.93*
uncomfortable/comfortable	1 %	1 %	10 %	28 %	34 %	20 %	7 %	4.80

Comparing pre-service teachers' attitudes between teaching mathematics and other subjects in inclusive settings showed the following results: Their affective attitudes about teaching other subjects in inclusive settings are slightly more positive than about teaching mathematics when focusing on the average of pre-service teachers' answers (Table 3). This means, that pre-service teachers in average feel more relaxed, more self-confident, more unburdened, more optimistic and more comfortable about teaching other subjects compared to mathematics in inclusive settings. Although this is just a descriptive result (if all numbers were rounded to integers, there would be no visible difference), it seems to be a result consistent with the assumption that it might be more difficult to teach mathematics in inclusive settings than other subjects (see section beliefs and attitudes; cf. Seitz et al., 2020). However, concentrating on the average does not seem to be very informative with regard to differences and similarities in pre-service teachers' attitudes about teaching mathematics and other subjects in inclusive settings. Therefore, we analyzed how often they do feel exactly the same, i. e. how many participants crossed out exactly the same for teaching mathematics and other subjects in inclusive settings. It turned out that between about 73 % (helpless/self-confident) and about 79 % (uncomfortable/comfortable) feel the same about teaching in inclusive settings no matter if they think about mathematics or other subjects. Nevertheless, some pre-service teachers see even big differences between teaching mathematics or other subjects in inclusive settings. Single participants even feel

[1] N = 240 for helpless/self-confident, N = 241 for all other opposite pairs

(very) burdened with respect to teaching mathematics but (very) unburdened with respect to teaching other subjects in inclusive settings. However, also the other way round could be identified, i. e. single participants who feel burdened with respect to teaching other subjects but unburdened with respect to teaching mathematics in inclusive settings.

Table 3: Pre-service teachers' affective attitudes in comparison of teaching mathematics or other subjects in inclusive settings (1 = very anxious and 7 = very relaxed)

	means before the course		means after the course	
	mathematics	other subjects	mathematics	other subjects
anxious/relaxed	4.37	4.46	4.23	4.39
helpless/self-confident	4.12	4.3	4.26	4.40
burdened/unburdened	3.79	3.93	3.72	3.93
pessimistic/optimistic	5.10	5.13	4.93	4.98
uncomfortable/comfortable	4.96	5.01	4.80	4.88

A pre-post-comparison did not show significant changes in pre-service teachers' affective attitudes about teaching other subjects in inclusive settings after they had completed the SLE-course. This might not be surprising because the course on SLEs especially focused on teaching mathematics in inclusive settings.

Discussion and conclusions

In total, results of the project 'Mathematics Inclusive' show that the underlying didactical concept of using SLEs and realizing a natural differentiation is suitable for inclusive classrooms. Moreover, the course concept with the combination of theoretical elements, concrete video examples and pupils' documents (lecture) and practical experiences (interviews at school) with a common reflection (seminar) could reach the mentioned project objectives (see Scherer, 2019b; 2021). However, only a few changes of pre-service teachers' attitudes and beliefs could be identified after they had completed the course (whereby participants still feel optimistic about teaching mathematics in inclusive settings but significantly less optimistic than before the course; see section results). On the one hand, it might be interesting to further develop the concept of the course in a way that pre-service teachers' emotions and feelings are going to be more in focus – especially the ones of pre-service teachers' who associate quite negative feelings about teaching mathematics in inclusive settings. On the other hand, beliefs and attitudes might not change within a course which lasts for one semester. Therefore, it would be interesting to analyze their beliefs and attitudes after a longer period of time.

Future research within the project will focus on a connection between pre-service teachers' pre-experiences with inclusive mathematics (see section previous results) and their beliefs and attitudes. For example, it could be interesting to compare their affective attitudes depending on their experiences (especially, because experiences seem to be an important factor that might influence pre-service teachers' beliefs and attitudes about inclusion (cf. Ruberg & Porsch, 2017)).

At the moment, the used items of the questionnaire for investigating pre-service teachers' affective attitudes take into account teaching mathematics in a class as a whole. It could be interesting to ask for pre-service teachers' affective attitudes in a narrower way, like we did for analyzing their competence development. For example, it could be focused on their feelings concerning interviews with pupils or planning and using SLEs in classroom. As pre-service teachers' feel a bit less optimistic after the course, interviews are planned to gain deeper insights in their affective attitudes. Possibly, the practical experiences within the course did lead to a less optimistic view because they experienced and might assess the specific requirements of inclusive mathematics teaching now more realistic. The differences and similarities concerning teaching mathematics or other subjects in inclusive mathematics could also be analyzed in more detail, if interviews were conducted.

Affective and mediational suitability of an inclusive mathematics program

Teresa F. Blanco[1], Alejandro Gorgal-Romarís[1], Cristina Núñez-García[1] and Pablo G. Sequeiros[2]

Keywords: Inclusive education, mathematics, didactical suitability and adolescents.

Introduction

One of the main objectives of the current education is to create inclusive teaching-learning processes that guarantee equal opportunities for all students. In recent years, several studies and reports (Renta et al., 2019; Save the Children, 2020) have revealed a worrying increase in adolescents at risk of social exclusion. The term social exclusion encompasses those sectors of society that are in a vulnerable social situation, which causes them to be outside certain rights relating to work, education and culture (Artuch-Garde et al., 2017). The fact of not receiving an adequate education prevents these sectors of society from being formed as citizens capable of functioning within the world that surrounds them, which does not help them to get out of the circle of exclusion.

In this work, we follow the Didactical Suitability Theory (DST) (Godino, 2013) in order to evaluate the didactical suitability of a socio-educational program promoting the mathematical stimulus to adolescents at risk of social exclusion. The DST analyses the didactical suitability of an instructional process through the study of six partial suitabilities: epistemic, cognitive, interactional, mediational, affective and ecological. Concretely, in this study, we focus on the study of both affective and mediational suitability of the program. Affective suitability refers to the degree of the students' involvement (interest, emotions, motivation, attitudes, and beliefs) in the study process; mediational suitability depends on the availability and adequacy of material and temporal resources in the teaching.

Methodology

The program is developed in 14 one-hour sessions addressing the mathematical stimulus by means of integrating the STEAM methodology (Blanco et al., 2018). These sessions were carried out fortnightly outside of school hours in three different secondary schools. The design of the activities carried out in each session contemplates diverse mathematical content from a variety of interdisciplinary contexts. In the "A mix that blows up?" activity, the students have to search through an experiment what is the proportion of vinegar and bicarbonate that establishes the chemical reaction to inflate a balloon as much as possible. The sample was made up of a total of 68 from the first level of the Spanish secondary education and from three different schools. The schools are located in semi-urban areas in which a large proportion of the population consists of families at risk of social exclusion. The students participating in the programme were selected in a joint meeting by the researchers, the mathematics teachers, and the orientation staff of the school, responsible for assessing and attending the educational and family needs of each pupil in his/her learning process. The instruments used for data-collection were the video recordings of the sessions, the researchers' notebook – as a record of participant observation – and semi-structured interviews with the secondary schools' mathematics teachers and orientation staff. In addition, a satisfaction questionnaire was applied for each activity carried out at the end of each session. In order to assess the mediational suitability, the following indicators given by the DST were analysed: the material resources, the number of students, the schedule and classroom conditions, and the duration of the sessions. For the affective suitability, students' interests and needs, their attitudes and emotions are some of the indicators studied.

Results

The results show a high degree of affective and mediational suitability due to the presence of at least 87 % of the indicators in all activities. The use of different materials, individualized work and varied workspaces favour that these students actively participate in the sessions (mediational suitability). The presence of a greater interest in activities leads to a positive attitude towards academic tasks (affective suitability), which has been evidenced, in fact, in better academic results. In conclusion, the role played by mediational suitability in this context is highlighted, with a direct influence on affective suitability, especially in terms of attitude towards the subject.

Problem-solving by students with Asperger's Syndrome

Ángeles Chico[1], Inmaculada Gómez[2] and Nuria Climent[3]

University of Huelva, Spain; [1]angeles.chico@ddi.uhu.es; [2]inmaculada.gomez@dedu.uhu.es; [3]climent@uhu.es

This study considers the use of heuristic strategies by pupils with Asperger's Syndrome in a problem-solving workshop. The strategies aimed to mitigate learning difficulties associated with the syndrome as a result of deficits in central coherence and executive functioning by introducing manipulatives and visual organisers to support the processes of understanding and finding solutions to the problems. The different heuristics employed during the comprehension, execution and verification phases, in addition to the visual and tactile nature of the materials, promote diversity in terms of the chosen strategies, and stimulate the pupils' abilities. The limitations imposed by literal thinking and cognitive rigidity, alongside weak attention and organisation, can be reduced by a more schematic, as opposed to mimetic, visual content, and a more explicit sequencing of the problem statement.

Keywords: Problem Solving, Asperger syndrome, inclusion, heuristic, inclusive Mathematics.

Introduction

This study aims to contribute to inclusive education regarding the needs of children with Asperger's Syndrome (AS). Specifically, it considers how a problem-solving approach (PS) can be adapted for use with students with AS, and trials classroom-based strategies that can be applied in any classroom. The mathematical focus targets PS, as this approach allows for the incorporation of tables, diagrams and other visual material, encouraging the organisation of data and developing cognitive flexibility (Liljedahl et al., 2011). This enables the teacher to design an environment conducive to diversity of thinking through the application of different heuristics, generalizable to other contexts.

The study explores how specific pedagogical strategies might be deployed in order to minimise the characteristics of AS which impede mathematical learning, and maximise those that promote it (Roos, 2013). The strategies were trialled in PS workshops with children from the Huelva Asperger's Syndrome Association (AOSA) and the results were analysed. The research questions were the following: What strategies facilitate PS with children with AS? What heuristics do they bring into play when they attempt to solve problems?

Theoretical framework

AS is a pervasive developmental disorder within the autism spectrum. The majority of students with AS have average to above-average intellectual abilities, but present characteristic personality traits and abilities. Research by Happé and Frith (2010) suggests that people with AS present deficits in central coherence, which translates to an incapacity to infer the larger meaning inherent in a communicative situation. The result is that they tend to process meanings without reference to the broader context, which can be manifested in difficulties with understanding non-verbal messages. People with AS tend to prefer fixed routines and patterns of behaviour, usually showing emotional vulnerability and often have a limited tolerance of frustration (Carr & Seah, 2019). Their motor skills are characterised by a low degree of coordination and limited fine motor skills. Many people with AS show weak executive functioning, which limits their flexibility of thinking, the capacity for internal representation, and organisation (Bae et al., 2015). By contrast, they show talent in certain areas, such that they may excel in terms of visual and mechanical memory, auditory perception, the ability to focus on detail, and pattern recognition (de Gimbattista et al., 2019). Into the bargain, those with savant syndrome display astonishing skills in different branches of the arts, and may present hyperlexia, hypermnesia or hypercalculia (Happè & Frith, 2010).

With regards to these characteristics, we consider PS ideally suited to pupils with AS as it provides a narrative context in which they can participate, helping them to assimilate concepts and processes. Finding solutions to problems allows the pupils to try different strategies and ways of thinking. Within the confines of this study, it provides with an excellent opportunity for exploring what it is they need to understand and process from the problem statement in order to proceed to a solution.

Improvements in the PS of pupils with AS through specific strategies have been reported. Among these are interventions aimed at improving sequencing (Klaren et al., 2017), which suggests that structuring the solution into stages would be beneficial. In this regard, the strategies and heuristics described in the work of Polya (1945) can be highlighted for the support they offer in interpreting the information and organising the answers. Various studies illustrate the benefits of simplifying and contextualising problems in terms of pupils' interests, deploying a set of strategies for representing the information and providing stages for solutions (Delisio et al., 2018). Also worth noting are transversal methods, such as the TEACCH programme, which use augmentative and alternative systems of communication to support written language with pictograms (Bruno et al., 2018). Finally, the literature review by Kribbs and Rogowsky (2016) brings together references to PS which foreground visualisation as the key feature, an essential issue in eliminating and/or limiting problems deriving from comprehension of written texts.

Methodology

In collaboration with the AOSA and the INCLUREC Project[1], we organised a two-day mathematics PS workshop featuring problems adapted for an age range of 6 to 18. The AOSA psychologists grouped the participating students according to age and characteristics. There were varying levels of ability; one group included pupils with ADHD (Group 1); two included pupils with limited cognitive capacity (Groups 2 and 4). After problems selection, a set of manipulatives were made, designed to illustrate through pictograms the sequence described in the problems These were accompanied by a visual organiser for recording the information and step-by-step solutions. The materials and problems were first trialled with a control group of schoolgirls not diagnosed with AS, of similar ages to those attending the workshop, aiming to gain experience of using the materials applicable to the workshop itself. The original selection included more problems than were ultimately used, as experimentation

[1] INCLUREC (from the Spanish for 'inclusion resources') is a Teaching Innovation Project (University of Huelva), which maintains a permanent workshop for developing and adapting teaching resources for students with special educational needs.

prompted a degree of reduction and adaptation to the needs of the pupils towards whom the workshop was directed (see Table 1 below, outlining the potential heuristics for each problem, according to each solving stage, drawing on Carrillo, 1998):

GROUP 1	GROUP 2	GROUP 3	GROUP 4
6 students	5 students	2 students	3 students
11, 12, 13 and 15 y.o.	12, 13 and 18 y.o.	6 and 7 y.o.	15 and 16 y.o.

Figure 1: Workshop groups

Content: Those problems that were pre-algebraic in nature were simplified, and those involving fractions were discarded altogether, on the premise that the workshop was oriented towards the use of strategies rather than arithmetic. The topics chosen for the problems was especially significant, and featured situations of interest to the students relating to their everyday lives; they also paid special attention to the characteristic of people with AS regarding specific topics.

Resources: A laminated visual organiser was supplied, which allowed the students to place the illustrations in position with Velcro, with room in a table alongside for them to note down any information that would help them to understand and carry out the problem. The set of illustrations and organiser was complemented by differently coloured tongue depressors to represent the information in tactile form. In the case of the second problem, involving farm animals, the pupils were free to represent the elements involved however they wished, but unlimited numbers of coloured dot stickers were available for representing the animals. In both cases the material allowed different ways of reaching a solution, given out directly after the instructions had been carefully read and sequenced.

Table 1: Problems, workshop materials and heuristics arising at each stage

<table>
<tr><td colspan="2">These figures are made from sticks which are all the same. How many sticks are needed to make 4 figures like these?
And 7 figures?</td><td>1B (Group 3)

1A (Group 1, 2 and 4)
</td><td>Coloured tongue depressors
Instructions with pictograms and illustrations
Visual organiser
Illustrations of 1-7 figures, held in place by Velcro</td></tr>
<tr><td rowspan="3">Heuristics and stages in the solution</td><td>Identification and understanding</td><td colspan="2">Promoting perception: observing the illustrations and the information they represent.
Representation: reproducing the information in the problem using depressors, pictures held in place by Velcro and a table for charting progress.
Exemplification: the illustrations enable the pupils to see examples of how to construct the figures with the right number of sticks.
Organising information: The organiser lets students note down the information alongside the illustrations.</td></tr>
<tr><td>Planning, exploration and execution</td><td colspan="2">Finding regularities: Noting whether the number of sticks varies from one figure to another.</td></tr>
<tr><td>Verification</td><td colspan="2">Generalising: finding a pattern which relates the number of sticks to the figures.</td></tr>
</table>

<table>
<tr><td colspan="3">2 (Groups 1, 2, 3 and a student from group 4)
Juan lives on a farm with some chickens and rabbits. If he counts all the animals, he counts 10 heads and 28 legs. How many chickens are there on the farm? How many rabbits?</td><td>Coloured dot stickers
Question statement with pictograms</td></tr>
<tr><td rowspan="3">Heuristics and stages in the solution</td><td>Identification and understanding</td><td colspan="2">Representation: Extracting the relevant information from the question statement, supported by pictograms and illustrations.</td></tr>
<tr><td>Planning, exploration and execution</td><td colspan="2">Focus on a single variable or condition: Starting from the number of heads, discard the other information, which then allows the pupil to simplify the beginning of the solution.
Trying numbers, randomly or systematically: Assigning a value to the number of chickens or rabbits.
Foreground the progress made along the way: Setting sub-goals helps pupils discover the relationship between the number of legs and heads as the pupils draw them.</td></tr>
<tr><td>Verification</td><td colspan="2">Checking the consistency of the solution and the process: While the pupils are drawing the animals, they check their solution by repeatedly counting of the number of legs.</td></tr>
</table>

Data collection from the PS processes during the workshop was carried out by means of observation and video-recording, along with the students' own comments while they were working their way through the material. The subsequent transcription enabled units of information to be obtained relating to the application of the heuristics, explanations of the strategies and difficulties arising at the comprehension and solution stages linked to the characteristics of the students. These units were then categorised according to the heuristic used and the pedagogical aspect involved, allowing for a comparison between the workshop and control groups.

Results and discussion

Use of heuristics

All those participating in the workshop managed to establish different generalisation strategies in problems 1A and 1B, developed through finding regularities and patterns among figures. Some added 9 sticks for each additional figure, developing a factual generalization (Radford, 2001); and others focused on the shared stick forming part of the heads, multiplying the number of figures by 10 and subtracting from that the number of figures less 1 (10n-(n-1)) through contextual generalization, since they could explain the construction of any given figure but did not manage to apply symbolic language (ibid., p. 83). In some instances, however, pupils had difficulty in generalising the pattern to larger numbers, such as 9 or 10. It was nevertheless very clear that the use of the manipulatives (i.e., the tongue depressors) and the table helped the pupils to sequence each step of the task. Ramón (Group 1) initially rejected the shared stick hypothesis. Instead, he noted down the data in his table as he counted the sticks for each set of figures, in order to establish a count back strategy, ignoring the visual evidence of the figures he had made. Unfortunately, his calculations were incorrect, largely because of his poor concentration skills due to ADHD.

Some students, such as Miguel Ángel and Juan (group 2), worked on a simpler mathematical plane by constructing successive figures and then counted the number of sticks. In this instance, the use of the table for keeping a running total of sticks for each new figure, enabled them to see the numerical pattern involved and anticipate the expected results. The implementation of this problem, albeit under guidance, gave the students the freedom to choose whether to use the organiser or the depressors according to their needs (Figures 2 and 3).

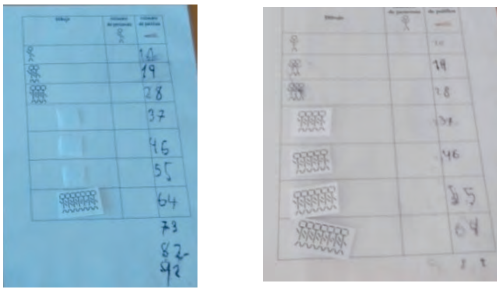

Figure 2: Generalisation in problem 1B

Figure 3: Representation in problem 1A

In Problem 2, the pupils were given free rein to use the materials in any way they chose to represent the animals. The results (Figures 4-7) ranged along a scale from the more literal to the more figurative. What can be noted from these illustrations is that the problem is more clearly understood when the representation is figurative (Kribbs & Rogowsky*,* 2016), as it draws attention to the relationship between the problem data and encourages the pupils to focus on the essential concepts involved rather than a mental image of the animals. The children whose representations approximated to the literality of Figure 5 later found it much harder to substitute rabbits for chickens, and vice versa. This kind of difficulty was no seen in the control group.

Establishing sub-goals promoted the development of pre-algebraic thinking, in that the relationship between two unknown variables needed to be determined. Starting from only one of them (the number of heads), represented by drawings or with dot stickers, the relationship with the number of legs could then be established, through use of the heuristic "trial and error", by which the number of rabbits and chickens was adjusted according to whether the total number was greater or smaller than that given in the problem statement. An unexpected strategy was the systematised trials (Figure 6), since pupils with AS tend to learn sequentially, have weak organisational skills, and lack flexible thinking (Bae et al., 2015), all of which were deployed in this solution.

Figure 4: Representing rabbits by drawing their heads and legs (Problem 2)

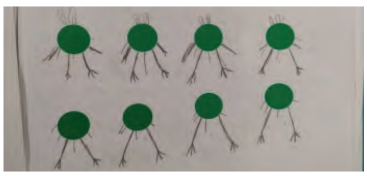

Figure 5: Substituting chickens for rabbits (Problem 2) resulted in 6-legged animals

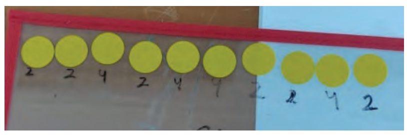

Figure 6: the number of legs is written underneath each sticker (Problem 2), alternating until the student hits the target

Educational aspects

Although the groups varied and there were differences in executive functioning, the key aspects in the teaching-learning process were the use of visual material and the sequencing of the task. Despite the organiser being available in Problems 1A and 1B, which allowed the students to separate out the information into rows and columns, and aids such as the depressors and illustrations on Velcro being supplied, the initial phase of the problem was characterised in 80% of the cases by the wait for instructions or suggestions on how to proceed, such as whether errors could be erased (Gabriel, Group 4), and questions about using the material, and the steps to follow in the solution. The latter example refers to Cristóbal (Group 2), who, despite finding the pattern to follow in the problem, stopped after completing each row to wait for further instructions. This kind of behaviour may have been the result of over-monitoring on the part of tutors, teachers, and family members, by which students with specific needs inadvertently have their range of responsibilities much reduced, disconnecting them from their own learning (Roos, 2013). Mechanisms of self-instruction also occurred, by which pupils attempted to set goals and meet the aims of the problem, although in the majority of cases the pupils followed the steps of their chosen strategy to the point of forgetting why they were doing so, highlighting limitations in their short-term memory. This was the case with Jaime (group 1), who organised the information in Problem 2 into a table but was unable to establish the relationship between the heads of the animals and their legs (Figure 7). Using stickers to represent both animals indiscriminately only increased the degree of difficulty, and he became more frustrated when he found he could not apply his strategy, nor remove the stickers ("I'm very bad at maths because I complicate things a lot"). Although the pupils needed continuous guidance, and were limited by cognitive rigidity the visual organiser and tongue depressors helped to promote a degree of diversity of thinking (Problem 1). Participants constructed the figures and noted down the number of sticks in the table, repeating the process as many times as necessary until they recognised the pattern, some requiring just one construction, others needing more examples to complete or check their calculations.

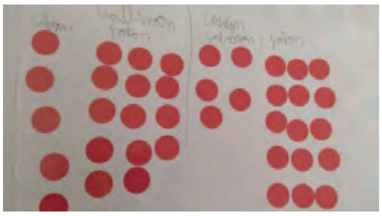

Figure 7: Tabular presentation of chickens and rabbits' heads and feet (Problem 2) using dot stickers

David (4):	It's like it was the 9 times table. You work it out according to the people in the drawing and you add 10 from the first one, which is the odd one out and doesn't follow the pattern.
Ignacio (2):	I'm changing the numbers in the table. To this one (a number in the units column) I take one away and I give it to the other one (a number in the tens column).
Tutor:	What if you didn't know the previous one? 9 people, for example.
Ignacio (2):	Then I take away 2 and I give it to the other one.
Marta (1):	For each figure you add 9 sticks to the others because they share this stick (pointing to the illustration held in place by Velcro).
Tutor:	And how do you then know how many sticks there are in 7 people?
Marta (1):	I count the number of people there are (x10) and I take away the shared sticks.

The acceptability of each strategy proved to be key to combatting frustration, and was a significant motivating factor for a group of students who were used to a kind of mathematics in which there was only one way to find a solution. It is worth noting that during the carrying out of the workshop, the students in Group 4 decided on comparing strategies for themselves, out of curiosity. An atmosphere of expectation was also created by presenting the problems as challenges, graded according to difficulty, such as the progression from 1A to 1B. This intrinsic motivation, together with empathy, proved to be the keys to emotional control and self-esteem (Goleman, 1995).

With respect to the visual nature of the solutions, it was clear that the use of colour made the difference in both understanding and solving Problems 1 and 2 (Figures 8 and 9). Nevertheless, literal thinking once again influenced the pupils' capacity for visualisation: Gabriel (Group 4) rejected the pattern of the shared stick (Problem 1B) because of the thickness of the lines in the illustrations; while Salvador (Group 2) refused to try and solve Problem 2 because the shape of the stickers did not match his mental image of what rabbits and chickens should look like.

Salvador (2): I know that you are referring to that rabbits have four legs and chickens two, but this is not a rabbit (draws a rabbit in great detail on the page).

Figure 8: Using dot stickers and different colour chalks for each animal to improve counting and understanding (Problem 2)

Figure 9: Using differently coloured sticks to distinguish what needed to be added to each figure (Problem 1B)

Conclusions

The visual element and colours helped to reduce the difficulties associated with understanding the problems, by complementing the verbal meaning and reducing the decoding process (Delisio et al., 2018). Nevertheless, literal thinking became an obstacle when the choice of illustration or visual representation did not match the mental image of the pupils. Hence, it is important to transform illustrative representations into schematic ones (Kribbs & Rogowsky, 2016) which form part of the solution itself, and are not limited to decorative additions or demonstrations of artistic ability. Such representations could also help to overcome limitations associated with visuospatial deficits and weak mental flexibility (Liljedahl et al., 2011). On another level, orderliness and organisation were both important and necessary (Klaren et al., 2017), as a dynamic part of the processes of understanding and carrying out the problems and were encouraged by the staged solutions and by heuristic strategies such as representation and the different types of generalisations (1A and 1B). It is necessary, however, to develop the visual organiser and materials which make up for the deficit in the executive function associated with AS (Delisio et al., 2018), ordering each stage of the strategy without losing sight of the objective and the information in the question statement. This was made evident in Problem 2, in which the trial and error and the sub-goal, although applied correctly, ended up becoming disconnected from the process of the problem. We would also highlight the spontaneous use by some of the pupils of heuristics such as best guessing – in some cases systematised – which might on first consideration appear incompatible with the rigidity of thinking and lack of intuition associated with AS, but which was successfully deployed in the workshop.

Based on this experience, we are considering PS workshops as an impetus for the development of student autonomy, whereby the pupils make use of different materials, types of representation and strategies for themselves, and for developing self-regulation and feedback techniques associated to the metacognitive processes.

STEM education provides students with 21st century skills considered critical to correspond to the increasing challenges of the real world, and to face an increasing demand for specialized STEM labor. However, there are several issues related to skills shortages in STEM fields, namely related to mathematics. In this regard, it is crucial to highlight the role of the M in STEM in order to innovate and improve the teaching of mathematics. This paper presents an integrated approach of STEM education highlighting the role of mathematics to understand a real-world problem in the context of COVID -19 pandemic. With a qualitative methodology and based on a case study, this research shows mathematical tasks to raise awareness of students of how the virus spreads and to understand the need for isolation measures, among others. Based on this research it is recommended to resort to mathematical tasks based on real world scenarios to promote meaningful learning in students.

Keywords: STEM education, mathematics education, hands-on, COVID-19 pandemic.

Introduction

To face an increasing demand for specialized STEM (Science, Technology, Engineering and Mathematics) labor, it is recommended to implement STEM education to provide students with 21st century skills considered critical to correspond to the challenges of the real world (e.g., Baker & Galanti, 2017). However, there are issues related to skills shortages in STEM fields, namely related to mathematics. For example, it is referred that mathematics contributes to the problem of insufficient STEM graduates (e.g., Beswick & Fraser, 2019). Therefore, there is a need to highlight the role of M in STEM in order to innovate and improve mathematics teaching (Stohlmann, 2018). In particular, a context that integrates M with Science, Technology and Engineering (STE) can provide meaningful connections between mathematics and STE subjects in students (Becker & Park, 2011).

This paper presents an integrated approach of STEM education highlighting the role of mathematics to understand a real-world problem. COVID-19 pandemic has invaded our world and conditioned our way of living (Padmanabhan et al., 2021). For example, students had to be isolated in their homes without going to face-to-face classes for several months. In addition, every day the news reveal the number deaths, of newly infected, and the total number of people infected, among other information related to the disease. The main research question is "How can mathematics be used to make students understand a real-life pandemic scenario?" To answer the research question, a case study of a 6th grade teacher, who participated in a Professional Development Programme (PDP) will be presented. Her example shows the implementation of integrated STEM tasks in class with focus on mathematics.

Literature Review

To face a fast-changing world and the complexity of modern societies, the literature advocates the need for motivating students to learn and gain skills related to STEM subjects (Kelley & Knowles, 2016; Roehrig et al., 2021). In addition, STEM education should make the transition from traditional lecture-based teaching strategies to more inquiry and project-based approaches (Breiner et al., 2012), with the aim of providing students with skills to solve real life challenges and improve their achievement (Beswick & Fraser, 2019; Geiger, 2019). In this regard, the introduction of STEM education, based on real life scenarios, motivates students to learn and promotes the development of 21st century skills (English, 2017; European Schoolnet, 2018; Maass et al., 2019). In Portugal, there are also increasing calls for innovative approaches, having recently emerged several guidelines, namely on Essential Learning (MEC, 2018) in conjunction with the Profile of Students When Completing Mandatory Schooling (ME/DGE, 2017). The last document mentions the need for educational systems that contribute for the development of skills that allow students to respond to the complex challenges of the 21st century, taking into account the evolution of knowledge and technology. In this sense, the curriculum must be interpreted by teachers to explore different themes that must be framed in everyday problems of both the students and the socio-cultural environment where they are inserted in (ME/DGE, 2017). In this regard, meaningful learning should be provided by relating the most important contents of the subject to be taught with relevant aspects of the student's cognitive structure including the environment where the student is inserted in (Ausubel, 2012).

An integrated approach of STEM education should include real-world scenarios with the aim of engaging students and providing them with meaningful learning (Kelley & Knowles, 2016; Maass et al., 2019). In fact, modern world face complex problems that involve interdisciplinary knowledge and skills to solve them, which requires for curricular integration in schools (Roehrig et al., 2021). In addition, mathematics should be more emphasized in STEM integration (Stohlmann, 2018). Moreover, STEM education can be a form of innovation for teaching mathematics (Fitzallen, 2015) and to increase mathematical performance (Stohlmann, 2018). Furthermore, there is a need to develop research to understand how STEM integration can promote mathematics education (Baker & Galanti, 2017). However, the role of mathematics is understated within the STEM field. Therefore, it is necessary to develop more research to make mathematics more meaningful across disciplines, and also to support teachers in this direction (Maass et al., 2019). In fact, teachers have a crucial role on adapting their practices to provide students with the contexts and strategies recommended to provide an effective STEM education in schools (Kelley & Knowles, 2016; Stohlmann et al., 2012). In addition, an increasing number of authors argue about the importance of integrating the four disciplines included in the STEM acronym (Costa et al., 2020; Kennedy & Odell, 2014).

In 2020, COVID -19 pandemic, caused by coronavirus SARS-COV-2, seriously affected all life in the world (Meehan et al., 2020). The pandemic reminded us that the future is uncertain and consequently there is a need for preparing citizens and education systems for what may come, which can include changes that we are not expecting (OECD, 2020). Therefore, virulent communicable diseases are one of the global challenges that must be addressed in the context of STEM education (Maass et al., 2019). More information about modelling COVID-19 pandemic can be provided by Meehan et al. (2019) and Padmanabhan et al. (2021).

Methodology

In this paper, we use a qualitative research methodology and an interpretative approach by resorting to a case study (Cohen, Lawrence, & Keith, 2007). A case study is an empirical research that observes a phenomenon within its real-life context, allowing a generalization of the results obtained, and requiring skills and expertise from the researchers (Yin, 2014).

First authors of this paper designed a PDP that includes several workshops with the aim of providing teachers with knowledge and skills to develop and implement STEM hands-on practices in class. In the school year 2020/2021 the programme occurred exclusively online because of the COVID-19 pandemic. Despite being online, the educators tried to preserve the hands-on practices by exemplifying them through videos and interactive sessions through the Zoom platform. Teacher Elisa (fictitious name) case study was chosen to exemplify how to develop an integrated approach of STEM education based on real life scenarios such as COVID-19 pandemic. She is a Mathematics and Natural Sciences teacher who participated in the referred PDP, aged 55 years old, 30 years of in-service experience and in charge of two 6th grade classes (10 to 11 years old). At the end of the PDP (2021 January), Elisa (like all the other teachers) presented a final report that includes a critical account and her perceptions about the programme, and also proposals of tasks to implement, as well as evidence of the activities developed in class. Data collected include participant observation that occurred during the workshops of the PDP (first author was present in all the workshops, where focus group was promoted) and content analysis of Elisa's final report. In addition, five interviews were conducted with the teacher by phone to better interpret the case.

Data analysis, results and discussion

In this section, it is analyzed Elisa's case study that shows the development and implementation of mathematical tasks within the context of COVID-19 pandemic. Elisa was very participative in the workshops. In addition, in the interviews she mentioned that she wanted to develop activities that were within the curricula she was lecturing and that had meaning for her students. It was not easy to choose a theme that was appropriate for her students and included in the curricula of their grade level. However, after several discussions with the educators, she finally opted by an interdisciplinary theme in the context of COVID-19 pandemic, in order to use mathematics to help interpret and predict the evolution of the pandemic according to various possible contagion scenarios Inspired on Providência (2020) paper, Elisa planned and developed several tasks to be implemented in class.

Table 1: Tasks implemented in the mathematics class

Tasks	Scenario of infection
1	Each student infects two colleagues
2	Each student infects three colleagues
3	Each student only infects one colleague
4	Probability to infect someone is less than one
5	80% of students are vaccinated

In a first stage, she introduced COVID-19 thematic in the Natural Sciences class because the virus context is part of the curricular contents of this discipline, in the field of Environmental Aggressions and Integrity of the Organism. In a second stage, she developed several tasks to be implemented in the mathematics' class. Table 1 describes some possible scenario of infection proposed to the students to help them understand the need for isolation or vaccination measures. It is important to notice that in the 6th grade level it is not possible to resort to advanced mathematics to model the pandemic.

In task 1, Elisa explained the scenario where “Each student infects two colleagues” and that “Sick students are isolated at home and no longer infect colleagues”. She also constructed a grid with 12 lines and 12 columns, where each square represents one student from a school (Figure 1). In addition, a table with the “Day” in the first column, the “Number of students who gets sick” in the second column and the “Total number of sick students” in the third column was constructed (Table 2). After, she asked the students to paint the number of sick students on the grid.

Teacher: Imagine that each square on a grid (Figure 1) represents a student from a school. One day, which we will call day 1, one of the students becomes sick with COVID-19. Represent him, painting a red square on the grid.

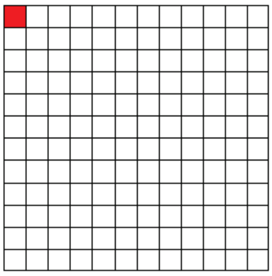

Figure 1: Grid where each square represents one student in a school with 144 students

She also asked students to fill in Table 2 with this information. Next, she gives information about how the sick student infects the others.

Teacher: Let’s now assume that each sick student infects two students on average. To say that it is on average means that it may be that only one person infects one colleague, but there is another that infects three. Therefore, on average, each person infects two colleagues. So, the next day, day 2, there are 2 more students with COVID-19 who were infected by the first student with this disease; in all, there are already 3 sick students. Therefore, paint two more squares on the grid, and fill in the table with this information: on day two, 2 in column two and 3 in column three.

Teacher: Again, sick students are isolated at home and no longer infect colleagues. Now, each of these two students is going to infect two other colleagues, and on the third day there are four more sick students. Therefore, paint four more squares on the grid, and fill in the table with this information.

Table 2: Each student infects two colleagues

Day	Number of students who gets sick	Total number of sick students
1	1	1
2	2	3
3	4	7
4	8	15
5	16	31
6	32	63
7	64	127
8	128	255

Next, she asks several questions:

a) How many new students will be infected on the 4th day?
b) And what is the total number of sick students?
c) In what day is everyone sick?

d) What if the school had 1000 students, after how many days would all students be sick?
e) Can you write the numbers of column 2 in powers of two?

Table 2 is filled with the numbers until the day where all the squares on the grid (Figure 1) are red, which means that all 144 students are sick. As can be seen, on the 8th day all students are sick, in a school with a number of students bigger than 127 and smaller or equal to 255 students. Almost all students from two classes of Elisa presented the results as stated on Table 2.

Only two students, one from each class, considered that the school only had 144 students, and for this reason, in the 8th day only 17 students get sick and consequently the total number of sick students is 144 (Figure 2, table on the left). Below follows the answer of one of these two students.

Student: On the 8th day, only 17 students get sick because in total there are only 144 students in the school and 127 students are already infected, so only 17 students are missing.

The same student also presented the table on the right of Figure 2 to answer that at the 10th day all students from a school with 1000 students would be sick.

Figure 3: Writing the numbers in column 2 in powers of two

In addition, Elisa asked students to write the numbers in column 2 in powers of two. A power of two is a number of the form 2^n where n is an integer, that is, the result of exponentiation with number two as the base and integer *n* as the exponent. Based on this question, she explained to the students that “the growth of students sick with COVID-19 was exponential”. Figure 3 gives examples of answers given by students. On the left, the result given by most of the students and on the right one of the students who considered the total number of students on the school as 144.

After ending task 1, teacher Elisa introduced the following tasks as stated on table 1. During the task 2, where “Each student infects three colleagues” teacher Elisa observed excitement in her students:

> At this stage, a high point of motivation of the students was visible in solving the task. They were excited because they understood the situation they are experiencing in their real life (Final report).

She continues, exemplifying students' discourse:

> "Now I understand, now I understand everything, this is so fast, contagion, ... and we are not counting everyone, families are missing and other people who have contact with them!"

Based on the tasks performed in class, reflection and discussion about them, Elisa recognizes motivation in her students who finally understood “frightening spread of the virus”. Although she already introduced this theme previously, she reinforces that it was with these tasks that students finally understood the need for measures to prevent propagation of the disease:

> I had already taught the content of “Microorganisms” and obviously had contextualized and integrated the whole problem of the pandemic, but it was with this activity that students finally understood the reason for measures to prevent the spread of the disease. (Final report)

This conclusion is in line with her goals, which was to raise awareness and understanding about the need for measures in the context of COVID-19 pandemic, such as social isolation or vaccination. In addition, Table 3 shows STEM contents included in the tasks developed and implemented by Elisa.

Table 3: STEM contents of the tasks implemented by teacher Elisa

Science	Technology	Engineering	Mathematics
Natural sciences Microorganisms Disease spread Pandemic	Computer Internet Wikipedia Power Point Excel.	Planning, designing and performing the activities.	Powers, Exponential growth Mathematical model Variable, Iteration Functions, Graphics Organization of tables and data visualization.

Also, she highlights the interdisciplinary approach provided in the tasks:

> On the other hand, the interdisciplinary aspect of the task allowed the articulation of the disciplines of Natural Sciences, Mathematics and Information and Communication Technologies and, thus, to participate in the Domain of Curricular Autonomy and Flexibility, as well as in the School Educational Project.

Finally, Elisa identifies the importance of implementing this approach to better prepare students to the real-world challenges. Moreover, she intends to keep participating in this type of PDP:

> In today's world, full of complex challenges, the development and integration of multiple literacies, inspired by real situations, will certainly allow for more meaningful learning in which talent, individual qualification, the scientific system and democratic citizenship are strengthened. We are grateful for the opportunity and we await other formative moments of undeniable value.

In summary, teacher Elisa case study exemplifies the implementation of interdisciplinary tasks related to STEM (Table 3), in particular highlighting the role of mathematics to understand real world problems such as the need for isolation measures or vaccination due to COVID-19 pandemic. As can be seen in Table 3, mathematical contents include Powers, Exponential growth, Mathematical model, Functions, Graphics, Organization of tables and data visualization, amongst others.

Conclusions

It was verified that Elisa did develop STEM practices within an authentic context for the purpose of connecting these subjects to enhance students' meaningful learning (Ausubel, 2012; Kelley & Knowles, 2016). In fact, she used the real scenario of COVID_19 pandemic with the aim of introducing tasks with meaning for her students and related to the curricula of Natural Sciences, Mathematics, and Information and Communication Technologies. Moreover, she achieved one of her main objectives, which was to make students understand various virus propagation scenarios and be aware for the need of isolation or vaccination measures to face the COVID_19 pandemic (Table 1). In addition, her example shows the development and implementation of integrated STEM tasks in the class with an important focus on Mathematics (Table 3). Furthermore, Elisa recognized that it was based on this approach that students finally understood the problematic of exponential grow of infection and its impact on real life. Also, she identified critical thinking skills and meaningfull learning as a consequence of this initiative. Her conclusion is in line with Stohlmann et al. (2012), who states that a strategic approach of STEM education provides students with higher levels of critical thinking skills, improves problem solving skills, and also increases learning retention. Moreover, relevant interdisciplinary learning environments were provided as recommended by some authors (Beswick, & Fraser, 2019; Geiger, 2019). In fact, Elisa highlights the interdisciplinary approach provided in the tasks she implemented in class and also the importance of implementing this approach that provides students with meaningful learning and better prepares them to the real-world challenges. Indeed, she promoted mathematics teaching with real life scenarios in the context of COVID-19 pandemic. Based on this research, it is recommended to resort to mathematical tasks based on real world scenarios to promote meaning learning in students.

Building the bridge for collaborative mathematical instruction: creating a community of practice among pre-service general and special education teachers

Rebecca Dibbs[1] and Susannah Boyle[2]

[1]Texas A&M University-Commerce, Faculty of Mathematics, Commerce, USA; rebecca.dibbs@tamuc.edu

[2]Millersville University, Faculty of Special Education, Millersville, USA; sboyle@millerville.edu

Keywords: Communities of practice, pre-service teachers, special education.

Introduction

A common reason for secondary teachers leaving is challenges with including students with disabilities into general education classrooms (Talmor et al., 2005). Pre-service general education teachers may not receive any instruction about how to effectively adapt their math instruction for students with disabilities (Dibbs et al., 2020). In addition, pre-service special and general education teachers may not be provided with opportunities to practice collaborating on designing lesson plans on math topics for students with disabilities (Trent et al., 2003). This lack of practice can lead to students with disabilities not receiving effective mathematical instruction, potentially leading to lower participation in school, community, and employment (Othman, 2020).

The purpose of this mixed methods study was to investigate how collaborating on lesson plan designs builds awareness of pedagogical content knowledge (PCK) for teaching students with disabilities, guided by the following questions: (1) Does writing collaborative lesson plans throughout the methods course significantly increase preservice teachers' PCK for inclusive mathematics? (2) What is the nature of the knowledge that pre-service mathematics teachers construct about teaching students with disabilities through collaborative lesson plan writing?

Theoretical framework

This study was conducted using situated learning as the lens for inquiry (Lave & Wenger, 1991). The pre-service mathematics teachers were introduced to special education through collaboration with their pre-service special education peers. There were two communities of practice that will occur, one among the pre-service teachers in their content areas, and the other with the pre-service teachers together. By purposefully placing them together, learning will be reinforced theoretically and practically. This study encompasses legitimate peripheral participation by creating a community of pre-service teachers who are familiar with best practices for special education in the general education classroom (Lave & Wenger, 1991).

Methods

A methods course for pre-service secondary teachers course and an upper-level course for pre-service special education teachers were chosen for this study. The pre-service mathematics teachers wrote two student-centered secondary lesson plans. Next, the lesson plans were given to the pre-service special education teachers who adapted each lesson for students with disabilities. Both sets of teachers completed reflection papers, which were coded separately by the authors, and then reconciled. The pre-service mathematics teachers also took a special education PCK instrument (Dibbs, 2021) as a pre- and post-test to measure their knowledge gains on inclusive teaching.

Findings

Three themes emerged from all of the pre-service mathematics teachers following the collaborative lesson plan writing. First, participants noted that the activity helped them to realize how little they knew about special education with respect to inclusive classrooms.

> Maria: "I have no experience with special education and I have very little knowledge of special education. It honestly opened my eyes on how a special education lesson plan is written and how I can adapt my lessons for students with disabilities. I am glad we did this lab because they gave good examples of resources to use for students with auditory, visual, and vocal disabilities."

Second, participants realized that their lesson plans were not as clear as they hoped they were, and much more thought was needed to keep all students engaged in classroom activities.

> Lucinda: "I learned [in the viewing tubes lesson] that students need more instruction, visual organizers, and help with technology than I think they do. It's also important to assign group roles so that all students are actively engaged."

Third, participants noted that the techniques used to support students with disabilities in the classroom could often be applied to all learners to improve the lesson. "Most of the adaptations to the lesson I wrote would actually help all of my students with the activity" Deanna noted in class. Implications of the results, the PCK pre- and post-test, as well as themes from the special education teachers will be discussed further on the poster.

"Individual Educational Plans" for "dyscalculic" students in primary schools of South Tyrol: A questionable law, poorly implied

Michael Gaidoschik

Free University of Bozen - Bolzano, Italy; michael.gaidoschikl@unibz.it

Italian law obliges teachers to draw up Individual Educational Plans (IEPs) for students diagnosed with "dyscalculia". The author analyzed both law and 23 IEPs regarding their compliance with recommendations as stated in current mathematics education literature about how to deal with mathematical learning difficulties (MLDs). Whilst the law clearly mirrors the medical paradigm and largely ignores mathematics education research on MLDs, the IEPs rarely take into account the three content areas that are indicated as crucial for MLDs by educational research. Instead, they tend to lower expectations in terms of reduced number range, continuous granting of compensation measures, and concentration on standard algorithms. The paper outlines key results of a content analysis of the IEPs and discusses their shortcomings with a view to possible consequences on the level of teacher training as well as of desirable changes of the legal and organizational framework.

Keywords: Mathematical learning difficulties/dyscalculia, diagnostic competences, individualization

Focus of the paper

Drawing on mathematics education research on mathematical learning difficulties (MLDs), the paper firstly scrutinizes the reasonableness of the legal and organizational framework for dealing with "dyscalculia" in Italy at present. Italian law foresees that for students with a diagnosed dyscalculia, a council of teachers (including the math teacher of the student) elaborate an "Individual Education Plan" (IEP) to be put into action, evaluated and renewed year after year. By analyzing 23 such IEPs from German speaking primary schools of the Italian province of Bolzano/South Tyrol, the paper secondly aims to gather indications about how adequately the framework is currently put into action in this very province. Finally, against the backdrop of this analysis, alternative and presumably more sensible ways to handle with MLDs are shortly discussed, taking into account the restricted diagnostic and thereto related didactical competences of South Tyrolean primary teachers that emerge from the analysis of the IEPs and maybe comparable to those that can be found in other countries.

Theoretical and empirical framework

MLDs have gained increasing interest from more than one scientific discipline in the last decades (for a current overview, see e.g. Fritz et al., 2019). Psychological and medical research, typically, follow a paradigm in which at least some forms of such learning difficulties are labelled as (symptoms of) a "disorder", nowadays usually termed "dyscalculia". Research in that field is centered on presumed organic, maybe genetic causes of this disorder. As a means for sorting out children afflicted by this disorder (and in order to differentiate them from children with MLDs supposed to be caused otherwise), various tests have been developed and standardized for different countries and age groups (see Kaufmann & von Aster, 2012, for an overview).

From a didactical point of view, as expressed in the recent position paper of the German "Gesellschaft für Didaktik der Mathematik – GDM" (Society for Didactics of Mathematics) (Gaidoschik et al., 2021), the labelling of a subgroup of children with a severe, long lasting MLD as "dyscalculic" is not helpful for pedagogical and didactical purposes and might even turn out to be detrimental. It is not helpful, as for planning remedial measures, we have to understand the concerned child's current stage of mathematical thinking, his or her competences, misunderstandings and shortcomings about fundamentals of arithmetic, in a much more detailed way than standardized tests point at. In addition, with a view to support a single child's mathematical learning, it is irrelevant whether this child belongs to the weakest (or strongest) 5 or 10 or whatever percent of his or her peers (Gaidoschik et al., 2021).

On the downside, being labelled as dyscalculic may have negative effects on the child's self-efficacy expectations and thereby aggravate the MLD (Bishara & Kaplan, 2021). It might also have counterproductive impact on teachers (who could react by just reducing their expectations, thus risking self-fulfilling prophecies, or might think of not being responsible and/or qualified for such "special cases") as well as parents (who could tend to be more interested in compensations for disadvantages than in supporting measures to overcome them) (see e.g. Algraygray & Boyle, 2017, for a broader discussion about possible negative effects of labelling in special education).

As indicated, the above-mentioned position paper of the GDM underlines the importance of process oriented, qualitative assessment of a child's current mathematical thinking. First and foremost, such assessment should focus on those content areas that have been identified by mathematics education research as being crucial for the development of MLDs, namely (cf. Gaidoschik et al., 2021):

Basic number concepts: Severe MLDs characteristically stem from a restricted understanding of natural numbers in that concerned students predominantly conceptualize them as positions within a sequence rather than as "numbers as compositions of other numbers" (Resnick, 1983, p. 114). On that insufficient basis, they struggle to conceive relations between numbers and operations that go beyond their ideas of "forward/backward" within the sequence of numbers, hence tend to stick to counting strategies as their prevailing way to add and subtract (Gaidoschik, 2019).

Place value understanding: Typically, MLDs go with what Fuson et al. (1997) characterized as a "concatenated single-digit conception" of multi-digit numbers. On that basis, children might well learn to perform some calculation algorithms and acquire a certain routine in diverse procedures, yet, lacking conceptual understanding of core principles of the decimal system (bundling and unbundling, multiplicative properties), they will hardly achieve flexibility in computing nor develop sufficient competences in estimating, proportional reasoning, and relational thinking (Gaidoschik et al., 2021).

Conceptual understanding of operations: Children with MLDs, generally, command a limited conceptual understanding of arithmetic operations, in particular of multiplication and division (Gaidoschik et al., 2021), and thus have difficulties to connect them to real-world contexts (Scherer et al., 2016). Subsequently, they often see no chance to solve word problems, if not by deliberately choosing an operation or trying to find a clue by remembering key words, or the like.

As a consequence of the cumulative character of arithmetic learning, if the shortcomings outlined above are not overcome by (remedial) instruction within the first years of schooling, they will nearly inevitably result in even greater difficulties for the concerned students to cope with the curricular content of the following years. Therefore, it is not surprising that we still find the very same problem areas and very similar deficits and misunderstandings as typical also for MLDs in secondary schools, of course amplified by additional deficits and misunderstandings of further content that could not be digested due to the lack of fundamental understanding (Gaidoschik et al., 2021).

From a mathematics education point of view, the high occurrence of such MLDs calls, in the first place, for increased efforts to prepare and enable primary (and already kindergarten) teachers so that they better exploit the considerable potential of preventing MLDs by research-guided instruction (Gaidoschik 2019; Gaidoschik et al. 2021). Then, of course, children who already *have* developed an MLD, need additional measures. The above mentioned position paper of the GDM (Gaidoschik et al., 2021) pleas for a combination of two approaches: On the one hand, teacher resources should be allocated as far as possible to allow for team teaching of mathematics by two well informed teachers. This team should strive to organize themselves so that, while *all* the students of the class are working on what Scherer et al. (2016, p. 641) describe as "substantial and rich learning environments", individual support can be given where needed to those students who otherwise would not be able to participate meaningfully in such mathematical activities, due to missing or deficient prerequisites. On the other hand, for students with MLDs, individualized remedial instruction should be secured to give them a chance to cope with those fundamentals they have not yet been able to acquire. However, this does not have to (and should not) lead to exclusion if class work comprises phases of individualized work for all pupils as a matter of course (Gaidoschik et al., 2021).

The cultural context: An Italian law and its shortcomings from the perspective of mathematics didactics

Of course, the current reality of how MLDs are handled in primary schools seems to be quite different from the recommendations stated above, at least in the Italian province of South Tyrol, to which the present study refers. In fact, though, empirical data about what actually happens in the classrooms are scarce. What can be analyzed and, as a first step, shall be elucidated in the following, is the legal and organizational framework set up in Italy for dealing with "dyscalculia", which is recognized by Italian law as one of several "specific school-related learning disorders" (Gazetta ufficiale, 2010; here and in the following translated by the author).

More accurately, national law 170 determines (article 3) that students diagnosed with "dyscalculia" have the right to receive "individual didactics, tailored to the person" as well as "means to compensate for". The law as a whole declares to aim to "ensure an adequate formation" and foster the "full use of the personal potential" of the student concerned (article 2) (Gazetta ufficiale, 2010). The thereto-related implementation rules of the province of South Tyrol state that the process of diagnosing "dyscalculia" may not be started before "the end of the first semester of year three" of primary school (age 8–9). In case of a diagnosis, to be in accord with law 170, the "team of teachers" of the respective student has to formulate an "Individual Educational Plan" (IEP). This plan has to be drawn up after the first weeks of a school year and is valid until the end of that year. It should consider the report and recommendations of the psychologist who did the diagnosis, and should comprise inter alia "the detailed description of the current level of performance and development" of the student as well as the "planning of the individual objectives" for the student (Brugger-Paggi, 2019; my translation).

Unlike with students diagnosed as "disabled" according to law 104, having a student with dyscalculia does not lead to the assignment of additional teacher's hours to this class. Thus, the mathematics teacher will not receive any support in form of a second teacher, not even at times, nor does the diagnosis entitle the child to receive remedial teaching in or outside the classroom, neither as an individual nor in a group setting (Ianes et al., 2020). Whereas the IEP has to be updated each year, the diagnosis, if made at the end of year 3, is usually reviewed only at the middle of year 5, with a view to the transition from primary to middle school, which in Italy is foreseen after year 5.

Law 170 claims to "consider newest scientific research" (Gazetta ufficiale, 2010). As outlined above, however, at least *mathematics education research* is hardly suitable as an appellate authority for linking *any* special measures for children with MLDs to a diagnosis of "dyscalculia". Secondly, mathematics education research clearly indicates that effective support for children with MLDs should include additional personal resources, which are not foreseen by law 170.

Thirdly, educational *as well as* psychological research shows that MLDs develop on the basis of misconceptions which, often enough, might already be detected in kindergarten and should in any case be in the attention of first grade teachers, so that also counter measures are initiated as soon as possible (Gaidoschik et al., 2021). Of course, law 170 also emphasizes the "duty" of schools and even kindergartens to "take appropriate measures to identify children suspected of having specific learning disorders" (Gazetta ufficiale, 2010). Nevertheless, the law and thereto related regulations link *additional* measures such as drawing up an IEP to the diagnosis of "dyscalculia", and at the same time dispose that such a diagnosis may not be made before year 3 – *against* psychologists who have developed standardized tests for "dyscalculia" already for the end of year 1, and tests that claim to detect "children at risk" already in kindergarten (Kaufmann & von Aster, 2012). If the diagnosis of "dyscalculia" were at all sensible, which is disputed by mathematics education, it would still require explanation (which the legal sources do not provide) why initiating such a diagnosis should be waited for until a child has proven for at least two and a half school years to have severe difficulties in mathematics.

Research questions

As an interim summary of the analysis given above, it has to be stated that the presumably only part of law 170 that may be approved also from a mathematics education point of view is the obligation to draw up an IEP for students diagnosed with dyscalculia. Once again, targeted considerations about how to support students with MLDs should not wait until year 3 or even later, and should not depend on whether the child has received a specific diagnosis. However, an IEP drawn up in a proper way, based on a process-oriented assessment of the current mathematical competences and shortcomings of the child, of course could form a precious guideline for teaching. At the same time, though, it has to be stated that even the best plan has to be readjusted continuously. Then, the additional "administrative load" (Scherer et al., 2019, p. 4622) connected with law 170 might also be seen as deduction of time resources that might better be invested in directly working with the concerned child.

Against this backdrop, the second part of this paper seeks answers to the following research questions:

(1) When South Tyrolean teachers have to state within an IEP the current stage of mathematical competences and shortcomings of the respective student, do they (and if, *how* do they) refer to the content areas that are held crucial for mathematical learning difficulties in mathematics education research and have been elucidated above, i.e. deficient number concepts and thereto linked

predominant use of counting strategies for addition and subtraction, fundamental deficits in understanding the decimal place value system, and lack of conceptual understanding of operations?

(2) Are the learning goals and remedial measures formulated in the IEPs in line with what mathematics education research advices for responding to severe mathematical learning difficulties?

If both questions could be answered with "yes", then, at least, it could be assumed that South Tyrolean schools have found sensible ways to deal with the legal requirements related to "dyscalculia". Of course, in this case it should further be checked what actually happens in the classrooms on the basis of the IEPs. The latter gains even more urgency if already the IEPs should prove to lack appropriateness. However, the present study is limited to the analysis of the IEPs themselves.

Methodology

According to statistical data provided by the educational authority of the province, in 2017/2018 a total of 46 students (or 0.2 %) of all students attending German speaking primary schools of South Tyrol were officially registered as "dyscalculic" and thus addressee of an IEP. As the IEPs underlie strict privacy rules, to analyze them for research purposes, the author had to ask the headmasters of the school districts to transmit anonymized versions of the IEPs. This was done for 23 students. It was not possible to identify the reasons why the other IEPs were not made available but may be assumed that this was due to the fact that anonymizing the IEPs by blackening sensitive data meant some work, and having free choice to participate, some schools might have preferred to avoid this work. Of course, it cannot be excluded that this contributed to a bias of the sample.

All 23 IEPs were submitted to a "qualitatively orientated category-based content analysis" (Mayring, 2020). The main categories were assigned deductively from educational research literature as summarized above, and complemented inductively based on recurring features of the IEPs. In the following, due to the limited space, only the results for those (all deductively formed) categories that are most important in view to the research questions are shortly elucidated. The <u>categories</u> are underlined. Quotes from the IEPs have been translated from German into English by the author.

Results

<u>Overall characteristics of the IEPs, range of elaborateness:</u> The 23 IEPs differ considerably in extent and detail (between 1 and 9 pages; mean: 3.8, median: 3). As explained, the regulations call for a *detailed* description of the student's current level followed by an *individualized* plan of *goals* and thereto related *measures*. Yet, if we take into account only those parts of the IEPs that actually refer to mathematics, we find that 10 out of 23 IEPs dedicate less than one page to both current level and goals/measures. 5 of them, in fact, refer to mathematics only with 2 or 3 lines, typically within a table with tick boxes for briefly formulated measures, such as "use of a calculator". In 7 IEPs the math part takes about one page, in 4 IEPs about 2, and in the two most comprehensive IEPs about 4 pages.

As for the <u>level of detail in which the current mathematical status of the student is described</u>, 3 types of IEPs can be identified, as follows: In 10 IEPs, the authors give a *relatively comprehensive list of curricular contents* (see below for more detail) that the student either has or has not yet mastered. In 6 other cases, only v*ery few content-related competences are named, but at least these clearly refer to mathematics,* such as "Masters the standard algorithms of addition and subtraction". 7 other IEPs practically do not provide *any* information about the *mathematical* competences of a child. One typical example: In one IEP, the child's description with regard to the "mathematical-logical area" is restricted to the following: "Needs much time to comprehend new content. Needs additional explanations and prompts and extended practice. Hardly grasps logical connections."

As for the level of detail with which goals and related measures are formulated, we find the analogous 3 types. As a rule, extent and detailedness of the description of current competences correspond to the attention given to goals/measures. In two cases, yet, a rather detailed status-quo-description is followed by very scarce, mainly general goals/measures, such as: "use of tables and collections of formula, use of specific didactic material, granting of additional working time, personal dedication".

Reference to the crucial content areas: As outlined, only 10 IEPs go into some detail about the concerned child's current mathematical competences and shortcomings. However, the fundamental question whether the child is still dependent from counting strategies for adding and subtracting, is explicitly addressed and answered in only 3 out of 23 IEPs (positively, as has to be expected according to research on MLDs). What's more, not a single IEP explicitly states that the elaboration of non-counting calculation strategies will be a goal of remedial instruction. One IEP, though, foresees "automatizing" basic facts of addition. On the other hand, 5 IEPs explicitly envisage that the child should constantly use material as a help to solve additions and subtractions, arousing the suspicion that the authors regard arithmetic material not as a means to elaborate non-counting strategies, but rather as a device to facilitate computing by counting.

As for the child's understanding of the decimal system, the second crucial area according to research, only 2 IEPs explicitly state problems with bundling/unbundling, in one case in a contradictory manner (the child would understand bundling but not be able to apply it). 6 other IEPs do explicitly indicate difficulties with multi-digit numbers, yet in the unspecified way of "problems to orientate herself with numbers". Accordingly, the related remedial measures stated in these IEPs remain in the vague, such as "consolidate numbers up to 1000". 6 IEPs state as a goal "identify tens, hundreds, thousands", but without explicitly indicating that this should include the elaboration of bundling/unbundling or trading, respectively, as the core principles underlying the place value system.

Finally, as for the child's conceptual understanding of arithmetic operations, only one IEP indicates difficulties with the basic concept of multiplication. Another states problems to connect operations with actions and situations. However, 8 IEPs record severe difficulties with word problems, but without any reference to operation sense as a fundamental prerequisite for solving such problems.

As an interim conclusion, it has to be stated that even those IEPs that, when describing *the current learning status* of a child, refer to mathematical content in some detail, hardly refer to those fundamental content areas that have been identified by research as being crucial for MLDs. Instead, if difficulties are specified on concrete mathematical content level, they mostly refer to *curricular content of year 3 and upwards*; content that can only be learned in a sustainable manner if a child has already acquired the basics which are more or less ignored in almost all IEPs.

As for the individual goals that are set up for the student in the IEP, a common feature of all 23 IEPs is a *reduction of expectations* as compared to the grade level. Only in 8 cases, though, this is combined with explicitly naming *goals also in the area of basic competences* such as single digit multiplication or working on place value in the way characterized above. 7 IEPs stipulate a *concentration on numbers up to 1000*, whereas the grade expectation would go beyond that number range. 12 IEPs explicitly state that the *difficulty and/or complexity of word problems* should be reduced, often in addition with the allowance of "individualized help". 6 other IEPs advocate a *"reduction of demands"* without specifications. The two explicit goals that are set up most frequently are *mastering the standard algorithms* (12 cases) and *automatizing single digit multiplication* (11 cases). On the other hand, 8 IEPs envisage the use of tables to look up single digit multiplications, often linked to the otherwise unrealistic expectation that the child, without having yet mastered *basic* multiplication, should nonetheless solve *multi-digit* multiplication using the standard algorithm.

Discussion and final remarks

Of course, as the only information we have got about the children is what we can read in the IEPs, the appropriateness of these plans can be judged only indirectly and tentatively, by comparing them to what kind of information they *should* comprise, according to mathematics education research, if the concerned child actually does have developed an MLD. Then, we can assess their *internal coherence* and their *compliance with recommendations* given by current mathematics didactics.

In this context, the high weight that many IEPs give to standard algorithms, whereas current literature clearly stresses the importance of mental strategies based on conceptual understanding, further contributes to the overall impression raised by the analysis of the 23 IEPs that may be summarized as follows: On the one hand, with a few selective exemptions, the authors seem to lack the extended didactical competences needed to assess, in a meaningful *qualitative* way, the mathematical status of a child with an MLD, as well as to decide upon appropriate learning goals that could and should be reached for in the next step. On the other hand, they tend to settle for a general reduction of the level that should be attained by the child, by limiting the number range, by allowing for permanent compensation measures, and by concentrating on the training of standard algorithms, notwithstanding the fact that such measures contribute to perpetuating the difficulties rather than overcoming them.

As stated, the present study is narrowly limited, based solely on a sample of 23 IEPs drawn up by teacher teams of South Tyrolean primary schools. Due to space restrictions, only parts of the analysis and very few examples of these plans could be presented. The aim is, of course, not to blame teachers for what they do to the best of their ability. As analysed in the first section of this paper, a law that is questionable in more than one respect obliges teachers to work out IEPs. The qualitative analysis presented in this paper indicates that, as a rule, South Tyrolean teachers are currently overstrained with this obligation. As a consequence, responsible school policies should strive to give support, such as targeted teacher training and the possibility to consult expert teachers specialized on MLDs. Of course, such efforts to extend the didactical and thereby diagnostic competences in primary education are likely to benefit children to an even greater extent if they could be implemented within a legal and organizational framework that allows for additional support of children with MLDs, also in terms of team teaching, starting from the first signs that a child is in danger of developing such difficulties.

“Counting with all children from the very beginning”: One attempt to promote early arithmetical skills based on part-whole thinking

Carina Gander

Free University of Bozen - Bolzano, Italy; c.gander@unibz.it

Currently, it seems to be difficult for teachers to create substantial learning environments of high quality to manage the arithmetical heterogeneity in First Grade. The 13 substantial learning environments based on part-whole thinking of the large-scale project “Counting with all children from the very beginning” might be one attempt at that. Following design-based research approaches, the substantial learning environments were first developed and then implemented in five mainstream classes with a total of 96 students in the Beta-cycle over a ten-week period. Data from the second cycle is the basis for the results presented in this paper. Preliminary results indicate that not all teachers succeeded in identifying problematic areas in their children’s arithmetical learning, especially in the instances of children who have underachieving mathematical skills and children with special educational needs (SEN).

Keywords: Early arithmetic education, part-whole thinking, computation without counting, inclusive mathematics education, concepts for mathematics education

Preliminary remarks

Every child has the right to access education of good *quality*, as international organisations such as UNICEF, UNESCO or the European Union affirm. Thus, the focus regarding inclusion of all children in developed countries is now on promoting the quality of the teaching and learning situation (Florian, 2008). However, there seems to be uncertainty in German-speaking countries about how to create inclusive learning environments of high quality for *all* children in mainstream classes, not only, but especially in early arithmetical education (Korff, 2016). Hence, the present research project seeks to design substantial learning environments based on *part-whole thinking* for First Grade.

In order to allow others to make comparisons between inclusive school education in different nations, the author of this paper draft the current situation that teachers might face regarding inclusive practices in early arithmetical education in *German-s*peaking countries, with a focus on Austria, where the research of this paper was conducted.

With the passage of time, the Austrian education system, like that of many other countries, has made great progress as far as the issue of inclusion is concerned. In particular the ratification of the UN Convention on the Rights of Persons with Disabilities in 2008 sparked debate about *inclusive* education (as in many countries) and the necessary measures for the common compulsory school system. Nonetheless, *even today*, Austria, like many other countries in the world, still focuses on a multi-track approach: Parents are free to decide whether to send their child to a (local) mainstream school or a special school. In total, in 2020-21, approximately five percent of the children in compulsory education belong to the group denoted as having special educational needs. (Statistik Austria, 2021). It should be made clear that these data refer *merely* to the positioning-oriented definition of inclusion (see below).

By the time children enrol in compulsory school in German-speaking countries (between the ages of six and seven), they have received considerably different targeted *early mathematical education*, depending inter alia on different educational plans in kindergarten and the mathematical knowledge of the kindergarten staff. The educational plans in kindergarten differ within and between German-speaking countries – in Austria, the educational document consists of a few pages, and early mathematical education is dealt with in a few words. The year before school enrolment all children will already have attended kindergarten. By the end of First Grade, it seems to be widely accepted within the relevant German literature, that all students should learn how to *compute without counting* fluently with numbers up to 20 (see also Häsel-Weide & Nührenbörger, 2013). Therefore, it seems to be helpful if teachers first get children to grasp that numbers (at least up to 10, if not up to 20) are composed of other numbers and then, based *merely* on that knowledge, initiate their understanding of addition and subtraction (see also Schipper et al., 2015; Gaidoschik, 2019a; 2019b).

The author of this paper is aware that in the field of *international* mathematics education, designing substantial learning environments of high quality in early arithmetical education is a central element for colleagues from other countries, where there are also likely to be challenges for teachers to teach mathematics inclusively. Thus, the following considerations concerning the implementation of part-whole thinking in early arithmetical teaching may apply to other nations as well.

Considerations on inclusive education in early arithmetical teaching

In the international inclusive education community, there is *no* clear working definition of inclusion. Consequently, in many nations inclusive practices are handled very differently, and these practices can differ also between schools in one country, or even within the same school (see also Booth & Ainscow, 1998). To specify inclusion, it has been defined as both a one-dimensional and/or a multidimensional oriented approach. The former means physical positioning and teaching of children in an ordinary class (Vislie, 2003), the latter represents a wide plurality with other qualities (for example a positive learning environment to promote all children's learning development) in addition to positioning. Many authors agree that inclusion in developed countries is now *not* merely about physical positioning, but has to comprise several aspects. Empirical research has also shown that positioning alone is *no guarantee* of meeting the needs of all children (see also Mitchell, 2014; Vislie, 2003).

The international *mathematics* education community will certainly respect the multidimensional oriented approach of inclusion. To understand how pupils learn, the theory of constructivist learning is vital. The students actively construct knowledge, and of course, there is huge variation amongst children with regard to how quickly and how sophisticatedly they are able to solve mathematical problems: "Children with different developmental backgrounds may well be able to get the same answers on an arithmetical task, but how they do so might differ significantly" (for more details of the discussion between constructivist views and other views on mathematics education theory and research, see Steffe & Kieren, 1994, p. 719).

Thus, in recent decades, some considerations on general inclusive (mathematics) didactics and *few* substantiated didactical concepts for inclusive mathematics education in primary school have been developed *in the mathematics education community*, but I am not aware of any (apart from the following), that *explicitly* deal with the utilization of the concept of numerical part-whole thinking in First Grade.

Considerations on the TIGER concept (Gaidoschik, 2019a)

All children in First Grade classes should be aware of "numbers as compositions of other numbers" (Resnick, 1983, p. 114), also termed the "part-whole schema" (Resnick, 1983, p. 115). Resnick describes this goal as "probably the major conceptual achievement of the early school years" (1983, p. 114), therefore a preferable alternative to computing by counting. According to this concept, children should learn to divide numbers in terms of part and whole relationships for all numbers at least up to 10. Children thus can be led to understand that any whole number can in fact be divided into smaller numbers, and so the number 7 for example, can be divided into 2 and 5. When put together, the parts 5 and 2 fulfil the requirement of being equivalent to the whole number 7. With that understanding, they might be able to solve addition (2+5; 5+2) as well as subtraction problems (7-5; 7-2) – without counting.

The *utilization* of the concept of numerical part-whole thinking in First Grade seems to be the standard in international mathematics education as in for example the "Number framework" (New Zealand Ministry of Education, NZME, 2008) and the "Mathematics programme of study" (UK Department of Education, 2013). Quite when this concept is taught in the academic year can differ across nations. Part-whole thinking is incorporated as *early as possible* in the school programme in these guidelines for teachers' actions. The New Zealand Number framework explicitly states:

> It is important for you to recognise that part-whole thinking is seen as fundamentally more complex and useful than counting strategies. One reason is that counting methods are strictly limited, whereas part-whole methods are more powerful. Counting strategies are an inadequate foundation for these ideas, and this means that for counters, many advanced number ideas are inaccessible. Therefore, your major objective is to assist students to understand and use part-whole thinking as soon as possible. (NZME, 2008, p. 7)

Current models and learning trajectories of these and other guidelines name different numerical stages for counting strategies, and give recommendations for teachers to follow and to work with their classes from one stage to the next. However, Gaidoschik (2019a) describes in detail a structure-genetic didactical attempt as an alternative approach to the already existing ones. The concept he has named TIGER (Gaidoschik, 2019a) attempts to show how to teach children addition and subtraction on the basis of *part-whole thinking*. The author of this paper will provide a more detailed explanation of the TIGER concept and list some examples of the learning situations of the current project.

The TIGER concept of part-whole thinking

The TIGER ("Teile im Ganzen Erkennen und damit Rechnen") concept, created by Gaidoschik (2019a), focuses on solid number concepts in early arithmetical teaching. The 13 learning situations of the current research project are based on these ideas. Drawing on this concept, the learning situations consist of the following three fundamental aspects, whereby the researcher (Gaidoschik, 2019a, p. 424) recommends teachers "work with children in all three Fields A to C more or less *concurrently*" and "it would not help to stick to one single theme for too long in a row […] the sites relate to each other":

Firstly, (A) a child needs to acquire a solid understanding of counting competences and should thus master the significance of cardinality as a means to understand "how many of whatever". This includes teaching the “counting principles”, defined by Gelman and Gallistel (1987). The substantial learning environments that have been designed try to allow all children to consolidate their *individual* counting competences in the counting activities, for example by counting the number of children present in the class. Counting is used almost every day: Is anyone absent today? Is the number different from yesterday and if so, how has it changed? Of course, First Grade classes will be quite heterogeneous in their counting competences: *Many* children will already have no problems with counting (forwards and/or backwards), while some children will need more counting activities than others. As a benchmark, all children should (at an earlier or later stage) be able to count easily up to at least 10, both forwards and backwards (Gaidoschik, 2007).

Secondly, (B) it is important that a child is able to judge very small sets without counting – through direct pattern recognition - and uses *subitizing* for smaller quantities (up to 4) and uses *perceptual subitizing* for quantities greater than 3 or 4. Perceptual subitizing is only possible for children and indeed us adults if bigger sets are presented in a structured way, so that counting can be avoided (see also Clements & Sarama, 2009). The learning situations that the author of this paper has created include activities to teach part-whole thinking, including in particular activities *using fingers*, recommended by Gaidoschik (for more details of fingers as a very useful “material”, see Gaidoschik, 2007). Thus, for example, children should learn at the beginning to show the right number of fingers without actually counting them, and without extending them one by one. As a starting point we should focus on (at least) all numbers up to 5. In the following activities, structured dot patterns, dice, then ten-frames are useful materials in the learning situations. All in all, the use of materials in the current research project is important for children to acquire *mental pictures* and finally automatized knowledge but the use of materials is limited to a *few* structured arithmetical materials, as mentioned above. Note that all the activities with material should be presented in a *structured* way so that children are able to identify quantities (first for quantities up to 5 and later for all numbers at least up to 10) at a glance. The focus of such early activities is to teach children the interpretation of these structures, their relations to 5 and 10; and especially their part-whole *compositions* (5 as consisting of 2 and 3, or of 4 and 1, etc.).

Thirdly, (C) a child should *compare* quantities and numbers. On the basis of one-to-one matching up, children should learn and/or consolidate that no counting is needed for pairing the items for number comparison such as identifying without counting (Gaidoschik, 2007). The learning situations focus on activities that foster children’s ability to compare quantities. Thus, inter alia in the learning activity “Throwing Tiles” they use one-to-one matching without needing to count the tiles, they create rows and then compare in pairs their quantities. In “Finger use” they should “show the right number of fingers without counting them” and then compare the fingers with other quantities and/or numbers.

Organising the created substantial learning environments in the classroom

To achieve a *balance* between children learning individually and learning together in (early arithmetical) education, which is the general consensus within the mathematics education community in German-speaking countries (see for example, Häsel-Weide & Nührenbörger, 2015), the current learning situations are divided into: (I) Whole-class instruction; (II) Individual Work; (III) Teamwork. Each teacher decides, depending on the class situation, which organisational structures are best and for which children. Presumably, for some children it might be useful at some point to be given additional or different activities to practice and/or consolidate their arithmetical knowledge. Nevertheless, as Feuser argues (1997), all pupils should, as much as possible, be working on the same activity even if it is being carried out on a different level. The learning situations in the current paper respect these ideas and try to give specific ideas for teacher's action in classes.

The research project, research method and research question

To be able to examine the effectiveness of the learning situations created, collective case studies following the framework of design-based research approaches (Euler, 2014) have been conducted. In the Alpha-cycle, conducted in the school year 2019-2020 with 45 First Grade students in two Tyrolean mainstream classes, video-recorded conclusions were drawn for the implementation and further development of the substantial learning environments. These results were processed in an additional cycle. The Beta-cycle, which is relevant for the present data analysis, was carried out in five Tyrolean primary school classes in the school year 2020-2021 with 95 students over a 10-week period in First Grade in inclusive mainstream classes. Before starting the classroom implementation, all teachers were instructed in using and adapting the learning situations. To generate insights into children's learning and their mathematical thinking, each lesson was video recorded, and framed as the basis for data analysis using "Qualitative Content Analysis" (Mayring, 2015).

The pairs of children analysed are, as far as possible, unchanged, so that conclusions can be drawn regarding the progress of their learning. Furthermore, "Assessment of Teaching-Learning-Situations in Mathematics of the Early Grades" (Steinweg, 2010) is used for data analysis, as an additional level of analysis. Steinweg's idea of dimensions focuses on the *teachers'* possibilities for action in First and Second Grade. The combination of both gives indications for (further) development of the substantial learning environments.

The questions guiding the paper are: (1) Do the analysed transcripts of the substantial learning environments based on part-whole thinking indicate any difficulties of understanding for many children and/or a particular group of children with certain arithmetical knowledge? (2) Are there difficulties in teaching the substantial learning environments based on part-whole thinking; and if so, are these observed in *several* scenes?

Preliminary results

It should be made clear that it is not the intention of the author to draw conclusions from specific scenes or class observations. The idea is not that a learning activity should be done just once in a class or that *all* children should be able to solve the arithmetic task (at the same time). Thus, the dimensions of Steinweg (2010) – consistent with the author's intention – are considered 'competence-oriented', that is to say, the (analysing) focus is more on the teacher's achievements than on their failings. When Steinweg's dimensions are used in a way that *several* scenarios of teachers' actions in classes are analysed, conclusions can then be drawn to give teachers targeted indications for the work in daily classes.

Drawing on these ideas, preliminary outcomes of the analysis of *some* transcripts using "Qualitative Content Analysis" (Mayring, 2015) indicates content related problematic areas in early arithmetic education: These are problematic areas of arithmetical knowledge that might be common to many children and/or a particular group of children. To illustrate by means there are some examples. In "Throwing Tiles" children take turns throwing 10 reversible tiles, which have a red side and a blue side. Then together they have to match one red with one blue tile, using one-to-one matching without counting. They create two rows to identify who has more tiles, and how many more there are of one colour compared to the other. Regarding Steinweg's idea of mathematical dimensions (2010), *not* all teachers were able to foster children's arithmetical competences and not all teachers were *consistently* able to identify these problematic areas of arithmetical knowledge. In some sequences, for example in this sequence "Throwing Tiles", some teachers did not realize that children require a solid understanding for one-to-one-matching up as a basis for further arithmetical strategies. Especially for underachieving children in mathematics and children with SEN the understanding and utilization of the one-to-one-matching process was *consistently* difficult in several instances on several days.

Again, it is the same group of children that seem to have difficulties in the following scenarios: One of the advanced activities of "Finger Use" is to work out the 5-plus-x structures of the numbers 6 to 10. The children play in pairs, and one says a number, for example 7, and the other child, with hands underneath the table, without looking at their fingers, has to show the right number of fingers without actually counting them, and without extending their fingers one by one. Their partner then checks the solution. In further exercises, they have to describe what they would do, without actually doing it. For example, "Seven. I have to show one full hand and two fingers on the other hand; in total that makes seven". Drawing on Steinweg's idea of mathematical dimensions (2010), even in this activity not all teachers were able to foster the use of fingers. For these children it might be worthwhile to give more thought-provoking stimuli to acquire part-whole thinking. Thus, the base numbers 5 and 10 (5 fingers on one hand, 10 fingers on both hands together) should be focused on first.

Thus, a *preliminary indication* of the analysed transcripts is that particular attention should be paid to the mathematical thinking of underachieving children and to children with SEN, and it is evident that teachers seem to find it especially difficult to meet the learning needs of those children.

Closing remarks

The current research project on early arithmetical teaching in First Grade, presented in this article, is *one* attempt to face challenges in teaching (arithmetic) inclusively. As has been outlined, the substantial learning environments that have been created are based on the TIGER concept (Gaidoschik, 2019a). The author of this paper agrees with the ideas of many researchers in the relevant mathematics education literature, that children who need special support in learning (mathematics) do *not* learn differently, nor need completely different *concepts* than are already recommended for all children (see Gaidoschik, 2019a, 2019b; Moser Opitz, 2008; van de Walle, 2004). Thus, their learning behaviour is not completely different from that of their classmates. Of course, some mathematical content might be acquired by some children at a later stage than other children, but all children should learn them at *some* point during their mathematical education. From the structure-genetic didactical analysis approach this idea seems logical because the mathematical content is the same for all children.

Nevertheless, empirical evidence (see for example, Pfister et al., 2015), as well as *some* interim results of this research project indicate how difficult it is for teachers to implement already *existing* concepts of mathematics education in their classes, even for those who participate voluntarily in in-service development programmes.

Thus, one conclusion of this research is that it is essential to enhance teachers' knowledge of relevant pedagogical methods *and* content, so that teachers can then fulfil all pupils' differing learning requirements. The other conclusion is that data analysis has also shown that for teachers to get a collective picture of their students' arithmetical knowledge, it might be worthwhile to identify problematic areas of arithmetical knowledge. The awareness of these problematic areas of arithmetical knowledge is crucial for *quality* teaching in inclusive mathematics education. Of course, this places high demands on the teacher's abilities.

Yet, in further data analysis something that needs to be evaluated is whether such problematic areas of arithmetical knowledge involve many children and/or a particular group of children in *different* classes that participated; and whether it was *consistently* difficult for the teachers to identify these problematic areas of arithmetical knowledge and to foster children's competences. This would allow us to develop further indications for the work with teachers and children.

A study was conducted in 2021 in Switzerland (Canton of Vaud) to evaluate two computer-based learning programs Calcularis[1] and Matheros[2] to help students improve their performance in calculation. Calcularis was especially designed to support students with mathematical learning difficulties. Then, our study focuses on the evaluation of the effect of Calcularis on the mathematical learning skills for students with mathematical learning difficulties in ordinary school context. We observed that Calcularis could allow a better progression compared to Matheros in calculation, number-line estimation task for students with mathematical learning difficulties.

Keywords: Mathematical learning difficulties, computer-based education, primary school, calculation.

Context of the study

Following the results of the PISA and TIMSS, some governments place the teaching of mathematics at the heart of their educational policy. This is for example the case of the canton of Vaud in Switzerland, which has set up a "mathematical mission" in 2018-2019 in order to improve the knowledge and skills in mathematics of elementary school students. One of the recommendations of this mission (Dias, 2019) is to propose a computer-based learning program to improve the performance of elementary school students in calculation. In order to choose this computer-based program, a study, leaded by the DGEO[1], was conducted to specifically compare two programs: *Calcularis*[2] and *Matheros*[3]. These programs were chosen by the DGEO because already used in some schools in the canton during the Covid-19 pandemic. One difference between these two programs is that *Calcularis* was designed for students with mathematical learning difficulties (MLD). This paper is focused on evaluating this computer-based program for students with and without MLD.

State of art

Mathematical learning difficulties

For several years, research on mathematical learning difficulties has been developing both in cognitive neuroscience and in mathematics education. Two recent literature reviews (Deruaz et al., 2020; Lewis & Fisher, 2016) report on the following issues in this fields of research: heterogeneity

---

[1] DGEO (Direction Générale de l'Enseignement Obligatoire) General management of compulsory school.

[2] https://dybuster.com/fr/calcularis/

[3] https://matheros.fr/

of definitions and characterizations (e.g., mathematical learning disabilities, dyscalculia, mathematical learning difficulties), a diversity of explanatory models, a variety of identification and support tools, a non-consideration from a didactical point of view.

Within the research group “Riteam” (http://riteam.ch/fr/), we are specifically interested in examining the mathematical learning difficulties in the school context and through didactical filters. That seems necessary and complementary to current studies, rather conducted out of class and within cognitive psychology. The aim is to take a more focused look at the teaching and learning processes.

According to Scherer and colleagues (2016), our prior research highlighted the need, for research in mathematics education, to broaden the definition of mathematical learning difficulties used most widely in cognitive sciences. However, in the school context, it is necessary to also consider students with difficulties that are not identified by a medical diagnosis. Thus, in mathematics education, research focuses on students with clinically diagnosed disorders, but also on students with severe difficulties in mathematics, identified by teachers (Deruaz et al., 2020). We also noted that research in mathematics education focuses more on interventions with students with mathematical learning difficulties. These are mostly case studies, outside the school context, evaluating the impact of a remediation intervention on a specific mathematical content. These interventions focus more on teaching strategies than on students' cognitive abilities. Among these teaching strategies, some are mediated by digital technology.

Computer-based intervention for students with mathematical learning difficulties

In 2006, Wilson and colleagues proposed a pioneering study in the design and evaluation of a digital tool for remediation (Wilson et al., 2006). They evaluated the impact of an adaptive digital game (Number Race) on the mathematical learning of students with dyscalculia. Their results show positive effects on student performance in basic mathematical tasks such as subitizing, non-symbolic comparison, number comparison, and subtraction (of two one-digit numbers). However, these effects do not generalize to counting or other arithmetic tasks (two-digit addition or subtraction). Regarding the *Calcularis* program, several studies have evaluated its impact on the mathematical performance of students with or without mathematical learning difficulties (Käser et al., 2013; Kucian et al., 2011; Rauscher et al., 2016). Kucian and colleagues (2011) conducted an initial evaluation of the *Calcularis* program for a group of students with mathematical learning difficulties. The results indicate that training with *Calcularis* leads to improved spatial representation of numbers and modulation of neuronal activation, both of which facilitate the processing of numerical tasks. More recently, Rauscher and colleagues (2016) conducted a study with control groups. Their results show significant progress of the *Calcularis* group compared to the control group, especially with regard to subtractions and spatial representation of numbers. In addition, five months after the end of the use of the application, their level of performance was stable. The authors conclude that *Calcularis* not only leads to short-term improvement, but also allows students to use these improvements to succeed in the long term.

To conclude, current research on mathematical learning difficulties in mathematics education focuses mainly on case studies evaluating the impact of a remediation intervention on specific mathematical content with students with mathematical learning difficulties. These interventions are often based on digital tools. Several meta-analyses have examined the effects of these interventions with digital tools and reveal positive effects (Kulik, 1994; Li & Ma, 2010). In particular, Li and Ma (2010) highlight their contributions to students with special educational needs in primary school. With regard to the *Calcularis* program, current studies highlight its impact on improving the spatial representation of numbers and solving simple subtractions in primary school students, with or without mathematical learning difficulties.

The current study

The current study aims to contribute to the evaluation of *Calcularis* on the performance of elementary school students with and without mathematical learning difficulties. Indeed, the aim is to evaluate *Calcularis* as a computer-based learning program for students with difficulties, in ordinary classrooms in the Vaud school context. The research question focuses on the impact of *Calcularis* on the learning progress of students with or without difficulties. For that, we compare the use of *Calcularis* to another computer-based program (*Matheros*).

Materials and Method

Compter-based learning program: *Calcularis* and *Matheros*

Calcularis 2.0 is a highly adaptative computer-based training program (von Aster et al., 2016). *Calcularis* is based on theoretical neurocognitive foundations of numerical cognition, such as the triple-code model (Dehaene,1992), the four-step developmental model (von Aster and Shavel, 2007) and further theoretical advancements (Kucian and Kaufmann, 2009). *Calcularis* has been designed according to insights on the typical and atypical development of mathematical abilities (Käser, 2013). The program aims to automatize the different number representations, to supports the formation and access to mental number line and to train arithmetic operations as well as arithmetic fact knowledge in expanding number ranges from 0-10 until 0-1,000 (Kohn et al., 2020). *Matheros* is one of the digital tools offered by the Monecole.fr site created in 2011 by L.Walter, a teacher and digital trainer in France. *Matheros* allows students to progress in mental calculation according to the principle of belts (as in martial arts) of skills (Monecole, 2021).

Sample

Our sample is composed of seven classes of third grade and eight classes of fourth grade (aged 8-9 years) in the canton of Vaud. This comprised 15 teachers and 260 students. The classes have been choice by the DGEO. There are 143 students in the *Calcularis* group (classes using the *Calcularis* program) and 117 students in the control group (classes using *Matheros* program). Students with MLD were defined as those whose score in two out of three tasks (see below) was situated in the bottom 20% for a given grade. This resulted in 18 students (10 in *Calcularis* group and 8 in *Matheros* group) in the third grade and 12 students (8 in *Calcularis* group and 4 in *Matheros* group) in the fourth grade.

Measures

We used three tasks to assess students' performance in mathematics.

Numeracy Fluency: we assessed the numeracy fluency with the subtest 6 of the Woodcock-Johnson Test III (Woodcock, McGrew, & Mather, 2001).

Number line estimation: we assessed the spatial representation of numbers with a number line estimation task, adapted to the subtest of the Zareki (Dellatolas & Von Aster, 2006).

Calculation: we assessed the calculations (with multi-digit numbers) with a task designed by our team to evaluate the expectations of the curriculum in the third and fourth grades. This task aligned with the swiss curriculum has four categories: addition, subtraction, multiplication and half/double. For example, in third grade: 87+9=; 4x3=; 140-52=; double of 55; and in fourth grade: 254+2005+17=; 1060-69=; half of 120. Each category is declined according to the different variables (e.g., for the addition: number of terms of the addition, size of the numbers at stake; presence of retention or not; possibility of complement to the top ten/hundred; associativity; commutativity; special procedure (+9)). Students can put the operation on the sheet if they want.

Procedure

The procedure was carried out in four stages. The first step refers to the pre-tests: teachers administered the three mathematical tasks to all their students in their own classrooms. The second step concerns the use of computer-based learning programs: for six weeks, teachers proposed to their students to use *Calcularis* (in *Calcularis* group) or *Matheros* (in control group) at least two times 20 minutes per week, individually, in class or at home. The logbooks kept by the teachers during the study attest to the achievement of this weekly time by the students. The third step is related to the post-tests: teachers administered the (same) mathematical tasks one week after the computer-based learning programs were completed. The fourth step refers to the delayed post-tests: teachers administered the (same) mathematical tasks again, 4.5 months after the computer-based learning programs were discontinued.

Results

Results for all students

In this part, the effect of using *Calcularis* on the three tasks (numeracy fluency, number-line estimation, and calculation) will be evaluated and compared to the effect of using *Matheros*, and the evaluation will be carried out for all students.

Pre-tests

In order to examine whether there was a group difference in the pre-tests, we carried out a one-way ANOVA4 on the pre-test score for the three tasks and the two grades separately. The results showed that in the third grade, compared to *Matheros* group, *Calcularis* group had significantly higher score in calculation test (18.0 vs 16.0, $F(1, 120) = 4.82$, $\eta 2p = .04$, $p = .03$) and marginally lower score in

[4] Analysis of variance (ANOVA) is an analysis tool.

fluency (37.8 vs 42.4, $F(1, 120) = 3.74$, $\eta 2p = .03$, $p = .06$) test. In the fourth grade, *Calcularis* group had significantly lower score than *Matheros* group in fluency test (53.6 vs 58.5, $F(1, 134) = 4.03$, $\eta 2p = .03$, $p = .047$). For the other tasks (number line tasks in third grade and fourth grade and calculation task in fourth grade), there are not significant differences between the two groups.

Post-tests and delayed post-tests

In order to examine the effect of group and pre-test score on the scores of post-tests and delayed post-tests, we ran a multiple linear regression for the three tasks and the two grades separately. Our analysis, that are presented in Table 1, revealed that in general, there was a significant effect of pre-test score on post-test and delayed post-test scores. The exceptions were found for number-line task during post-test for *Calcularis* group in the third grade and for *Matheros* group in the fourth grade. Furthermore, in the post-test, *Calcularis* had an advantage over *Matheros* in the third grade for calculation task ($t(114) = 2.88$, $p = .005$) but a disadvantage for number-line task ($t(102) = –2.44$, $p = .02$). In the delayed post-test, in the fouth grade, there was a difference to the disadvantage of *Calcularis* for fluency task ($t(126) = –3.06$, $p = .003$).

Table 1. The slopes of post-test and delayed post-test as a function of pre-test

Grade	Task	Group	Post-test		Delayed post-test	
			Slope	*p*	Slope	*p*
3rd	Calculation	Calcularis	0.80	< .001	0.60	< .001
		Matheros	0.48	< .001	0.55	< .001
	Number line	Calcularis	0.05	ns	0.18	.06
		Matheros	0.42	< .001	0.21	.051
	Fluency	Calcularis	0.85	< .001	0.89	< .001
		Matheros	0.65	< .001	0.75	< .001
4th	Calculation	Calcularis	0.70	< .001	0.53	< .001
		Matheros	0.75	< .001	0.29	.03

		Matheros	0.92	< .001	1.19	< .001

Note. ns: non-significant differences

Analyses for students with mathematical learning difficulties

In this part, the effect of using *Calcularis* on the three tasks (fluency, number-line estimation, and calculation) will be evaluated and compared to the effect of using *Matheros*, but the evaluation will be carried out only for students with MLD. The performance of students with MLD was evaluated in the term of predicted and real observed scores of both post-test and delayed post-test. To obtain the predicted scores, we ran a multiple linear regression based on the scores of the students who were not categorized as students with MLD. The obtained slopes for a given tasks and a given grade were then used to calculate the predicted scores of students with MLD. These predicted scores were then compared to the observed scores of these students by means of a one-sample t-test.

The results for students with MLD are presented in Table 2. In the phase of post-test, there was no difference between the observed and predicted scores, except for calculation task in *Matheros* group of the third grade, in which the observed score was significantly lower than the predicted score. In fact, the gap obtained in this group was significantly larger than in *Calcularis* group (t(16) = 2.11, p = .051). In the phase of delayed post-test, the observed score in the *Matheros* group of the third grade was significantly lower than the predicted score for calculation and number-line tasks. Again, these gaps were significantly larger than in *Calcularis* group (t(16) = 2.93, p = .01 for calculation and t(15) = 3.22, p = .006 for number-line task).

Table 2. The difference between observed and predicted scores of post-test and delayed post-test for students with MLD

Grade	Task	Group	Post-test		Delayed post-test	
			Difference	*p*	Difference	*p*
3rd	Calculation	Calcularis	–0.72	ns	0.66	ns
		Matheros	–3.82	.03	–6.16	.02
	Number line	Calcularis	–0.24	ns	0.95	ns
		Matheros	–1.43	ns	–1.41	.02
	Fluency	Calcularis	–0.54	ns	0.47	ns
		Matheros	7.33	ns	7.99	ns
4th	Calculation	Calcularis	1.16	ns	–0.47	ns
		Matheros	–1.94	ns	–0.25	ns
	Number line	Calcularis	–0.22	ns	–1.56	ns
		Matheros	1.41	Ns	0.30	ns
	Fluency	Calcularis	0.77	Ns	–3.67	ns
		Matheros	–7.87	Ns	–4.86	ns

Note. Positive differences imply higher observed score than predicted score. ns: non-significant differences.

Discussion

Concerning the impact of *Calcularis* on the learning progress of student with and without difficulties, our results show that *Calcularis* allows all students to progress in calculation and numeracy fluency significantly after a 6-week use (post-test) and at a deadline of 4.5 months (delayed post-test). For the spatial number representation, the results are more nuanced. *Calcularis* allows fourth grade students to progress significantly but not for third grade students. Concerning the comparison between *Calcularis* and the other computer-based program, *Calcularis* is more efficient than the other computer-based learning program (*Matheros*) for third grade calculation. On the other hand, the other computer-based learning program (*Matheros*) seems more efficient in third grade. Concerning the students with MLD in the *Calcularis* group, they progress more than students with MLD in the Control group for the calculation in third grade. We also see better efficiency for third grade students on the number line estimation task.

These results obtained for students with MLD can be explained by two reasons. First, the specific design of *Calcularis* is based on theoretical neurocognitive foundations of numerical cognition (Kohn et al., 2020). Initially, the aim and conception of *Calcularis* is to support students with MLD. In *Calcularis*, the use of machine learning make takes more progressive being slightly challenging and thus may foster the development of new skills (Kohn et al., 2020). This technology is another major difference with the other computer-based learning program *Matheros*. In contrary, *Matheros* offers a linear path, without the possibility of playing on the difficulty of the proposed calculations. It is possible to change the time given to perform the calculations but the teachers in our control group did not use it. Secondly, the finding that *Calcularis* allows third graders to make more progress in numeracy, especially for students with MLD, is consistent with our didactical analysis of the content of this computer-based learning program. Indeed, by comparing the contents of this program with the curriculum, we have highlighted a more appropriate calibration of *Calcularis* for third grade students, in particular due to machine learning.

The results obtained for students with MLD confirm the results of previous studies in numeracy fluency and number line test (Käser et al., 2013, Kohn et al., 2020, Rauscher, 2016). Rauscher (2016) demonstrates that *Calcularis* can be used effectively to support children in their numerical development and to enhance subtraction and spatial number representation. Käser (2013) found significant results in subtraction for students who used *Calcularis* for 6-8 weeks. This involved subtraction of two single-digit numbers, to be performed mentally. As far as we know, studies concerning posed calculations (with multi-digit numbers) are not very frequent. Therefore, our study provides new results on the effectiveness of *Calcularis* in improving numerical skills in students with MLD in the school context.

In sum, our findings are in line with previous research however they provide a complement because the study was conducted in ordinary classes. *Calcularis* seems particularly interesting as a computer-based learning programs to help students with MLD. In future research, we will analyze the data collected in the application (game duration, skills acquired, number of exercises performed correctly, etc.) to see if the application could be used as a tool for identifying students with MLD by teachers.

Acknowledgment

We thank the school principals, the teachers, the students of the classes involved.

We present the first results of the OPEN-MATH project that aims at the accomplishment of inclusive mathematics learning environments via the construction of the Open Activity Theory Lesson Plan (OATLP). We built a theoretical framework for inclusion that stems from the networking of differentiation for all, featured as open learning and the theory of objectification. We describe the interplay between theory and practice. Its outcome is a conceptual framework for inclusive mathematics and the development of the OATLP model across 3 implementations involving an Italian middle school class.

Keywords: Inclusion, Differentiation, Open learning, Theory of objectification.

Introduction

The debate about inclusion in mathematics education has broadened in recent years, polarizing on two complementary aspects: those related to the questioning of the term itself, and its meaning in relation to mathematics education, and those related to classroom practices (Roos, 2019). In the project OPEN-MATH, funded by the Free University of Bozen, we tried to build a link between these two polarizations, defining inclusion from the perspective of mathematics education and trying to arrive at a set of design principles that can enhance the participation and learning of each one in the classroom. For that purpose, we decided to combine two approaches, that of the theory of objectification (Radford, 2021), which serves as background theory to define learning in mathematics, and the didactical differentiation (Tomlinson, 2014), which instead provides the inclusive perspective regarding classroom management. We need to recall that in Italy, students with and without SEN attend the same classrooms since 1977. Therefore, the perspective taken in the project starts from the assumption that inclusion does not only mean that all students can attend the same class, but that the educational environment must allow meaningful learning and participation for each student, according to her own characteristics (Aiscow, 2016). In the next pages we present the theoretical background of the project and the developing of the Open Activity Theory Lesson Plan (OATLP) that allowed us to define the first set of design principles for inclusive mathematics education in the classroom combining the theory of objectification and didactical differentiation. What we want to show, is how these two theoretical approaches can shape classroom activity to foster the inclusion of each student according to his or her characteristics.

Theoretical Framework

Inclusive Education

Inclusive education has been conceptualized in several ways. In literature, we find a certain consensus on a general distinction between narrow and broad definitions (Nilholm & Göransson, 2017). Narrow definitions focus on students with disabilities, their presence in mainstream schools and classes and the needed support. Broad definitions are about school systems and school communities and their commitment and capacity of welcoming all students with all their individual differences, granting participation and effective learning processes. Tomlinson (2014) encourages a view that assumes difference as the norm in learning and that places differentiation in the normality of instructional design for all. A broad idea of inclusion poses a great challenge to the way learning processes can be supported in schools both considering all students' differences and granting their participation to a common learning project. Differentiation has been discussed by several authors as a tool that can contribute to tackle the challenge. Within the broad understanding of inclusion that we advocate in our work, we will follow Tomlinson's approach to differentiation. Open education (Demo, 2016) is a learning strategy that accomplishes differentiation for all by promoting students' opportunity to organize the learning process for their own, working on different tasks at the same time in the same space: this is consistent with the broad idea of inclusion presented in Tomlinson's Differentiation framework. Students are expected to be active in their learning processes, aware about the way they learn and to take decisions according to the activities they are exposed to. We can describe three possible areas of decision-making for pupils in terms of learning: 1. organization (spaces, times, learning partners), 2. methodology (how to solve a task), 3. aims and objectives (content and goals). In the project, we used open learning in relation to organization and methodology using learning stations.

The Theory of Objectification

According to the Theory of Objectification, thinking is a *praxis cogitans* (Radford, 2021). Conceptual objects, thinking, learning, and meaning in mathematics are intertwined in reflexive mediated activity that unfolds as joint labour. Learning is a specific *praxis cogitans* termed *process of objectification* that allows the student to notice, find and encounter the cultural object. The artifacts that mediate reflexive activity and accomplish the objectification processes are called *semiotic means of objectification*: objects, tools, linguistic devices, and signs that individuals intentionally use to carry out their actions and attain the goal of their activities. Radford, resorting to a dialectic materialistic stance, conceives embodiment as a sensuous cognition, that is, a multimodal sentient form (perceptual, sensible, and imaginative) of responding to the world sprouting from cultural and historical activity. In this respect, objectification unfolds as a materialization of mathematical knowledge in the student's sensuous cognition and can happen in various ways, according to the individual characteristics of the student. The dialectic interplay between a cultural-historical environment, the individual and reflexive activity gives rise to a double-sided construct: objectification-subjectification. Subjectification, the counterpart of objectification, is related to the production of subjectivities as they engage in the reflexive mediated activity. The Theory of Objectification outlines a dialectical co-production between individuals and their cultural and historical reality. The individual, according to Radford, is continuously inscribing herself in the social world, producing her subjectivity according to the possibilities given by her environment.

A conceptual framework for inclusive mathematics learning

According to the combining-coordinating strategy (Bikner-Ahsbahs & Prediger, 2014), we networked the Theory of Objectification and Differentiation, featured as open learning, to draw a conceptual framework for inclusive learning in mathematics with the following elements (Demo et al., 2021):

Definition of inclusion. Inclusion is conceived as the dialectical and critical positioning (subjectification) of all students in the cultural-historical practice of mathematics, who act, feel, and think according to their individual distinctive traits to pursue their project of life. The process of subjectification described is equated with meaningful participation and learning, which can be defined only with respect to a cultural practice.

Mathematical activity. Mathematical reflexive mediated activity, in its multimodal acceptation, is the meeting point of the social and individual dimension of mathematical learning. The notion of sensuous cognition allows us to keep together social interaction and individual self-determination. Semiotics means of objectification allow multimodal activity both as open learning, making available to different students different learning path, and joint labor with respect to common learning goals.

Teaching-learning model. Starting from the Theory of Objectification we have developed an inclusive lesson plan that intertwines social interaction and individual self-determination. We have added to the original Activity Theory design (Radford, 2021), which alternates phases of small group work and of whole classroom discussion, elements of individual differentiated work, stations work, made according to Open Learning. Multimodality characterizes every aspect of the cycle, giving the possibilities to different students to experience different ways to reach the same learning goal. The outcome is what we have called Open Activity Theory Lesson Plan (OATLP) and it is presented in Figure 1.

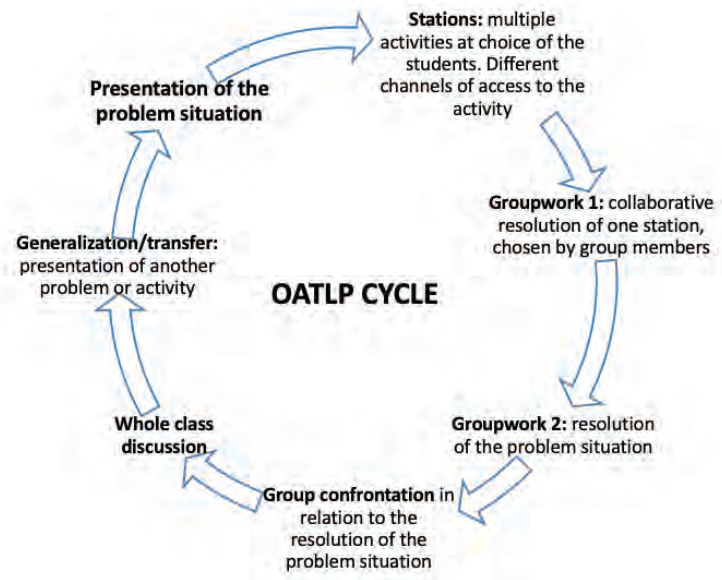

Figure 1: The OATLP Cycle and its different phases.

Stations (Demo, 2016; Tomlinson, 2014) are one of the possible strategies related to the implementation of open education and represent a way to put differentiation into practice by developing classroom environments in which learning processes are multimodal, decentralized and plural. Different learning activities related to a main didactical objective are structured in different stations. Students can move from station to station and choose which ones to complete and with whom. Decision making is enhanced with respect to organization of times (1) and to methodology (2): in fact, students can decide how long to work on each station, and to avoid one or more activities. The activities are connected to the same learning goal but exploit different means to reach them. A "passport" is used for the student to take note of the stations completed, the difficulties encountered, and what enabled them to learn in the most effective or enjoyable way, but it also allows the teacher to keep track of and understand individual differences in learning mathematics.

The evolution of the OATLP model during the research project.

In this section we show how the structure of OATLP cycle has gone through subsequent changes when applied to different topics, with the same classroom during the school year 2020/2021. The changes have been made accordingly to the analysis of the processes of objectification-subjectification, of the levels of participations and of the level of self-determination experienced by the students. The process of reworking and reflection on the OATLP cycle was carried out in accordance with the principles of Educational Design Research (McKenney & Reeves, 2019) in order to understand and develop how the educational intervention could be adapted to a real classroom context maintaining a connection with the theoretical principles defined above. The model has been implemented in a lower secondary school class of 17 students, among which 4 students have special educational needs, during the mathematics lessons. Throughout the experimentation, the OATLP model has been modified both in its structure and in its time scheduling. The set of every cycle's analysed data consists in videorecording of groupwork, collected students' materials and interviews with six chosen student and with the teacher.

In this contribution we analyse the main transformations of the OATLP model across 3 of the 5 cycles we implemented in school, each cycle is related to a different topic, and we addressed each topic only once. The addressed topics are, from cycle number 1 to cycle number 5: Ratios and Proportions, Circle and Circumference, Pythagorean theorems, Area estimation, Quadrilaterals. The first three cycles introduce a new topic, the 4th and the 5th work more on problem solving in relation to already faced topic.

Circle and circumference

Design of the activities

<u>Objectives in the national indications for mathematics</u>: The student is required to know definitions and properties of the circle and to calculate the area of the circle and the length of the circumference, knowing the radius.

<u>Stations</u> (120 min): Focus on the definition of circle and circumference and the elements that characterise them. The activities are designed differentiating according to different approaches to knowledge (Sousa & Tomlinson, 2011). E.g., in station 1 students have to draw a circle using a rope and a pen, in station 4 they make a drawing representing circle and circumference and in station 5 they are asked to define the figures verbally.

Groupwork (80 min): the students are exposed to a problem that contains 3 questions. The aim is to distinguish the definitions of circle and circumference and to calculate the area of the circle. In the last question they are asked to calculate an area corresponding to ¾ of the area of the circle.

Changes made compared to the previous intervention

Four different roles are assigned to students for the groupwork (mediator, designer, verbalist and controller); a procedure is established to handle the request for help during station activity (three coloured cards representing independent work, need for a classmate, need for the teacher); Stations are made shorter, and their objective becomes more precise and defined. Introduction of a framework defining different individual attitudes to learning that have informed the design of the stations.

Retrospective analysis

Strengths: stations are more effective and differentiated; the cards used to ask for help are appreciated both by the teacher and the students. In group work, according to the teacher, students begin to self-organize and divide tasks among them independently.

Critical issues: tight timeframes scheduled for activities hinder the completion of the OATLP cycle and do not acknowledge the students' need to express their different attitudes to learning; the connection between stations and group work needs to be refined; in groupwork, more attention needs to be given on division of roles and collaboration aimed at learning and not just at completing the task.

Pythagorean Theorem

Design of the activities

Objectives in the national indications for mathematics: The student is required to know the Pythagorean Theorem and its applications in mathematics and concrete situations.

Stations (150 min): Focus on the statement of the Pythagorean theorem, from a 'geometric' point of view (equivalence between areas). Some examples are given in Figure 2

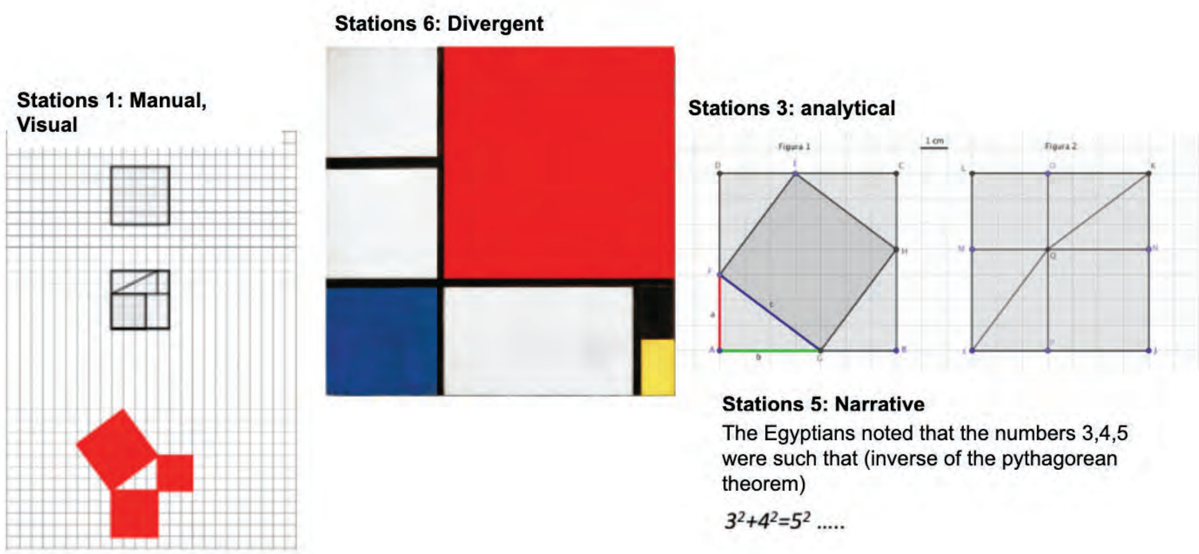

Figure 2: Parts of the stations proposed in relation to the Pythagorean Theorem.

Group (220 min): A double task is proposed: the application of the theorem to a given problem and an activity of problem posing related to the theorem. The groups then exchange the invented problems, solve them, and give feedback to the group that invented it. The feedback must be about the mathematical correctness, clarity, beauty, and interest of the problem. Invention of another problem that can be solved with the Pythagorean theorem is requested at the end of the confrontation.

Changes made compared to the previous intervention

We expanded the timeframe of the OATLP cycle, 2 weeks instead of one; greater attention is given to aspects related to the confrontation among students and a moment of confrontation between groups is introduced; the task for groupwork presents open questions that can adapt to different solving strategies and cognitive approaches; introduction of problem posing activities in the task for the groupwork.

Retrospective analysis

Strengths: Stations are appreciated by students for the variety of attitudes they encompass, and both students and the teacher notice the potentialities of problem posing in relation to the understanding of the Pythagorean Theorem.

Critical issues: insufficient connection between stations and group work, in this OATLP cycle the geometric aspects (stations) and the algebraic aspects (groupwork) of the Pythagorean theorem that needs to be made explicit.

Problems solving on area estimation

Design of the activities

Objectives in the national indications for mathematics: The student is required to determine the area of simple figures by breaking them down into elementary figures, e.g., triangles, or by using the most common formulas and to estimate the area of a figure, including curved lines, by default and by excess.

Stations (150 min): The stations try to emphasize different moments of problem solving: reading and understanding the text, choosing a strategy, implementing it, checking the results, etc. For instance, one station requests to invent a problem starting from the image of a polygon, another to rewrite the text of a given problem before solving it, to make a drawing of the situation, or simply trying to solve a problem and justifying the chosen procedure.

Group (90 min): A problem on the estimation of the area is proposed. Students have to find two different methods, justifying their choices and to explain differences between methods (Figure 3).

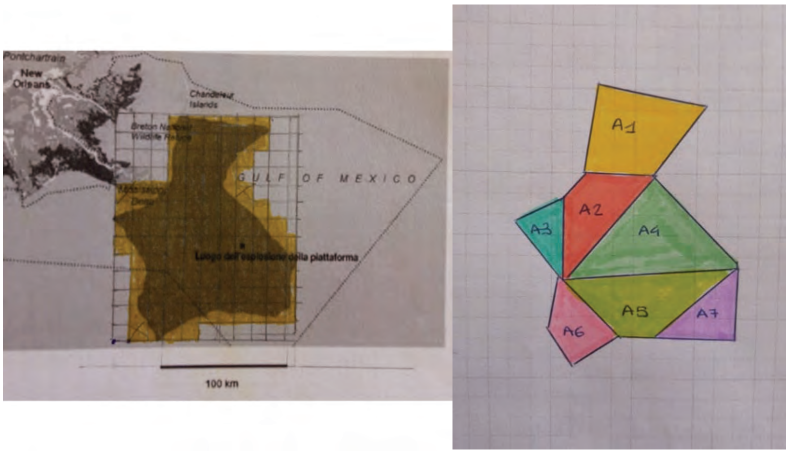

Figure 3: Two different methods implemented by students to calculate the area of the figure.

Changes made compared to the previous intervention

OATLP is designed specifically to work on the ability of problem solving and not in relation to a specific mathematical object like the circle or the Pythagorean Theorem. In this respect, stations and groupwork have a stronger relationship, which can be found in the metacognitive reflection on the different strategies of problem solving.

Retrospective analysis

Strengths: During groupwork students recall the activities done during the stations and build on them to face the new task.

Critical issues: we decide to introduce in the next OATLP cycle a moment of collective resolution (in group) of one of the stations, chosen by the members of the group. This allows students to compare different solving methods and overcome difficulties encountered. Furthermore, we acknowledge the need for a stronger connection between the stations and the groupwork.

Discussion and conclusions

The OATLP cycle is the result of its subsequent implementations with the lower secondary school class involved in the OPEN-MATH project. It is intended as a model that promotes inclusive mathematics education in school. The research project developed in a constant dialogue between the theoretical design principles and classroom activities in a real learning context. In their confrontation, both the theoretical principles and the structure of the model modified: the Theory of Objectification allowed us to focus on multimodality of mathematics education and the relation between subject and mathematical culture. From the theory of objectification come the focus on problem solving and the design of moment of interaction where students are asked to justify their choices and strategies, but also the attention in the choice and role of artifacts in station and groupwork. Didactical differentiation, through Open learning methodology, allowed us to focus on the individual in the process of encountering mathematical culture. In particular, Open Learning allows us to consider the specific learning approaches and bring to the fore strategies to manage the differentiated classroom, for instance through stations, the use of the passport, or the introduction of specific roles during groupwork. These aspects go beyond the specificity of OATLP model and allow to define a set of general design principles that will be a reference for further research on the efficacy of OATLP:

- Alternate modes of work (group, individual, whole class).
- Provide a plurality of semiotic means of objectification and of activities starting from the needs of students in the classroom.
- Work on explication and justification of solving processes and argumentative practices.
