The findings from this study highlight the use of isomorphism as a strategy in combinatorial problem-solving, particularly through re-coding. Alex demonstrated four instances of re-coding during the interview, where he unconsciously translated Dyck words and paths into parenthetical expressions or other familiar representations. All the situations where the re-coding strategy was used were used the isomorphism based on substitution of the characters (Medová & Jančařík, 2024) which can be according to Greer and Harel (1998) considered as surface-level isomorphism. The re-coding allowed Alex to rely on a more intuitive understanding of parentheses, facilitating his ability to assess the correctness of the strings without performing step-by-step verifications. The re-coding of the combinatorial tasks into a form where the rules were more immediately recognizable (e.g., parentheses) enabled Alex to redirect his cognitive efforts toward more complex aspects of the problem.

Additionally, the findings suggest that the ability to switch between different representations of combinatorial problems—such as Dyck words, mountain ranges, and pairings—can be a powerful tool for students. The language of parentheses appeared to be a natural and efficient medium for Alex to process and solve problems, indicating that encouraging students to recognize isomorphic relationships and consciously choose familiar representations may enhance problem-solving efficiency. These results point to the potential for re-coding strategies and isomorphism to reduce cognitive load and improve students' success in solving combinatorial problems, particularly in tasks involving Catalan numbers.

Assessing Abstraction Skills Among Secondary School Students: A Study of a Block-based Programming Environment (BBPE) Enhanced by Augmented Reality (AR)

Fajar Meirani[1] and Sylvia van Borkulo[1]

[1]Utrecht University, Faculty of Science, Freudenthal Institute, Utrecht, The Netherlands;
s.vanborkulo@uu.nl

In the 21st century, educators are increasingly focused on promoting Computational Thinking (CT), crucial for careers in STEM (Science, Technology, Engineering, and Mathematics). A key CT skill is abstraction, which is vital for solving complex problems. This case study explores the development and assessment of abstraction skills in novice 16-year-old programmers in secondary school using a Block-based Programming Environment (BBPE) with Augmented Reality (AR). Data from screen recordings, audio, and interviews show that while students show proficiency in pattern recognition, eliminating, and focusing, they frequently lack higher-order abstraction skills like generalization, decomposition, and debugging. Although most students attain an abstraction level that enables them to organize their thoughts and create logical plans, they often find it challenging to generalize their solutions to more complex problems.

Keywords: Secondary mathematics education, CT, abstraction, block-based programming, AR.

Introduction

In the 21st century, the emphasis on STEM literacy and digital skills has increased due to the importance of computing technologies. Computational Thinking (CT) is crucial for problem-solving in STEM careers (Çakiroğlu & Çevik, 2022), with Wing (2010) defining it as the process of formulating problems so that solutions can be executed by an information-processing agent. Abstraction, a key CT skill, is fundamental in computer science, involving the identification and elimination of unnecessary data (Wing, 2006). Students with weak abstraction skills struggle with complex problems (Kramer, 2007), highlighting the need to teach this skill early (Gibson, 2012).

New technologies such as Block-based Programming Environments (BBPEs) offer strategies for teaching abstraction. BBPEs help students understand basic programming through building blocks (Weintrop & Wilensky, 2017). While popular tools like the Scratch BBPE are widely used, Weintrop & Wilensky (2017) examined that students encountered confusion and difficulties due to the challenge of identifying errors within the complex code. To address this concern, the role of immediate feedback is crucial in BBPEs. Immediate feedback in BBPEs, such as that provided by the <colette> app using Augmented Reality (AR) (Colette-Project, 2022; Milicic et al., 2021), helps students better understand and debug code (Cheli et al., 2018). This study investigates how <colette/> tasks using a BBPE enhanced with AR can improve abstraction skills in novice secondary school programmers.

Theoretical Framework

CT is a concept pioneered by Seymour Papert in 1980. Papert (1980) emphasized two key facets of computation: employing it to generate knowledge and using computers to augment thinking processes for accessing knowledge. The theory from Papert (1980) was then formally introduced by Wing (2006) as the concept of CT. Wing (2006) suggested that CT is the process of using abstraction when solving sizeable complex problems. It includes the skills of "using, modifying, and influencing a large complex system without understanding its every detail" (p. 33).

Various researchers have since refined the concept of abstraction within CT. Csizmadia et al. (2015) described it as eliminating irrelevant information, while Barr & Stephenson (2011) and Lee et al., (2011) emphasized its role in simplifying and generalizing problems. Çakiroğlu & Çevik (2022) expanded on this by identifying five sub-skills of abstraction: pattern recognition, generalization, focusing, eliminating, and decomposition. These sub-skills collectively help reduce problem complexity, making solutions more applicable across different contexts.

Abstraction skills in K-12 education can be developed BBPEs, which simplify programming by representing it as building blocks, making it easier for students to understand and reducing syntax errors. Studies have shown that BBPEs can enhance students' abstraction skills, though further research is needed to identify which specific sub-skills are most effectively developed. For example Rose et al. (2020) found that a BBPE game could improve procedural abstraction but did not specify which sub-skills were involved.

Frameworks to assess abstraction skills in BBPE have also been proposed. For example, Cetin & Dubinsky (2017) proposed a framework which emphasizes the development of mental structures through reflective abstraction to understand CT concepts. This framework, however, primarily focuses on developing students' mental structures through reflective abstraction and does not offer detailed strategies for cognitively assessing the level of abstraction that students attain. Çakiroğlu & Çevik (2022) adapted the RBC Abstraction Model, which outlines three stages—Recognizing, Building with, and Constructing (RBC)—through which students progress in their abstraction skills. They suggested that these stages in BBPEs can be observed across three dimensions: interface use, problem-solving processes, and block structure. In these dimensions, students abstract key components, prioritize efficient solutions, and selectively use code blocks to solve problems, thereby developing their abstraction capabilities.

With respect to levels of abstraction, Ye & Salvendy (1996) proposed a framework for understanding levels of abstraction in computer programming. The framework includes five levels: physical, logical, functional, conceptual, and objective, with each level representing a different depth of understanding in programming. The physical level involves basic syntactic knowledge, which in the context of BBPE relates to how students interact with programming blocks to create code. The logical level goes deeper, involving an understanding of the semantics and purposes of different blocks and how they function when the program is run. At the functional level, students begin to develop a step-by-step plan or algorithm to solve specific problems using the programming blocks. The conceptual level requires understanding the generalized functioning of blocks and recognizing patterns that can be applied to broader contexts. The highest level, the objective level, relates to the comprehensive

analysis of system requirements, but this level is less applicable to BBPE, which focuses on basic programming skills rather than advanced system design.

Augmented Reality (AR) enhances 3D visualization's ability to represent spatial structures more effectively than 2D by integrating real and virtual elements, creating realistic and engaging learning experiences (Ke & Hsu, 2015). Chung and Hsiao (2020) found that AR significantly enhances CT skills, with participants using AR support producing higher-quality programs with fewer errors and edits than those using non-AR methods. While research indicates that AR tools can improve CT skills overall, studies specifically examining their impact on improving abstraction remain scarce, underscoring the need for further investigation into AR's potential to develop abstraction skills in educational settings.

The study utilized the <colette/> app, developed by seven European institutions, to teach CT by enabling students to use their own devices, such as smartphones or tablets, during regular lessons (Milicic et al., 2021). Teachers can select and customize tasks, such as building cubes, where students code structures in a 3D map using Google Blocky. The app also incorporates AR to help students visualize and test their coded structures, enhancing their ability to identify and correct errors in real-time.

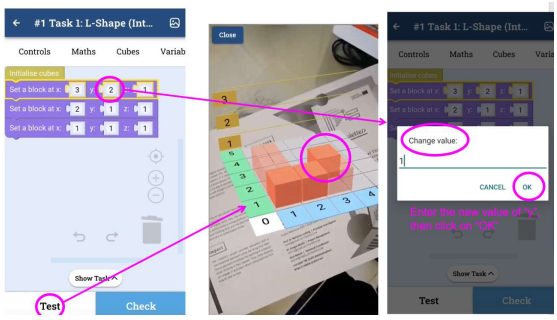

Figure 1: A Screenshot of the task in the <colette/> app in the AR Mode

In summary, this study on BBP tasks in the <colette/> app using AR applies the framework by Çakiroğlu & Çevik (2022), focusing on the dimensions of interface use, problem-solving processes, and block structure. We assess students' abstraction skills, including the sub-skills of pattern recognition, generalization, focusing, eliminating, and decomposition, while considering the levels of abstraction outlined by Ye and Salvendy (1996).

The current study seeks to answer the following research questions:

1. How are abstraction skills developed in the <colette/> Block-based Programming Environment (BBPE) using Augmented Reality (AR) among novice programmers secondary school students?
2. To what extent do students demonstrate different aspects of abstraction skills and levels of abstraction while using the <colette/> BBPE enhanced by AR?

Method

This study was conducted as an explanatory case study to explain how abstraction skills are embedded in BBPE enhanced by AR. An explanatory case study aims to elucidate the underlying causes of a phenomenon, processes, or relationships within a specific research situation (Denscombe, 2021).

In this study, students used the <colette/> app to learn programming with AR. Seven cube-building tasks were created, covering various BBP concepts across four abstraction levels.

The research was conducted at Amsterdam International Community School (AICS) and involved 16 10th-grade novice programmers working in pairs using tablets. The study aimed to observe and analyze students' abstraction skills through task performance and post-task interviews. The study ensured informed consent and anonymous data handling.

Data collection in this study involved screen and audio recordings to analyze students' interactions with the <colette/> app, focusing on their use of interface, problem-solving, and block structures. Semi-structured interviews with six students offered deeper understanding of their reasoning and cognitive processes while performing tasks. Quantitative data further supported the analysis.

To investigate abstraction skills, we used the Çakiroğlu & Çevik (2022) framework within the context of the <colette/> BBPE, with the dimensions interface structure, problem-solving process, and block structure, focusing on pattern recognition, generalization, focusing, eliminating, decomposition, and debugging.

For the first research question, we created an observation form to identify abstraction sub-skills. One of the researchers who is an expert teacher in <colette/> reviewed this form, which included indicators for abstraction in the interface, problem-solving, and block structures. Scores were categorized as “Insufficient”, “Sufficient”, or “Advanced”, and inter-rater reliability was assessed using Cohen's Kappa, comparing a researcher’s and a computer science teacher’s observations (0.79 with 94.98% agreement).

For the second research question, we conducted thematic analysis of interviews to understand students’ behaviors related to abstraction sub-skills. We triangulated data from observations and interviews to evaluate students' abstraction levels according to Ye & Salvendy (1996).

Results

To answer the research questions, we examined the data across three dimensions: interface structure, problem-solving process, and block structure.

The observation result of eight groups of students assessed on their proficiency in abstraction within the context of interface structure in the BBPE indicates that all groups have achieved an advanced level of performance across all four sub-skills. The proficiency levels of students’ problem solving process in the five abstraction sub-skills pattern recognition, generalization, focusing, eliminating, decomposition, and in addition debugging are depicted in Figure 2. The data indicates that students excel in pattern recognition, focusing, and eliminating. However, generalization, decomposition, and debugging emerge as areas of concern.

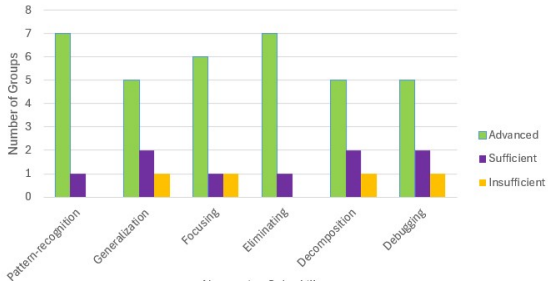

Figure 2: Frequencies of groups performed different abstraction sub-skills in problem solving process

The analysis of students' performance in abstraction sub-skills within block structures presented in Figure 3. The data indicates that a significant majority of groups achieved an advanced level in pattern recognition, focusing, and eliminating.

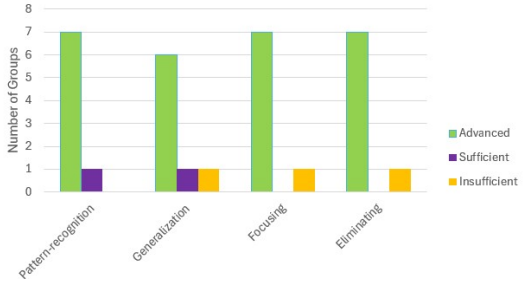

Figure 3: Frequencies of students performed different abstraction sub-skills in the block structures

To further explore the reached levels of abstraction, we analyzed task performance, classroom observations, screen recordings, and interview data. We evaluated students' abstraction level based on two criteria: the correctness of the code and the approach taken to develop the code. A comprehensive analysis of the performance of eight student groups across seven tasks and a qualitative assessment of each group's abstraction level triangulating the different data sources revealed that a majority of four groups achieved a functional level of abstraction, while one group remained at the logical level, and three groups achieved the conceptual level.

A comparison of Groups 2 and 6 highlights differences in task completion and abstraction levels. Both groups completed only the introductory tasks but struggled with the more complex Tasks 3 to 7. Group 2 failed to decompose the solution and attempted to use the same strategy from Task 2 to solve the more complex tasks. A student from group 2 commented on task 4:

> Student 1: … we know this is just 3 different L-shapes, but this is too big. (…) I know we can make it simpler with a repeat block, but we don't know how to do it…

Group 6, despite completing the same number of tasks, showed a deeper understanding of abstraction principles, though they struggled with debugging. Their ability to plan logical sequences placed them at the functional level of abstraction. Reflecting on Task 4, two students from Group 6 commented:.

> Student 2: …the goal of the task was, I think was to use the four loop and understand how to change the dimensions of x, y, z coordinate…
> Student 3: …we just confused what was wrong with our code. We sure it was correct but when we checked it, it always failure…

In contrast, Groups 1, 4, and 8 completed nearly all tasks correctly and effectively , demonstrating abstraction at the conceptual level. A Group 4 student explained their approach to Task 7:

> Student 4: … so the pyramid, it was a three-dimensional structure and we had to use the four loop to do the base and then we have to start slowly decreasing the x and y coordinate… … With that you could make it smaller.

Discussion & Conclusion

Çakıroğlu et al. (2021) emphasize the importance of abstraction skills in problem-solving, highlighting that students who excel in abstraction can solve problems more efficiently. Various approaches, such as game-based learning and robotics, have been explored to enhance these skills. However, previous studies lacked a focus on specific sub-skills of abstraction were embedded. Our study addressed this gap by focusing on what specific abstraction sub-skills are addressed in a BBPE.

Initially, our study focused explicitly on the abstraction sub-skills suggested by Çakiroğlu & Çevik (2022): pattern recognition, generalization, focusing, eliminating, and decomposition. However, during the observation, it became evident that AR in the <colette/> app played a significant role in debugging, assisting students in identifying and fixing errors. Consequently, this study focused on the six sub-skills of abstraction: pattern recognition, generalization, focusing, eliminating, decomposition, and debugging.

In relation to our research questions, we found that while students demonstrated advanced skills in using the interface, and applying pattern recognition, focusing, and eliminating in problem-solving process, they struggled with generalization, decomposition, and debugging, particularly in complex tasks. The study revealed that AR in the <colette/> app supports the development of abstraction skills by guiding students through simple debugging tasks, such as identifying errors in code blocks and providing visual cues for correction. AR feature in the <colette/> app helped students recognize patterns in their mistakes and improve problem-solving. However, the AR support was less effective when the students faced duplicate code in more complex scenarios, suggesting that students struggled to apply higher-order abstraction skills, such as debugging, without additional guidance. This insight suggests areas for improvement in AR-enhanced BBPEs to better support advanced skills.

Furthermore, the decomposition and generalization skills of the students were relatively weak, with some students still struggling to break down complex problems and apply the same code blocks to different tasks. The nature of the tasks, including their complexity and the students' lack of experience with diverse building blocks, hindered their ability to effectively decompose and generalize solutions. Designing tasks with more in-depth scaffolding could address these challenges by providing clearer guidance, breaking problems into manageable steps, and offering examples that show how to apply solutions across contexts. This approach would support the development of higher-order abstraction skills.

The study validated and applied the framework by Çakiroğlu & Çevik (2022) for assessing abstraction skills on the dimensions interface structure, problem-solving process, and block structure. However, we found that the framework's broad categories of "insufficient," "sufficient," and "advanced" were not nuanced enough to capture the diversity in student performance. The incorporation of Ye and Salvendy’s (1996) five levels of abstraction provided a more detailed evaluation.

Most students reached the functional level of abstraction, showing the ability to organize and plan solutions but struggling with generalization in complex tasks. A few reached the conceptual level, demonstrating the ability to break down and generalize solutions, while one group remained at the logical level, understanding block purposes but failing to provide complete solutions. These findings provided deeper insights into the development of abstraction skills when using a BBPE with AR.

The study highlighted the value of immediate feedback, such as AR features, in enhancing debugging skills but noted limitations in handling duplicate code. This limitation led to students expecting to have the correct solution, but their solution was not acknowledged by the system as correct. Their inability to effectively debug and complete the assigned tasks resulted in them remaining at a functional level, rather than progressing to higher levels of abstraction. Future studies should investigate enhanced AR interactions, emphasizing scaffolding that supports generalization, decomposition, and advanced debugging mechanisms. By enhancing the AR feature of BBPE, researchers could investigate how such advancements might facilitate the development of higher level of abstraction, enabling students to move beyond the functional level to achieve a higher level of abstraction in programming tasks. Furthermore, although the study's small sample size and short duration limit generalizability, it offers valuable insights into assessing abstraction skills in AR-enhanced BBPEs.

Acknowledgment

This study was performed under the ethical guidelines from the Faculty of Science from Utrecht University as part of a master's degree program.

“Same, same but different?” – Extending a mathematical problem-solving model to computer science problems

Deng-Xin Ken Oehler[1] and Matthias Ludwig[1]

[1]Goethe University, Department of Mathematics and Computer Science Education, Frankfurt, Germany; oehler@math.uni-frankfurt.de

The long tradition of problem-solving in mathematics education research drew the attention of other disciplines to the emerging models for characterising problem-solving processes. One such discipline is computer science, which relies to a similar extent on its own models as it does rely on Polya's pioneering four-phase model from 1945. However, these applications of Polya's model are neither based on empirical evidence of the suitability of this mathematical model for computer science problem-solving processes nor do they consider further developments since then. The study presented here focuses precisely on this empirical legitimisation ensuring that the models used are up to date and providing first indications that an interdisciplinary model might indeed be appropriate.

Keywords: Problem-solving, Polya, Computer science education, Secondary education.

Problem-solving in mathematics and computer science education

Problem-solving in mathematics education has been a tradition for more than a century. It has been an integral part of school curricula for mathematics around the globe for many years (OECD, 2020). Despite or precisely because of its long-known relevance for mathematics education, the research around mathematical problem-solving has constantly evolved (Liljedahl & Cai, 2021), starting with George Polya’s (1945) famous normative four-phase model, consisting of (i) *Understanding the problem*, (ii) *Devising a plan*, (iii) *Carrying out the plan* and (iv) *Looking back*. Polya marked the beginning of a new era by re-introducing heuristics to the science of problem-solving, generally applicable questions to guide problem-solving processes and a variety of practical examples for teachers and scientists alike. With Schoenfeld (1985) the understanding of mathematical problem-solving receives a more goal-driven character, leading to a new *Exploration* phase, refined definitions of Polya’s existing phases, and a partially circular structure. Fostering detours and improving the quantifiability of problem-solving processes, Rott et al. (2021) present a descriptive five-phase model incorporating the fundamental ideas of problem-solving by Polya (1945) and the advances by Schoenfeld (1985). These and many more studies are proof not only of the intense problem-solving research conducted in mathematics education – currently focusing on teachers’ professional development (Chanudet & Favier, 2023) and interdisciplinary chances (Tran & Nguyen, 2023) – but also of the development since Polya (1945) published *How to solve it*.

In computer science (CS) education, however, problem-solving research is still at its beginnings with only a few forays (Romeike, 2008; Schubert & Schwill, 2011) and no fixed place for problem-solving in school curricula, since CS communities in many countries are still discussing what these curricula should look like (Webb et al., 2017). Nonetheless, in discussions about the CS curricula creation and reform, problem-solving is deemed to be an integral part (European Commission: European Education and Culture Executive Agency, 2022), which highlights the importance of understanding CS problem-solving processes to contribute strategies and material for teaching problem-solving in

future CS classes at school. A closer look at existing CS problem-solving research reveals that a substantial part is guided by Polya's (1945) model, although it is primarily mathematical (Nance, 2016; Oehler & Ludwig, 2024; Thompson, 1996). One possible reason for a mathematical problem-solving model being used in CS could be the increasing research on interdisciplinary skill development in recent years (Tran & Nguyen, 2023) which motivates the investigation of problem-solving processes under the influence of each other's disciplines. Yet, neither evidence nor research justifying the actual applicability of a mathematical model in CS nor in-depth considerations of the described advances in mathematical problem-solving can be found in the CS studies using Polya.

Research question

Considering the historical and current state of problem-solving research in mathematics and CS education, a need for empirical research on existing and future interdisciplinary usage (between mathematics and CS) of mathematical problem-solving models emerges. The pilot study presented in this article is tackling this need by investigating the following research question:

Is it possible to extend a recent mathematical problem-solving model and the corresponding coding manual in a way that meets the requirements of problems from both disciplines?

The answer to this research question holds the potential to provide the theoretical, model-based foundation for the implicit assumption of previous CS problem-solving studies that Polya's model is – to a certain degree – suitable for CS problem-solving processes. The desirable result of this study would be a refined model with a coding manual suitable for problem-solving processes of both disciplines. To decide whether mathematical and CS problem-solving processes might be too far apart for a reasonable interdisciplinary model the following preliminary criteria have been developed:

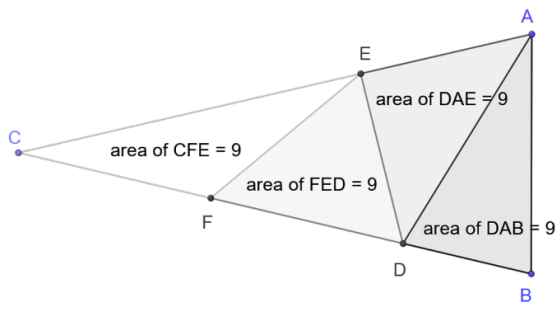
(i) *Can each phase of the chosen mathematical model be identified in most of the investigated CS problem-solving processes?* This criterion assumes that for an interdisciplinary model, each phase should have relevance in problem-solving processes of both subjects.

(ii) *Can a sufficiently large percentage of each process be coded with the derived model?* Since the extended model should serve both disciplines evenly, this *sufficiently large percentage* should at least be over 50 percent and in most cases significantly higher. Equivalent to criterion 3, the exact threshold depends on the problems, problem solvers and the surrounding setting.

(iii) *Does the unresolved percentage contain less than three new definable phases?* Three, since over the last 75 years most Polya-related models did not exceed five phases (Rott et al., 2021) and extending an existing model by over half might rather call for a completely new model.

(iv) *Can the potentially newly defined phases be found in mathematical processes?* In line with the conditions of criterion 2, newly identified phases should also serve both disciplines. This means that in suitable and comparable settings (e.g. mathematical problems with the use of technology) the newly identified phases can also be found in mathematical problem-solving processes. Findings under this criterion can further motivate research in mathematical problem-solving.

Methods



Study design: The core methodological output of this study – of which only the piloting results are presented here – is the development of an interdisciplinary problem-solving model with a corresponding coding manual. This study uses a recent mathematical problem-solving model (described in the next section), serving as the foundation for the deductive development of this manual. The next development step is an inductive extension by analysing problem-solving processes from four different settings (see section "Settings & Problems"). In total, eight pairs of upper secondary students will receive one problem from all settings with each pair solving the problems in a different order – according to the Latin-Square-Design (Field, 2002). The students are selected from the German enrichment program *Digitechnikum* (Wetzel & Ludwig, 2020) to ensure a minimum of comparable prior CS knowledge. The pilot study comprised the deductive derivation and a first glance into one process from each setting, to clarify whether an inductive extension with an interdisciplinary background could lead to a reasonable model considering the developed criteria. Four upper-secondary students (3 male, 1 female) from the *Digitechnikum* with comparable knowledge in CS were grouped in pairs. Each pair was asked to solve two of the four problems while being filmed with no content-related interventions. These processes were then coded using the deductively derived coding manual described in the next paragraph.

Model & Manual: As it is required to consider both Polya's original model and the major developments in recent problem-solving research after Polya, the decision for an initial model, from which an interdisciplinary one could be derived, falls on the descriptive five-phase model of Rott et al. (2021). This model is especially suited for several reasons. Firstly, it evolved directly from Polya (1945) via Schoenfeld (1985) comprising the five phases described in Schoenfeld (1985): *Analysis* [A], *Planning* [P], *Exploration* [E], *Implementation* [I] and *Verification* [V]. Secondly, Rott et al. (2021) describe four additional phases not specific to problem-solving – *Reading* [R] (already in Schoenfeld, 1985), *Writing* [W], *Organisation* [O] and *Digression* [D] – allowing a mathematical problem-solving process to be sufficiently characterised. Thirdly, this model allows for transitions from each phase to another accounting for any possible detour with the potential to reveal process patterns among different tasks, problem solvers or – as in this case – settings. The manual was newly developed deductively by searching for definitions and indicators for each phase in Polya (1945), Schoenfeld (1985) and Rott et al. (2021). Indicators which have changed over time are represented by their most recent version. The resulting manual was first tested in Oehler & Ludwig (2024) and further improved before the usage presented in this paper (see section "Results").

Episodes: Schoenfeld defines an episode semantically as "[…] a period of time during which an individual or a problem-solving group is engaged in one large task […]" (Schoenfeld, 1985, p. 292) and Rott et al. (2021) highlight that "the idea of episodes as macroscopic chunks implies a certain length, thus individual statements do not comprise an episode […]" (Rott et al., 2021, p. 743). In this pilot study each process was first pre-partitioned into semantic episodes, followed by assigning phases to these episodes. However, in contrast to Rott et al. (2021), the coders were advised to not only consider macroscopic chunks but also shorter, maybe simultaneous episodes, since no respective knowledge about CS problem-solving process characteristics is known, yet. This slight change makes it possible to later uncover new dependencies between different phases. Simultaneously, such

empirically observed characteristics of mathematical problem-solving processes like *Planning* and *Implementation* often appearing together or *Verification* only being expected at the end of a process (Rott et al., 2021, Schoenfeld, 1985) have not been given to the coders as guidelines to allow for a more unbiased look at CS processes.

Settings & Problems: Four settings were defined to cover a large field of problem application in both disciplines (M-P, M-C, CS-P, CS-C): Problems from mathematics (M) and computer science (CS) were selected to be either solved by using pen and paper (P) or the computer (C). The latter required the task to be accomplished in a digital environment e.g. GeoGebra in mathematics or the Java Editor in CS. For this pilot study, one problem for each setting was developed of which two are shown in Figure 1, while the remaining two can be viewed in Oehler & Ludwig (2024). In settings M-C and CS-C, students were given a computer with the respective digital environment running and explicit advice beforehand that they were not restricted in using the computer or the internet, respectively. This comment was not given to students in setting M-P and CS-P, which will become relevant when evaluating and discussing the results. To increase the chances of observing proper problem-solving processes, the problems were especially difficult – knowingly at the risk of preventing acceptable solutions in time. In M-C (see Figure 1, upper problem), the students mainly struggled with identifying tools in GeoGebra which would give them more freedom in testing different approaches for constructing the given figure. One student checked an earlier task in GeoGebra using the smartphone. In CS-P (Figure 1, lower problem), the students successfully identified other alignments for the given example and developed an algorithm. However, upon *Verification* they found that their algorithm lacked the optimisation aspects required in the task and did not finish the next version in time.

M-C: Special mosaic windows: A glazier would like to produce mosaic windows in the form of isosceles triangles (here triangle ABC) with the pattern shown in the illustration, whereby each of the partial triangles (these do not have to be isosceles) should have the same area. Construct such an isosceles triangle window in GeoGebra, which retains its properties even if it is stretched in width or length. Can you find a procedure for any number of equilateral triangles?

CS-P: Sequence alignment: One area of bioinformatics is dedicated to the comparison of known DNA sections in of species, which are assumed to have the same function. During evolution, changes have occurred in these sequences due to mutations (insertions, deletions, substitutions), so that these sequences are no longer identical. The aim is now to fit these sequences, considering the different mutation types, so that as many parts of the sequences as possible match – this is known as *sequence alignment*. In the example to the right there are two deletions in S1 (or insertions in S2) which are displayed by so-called gaps "_"), as well as a substitution in the second position. How many other alignments for S1 and S2 can you find with the same number of gaps and substitutions? Develop an algorithm (step-by-step or as pseudocode) that outputs as many alignments with as many matching characters as possible and the least number of gaps necessary between two sequences.

Figure 1: Problems for settings M-C and CS-P developed and translated by the first author

Results

The average process length was 52:05 min (SD = 05:11 min) and no process was finished successfully – an expected result given the complexity of the problems. Nonetheless, each team fully engaged in the problem situation and tested, as well as verified different approaches. The pre-partitioning in semantic episodes was conducted as consensus coding among two raters for the first two videos and completed by the first author for the remaining two videos. This led to an average number of episodes of 37 (SD = 11.34) and a mean duration of 01:35 min (SD = 16.58 sec) with both processes using pen and paper having visibly fewer and longer episodes than those using the computer. These episodes were then coded using the nine phases from Rott et al. (2021) plus a tenth phase *Unknown* [U] (none of the nine known phases matches an episode) by two additional raters, as well as the first author. The IRR using Fleiss' Kappa is displayed in Table 1 for all phases specific to problem-solving and cumulated for each of the four settings (cumulated values also consider the phases R, W, O and D). A clear improvement from the first analysis in Oehler and Ludwig (2024) is visible, with four out of five problem-solving specific phases now having *substantial to almost perfect agreement* ($\kappa > .60$) after Landis and Koch (1997). Only *Exploration* falls short with *fair to moderate agreement* ($.21 \leq \kappa \leq .61$). The *poor to slight agreement* ($\kappa < .21$) values, especially for *Writing*, root mostly from only a few episodes being coded as such by one rater. The same applies to *Unknown* in process M-C – yet this process plus process CS-C reveal an interesting novelty. In Oehler and Ludwig (2024) – where episodes were defined as 10 consecutive seconds – for process CS-C, all episodes coded as *Unknown* were independently characterised by both raters as *Research* (with $\kappa = .87$), which led to a preliminary definition of this phase as *the active search for helpful information that can be found neither in the task nor in one's memories. The search is carried out in an external, knowledge-encompassing medium (e.g. formulary, Internet, etc.) by setting search goals and parameters in advance.*

Table 1: IRR using Fleiss' Kappa (κ). All mean values were separately calculated also considering the not problem-solving specific phases *Reading, Writing, Organisation* and *Digression*

Phase → Setting ↓	A	E	P	I	V	U	Mean (setting)
M	*.63*	*.25*	*.61*	*.82*	*.67*	*< .01*	*.65*
CS	*.68*	*.58*	*.63*	*.65*	*.79*	*1.0*	*.72*
P	*.74*	*.43*	*.42*	*.57*	*.65*	*NA*	*.60*
C	*.59*	*.32*	*.78*	*.83*	*.79*	*.85*	*.73*
Mean (total)	*.66*	*.38*	*.62*	*.73*	*.71*	*.85*	*.69*

In this second analysis, the semantic pre-partitioning yielded episodes at the same positions and both raters rated them independently as *Research* – this time with *perfect agreement*. Moreover, the only *Unknown* episode in process M-C was also characterised as *Research* by one rater and subsequently confirmed in a consensus coding. To complete this finding, no other potentially new phase was

characterised in the context of the *Unknown* phase. Since the overall IRR greatly improved to a point where no phase has a mean agreement less than *fair to moderate* with the majority showing even *substantial to perfect agreement*, a consensus phase coding was conducted for each process. This, in return, allowed for the investigation of problem-solving-specific phase transitions displayed in Figure 2. A transition describes the change from two consecutive phases (e.g.: E followed by Z followed by I: E→I with Z being skipped) or one phase starting and ending within the scope of another phase (e.g.: U while I: I→U→I). This type of visualisation can uncover relationships and indicate dependencies among certain phases. Looking at *Planning* and *Implementation*, which was reported by Schoenfeld (1985) to often appear together, the bidirectional transitions in three out of four processes seem to confirm this tendency. Interestingly, in all processes, bidirectional transitions between *Exploration* and *Implementation* can be observed, as well. In the same way, the absence of transitions holds information about possible process directions, such as *Verification* never following *Analysis* indicating that a certain amount of insight and progress via *Exploration*, *Planning* and *Implementation* must be achieved before *Validation* is possible.

Focusing on the new phase *Research* in M-C and CS-C, there seems to be a tendency for it to appear in interplay with *Implementation*, although more data is required to support this observation. Furthermore, is that all processes start with *Analysis* and end either with *Implementation* or *Verification*. Concerning the four criteria the following preliminary results can be observed: (i) Each original phase of Rott et al. (2021) could be observed in all processes apart from *Verification* in CS-C. (ii) After the consensus coding, no episode was left unassigned, and only in CS-C *Unknown* (later characterised as *Research*) comprised six out of 49 episodes. (iii) Considering all processes, all episodes coded as *Unknown* were – in six out of seven cases independently – characterised as *Research* and no other new phase was identified. (iv) Only one episode in M-C was coded as *Research* in the consensus coding, with M-P not having explicit research opportunities during the process.

Conclusion

This study was motivated by the numerous occurrences of George Polya's (1945) problem-solving model in CS education studies (Nance, 2016; Thompson, 1996), neglecting the profound research and developments in mathematics education since then concerning his and many other problem-

solving models (Liljedahl & Cai, 2021). In times when mathematics and CS education share increasing fields of application and the boundaries between these disciplines become more and more blurred (Romeike, 2008), a solid empirical foundation about the usability of mathematical problem-solving models in CS education is required. Hence, this research project investigates whether it is *possible to extend a recent mathematical problem-solving model and the corresponding coding manual in a way that it meets the requirements of problems from both disciplines.* Four criteria have been defined to eventually answer this question. During this pilot study, first preliminary results concerning these criteria could be collected: Criteria (i)-(iii) were met, which means that (i) each phase of the descriptive problem-solving model by Rott et al. (2021) based on Polya (1945) and Schoenfeld (1985) could be found, (ii) each process was sufficiently codable using this model and (iii) not more than three new phases were identified analysing the episodes coded as *Unknown*. Still, the latter resulted in the definition of one potential new interdisciplinary problem-solving phase – *Research*. In Oehler and Ludwig (2024) *Research* was one of the few reliably coded phases ($\kappa = .87$) and independently characterised as such. This impression could now be confirmed using semantic episodes (with perfect agreement). Criterion (iv) was missing data to get a solid impression of whether *Research* does appear in mathematical problem-solving processes, as well. In addition, students in M-P and CS-P were not explicitly given the opportunity to research, which requires investigating, whether the occurrence of *Research* is rooted in CS problems or the work with computers, in general. In addition, the complexity of the problems prevents a more realistic view of the *Verification* phase and *Exploration* still requires sharpening in the manual. Nonetheless, having three out of four criteria being met – even with little data – the authors are confident that an extended interdisciplinary problem-solving model for mathematics and CS education is indeed possible.

On the use of Conceptual Knowledge from Computer Science in Mathematics Education

Reinhard Oldenburg[1]

[1]Augsburg University, Mathematics Institute, Augsburg, Germany;
reinhard.oldenburg@math.uni-augsburg.de

In its need to describe formal system so precisely that they can be implemented on machines, computer science has developed many ideas that can also help to describe and understand mathematics. In fact, some of these ideas just refine and clarify older mathematical notions. Computer realizations of concepts prove (similar to the role of models in model theory) that concepts are free of self-contradictions. The clarification of objects and their relations has, moreover, the potential to improve students' learning. The paper will investigate formal calculi, type theory, lambda calculus and the Curry-Howard correspondence and explain their contribution to math education.

Keywords: Algebra education, computer science, lambda calculus, reification, type theory.

Introduction

The relationship between mathematics and computer science (CS) is multi-faceted, multidimensional and time-dependent (Modeste, 2015). As an offspring of math and engineering it inherits methods and knowledge from mathematics, and it gives tools to mathematics as is highlighted in the movement for computational thinking (Wing, 2006; Broley et al., 2023). A great deal of current research on this investigates algorithms and procedural tasks that can be carried out by machines, i.e. how actual computation (ranging in scope from using dynamic geometry to programs written by the learner) is useful in learning mathematics. The present paper discusses a relationship that is less prominent: Computer science can provide conceptual knowledge that explains and supports certain aspects of the learning of mathematics. Only very few publications have addressed this explicitly (e.g., Kortenkamp, 2006). There is a partial overlap with a prior more foundational paper (Oldenburg, 2024) but here the aim is to collect ideas that prepare the ground for actual teaching interventions.

Among the tasks of mathematics education is the clarification of the ontological status of mathematical objects and the understanding of how symbols acquire meaning (e.g., Queiroz, 2008). Computer science faces some similar problems, although a bit more difficult due to the fact that computer science needs to put its theories to test by implementing them on computers.

Methods

In its quest to define consistent and meaningful formal systems, CS has developed a bunch of concepts. If they can be successfully realized in soft- and hardware, then one may conclude that they are self-consistent (in analogy to the role of models in logic, see e.g., Mendelson, 2015). Extending this line of argument, one has the following methods on how to transfer conceptual knowledge from CS to math and math education my means of analogical reasoning (Bartha, 2010):

1) If a method of CS allows unambiguous definition of concepts, and if it allows interpretation by humans, then one expects that the method can clarify concepts for humans, too.

2) If a distinction between realizations of mathematical concepts is necessary in CS, one has reason to expect that this distinction is useful for understanding mathematics.

It is important to note that these are heuristic rules, they provide evidence, but no proof. Nevertheless, the research question of this paper is: Do these principles yield plausible results in a number of application cases? This question will be investigated in five topics. The choice of these topics was guided by the wish to present ideas that are hardly discussed in the didactical literature, and to span a range from more concrete to rather abstract and philosophical bridges between the domains.

Topic 1: Make properties of calculi explicit

Mathematics develops and justifies calculi (e.g., Baader & Nipkow, 1998). They are, in a sense, even more fundamental than algorithms: One can view functional algorithms as functional (lambda) calculus together with an evaluation strategy (Barendregt, 1984). Calculi are used in two different ways: They may either be used for semi-automatic reasoning in a given pre-existing theory, then one seeks for calculi that are correct and, if possible, complete (i.e. give the full theory), or they may be used in a creative sense to create a theory, e.g. when a group is defined from generators and relations.

In school, students learn a lot of calculi, e.g. the calculus of equivalent transformations of algebraic expressions, the calculus of transforming equations, forming the derivative or the anti-derivative. It might be beneficial for students to develop some conceptual knowledge about calculi and their properties. For example, equivalence of expressions and equations can be defined exactly the same way (as yielding the same (truth) value under any assignment of values to the variables), and rules of the equivalence calculus are correct but not complete. The derivative calculus is correct (by the usual proofs) and complete on the class of elementary school functions, while the school calculus of anti-derivates is obviously not complete. A complete calculus exists, but is beyond scope in school. An explicit treatment of calculi could also trigger epistemological and ontological considerations: What are the objects that are differentiated? Functions (e.g. as subsets of $\mathbb{R} \times \mathbb{R}$ with some properties) or expressions (i.e. strings of symbols formulated according to algebraic grammar)? Experience shows that the vast majority of teacher students in their third year at university have no idea about this and tend to get confused when asked about it. Most of them cannot even name and explain a difference between functions and expressions. But after explaining that the symbolic text of an expression can be "compiled" to a set-theoretic function, they usually appreciate the diagram in Figure 1.

Confluence is another property of calculi that might be useful to find orientation in the world of symbolic algebra. Moreover, specifying calculus rules often requires concepts that are rarely dealt explicit with in math lessons, e.g. the order of variables and monomials.

Figure 1: Relation of calculus and objects exemplified for the derivative

Topic 2: The distinction between program-time and run-time

Perhaps every algebra teacher in school knows situation in which students are confused when the values of variables may be changed. This problem even went into a cartoon where a pupil objects the solution $x = 5$ of an equation by arguing that the day before the teacher had said that $x = 3$. Understanding variable conventions correctly seems, however, to be a necessary condition for mastering other parts of elementary algebra (Oldenburg & Stacey, 2024). It is my suspect that the didactical concepts of variables as changing quantities or variables representing many numbers simultaneously are not helpful in this respect (Oldenburg, 2023), but that the distinction between program-time (or design-time) and run-time that students experience from day 1 when starting to program, may help. In fact, this distinction is even more wide-spread: When composing a PowerPoint presentation one can clearly distinguish design-time and presentation-time. This concept of different logical times explains the mentioned algebraic problem easily: One may distinguish between calculus-time where on sets up expressions, transforms them by calculus rules, and chooses (and changes) assignments for variables on one hand, and, on the other hand, calculation-time when an assignment of numbers for every variable is fixed and expressions are evaluated with respect to this assignment. At calculation-time each variable stands for one and only one number, but at calculus-time no value needs to be fixed at all. Changing the value of variables is the same as running a program several times with different inputs.

Topic 3: Type theory and algebra: Enabling the substitution principle

In programming, the data type of objects determine what operations are possible with the objects. Type declarations can ease the understanding of code. In mathematics, type theory has evolved since its incarnation in Russell's approach to avoid paradoxes to a complex system of theories (The Univalent Foundations Program, 2013) that is believed by some mathematicians to be a replacement for set theory and first order logic as foundation of mathematics (Altenkirch, 2023). For the working mathematician and for educational purposes, the less ambiguous simple type theory (Farmer, 2023) provides many benefits, but a discussion of this is far beyond the scope of this paper. Here, I'd like to draw attention to the fact that type declarations can clarify the semantics and support learning. It has been shown (e.g., Hanenberg et al., 2013) that type annotations in programming languages can improve program comprehension and detection of errors. It is plausible that analogous results hold at least in higher mathematics. Consider e.g. the action functional in Lagrangian mechanics which is often abbreviated as $S(q, \dot{q})$ although a correct definition would be $S(q) \coloneqq \int_a^b L(q(t), \dot{q}(t), t)dt$, i.e. the argument of S is a function (i.e. of type $\mathbb{R} \to \mathbb{R}$, rather than type $\mathbb{R}$), so that the type of S is $(\mathbb{R} \to \mathbb{R}) \to \mathbb{R}$. Giving correct type information might help in understanding the theory, although it seems that this has not been investigated. Moreover, one may conjecture that type declarations may support learning of more elementary mathematics as well.

From an ontological point of view, types require less commitment than set theoretic notions: Understanding the full meaning of $x \in \mathbb{R}$ requires to mentally construct the set of all real numbers and saying that x is one of its uncountably many elements. In contrast, the type declaration $x\colon \mathbb{R}$ just says that x is a real number, and to understand this one just needs an idea what a single real number

is, not what the set of all real numbers is. To emphasize this point even more, compare the statements "Snoopy is a dog" and "Snoopy is in the set of all dogs". The latter requires thinking about a complex construct, the set of all dogs (only living or also past and future dogs? Are wolves included?), while the former one only needs the ability to identify Snoopy as a dog. Of course, one has to admit that often the explicit use of sets and classes can be eliminated from propositions ("virtual classes" in the parlance of Quine (1969)), but this eases difficulties that may not be present if set theory would be replaced by type theory from the start.

There is another issue that may pose difficulties for learners and that may be clarified by giving explicit declarations. Leibniz defined identity in terms of substitution: Two expressions have identical meaning if one can be substituted for the other everywhere without changing the truth value of statements (salve veritate) (see, e.g. Mates, 1986). Quine (1960) has noted that there are opaque contexts in language that may violate this principle, e.g. although "Paris" and "the capital of France" refer to the same thing and are thus identical, it may be true that "Peter believes that London is the capital of France" but the substituted version "Peter believes that London is Paris" may be false. In fact, similar contexts exist in algebra: Although $2(x+1) = 2x+2$ holds, one may not substitute one for the other in the proposition "$2(x+1)$ is factorized" because this yields the wrong statement "$2x+2$ is factorized". The problem can be resolved by recognizing, that the type of $2x+2$ is not declared. If one declares $2x+2 : \mathbb{R}$ and $2(x+1) : \mathbb{R}$, then they are equal and can be substituted for each other. However, "factorized" is not a predicate for objects of type $\mathbb{R}$. On the other hand, if the expressions are declared to be of type 'expression', then they differ and one has the property of being factorized, the other not. Hence, type-respecting substitutions heal this problem.

Topic 4: Reification can be formally understood as functional abstraction

The mental construction of mental objects is considered in a large variety of approaches, e.g. reification theory (Sfard, 1991), APOS theory (Dubinsky & Mcdonald, 2001), or procept theory (Tall, 2014). These approaches share a lot but differ in detail. All of them are, however, only described informally and their consistency is implicitly deduced from their plausibility. However, since Church introduced the realizations of natural numbers in pure lambda calculus (Church, 1936), it has been known that objects can be constructed from functions, i.e. from processes. Other examples are the constructions of tuples from procedures (Abelson et al., 1996). Although these examples are loaded with the burden of some technical details that are absent in a natural language explanation, they have the benefit that they can be tested by realizations on computer and that they make the object creation step explicit: Functional abstraction prevents an expression to be evaluated and captures it in a "frozen" form. The same mechanism also enables to deal with infinite sequences, e.g. the sequence of natural numbers or of prime numbers. At first sight, there is little didactical benefit from this insight because it is well known that students need to overcome the urge to carry out calculations and to accept "open expression" (lack of closure obstacle, Thompson & Tall, 1991) – i.e. they need to learn to freeze a calculation to an object. What is, however, interesting is the conclusion that delaying the evaluation and capturing the calculation in unevaluated form is at least at this level not only necessary but sufficient to build new objects. This supports e.g. the sensibility of exercises that present a numerical expression and ask students to explain the structure without calculating it.

Topic 5: The Curry-Howard correspondence bridges "meaning by reference" and "meaning by use"

To understand where the meaning of words and sentences comes from is a major goal of philosophy and several theories have been developed. For the understanding of mathematics two theories (or families of theories) may be considered most influential:

Referential theories: Words acquire meaning because they refer to something. The standard interpretation of predicate logic following the line of Hilbert (Hilbert & Ackermann, 1967), Tarski (1941) and Quine (1981) falls in this class, because interpretations of symbols must be fixed, that assign e.g. a function to each function symbol, and this fixes the symbol's meaning.

Language play theories: The idea that the meaning of words is given by the way they are used in the language game is due to Wittgenstein (1958), but has spread further (e.g., Kripke, 1982).

It is clear that referential theories are more naturally combined with realistic or relativistic convictions on the status of mathematical objects, while language play theory is more in line with constructivist theories. Of course, this dichotomy over-simplifies the philosophy of meaning, but it is quite useful in its application to the learning in general (and of math in particular) and the semantics of programming languages: Assume I shall explain what the German word "Baum" means. One way is to ostentatiously exhibit objects the word "Baum" refers to, i.e., I shall point to trees, or I give examples of sentences where the word is used. Another example bridges math and computer science: What does + mean? The referential explanation is that it refers to the operation of adding numbers. This can be made concrete e.g. in the programming language Scheme, were + refers to a function object that can be applied to numbers, but it can also be stored in data structures or passed to functions. The meaning of + can also be fixed by language play. Then, + does not refer to anything, it is just a symbol that can be used according to some rules, e.g. the rule that $x + 0$ can always be changed to x or that $x + y$ can always be changed to $y + x$. In computer science, this is realized in term rewriting systems (Baader & Nipkow, 1998) such as Mathematica (Wolfram Research, 2024). Lambda calculus can be seen as a term rewriting programming language.

Both theories are in a sense in opposition: For referential theories, objects are fundamental, and language plays the secondary role of describing objects and their relations. In contrast, in language play theories, of course, language is fundamental, and objects emerge from talking as is they were there. This carries over directly to logic: The meaning of $\forall x: p(x)$ in referential theory means that $p(x)$ is true, whatever object x refers to. In language play theory it means that $p(x)$ is true, whatever expression is inserted for in place of x in the formula $p(x)$ (in philosophy, the terms used are usually objectual and substitutional quantification, see Hand, 2007). These two interpretations of quantification may be different: There are only countable many expressions, but maybe more than countably many objects. The mainstream in mathematical logic adopts the referential interpretation and justifies the rules of proof systems from this (Mendelson, 2015). The "world" of referential theories thus includes objects, model theory, denotational semantics-based proof theory as well as referential programming languages like Scheme or Julia. Besides obvious strengths, a clear drawback, especially as seen from an educational perspective is that these theories assume (at least as hypothesis in the sense of model theory or relativistic ontology) that the objects that symbols refer to "exists" in

some form. Language play theory in contrast does need such assumptions. One may first fix conventions of the language game and then objects may emerge from this when one observes that it is a good interpretation of words to assume that they refer to some object. Consider the intersection of sets: from a referential point of view, one may think of A, B as existing sets of existing objects and form $\{x: x \in A \wedge x \in B\}$. From a language play theory, one may know how to speak about having property A or property B and establish rules how to speak about things that have both properties. From this use of language, it may emerge that it is sensible to assume that there are sets of these things. So, language play theory includes processes, term rewriting, much of type theory, and programming languages such as lambda calculus, Pure or Wolfram Mathematica. I should be said that this simple dichotomic picture is adequate only when restricting to the main-stream approaches. However, there is the concept of proof-theoretic semantics which puts semantics in the language world, and models for type theories which puts type theories into the referential world.

With reification theory, we have already met a bridge between these worlds, showing that processes can be turned into objects. This bridge can be extended to span all of the two worlds: The famous Curry-Howard correspondence (Curry & Feys, 1958; Girard et al. 1989; Mimram, 2020) gives an isomorphism between formalized proofs and programs in typed lambda calculus, i.e. programs are proofs, and their types are the propositions proved by them. This surprising result seems not to be recognized much in educational sciences (Oldenburg, 2024). The whole theory is quite involved, but a key idea is that logical modus ponens is the same deriving $f(a): B$ from $a: A, f: A \to B$.

There are several insights gained from this: First of all, the two seemingly distinct worlds described above are tightly linked and therefore consistent. The important role of types that was already pointed out above is further emphasized. Computational thinking (e.g., Wing, 2006) is brought even closer to mathematical thinking because, in the language of ATD (Chevallard, 2019), the connections between the logos of math and computer science extend to the whole praxeologies of both domains. The traditional emphasis of math education on functional thinking is justified. Moreover, it seems plausible that the learning process may start out with language play and referential interpretations may represents a more developed form that should be supported by teaching.

Conclusion

This paper began by questioning whether the principles of transferring conceptual knowledge from computer science to mathematics education can provide valuable insights. The conclusion, as evidenced by the examples provided, is affirmative. The exact way this transfer is accomplished is somewhat different between the five topics, but this is not uncommon with heuristic methods. A key didactical implication is the need to place greater emphasis on precisely defining types, as clarity about types parallels clarity about propositions. It should be noted that the list of five topics discussed is not exhaustive. Additional topics worthy of consideration in this context include generative grammars, the parsing of expressions, and the concept of effective computability—a property that, for instance, the supremum of a bounded subset of $\mathbb{R}$ generally lacks. Clearly, there is an abundance of ideas in this area that remain to be explored.

Using computational thinking to solve the Josephus problem: Insights from participants with different educational backgrounds

Valentina Postelnicu

Governors State University, USA; vpostelnicu@govst.edu

A study was conducted with the aim of gaining insights into how participants with different educational backgrounds employ computational thinking (CT) to solve a problem that lies at the intersection of mathematics and computer science. Three participants—one with a mathematics and computer science educational background, another one only with a strong mathematics educational background, and a third one with a social sciences education background and self-taught programming knowledge—solved the Josephus problem and reflected on their solution. A conceptual analysis was used to examine their responses, organized around the key CT features: decomposition, pattern recognition, abstraction, and algorithm design. The participants' application of CT varied depending on their educational background and prior knowledge. They approached the problem abstraction differently - the first two participants used mathematical models, while the third one used visual representations. This study draws attention to the flexibility of the CT approach to problem-solving across various educational backgrounds and raises the issue of the nature of the solution.

Keywords: Computational thinking, Josephus problem, Problem-solving

Introduction

Computational thinking (CT) has emerged as a critical competency of the 21st century, like reading and writing. CT skills are essential for solving complex problems in various fields and are now being acknowledged as important for all students, not just those in traditional STEM (science, technology, engineering, mathematics) fields (Grover & Pea, 2013). Wing (2006) defined CT as the ability to formulate problems with computable solutions in a way that can be executed by a computer or human, or a combination of both. The key features of CT include decomposition, pattern recognition, abstraction, and algorithm design.

The Josephus problem (JP) is an old problem in mathematics and computer science. Its solution attracted a lot of attention (Graham et al., 1989; Robinson, 1960; Sullivan & Beatty, 2012). Robinson (1960) mentions the original version of the problem. The JP was chosen because it is non-trivial and can be solved from a mathematical perspective with complex proofs, or from a computer science perspective that makes it accessible to solvers without advanced mathematical knowledge. A reformulated version, used in this study, is the following: N people, labeled 1, 2, 3, …, N stand in a circle. The counting starts from the first person (position 1), and the k-th person is eliminated. The counting continues from the next person (position k+1), and the k-th person is eliminated. The game ends when only one person remains. Given N and the step size k, the goal is to determine the initial position of the last person remaining in the game.

This study aims to gain insights into how three participants with different educational backgrounds employ CT to solve the JP, thus contributing to a broader understanding of the way the CT skills are employed across various educational backgrounds.

The following research question is addressed in this study: **How do participants with different educational backgrounds approach the Josephus problem using CT?**

To answer this question, we analyzed the participants' reflections on their problem-solving process, after they solved the JP. The reflection was structured around the participants' use of the key features of CT: decomposition, pattern recognition, abstraction, and algorithm design.

Theoretical background

Scholars conducting research in problem-solving are recognizing the importance of CT as essential for helping students develop the necessary problem-solving skills to effectively address complex problems (Angeli & Giannakos, 2020; Barr & Stephenson, 2011; Grover & Pea, 2013; Kafai & Proctor, 2022; Li et al., 2020; Wing, 2006, 2008). CT is different than other cognitive approaches to problem-solving, like mathematical thinking or algorithmic thinking (Aho, 2012; Li et al., 2020; Weintrop et al., 2016; Wing, 2006, 2008). Mathematical thinking employs rigorous logical reasoning, abstraction, generalization, and proof to solve well-defined problems within formal mathematical systems. Algorithmic thinking focuses on procedural problem-solving by designing repeatable, step-by-step procedures, and considers the efficiency and complexity of those procedures. CT has been characterized by a list of essential components like abstraction, generalization, decomposition, and algorithmic thinking (Aho, 2012; Angeli et al., 2016; Angeli & Giannakos, 2020; Grover & Pea, 2013; Wing, 2006). Looking for a definition of CT in empirical research, Ezeamuzie & Leung (2022) reviewed 18 studies. They found various approaches to the definition of CT, with most studies defining CT using a list of its main characteristics. The list differs from study to study, indicating that the CT definition remains, for now, an open issue, subjective to researchers' theoretical sensitivity.

Integrating CT into curricula comes with challenges, starting with the lack of consensus regarding a definition of CT, and continuing with preparing our teachers to create and implement pedagogical practices that are tailored specifically to the development of CT skills (Sands et al., 2018). When employed in classrooms, for example in mathematics and science classrooms, CT is conducive to pedagogical practices that enhance the content of those disciplines (Weintrop et al., 2016). Postelnicu & Postelnicu (2020) describe a successful teaching experiment with high school students involved in solving a problem that encourages the development of computational thinking skills. Educators advocate for inclusivity and access (Grover & Pea, 2013) and recommend that CT should not be seen as just another set of problem-solving skills suited for the digital age, and it should be accompanied by a critical understanding of the societal impact of technological advances (Kafai & Proctor, 2022).

Based on the literature review, we adopted the following working definition: *CT is the cognitive process of solving complex problems by formulating them in a way that enables their solution through a series of computational steps or algorithms, which can be executed by a human, a computer, or a combination of both. It involves systematically breaking down problems into manageable components (**decomposition**), identifying patterns or similarities within these components (**pattern recognition**), creating generalizations or models (**abstraction**), and developing step-by-step procedures or rules for solving problems (**algorithm design**).*

Decomposition is the process of breaking down a complex problem into smaller, manageable components. (Barr & Stephenson, 2011; Postelnicu & Postelnicu, 2020). In the case of the JP

problem, one may consider reducing the circle size N or the step k and solving recursively. The original JP problem had N=41 and k=3 (Robinson, 1960). When trying to solve the JP for the general case, one may start with k=2 and various, small values for N. The recursive approach is evident, given the elimination rule given in the problem.

Pattern recognition refers to the ability to identify similarities or recurring themes within problems or their components (Shute et al., 2017). For the JP, this means identifying the recursive relation, defined by the elimination rule from the game.

Abstraction is the process of focusing on the essential aspects of the problem and translating it into a mathematical model or representation (Grover & Pea, 2013, Postelnicu & Postelnicu, 2020). The creation of the model or representation has the benefit of simplifying the problem, reducing its complexity, and helping with the algorithm design. For the JP solution for small values of N and k, the participants used visual representations like a rotary phone dial, a circle or a line of objects, or a deck of cards. For the model with a deck of cards see also Sullivan & Beatty (2012). Depending on the mathematical knowledge, one may find recursive relations to describe the elimination rule of the game, and then a general formula to identify the winning position in the initial circle.

Algorithm design entails creating an algorithm to solve the problem (Postelnicu & Postelnicu, 2020; Wing, 2008). It may include testing and debugging, especially if one uses the algorithm to write a program (code) in some programming language. Solving JP entails a recursive algorithm, given the elimination rule. However, writing a program and executing it are optional, and dependent on one's programming skills and access to appropriate technology.

The CT features may overlap, for example, one may use abstraction to simplify a complex problem by identifying patterns and focusing on relevant details. The abstraction process may lead to a model or representation that will help with the algorithm design.

Methods

Given the nature of the JP, at the intersection between mathematics and computer science, the selection of the participants was based on their educational backgrounds and propensity to successfully solve the JP from a mathematical and/or computer science perspective — Ava, with an educational background allowing her to successfully solve JP from both mathematical and computer science perspectives, and Bob and Cora, with educational backgrounds that restricted them to only one perspective, the mathematical and the computer science perspective, respectively.

Ava is a high school mathematics teacher with a Master's degree in mathematics and strong computer science knowledge. She teaches advanced mathematics and computer science (programming) courses, and values both mathematical and computer science approaches to problem solving. Bob is a university professor with a PhD in mathematics without any computer science training. His research focuses on the foundations of mathematics, the way mathematical knowledge is constructed. For him, games with algorithms describing winning strategies, are not interesting. Cora is a high school social sciences teacher, with a Bachelor's degree in psychology, who loves computer games and has learned programming (Python) on her own. She claims that she has never been good at math, and therefore avoided mathematics since she graduated from high school. The most advanced mathematics course

she took was the equivalent of College Algebra, taken in high school, more than 30 years ago. As a teacher, she has employed Snap! (block-based, graphical programming language) and Python to teach high school students how to design algorithms and write code for games and animations.

The participants were asked to solve the JP and were allotted as much time as needed (from several days to more than one week). The original problem given to them was titled the Sword Problem, and there was no mention of the Josephus problem. When they solved the problem, none of the participants knew that the Sword Problem was the same as the JP. After they solved the problem, a questionnaire containing the working definition of CT (stated above, in italics) and the following question was administered by email: *To what extent does the JP facilitate the development of computational thinking skills? Discuss how solving the problem encourages decomposition, pattern recognition, abstraction, and algorithm design, and provide examples to support your answer.*

The participants' written responses were analyzed using a conceptual analysis. To perform the conceptual analysis (Postelnicu & Postelnicu, 2013; Thompson, 2008), we focused on understanding the constructions elicited by participants. Conceptual analysis involves creating models of understanding that hypothesize the mental actions one must perform to perceive a situation in a particular way. To understand another's understanding the researcher needs to construct a coherent interpretation of their meanings, a compatible fit with what they demonstrated through observable actions, in this case, the participants' responses, structured by the main CT features: decomposition, pattern recognition, abstraction, and algorithm design.

The participants' written answers included both the solutions and the reflections on the JP solutions. Their reflections did not contradict in any way their solutions. Given the space constraints, we analyze here only the participants' reflections on their problem-solving process. We present the analysis for each CT feature and participant, using the excerpts from the participants' reflections (see Table 1, below).

Analysis

Table 1. Excerpts from the participants' answers structured by CT features

CT	Participants' Answers		
	Ava	**Bob**	**Cora**
Decomposition	"JP can be simplified by considering $k = 2$ and taking some samples for N the number of people. If $k = 2$, each round around the circle reduces N by approximately half. […]"	" One will try several concrete cases […] Looking at small steps will teach you what is happening there, and then you can create conjectures for some other cases, and then you may prove them in the general case."	"Trying to keep track of a shrinking circle of people […] I literally was bouncing the nickel around the circle of pennies "killing" every other one until the ultimate final person. […]" (*Researcher's note: Initially, Cora solved JP for k =2).*

Pattern recognition	"[…]Thus, the use of the rule of the game leads to a reduction in the number *N* each round, and after a finite number of complete turns, the diminished *N* decreases to reach 1."	"[…]Next comes pattern recognition, as one needs to know what happens modulo some number."	"I was thinking about a solution to the JP […], just to see if there were any kinds of patterns I could notice to even set up a plan for solving the problem."
Abstraction	"From a mathematical perspective, JP is difficult to approach. The case *k*= 2 involves mathematical induction, and use of special functions, like floor function, which are not accessible to most high school students."	"[…] One needs to come up with a formula for the function defined recursively. In the absence of inspiration, one will try several concrete cases and guess a formula, to be then proved by induction."	"[…] I literally took a bunch of pennies […] and tried to just play with the pieces of the problem. The breakthrough […] was reimagining the 'circle of people' as a 'line of people' instead. […]It was much easier to picture it as survivors 'going back to the end of the line.' […] One last final abstraction […] was reimagining the problem as a deck of cards.[…] "
Algorithm design	"To account for the remaining players after each round a possible solution for the algorithm involves two lists. The first list will hold the remaining players after each round, being updated after each round. The other list will have the rule of elimination applied for the new round, and then will replace the first list."	"[…]One needs to come up with a formula […] So, one cannot call the solution to the problem simply computational, given that there is no general rule for the solution of such problems."	"From here – solving the JP was pretty straightforward: […] using python – create a variable that is an empty list; populate that list with a random number of people (the circle or line of people in the JP); copy item 0 to the back end of the list; remove item 0 from the list; repeat until the length of list is 1.[…] Reimagining the problem as a deck of cards; […] 1. Take the top card and place it on the bottom of the deck; 2. Take the top card and remove it from the deck; 3. Repeat until there is only one card remaining."

Decomposition – see Table 1, the row referring to decomposition: Ava managed the complexity of the problem by considering concrete and smaller values for *N* and *k* and using recursive reasoning to decrease the number *N* according to the elimination rule of the game. Likewise, Bob started by solving the problem for concrete, small values of *N* and *k*, and focused on establishing a recurrence relation to describe the rule of the game and solving smaller instances to understand the problem better. To keep track of the way *N* decreased with each iteration of the game, Cora used *k*= 2 and tried to reason recursively, for the case *k* =2 and small values of *N*.

Pattern Recognition – see Table 1, the row referring to pattern recognition: Using the rule of the game and recursive reasoning, Ava noticed the way *N* decreased with each iteration of the game. Bob used modular arithmetic to find a formula for the position of the winning person in the game. Cora sought patterns to establish a plan for solving the problem and after successful abstraction, she would find the recursive pattern of the game.

Abstraction– see Table 1, the row referring to abstraction: Ava found a formula for the initial position of the winner of the game (for the case k= 2) and proved it using mathematical induction. Then, she found a general formula for any *N* and *k*. Likewise, Bob used the recursive definition and found a formula for k=2. Cora used representations (e.g., line of pennies, deck of cards). Interestingly, the representation with the deck of cards led her to discover the JP rule for the case k=2, known as the Australian Shuffle (Sullivan & Beatty, 2012).

Algorithm Design– see Table 1, the row referring to algorithm design: Ava designed a recursive algorithm using two lists to manage the players and the rule of elimination. Bob used the algorithmic steps embedded in the rule of elimination to make and test conjectures but remained focused on finding a general formula and proving it. For him, JP needed to have a solution expressed as a general formula, rather than a recursive, algorithmic one that could be executed by a computer. Cora created an algorithm and a program in Python, based on her abstractions from the representations with pennies and the deck of cards.

To summarize, the analysis revealed that the participants approached the JP differently. Ava used both her mathematical and computer science knowledge. She decomposed the problem by reducing *N* and *k*, recognized the recursive pattern imposed by the rule of elimination and use it to design an algorithm. She found the general formula and proved it by mathematical induction. Bob relied on his strong mathematical knowledge. He used particular values for *N* and *k* and the recursive rule of elimination to make and test conjectures for a general formula. His goal was a general formula, not a recursive algorithm. Cora abstracted the problem through visual representations (a circle of pennies that became a line of pennies, a deck of cards). The abstraction helped her formulate the problem in an algorithmic way and she could write the code (program in Python). She considered the problem solved once the program was executed successfully.

Discussion and conclusion

JP, with its elimination rule, was formulated in a way that supported algorithmic thinking. It was not surprising that Bob and Ava approached the JP based on their mathematical and computer science knowledge, given their educational backgrounds. Both mathematical thinking and CT share algorithmic thinking (Li et al., 2020). The surprise was Cora, who identified herself as a "visual learner" and used representations "to create a mental image or abstraction of the problem." Those powerful abstractions helped her with the complexity of the problem by reducing the number of people *N* and the step *k* (decomposition), pattern recognition (she imaged the deck of cards and discovered the rule of the game as the Australian Shuffle), and the algorithm design (the way the game played when she replaced the circle by a line helped with the design of the algorithm with lists). The analysis of these three different problem-solving approaches helps us gain insight into the role of the educational background and prior knowledge in shaping someone's CT skills. The participants

approached the problem abstraction differently - Ava and Bob had strong mathematical backgrounds and used mathematical models, while Cora used visual representations. Moreover, Ava and Bob employed proofs (mathematical induction) to check their solution that included a general formula for any N and k, while Cora had no way of checking the correctness of her solution outside the algorithm she designed. Her solution was viable only for concrete values of N and k.

Historically, computer science evolved as a branch of mathematics. Computer science and the development of CT skills seemed like a natural addition to STEM disciplines. Cora's problem-solving strategy, based on abstractions derived from visual representations, draws attention to the flexibility of CT across various educational backgrounds. As such, the findings of this study suggest that the development of CT skills may expand to non-traditional STEM disciplines like history, literature, and art, as recommended by Grover & Pea (2013). At the same time, the study raises the issue of the kinds of problems that can be solved by employing CT and what constitutes a solution for problems like the JP, in the absence of a mathematical model or proof.

This study had only three participants, only one problem from discrete mathematics, and analyzed only the participants' reflections on their problem-solving processes. Because of these limitations, we cannot make claims of generalization. More research studies should be conducted, with larger numbers of participants from varied educational backgrounds, using a variety of problems requiring the use of CT skills. Future research should focus on the design and implementation of interdisciplinary curricula that foster the development of CT skills.

Computational problem-solving practices in a Scratch-supported geometry and measurement teaching

Hümeyra Türkmen[1] and Hatice Akkoç[2]

[1]Cengiz Topel Middle School, Sancaktepe, Istanbul, Türkiye; hmeyratrkmen@gmail.com

[2]Marmara University, Atatürk Faculty of Education, Istanbul, Türkiye

This study investigates the development of a middle school student's computational problem-solving (CT-PS) practices in the Scratch-supported geometry and measurement problem-solving (PS) process. Synthesizing related literature, we identified a conceptual framework with seven computational problem-solving practices. This study adopted the teaching experiment method to examine the development of computational thinking (CT) skills. The data comes from the third teaching sequence and an interview with a selected student. We analysed video recordings of two lessons, final versions of the student's Scratch project, worksheets, field notes, and interview transcripts. The findings indicated a cyclical process between the CT-PS practices. We will discuss the findings in the context of CT and the co-devolution of CT and mathematical thinking.

Keywords: Computational thinking, computational problem-solving practices, geometry and measurement, scratch.

Introduction

Numerous scholars have investigated how computer programming can aid in teaching mathematics since the 1960s. According to Papert (1980), students can use programming to verify their ideas through coding and gain a better understanding of mathematics through debugging. Although there are many studies on CT, it is still unclear how teaching mathematics and CT benefit one another (Ye et al., 2023).

CT can help students develop a deeper understanding of mathematical concepts by requiring them to decompose complex problems into simpler parts and identify patterns and relationships (Brennan & Resnick, 2012; Wing, 2006). This process can enhance students' ability to reason abstractly and quantitatively, which are key components of mathematical thinking (CCSSO, 2010).

Conversely, mathematical thinking can support CT by providing a foundation for understanding algorithms, logic, and PS strategies. Mathematical topics such as algebra, geometry, and calculus provide contexts for developing CT skills, such as pattern recognition, abstraction, and algorithmic design (Grover & Pea, 2013).

Hickmott et al. (2018) emphasized that while the literature emphasizes the reciprocal relationship between CT and mathematical concepts, there is still a lack of research on how CT and mathematics might co-develop (Ye et al., 2023). Lockwood and De Chenne (2020) argue that while programming facilitates learning mathematics in specific contexts, it cannot be claimed to be superior to traditional paper-and-pencil methods across all mathematical domains. Consequently, further research is needed to explore the interactions between mathematical thinking and CT and investigate the advantages and challenges of integrating these approaches. This study examines the development of a middle school

student's CT-PS practices in the Scratch-supported geometry and measurement PS process. In the CT investigation approach of this study, geometry and measurement provide contexts for developing CT skills. Specifically, the study seeks to answer the following research question: How does a middle school student develop computational problem-solving (CT-PS) practices within the context of Scratch-supported geometry and measurement problem solving?

Conceptual Framework: Computational Problem-Solving (CT-PS) Practices

Weintrop et al. (2016) provided a taxonomy to assess computational practices in mathematical and scientific activities comprehensively. They grouped PS practices that are effective for working with computational tools under the term "computational problem-solving practices." Later, various researchers proposed different CT practices (Brennan & Resnick, 2012) and CT-PS practices (Kong, 2019; Ng & Cui, 2021).

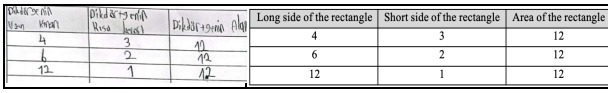
To provide a holistic analysis of the CT-PS process, the conceptual framework of the present study includes the following seven practices considering the related literature as reported above: (1) *problem decomposition*, the process of breaking down a complex problem into smaller, more manageable components to simplify it (Waller, 2016), (2) *being incremental and iterative*, an approach to incrementally improve and iteratively enhance solutions through continuous feedback and adjustments (Brennan & Resnick, 2012), (3) *modelling*, creating abstract representations or simulations of real-world problems to analyse, understand, and develop solutions more systematically (Greefrath et al. 2018), (4) *algorithmic thinking*, the process of designing step-by-step procedures or instructions to solve problems efficiently and systematically (Wing, 2006), (5) *abstraction and modularization*, breaking down complex systems into simpler, manageable parts and focusing on essential aspects while concealing unnecessary details (Brennan & Resnick, 2012), (6) *reuse and remixing*, taking existing ideas or components and adapting them to create new solutions or enhancements (Brennan & Resnick, 2012), and (7) *testing and debugging*, systematically examining and fixing problems or errors in a system or code to make sure it works as intended (Brennan & Resnick, 2012). These practices are critical for understanding the cognitive strategies students develop at different stages of the PS process and for improving the efficiency of the process.

Methods

This study adopted the teaching experiment methodology, one of the qualitative research methods (Steffe & Thompson, 2000). The teaching experiment aimed to examine the development of CT skills. It focused on developing CT concepts, CT-PS practices, and CT perspectives. This study is limited to CT-PS practices. The mathematical context is geometry and measurement. The teaching experiment consisted of three teaching sequences. It was implemented in a class of 30 students in the 5th grade of a middle public school in Istanbul, Türkiye, during the academic year 2021-2022. The first author was the mathematics teacher of the class, and the study was conducted in the school's computer laboratory. In each teaching sequence, students sat in pairs and worked on worksheets containing geometry and measurement problems. After solving the problems and writing the algorithms for their solutions, the students coded the algorithm they had written in the Scratch environment.

The study's data consisted of video recordings of two lessons, final versions of the student's Scratch project, worksheets, field notes, and transcripts of the interviews with a selected student. The interview questions with this student were determined by analysing his work in the classroom and observation data during the teaching sequence. The data of each teaching sequence were analysed, and the subsequent teaching sequence was designed. This study focused on Burak's (pseudonym) data from the third teaching sequence (which consists of an 80-minute lesson) to examine the development process of his CT-PS practices in depth.

In the third teaching sequence, students worked on the following problem:



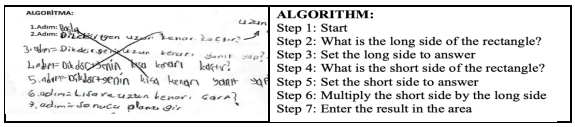
A carpet factory wants to produce a rectangular carpet with an area of 12 square meters. Calculate how many types of rectangular carpets can be produced with an area of 12 square meters. Create a program that calculates the area of a rectangle.

The problem did not explicitly state that the side lengths of the carpet should be integers, which may have influenced how students approached the problem. This limitation was addressed through teacher guidance during the teaching sequence. Grounded in pedagogical principles and supported by existing literature, the teacher led students through a structured process that encouraged them to use models to solve the problem, derive the intended algorithm, and implement it within the Scratch environment. During the data analysis process, the researchers analysed lessons' video recordings, interview transcripts, the student's Scratch project, student worksheets, and field notes of the selected teaching sequence. They evaluated the data within the scope of the CT-PS practices that constitute the conceptual framework. Since the teacher was a participant observer, the second author also codded the data, and possible disagreements were resolved to increase the study's trustworthiness.

The collected data were analysed using thematic analysis (Braun & Clarke, 2006) to examine the student's CT-PS practices. Initially, the researchers open-coded the data from student interviews, Scratch projects, and observation notes. These codes were then grouped into themes based on the CT-PS practices outlined in the conceptual framework (e.g., Brennan & Resnick, 2012; Kong, 2019). For example, instances where the student revised their algorithm after testing it using Scratch were categorized as "incremental and iterative." The first author conducted the analysis manually to ensure a detailed understanding of the data. The second author reviewed the emerging themes and their alignment with the framework for accuracy and consistency, enhancing the reliability of the findings.

Findings

This section first presents the findings on working on the worksheets before using Scratch. Afterward, the findings on programming in the Scratch environment will be presented within the framework of the CT-PS practices, considering the interactions between the practices.

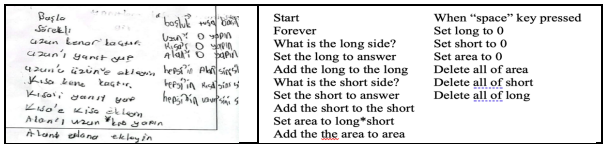


Long side of the rectangle	Short side of the rectangle	Area of the rectangle
4	3	12
6	2	12
12	1	12

Figure 1: Table prepared by Burak to solve the problem

Concerning the process of working on the worksheets, the first finding is related to Burak's difficulty with formulating the problem. During the interview, the student stated that he could not understand

the expression ‘types of rectangles’ in the problem. After the teacher explained it on the board, he realized that he had to create different rectangles and reached the solution by creating rectangle with his friend. This finding showed that the student initially had difficulty understanding the problem and overcame this difficulty with the support of the teacher and his friend.



Another finding is that the student solved the problem by drawing rectangles. During the interview, the student stated that he drew rectangles and found their area as 12 square meters, but he did not use the table (See Figure 1) during the solution. Immediately afterward he stated that the table helped him write the algorithm and that he added whatever he did in the table to the algorithm (See Figure 2). The student expressed the variables as the short side of the rectangle, the long side of the rectangle, and the area of the rectangle in the table on the worksheet and recorded the rectangles he found in the bottom rows (Figure 1).

ALGORITHM:
Step 1: Start
Step 2: What is the long side of the rectangle?
Step 3: Set the long side to answer
Step 4: What is the short side of the rectangle?
Step 5: Set the short side to answer
Step 6: Multiply the short side by the long side
Step 7: Enter the result in the area

Figure 2: Algorithm written by the student on paper before working with Scratch

Drawing different rectangles helped the student solve and decompose the problem. In addition, recording the sides and area of the rectangles found by drawing as dependent and independent variables in the table (See Figure 1) contributed to the problem's decomposition. At the same time, as the student said, this process helped him write the algorithm.

Start	When “space” key pressed
Forever	Set long to 0
What is the long side?	Set short to 0
Set the long to answer	Set area to 0
Add the long to the long	Delete all of area
What is the short side?	Delete all of short
Set the short to answer	Delete all of long
Add the short to the short	
Set area to long*short	
Add the the area to area	

Figure 3: The algorithm written by Burak after completing his Scratch project

The teacher expected the student to solve the problem, decompose it, identify the variables in the problem, and write the process step by step in the form of an algorithm by identifying the relationships between these variables. However, the algorithm he wrote was incomplete (Figure 2). Although the teacher asked the student to write the algorithm in more detail, the student went directly to Scratch without any editing and coded on Scratch based on the incomplete algorithm he wrote (See Figure 2). The video recording shows that the student rewrote the algorithm (See Figure 3) by looking at the code file he created after completing his work in Scratch (Click here to see the Scratch Project).

The student put a cross on the algorithm he first wrote (Figure 2) on the worksheet and wrote the new algorithm he wrote by looking at Scratch (Figure 3). In the interview, the student expressed why he had difficulty in writing algorithms as follows:

Teacher: Why is it difficult to write an algorithm?
Burak: […] What I do in Scratch is easy, but the algorithm is complex and boring.
Teacher: Do you prefer to write algorithms before or after Scratch?
Burak: After.
Teacher: Why?
Burak: In Scratch, we can experiment as we want. If the coding is correct, I write the algorithm from there. If my coding is correct, my algorithm is correct.

Although the excerpt above shows that the student found writing algorithms difficult and boring, he stated that he used the algorithm to explain how he organized the scripts:

Teacher: How did you arrange the scripts?
Burak: […] Even if the algorithm I wrote is incomplete or incorrect, it shows how it should be.
Teacher: So, you still got help from the algorithm. Is that what you're saying?
Burak: Yes, I get help from the algorithm, even if it is incomplete or incorrect

Although the student struggled to write an algorithm and avoided it, he completed his work using Scratch. This shows that he preferred producing solutions by testing with Scratch instead of writing the algorithm directly first.

While working on the problem, the student effectively used his prior knowledge from the previous teaching sequences and the information technologies course, as he reported. He also applied the commands such as 'condition, greater than, less than,' which are the learning objectives of the teaching sequence. After completing his Scratch project, he improved it by adding new commands, such as voice and sprite changes in the Scratch environment. During the interview, he said he made these revisions by testing the project. All these processes indicate *being incremental and iterative.*

Figure 4: Scripts to reset variables and lists in the Scratch project created by Burak

Burak stated that he organized the scripts according to the algorithm he wrote. He assigned all the scripts that reset variables and lists to the "when space key pressed" block (Figure 4). By identifying the variables in the problem, he reached a general expression to calculate the area of a rectangle with the models he constructed. Also, in this teaching sequence, he learned the condition command and emphasized that the program should give an error if the long side length of the rectangle is not greater than the short side length. While creating the program, he used the "forever" command to ensure that the sprite in Scratch asks the same questions continuously. He stated that the choice of sprite does not affect the results of the process and that no matter which sprite he uses, it will perform the same operations. Regarding the choice of sprite, he commented, "Even if I put an airplane, it will do the same things." These processes show the development of *abstracting and modularizing*.

Burak said he learned new code blocks such as 'conditions, greater than, and less than' and successfully integrated these codes. In addition, he used the module ("when space key pressed" block), as shown in Figure 4, in all his works similarly. These observations reveal the student's development of *reusing and remixing*.

Burak explained that he preferred to work on Scratch instead of writing algorithms and that he explained this preference by the fact that Scratch offers the opportunity to test how the sequences work by constantly trying them out and editing them when they do not work. In this process, the student tested the scripts. During the interview, Burak mentioned that the code list worked smoothly and that there was no error. However, later in the interview, the code for the sprite change did not

work, and he realized the error and explained how to fix it. He described the errors he made during the lesson and stated that he checked the codes in the part of the program where the error occurred instead of reviewing all the code blocks during the *debugging* process as follows:

Teacher: How do you solve the problem? How do you know where is the error? For example, there was an error with the sprite. Did you look at the sprite or all the codes?
Burak: No, I looked at the sprite. There were no errors in others; I did not bother with them.

From this dialogue and the student's willingness to experiment with Scratch before completing the algorithm or adding new things, we can infer that the student has improved in the testing and debugging process.

Discussion and Conclusion

This study aimed to investigate the development of CT-PS practices of a middle school student in Scratch-supported geometry and measurement PS environment. The findings reveal a cyclical and interconnected development of various CT-PS practices, which provide insights into the integration of CT and mathematical thinking.

The student's preference to test the incomplete algorithm on Scratch and try the new commands on Scratch after completing the project shows the importance of the *testing and debugging*. Since this process helped the student to revise the algorithm written on paper, this finding also points to the development of *algorithmic thinking*. It is also related to *being incremental and iterative* because he switched back and forth between the algorithm on paper and the scripts written in the Scratch environment. Moreover, the student's approach of examining only the code that does not work in the program instead of reviewing all code blocks (Brennan & Resnick, 2012) reflects the development of *testing and debugging*. These findings indicate a cyclical process among the CT-PS practices.

Some computer scientists direct argue that coding might enhance one's understanding of the problem without algorithms beforehand (Knuth, 1997), while others stress the pedagogical importance of writing algorithms (Wing, 2006). In this context, the use of an incomplete algorithm highlights the importance of algorithms.

The student's difficulty understanding the expression 'types of rectangles' and that the student overcame this difficulty with the teacher's support and progressed more easily in problem decomposition reveal that the student had difficulty in the problem formulation phase. Considering this finding, we propose adding *a problem formulation* practice to the CT-PS practices framework, as suggested by Kong (2019).

Considering the findings regarding solving by drawing a model, noticing the variables, making generalizations with the help of a table, and updating the algorithm, we claim that problem-solving, problem decomposition, and modelling stages are preliminary stages for writing an algorithm.

Although the teaching experiment aimed to develop CT rather than mathematical thinking or mathematical learning outcomes, many CT-related concepts, such as the PS process, models used, variables, relationship between variables, and conditional statements, contributed to the development of mathematical concepts and processes. The first implication of how CT supports mathematical thinking is about early algebra. In this regard, the student determined the dependent and independent

variables without knowing the concept of the variable and reached the general expression by *modelling*. This finding indicates that early algebra (Carraher et al., 2008) can develop during CT development. Indeed, Bråting and Kilhamn (2021) recommend further research to examine the relationship between CT and algebraic thinking, particularly regarding the distinction between the concept of a variable in CT and in mathematics.

The second implication of how CT supports mathematical thinking is the relationship between mathematical and *algorithmic thinking*. For example, the student's successful completion of the desired program on Scratch without writing the complete algorithm on paper, his generalizations by drawing rectangles and using tables, and his identification of dependent and independent variables showed that CT deepens mathematical concepts with the development of *algorithmic thinking* (Brennan & Resnick, 2012; Wing, 2006).

Although Bråting and Kilhamn (2021) argue that misconceptions emerge during the development of mathematical concepts in the Scratch environment, studies are showing that it is essential to apply mathematical knowledge to create tasks aimed at developing CT (Grizioti & Kynigos, 2021). In this context, as a future study, we suggest developing mathematical concepts and possible misconceptions while examining the co-development of CT and mathematics. However, it should be noted that this study focuses on an in-depth analysis of the data from a single student, which limits the generalizability of the findings. While this approach provides valuable insights into the development of CT-PS practices, future studies should include larger and more diverse samples to validate and extend these findings.

Acknowledgment

This study is part of the MSc thesis of the first author entitled "Examining the Development of Computational Thinking in the Process of Scratch Assisted Geometry and Measurement Problem Solving of Secondary School 5th Grade Students," submitted to the Institute of Education at Marmara University, Istanbul, Türkiye.

Investigating students' testing and evaluating as part of computational thinking with the TEC model

Till von Monkiewitsch[1] and Carina Büscher[1]

[1]University of Cologne, Germany; till.monkiewitsch@uni-koeln.de

Computational Thinking (CT) allows learners to understand the world around them, which can be considered necessary for general education. Therefore, CT is regarded as an increasingly important learning content. Although extensive work has been done to craft definitions of CT, there is lack of a consensus and little regard for learners' actual processes. This study focuses on Testing and Evaluating (TE) as one CT activity. It presents a model of five Testing and Evaluating Components (TEC) as a framework for capturing learners' TE. This TEC model enables a more differentiated view on learners' TE by identifying and illustrating their differences and similarities. While every pair of learners in this study performed TE, they did so with varying levels of success. Explicating one's observations and comparisons followed by their use to justify the consequences was identified as important predictor of success. Implications for teaching as well as further research are discussed.

Keywords: Computational thinking, evaluative thinking, geometry, design research.

Theoretical Background

Computational Thinking (CT) is mainly traced back to the ideas of Papert (1980), whose school of thought can be described as 'thinking like a computer'. It is often referenced as a vital 21st century skill and should therefore be included in general education. Shute et al. (2017) equate the possession of CT in today's world with the ability to write in the Middle Ages. This assertion draws from the aspect of CT as a form of communication with computers, following Wing's (2017) definition of CT as processes involved in formulation of problems and their solutions such that a (human) computer can carry them out. Following this, CT may be necessary for individuals to participate in an ever more digitalized society. Based on Selby and Woollard (2013), Büscher (2025) specifies the following CT activities to focus on learner's approaches when engaging with mathematical content:

- *Reusing and Modifying*: Reuse and modify existing code as needed
- *Decomposing*: Decompose a problem into subproblems
- *Testing and evaluating*: Testing and targeted adaptation
- *Algorithmitizing*: Plan a step-by-step approach
- *Abstracting*: See general properties in special cases
- *Generalizing*: Inferring a common aspect from different special cases (p. 368)

Testing and Evaluating (TE) as a CT activity enables learners to gather fruitful learning strategies (Papert, 1980) and (employ these to) understand the world around them. *Debugging* could be considered a subset of TE, as it usually only regards the identification and fixing of errors (Shute et al., 2017), not overall evaluative processes. The identification and correction of *programming* errors is considered (software-) debugging in computer science (CS), where Böttcher et al. (2016) see this as a complex and difficult to learn skill, proposing a cyclic debugging process. This process cyclically narrows down where the error occurs and lastly fixes it. Building on this, Michaeli and Romeike

(2019) show a promising approach how software debugging might be taught with the help of teaching a systematic approach; they also note that there are also step–by–step procedures of debugging which were developed for LOGO, Papert's (1980) educational driven programming language. As TE is a broader activity than software debugging, abstracting concepts/ideas from CS (education) research into the latter might aid in closing the research gap for TE, for example by providing starting points.

Despite research efforts into definitions of CT (Grover & Pea, 2013; Selby & Woollard, 2013; Shute et al., 2017; Wing, 2017), not much is known about learners' cognitive processes in CT, even though CT is usually defined as a cognitive or thought/mental process (Selby & Woollard, 2013; Wing, 2017). Additionally, Broley et al. (2017) on CERME10 concluded the necessity to closer examine the experiences of students. Büscher (2024, 2025) presents that students exhibit different manifestations of CT and its activities. She preliminarily characterizes unsystematic, systematic and strategic TE as different approaches (Büscher, 2024). While this enables characterization of pupils' overall approach, albeit presently constrained to geometric programming, the question remains how TE works as a (cognitive) process and differs among learners. Thus, the research question (RQ) is:

RQ: How are TE processes composed and how do they differ between learners?

Methods

This research is part of a larger design research project aiming to understand how CT and mathematics (lessons) can mutually promote learning. By nature, it consists of cyclic phases of design experiments, which inform local theories about the nature of the learning object as well as typical learning progressions and obstacles of learners (Prediger et al., 2015). This study presents the initial local theories regarding TE, stemming from our first cycle. In this design experiment cycle, 26 learners (aged 13–15) were videotaped solving geometric tasks as pairs in a laboratory setting using Turtlecoder (cf. Figure 1), resulting in 638 minutes of recorded activities. Firstly, in a broad analysis, scenes were identified where tests appeared to be conducted by executing the program. These passages were transcribed and qualitatively analysed in a category-forming, inductive process (Kuckartz, 2019), producing five inductive components of TE processes. These categories were subsequently employed for a turn-by-turn analysis coding statements and actions (e.g. implementing an instruction), as recorded graphically in a timeline (Figures 3 & 5).

At first, the students were introduced to the program by drawing a square with a side length of 200 units. The next task involved drawing a larger square of 400 units, which added complexity due to the turtle leaving the screen unless the starting position was adjusted. Following this, they were tasked to draw a rectangle and then a parallelogram with side lengths of 100 and 200 units. Now, pupils were challenged to draw a trapezoid with parallel sides of 100 and 200 units. The final tasks included drawing the House of Saint Nicholas (HSN, Figure 1), a drawing puzzle, and a five-pointed star with 100 units long sides. It should be noted that not all students started the star. In this context, 'drawing' could be described as 'designing an algorithm and implementing its code, which lets the turtle draw'.

Derived from our qualitative analysis, we propose a model of components for the TE process. The next section presents this finding as a theoretical framework. Subsequent empirical insights show the frameworks ability to portray differences in learners' processes and propose potential explanations.

Framework: Testing and Evaluating Components (TEC) Model

This section presents our empirically based model of TE as a key finding of this research. It is segmented into five components which are outlined below. Later empirical insights will demonstrate that these components may overlap, are neither strictly separable nor follow a strictly linear order. We aim to investigate further whether and how a coherent structural model can be devised.

A *cause for the test* is implicitly linked with the goal learners express when testing and evaluating. The reason is rarely made explicit, though the analysis indicates that it often can be inferred from the communication of the partners before they execute the test. In cases where this was not possible, it could sometimes be inferred by the actions the pupils took after executing the test. Such inferences are naturally circumstantial and open to discussion, hence no claim to absolute correctness is made.

The *test* is simply comprised of enacting a solution plan, which in this study can typically be considered as executing the code in the programming environment. However, another form of testing seems to exist, characterized by the fact that it predicts the result of a code without ever executing it. While not further discussed in this paper, this apparent mental simulation of the code shows promising points of contact for further studies examining non-programming tasks engaging with CT-activities.

In the third component one *observes the result or execution* of the solution-plan, in our case it is the step-by-step execution of the code within the learning environment. For example, this is observable, when learners narrate the path their turtle draws or explicitly describe the drawn figure.

It is linked with*, the comparison with one's expectations*, where pupils might verbalize differences in result and expectation or specification. (i.e. sketch from task). Comparing expectations presupposes their existence, which is not always given. Learners (e.g.) describe how the turtle drew 'wrongly'.

As a last component, learners *draw conclusions*, which might stem from their observations and/or comparisons, for example the need to change the parameter of an instruction. It can be seen that in such cases learners often had the next cause for a test to check the new value for the parameter, in this context a length or an angle of rotation. Such cases are called *retests* in this study.

Empirical Insights

The study provides insights into learners' processes of programming geometric shapes in the context of TE as part of CT. For instance, TE proved useful for identifying parameters whose values were not immediately apparent, particularly the lengths of the non-parallel sides of the trapezoids, the 'roof' of HSN, the angle(s) of rotation for these sides, and the lines of the star. We will now portray two compositions through the TEC model that reflect different observed general cases. The first composition (Finn & Felix) is notably structured, possibly cyclic, and demonstrates success as both participants effectively argue their consequences based on explicit observations and comparisons. In contrast, Adam and Anika's engagement with different subproblems often lacks clear argumentation for consequences or elaboration of observations/comparisons, resulting in teacher intervention.

The case of Finn and Felix –justifying consequences with observations and comparisons:

Finn and Felix have already drawn a part of their HSN (Turns 476–704) as can be seen in Figure 2a. Now they are discussing how to approach drawing the second inner diagonal.

711	Finn:	A hundred or so, no clue.
712	Felix:	Hundred, okay, how do we want to do this? [adds instruction leftTurn(100)]
713	Felix:	And then I also do it directly, how much did we have with that one again? [points to the first inner diagonal]
714	Finn:	Ehm, Turtle, so.
715	Felix:	No, I mean the length.
716	Finn:	I think the length was also a hundred.
717	Felix:	Nah, I took hundred forty, because this here triggered me [points to the left upper corner, where the three lines meet].
718	Finn:	Oh, that's right. [Felix adds instruction forward(140); executes program, cf. Figure 2b]

Starting in Turn 711 Finn suggests that they turn their turtle 100°. Felix then asks how they want to do it and implements a 100° turn counterclockwise (Turn 712). Following this, they also add an instruction to move the turtle 140 spaces (Turns 714–718). Felix asking his partner how they want to do it (Turn 712) shows that they intend to evaluate the merit of their approach as their *cause for a test*. If he was certain about the correctness of their idea and its implementation, he wouldn't ask how to do it. This heavily implies that the cause for a test can be temporally prior, with the test not necessarily occurring immediately afterwards. They formulate their plan and execute their code in Turn 718, which is their explicit *test*, the result of which is Figure 2b. They draw their conclusions from this in the subsequent turns:

719	Felix:	So, we have to go diagonal, eh?
720	Finn:	Mhm.
721	Finn:	Ah.
722	Felix:	Wrong direction.
723	Finn:	Then turtle, turn right.
724	Felix:	Yes, only possible.
725	Felix:	Hundred, eh? [changes the last rotation instruction to rightTurn(100)]
726	Finn:	Mhm.
727	Felix:	But from the rotation, it didn't look too bad.
728	Felix:	We try it out. [executes program, cf. Figure 2c]

Finn and Felix verbalize their *observations* in Turns 719 to 722, where Felix' assertion "wrong direction" (Turn 722) is also considered to be a *comparison with expectations*, assuming he

considered their solution to be somewhat correct. Subsequently, they *draw conclusions*, when they change/modify the rotation instruction to turn right instead of left (Turns 723–725). Now a new TE process is in progress, as evident by the (re-)test in Turn 728 (Figure 2c for result). While these two TE processes are undoubtedly connected, they are distinct processes. The evaluation of the new solution is considered a new and distinct reason for testing, which is supported by Felix' assertion to "[…] try it out" (Turn 728). Further, the two learners go through two more TE processes with retests:

729	Felix:	Okay, a bit less, or do we have to increase, nope less.
730	Felix:	Okay .. relaxed.
731	Felix:	Right, eighty-five or so, if not we go back to ninety. [changes last rotation instruction to rightTurn(85); executes program, cf. Figure 2d]
732	Felix:	Ninety like this, or #
733	Finn:	# yes, yes, yes.
734	Felix:	Turtle, we just have to once again. [changes last rotation instruction to rightTurn(90); executes program, cf. Figure 2e]

Four tests are conducted with results seen in Figures 2b–e while Figure 2f shows the diagonal unobscured. This approach is deemed systematic TE following the categories of Büscher (2024).

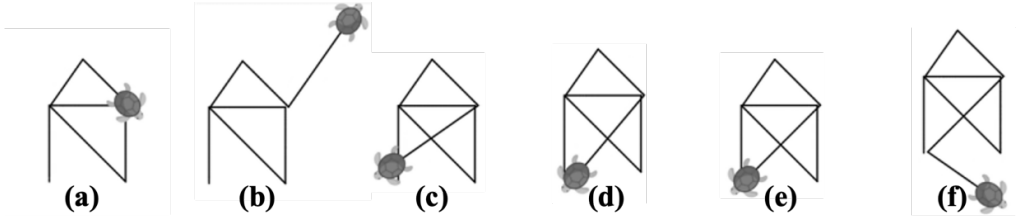

Figure 2: Finn and Felix draw the second diagonal of their HSN (© Helliwood media & education)

Figure 3 illustrates the aforementioned timeline of Finn and Felix' TE (process). It is created using the TEC model to assign explicitly observable statements and actions of one learner to one or more components. If neither action nor statement is observably present, or if they cannot be (clearly) linked to a component, the corresponding space remains empty. One second is used as the smallest measure of time. Here, Finn is represented in blue and Felix in green. Orange denotes overlap between the two, due to simultaneous actions/statements. For example, both use the same execution of the program as a test, lasting 15 seconds in this instance. This timeline illustrates the overlapping of components, for example around 50:36, when *Cause for Test* and *Test* overlap. The inability to sharply separate these subcomponents, partly due to scope for interpretation, is again evident in Felix exclaiming "Wrong Direction" (Turn 722, 50:24–50:25).

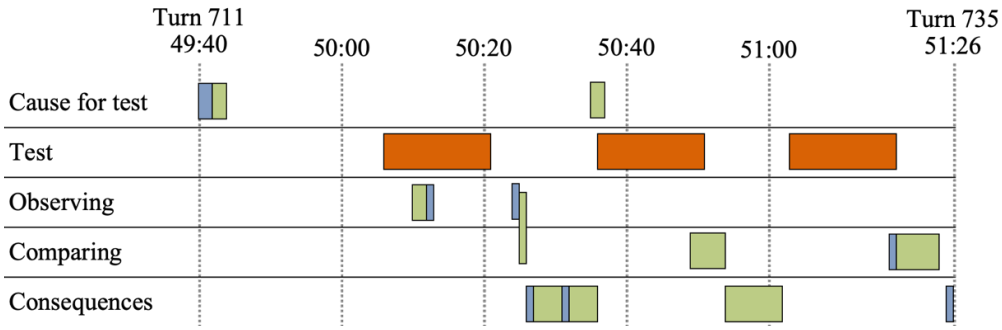

Figure 3: Timeline of Finn (blue) and Felix' (green) TEC (Turns 711–735)

This example demonstrates that the components of TE can overlap, that they cannot always be sharply separated, and that the cause of the test is open to interpretation.

The case of Adam and Anika – no justification of consequences with observations or comparisons

Adam and Anika are also working on their HSN, more precisely they try to construct their first inner diagonal and baseline. Their timeline (Figure 5) visualizes Turns 233 to 247 and was constructed as elaborated for Finn and Felix. Due to space constraints, we limit our explanations to notable sections.

231	Adam:	Yes. [Anika enters instruction rightTurn(45)]
232	Teacher:	Otherwise, I also have a tip for you.
233	Adam:	Yes okay, we can give it a try. [Anika enters instruction forward(100) and executes program, cf. Figure 4a]
234	Anika:	Ah well. [changes to leftTurn(45); executes program, cf. Figure 4b]
235	Adam:	But the line [points to slope] is too short, we have to make something longer there.
236	Anika:	Like this? [changes drawing instruction for the slope to forward(150)]
237	Adam:	Yea, let us try it. [executes program, cf. Figure 4c]

Both refer to different subproblems: While Anika retests her adjusted angle of rotation, Adam considers the slope (Turn 235) from the initial test (Turn 233) to which her retest (Turn 234) does not add new information. This raises the question which test Adam refers to. As he verbalizes a test cause in Turn 233, we consider the first test as his initial point of comparison (see Figure 5, 29:54–30:35).

238	Adam:	And there they are again, make it one hundred and fifty and then #
239	Anika:	# We have to here like this, here like this. [Anika deletes the parameter of leftTurn(45)]

Between 30:19 and 31:16 Figure 5 depicts how both jump between components of the TEC model. They are no longer in sync when they talk over each another and Anika programs while Adam speaks (cf. Turns 238–239, 30:48–30:50). It is also evident that Anika does not wait for her partner's verbal approval before executing the test, as Adams cause for test is observed a second after Anika starts it.

246	Adam:	Yes that is, that could be good, yes one hundred twenty-five is actually quite good .. then ninety, then must one hundred thirty-five go there. [Anika changes rotation to leftTurn(135) and executes the program, cf. Figure 4e]
247	Anika:	Nope, doesn't fit. [changes forward(125) into forward(1130); executes program, result not shown]

Again, Anika implements *consequences*, while Adam verbalizes his *comparison* (Turn 246, 31:35–31:37) and even simultaneously draws her comparison and consequences (Turn 247, 31:46–31:48).

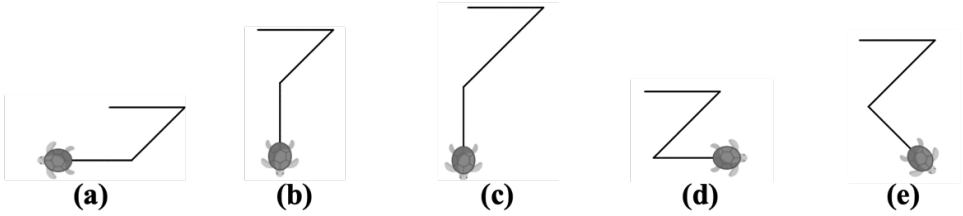

Figure 4: Adam and Anika's first attempt at the HSN (© Helliwood media & education)

This example underscores how TEC can overlap and resist clear separation. It also exemplifies how the TEC model facilitates a nuanced examination of individual processes, even with student pairs.

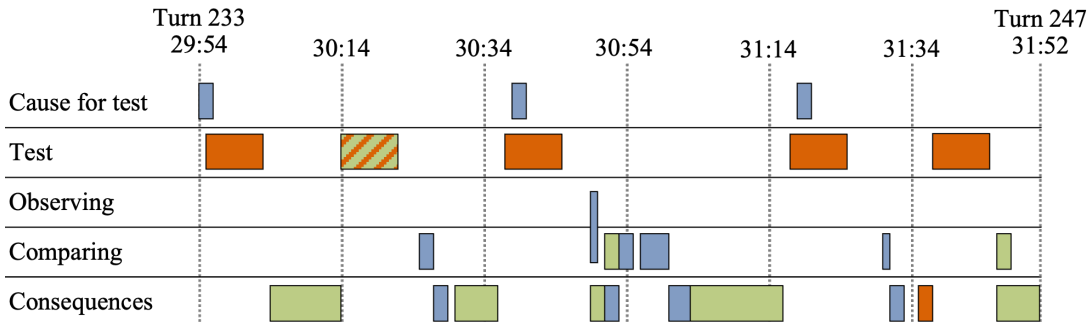

Figure 5: Timeline of Adam (blue) and Anika's (green) TEC (Turns 233–247)

Contrasting the cases

Finn and Felix's TE process(es) lead to them solving their (sub)problem at hand and later successfully constructing a HSN. Adam and Anika did not achieve their desired outcome and later started over with the teacher's help. Using the TEC model makes a major difference tangible: Finn and Felix explicate their observations/comparisons more precisely and use them to argue their consequences. Conversely, Adam and Anika often fail to justify their consequences, also worsening communication.

Various factors, such as communication, influence the success of TE processes. Tasks should thus encourage learners to articulate their observations and comparisons. By providing a structure for arguing consequences, this approach aims to enhance their processes to achieve success similar to Finn and Felix's. Teachers and researchers benefit by being able to better diagnose their pupils' processes. Successful TE processes, as exemplified by Finn and Felix, often appear as systematically structured sequences of TEC. It is unclear how this may contribute to further defining TE or may aid in constructing a coherent structural model of the components – questions we seek to explore.

Conclusion

This study invented, based on empirical observations of learners programming in a geometric context, a five-component model for describing the learners' TE. The TEC model facilitates the analysis and visualization of pupils' TE processes. When applied it demonstrates that its components can overlap, are not always distinctly separated, may appear at different times, and do not follow a strictly linear progression. Given the current small sample size, further research should assess if these components are transferable to other domains and whether a coherent structural model of TEC can be formulated.

Still, the first qualitative insights illustrate that the approach could allow for identifying potential predictors of learners' success. Explicating observations and comparisons, as discussed, seems to be helpful for justifying derived consequences. Therefore, tasks should offer learners opportunities to further these skills. Learning TE on a meta-level might also enable students to acquire learning strategies (Papert, 1980). CT coding interventions can enhance children's executive functions (Montuori et al., 2024). Our study offers initial insights into pupils' TE processes, which could explain these benefits. Teaching software debugging with a systematic process is beneficial (Michaeli & Romeike, 2019). Adapting this CS education research to TE and the TEC model provide a foundation for further research into teaching/learning TE. Thereby, the role of immediate feedback from the learning environment, which allows concentration on observing, merits further investigation.

Acknowledgment

We thank Ms. Lena Kessel, whose work on her master thesis supplied the data investigated here.

Analysing post-intervention mistakes in combinatorial problem solving: A study on Czech secondary students

David Zenkl[1] and Naďa Vondrová[1]

[1]Charles University, Faculty of Education, Prague, Czech Republic; david-zenkl@seznam.cz

This study examines the mistakes made by Czech secondary students after participating in a constructivism-based intervention. The intervention aimed to reduce the students' reliance on memorised formulas and promote diverse problem-solving strategies. The study concerns four classes with 88 students who underwent an intervention within design-based research. Following the intervention, students completed a test with combinatorial problems and their solutions were analysed to identify mistakes. The results revealed that while students' overall success rates were relatively low, the intervention resulted in less frequent formula-related mistakes but highlighted persistent issues with systematic listing and partitioning. Notably, a new type of mistake emerged, involving mistakes in counting natural numbers in an interval. The findings suggest that additional focus is needed on systematic problem-solving techniques and unfamiliar problem types to further enhance students' combinatorial reasoning in the intervention.

Keywords: Combinatorics, classification of mistakes, combinatorial model and operation.

Introduction

Combinatorics belongs among school topics which present difficulties to many students due to its complexity and teaching overlying on presenting formulas as the primary solving strategy. Research on combinatorics uncovered types of mistakes students make when solving combinatorial problems, with the ones related to (mis)use of combinatorial formulas being prominent (Fischbein & Gazit, 1988; Maschiach Eizenberg & Zaslavsky, 2004; Wasserman & Galarza, 2019). On the other hand, researchers focused on students' understanding in combinatorics and how to develop it (English, 2005; Maher et al., 2010; Uptegrove, 2015).

In the Czech Republic, students often lack understanding of combinatorial problems and rely too much on formulas (Hejný & Jirotková, 2012). Textbooks do not aid teachers who want alternative methods. The first author developed an intervention based on constructivism, emphasising active learning and various solving strategies (Zenkl & Vondrová, 2023), and implemented it through design-based research. The study examines students' success and errors in combinatorial problems post-intervention.

Theoretical background

This section starts with an insight into the nature of combinatorial problems and students' mistakes when solving them, as both are necessary to design effective teaching strategies. Literature on the teaching of combinatorics follows.

The literature posits that combinatorial problems can be classified according to four aspects (Batanero et al., 1997; Fischbein & Gazit, 1988). The main classification is based on the *combinatorial model* of a) selection (selecting elements from the set), b) distribution (assigning elements to compartments)

and c) partition (decomposing a set into subsets) (Batanero et al., 1997). Problems can involve permutation, arrangement or combination *operations*, with(out) repetition. Problems also differ in *context* (numbers, letters, colours, people, etc.; Fischbein & Gazit, 1988) and in the total *number of configurations* (small, medium and large; Lamanna et al., 2022). Considering students' perspective, combination operations problems fall into two categories: unordered selection of distinguishable objects (I) and ordered sequence of indistinguishable objects (II), with students using a combination approach more frequently and correctly in the former (Lockwood et al., 2018; Wasserman & Galarza, 2019).

Piaget and Inhelder (1951/1975) identified students' mistakes in solving combinatorial problems by analysing systematic and non-systematic approaches from the viewpoint of developmental psychology. Non-systematic methods can lead to failure as they do not guarantee counting all valid options once (English, 2005).

Our study capitalises on the seminal work of Fischbein and Gazit (1988), who identified four types of mistakes, e.g., the use of a wrong combinatorial formula than required or a mere multiplication of the numbers from the assignment. Batanero et al. (1997) extended this list into 14 types of mistakes (Table 1). For example, they distinguished two types of wrong-identifying combinatorial operations: M2 and M3.

Table 1: Errors described by Batanero et al. (1997); the authors' code is in brackets

Code	Mistake	Code	Mistake
M1 (statement)	misinterpretation of the problem statement	M8 (operations)	incorrect arithmetic operations
M2 (order)	confusing if order matters	M9 (formula)	using an incorrect formula of a combinatorial operation that has been correctly identified
M3 (repetition)	confusing if repetition is possible	M10 (parameters)	misunderstanding the meaning of values of parameters in the formula
M4 (objects)	wrong distinguishing of identical/different objects	M11 (treediag)	faulty interpretation of the tree diagram
M5 (exclusion)	excluding some elements to form the configurations	M12 (property)	failing to apply the property of the binomial coefficient
M6 (listing)	non-systematic listing	M13 (cells)	wrong distinguishing of identical/different cells
M7 (intanswer)	mistaken (intuitive) solution without justifying	M14 (partition)	some partitions or types of partitions were forgotten

Batanero et al. (1997) compared the mistakes of students who were taught combinatorics with those of students who were not. Most students without instruction could not list the options systematically (M6), but after the instruction, the main problem lay in deciding if elements could be repeated or if the order mattered (M2 and M3) and there was hardly any M6. Moreover, the students made new types of mistakes, namely, using an incorrect formula of a combinatorial operation that has been correctly identified (M9) or a faulty interpretation of the tree diagram (M11).

Batanero et al. (1997) and others (Hejný & Jirotková, 2012; Maschiach Eizenberg & Zaslavsky, 2004) thus point to teaching overemphasising formulae as one source of students' difficulties. Some propose teaching combinatorics without formulae (Godino et al., 2005) and providing students with opportunities to engage with combinatorial problems, which can lead, by their nature, to rich and challenging mathematical thinking (Lockwood et al., 2020; Uptegrove, 2015). Combinatorial

problems are accessible for secondary students as they "are able to understand what a question is asking, they can begin a solution path by symbolizing outcomes, and, in the process of symbolizing these outcomes, they can engage with and discuss key combinatorial ideas" (Lockwood et al., 2020, p. 5). Research has identified recognising isomorphic problems as a powerful instructional tool (English, 2005; Maher et al., 2010; Wasserman & Galarza; 2019). Building meaning first and then developing the symbolic vocabulary (e.g., factorial, binomial coefficient) supports deep understanding (Uptegrove, 2015). Moreover, instruction based on appropriately selected problems with little teacher intervention and maximum attention to students' reasoning leads to high-level mathematical skills (Maher et al., 2010).

Context and research aim

To enhance Czech students' understanding of combinatorics and prevent their overreliance on formulas, the first author designed a constructivism-based intervention implemented by trained teachers within design-based research. The intervention is grounded in students solving isomorphic combinatorial problems (Maher et al., 2010; Maschiach Eizenberg & Zaslavsky, 2004; Uptegrove, 2015). They are encouraged to develop their own solving strategies and compare them. Among others, the systematic listing strategy is encouraged as even partial listing helps students identify patterns and structure within partial lists of outcomes and reach the correct solution (Lockwood & Gibson, 2016). Teachers allow students to use different approaches (English, 2005) and strive to engage them in mathematically rich discussions (Maher et al., 2010) without presenting combinatorial formulas and mentioning the names of combinatorial operations. Related formulas are to be used only by students who discover them by generalising solutions to isomorphic problems.

The study aims to determine how successful the students are in solving different types of combinatorial problems after the above intervention and what mistakes they still make.

Methods

The study involves 88 students aged 16-19 years from four classes in three secondary grammar schools participating in the intervention delivered by four trained cooperating teachers.

After the intervention, the students were assigned a test of five combinatorial problems of different difficulty (from easy ones such as Code and Rabbit to difficult ones such as Candy and Obraz, see below the problems from one test version) and with a different combinatorial model, combinatorial operation, context and number of configurations (see Table 2). Two equivalent test variants were created to prevent copying, and the order of the problems varied to prevent any undue influence of the place of the problem in the test.

Table 2: Characteristics of the combinatorial problems

Problem	Combinatorial model	Combinatorial operation	Context	Answer
Candy	distribution	combination with repetition	children/equation	20
Code	selection	---	numbers and letters	140
Rabbits	distribution	arrangements with repetition	animals	8
Stamps	partition	combination	slips	20
Obraz	---	---	letters	ZBAOR

Candy/Equation. Choose one of the tasks A, B.

A. Distribute 3 equal candies among 4 children: Adam, Bara, Cecilia and Dan. Identify all the ways this division can be done. (For example, we can give Adam 1 candy, Bara gets nothing, Cecilia gets 2 candies, and Dan gets nothing.)

B. Find all non-negative integer solutions to the equation: $x_1 + x_2 + x_3 + x_4 = 3$. (For example, one solution to the equation is $x_1 = 1, x_2 = 0, x_3 = 2, x_4 = 0$, and the other solution is $x_1 = 0, x_2 = 1, x_3 = 2, x_4 = 0$.)

Combination problems of category II (Lockwood et al., 2018) A and B are isomorphic (Zenkl & Vondrová, 2023) based on the binomial coefficient "6 choose 3". We can code it as *3*-sized subjects of distinct positions (Wasserman & Galarza; 2019) by putting three stickers separating four children, or four adders between three dots representing candies, or the sum on the right side of the equation.

Code. In a three-digit code, the first position is one of the letters A, B, C, or D. The next two positions are any two-digit number from 11 to 45. There are, e.g., codes A22, B45, etc. Determine the number of all the codes thus formed.

There are four possibilities for choosing a letter and 35 possibilities for choosing a number; thus, the result of this selection problem is 140.

Rabbits. A rabbit breeder wants to place 3 rabbits (white, black and spotted) in 2 pens: upper or lower. How many options does he have for housing all these rabbits? Justify which of the results corresponds to the correct solution (the pen can be left empty):
a) $2 + 3$, b) $2 \cdot 3$, c) 3^2, d) 2^3, e) $\frac{3 \cdot 2}{2}$, f) any other number.

Because three distinguishable rabbits are distributed into two distinguishable pens, there are $2^3 = 8$ possibilities for doing so.

Stamps. Mary and Cindy have six post stamps numbered from 1 to 6. They decided to share the stamps, three for each of them. In how many ways can they share the stamps?

A combination problem of category I (Lockwood et al., 2018) which can be solved via the binomial coefficient "6 choose 3" (inspired by Batanero et al., 1997).

Obraz (Picture). The letters of the word OBRAZ can be rearranged in five different positions. It can create, e.g., the "words" BAZOR, AZORB or ZOBRA. Order all these rearrangements of letters alphabetically. What word will be in position 103?

The expected strategy of this problem (De Chenne & Lockwood, 2022) is sub-problems decomposition: 24 of the 120 permutations start with A, the other 24 with B, and so on, i.e., the 97th to 120th permutations start with Z. The first six (97th to 102nd) start with ZA, so the 103rd is the first to start with ZB. The other positions are taken alphabetically by the remaining letters: ZBAOR.

Data and data analysis

Data from 88 students, covering 440 solutions, were analysed. First, the overall success rate was calculated, and incorrect solutions were identified. Mistakes were classified using Table 1, with only

the primary cause of failure coded if the solution included several mistakes. During the coding, a mistake appeared that could not be classified according to Table 1 and coded M15. Indeterminate or crossed-out (unreadable) solutions were coded as "other mistakes", and empty solutions were coded as N/A. Absolute and relative frequencies were then calculated.

Results

Table 3 shows that the average success rates ranged from 23% to 45%. The overall average success rate for all the problems was almost 38%. The students produced 167 correct solutions, 217 solutions with distinguishable mistakes, 24 other mistakes and 32 empty solutions.

Table 3: Students' average success rates for the problems

Obraz	Stamps (partition)	Candy (distribution)	Rabbits (distribution)	Code (selection)
23%	28%	32%	42%	45%

The students solved both problems with combination with(out) repetition with lower success rates than the problem with arrangement with repetition. As expected, they were most successful in solving *Code;* this problem has a familiar context and can be solved by multiplying the number of letters and numbers. The students were the least successful in solving *Obraz*, which was also the most unsolved problem (in 16 cases). The reason might be that *Obraz* was not similar to any of the problems from the intervention. It required finding the configuration in a certain position, not the total number of configurations. The success rate for *Rabbits* was the second highest, and only one student did not attempt to solve it. It is a closed problem, which may have increased its success rate.

The bold frequencies of mistakes in Table 4 warrant our attention. Forgetting some partitions or types of partitions (M14) was the most common for two "distribution" problems: *Candy* and *Rabbits*. Figure 1 illustrates this mistake; the student solving *Candy* forgot configuration 1 1 1 0, which can be permutated; therefore, four configurations are missing.

Table 4: Frequency of mistakes per problem

	M1	M2	M3	M4	M5	M6	M7	M8	M9	M10	M11	M12	M13	M14	M15	other
Candy	3	0	0	0	0	**14**	2	**11**	1	0	1	0	1	**16**	0	1
Code	7	0	1	0	0	0	0	2	0	0	0	0	0	0	**26**	3
Rabbits	3	1	0	10	0	3	8	3	0	1	2	0	0	**14**	0	1
Stamps	1	3	1	0	0	**16**	4	**18**	2	2	0	4	2	0	0	4
Obraz	5	0	0	0	0	7	**13**	2	0	0	0	0	0	2	5	**15**
Total	**19**	4	2	10	0	**40**	**27**	**36**	3	3	3	4	3	**32**	**31**	24

The problems *Code* and *Obraz* cannot be assigned any model/operation, and Batanero et al.'s (1997) study did not address such problems. In many cases, we identified a new type of mistake in the solutions to *Code*, namely, M15: Translation by 1. It consists of the student failing to count the first or the last number from the interval of natural numbers or (in fewer cases) adding one more number. For example, the students usually determined the number between 11 and 45 as $45 - 11 = 34$. The most frequent mistake in *Obraz* was the inability to start solving the problem. The students usually did not write anything or crossed out their previous records.

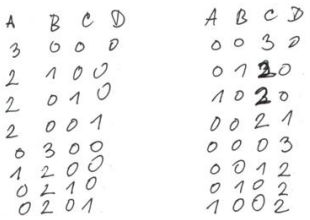

Figure 1: Students' solution to *Candy*, illustrating M14

The most frequent mistake was M6, which appeared in all the problems except *Code*. The students also had difficulties using correct arithmetic operations (M8), considering all partitions or sub-problems (M14) or counting all the numbers of the set (M15). Moreover, many students did not justify their incorrect solution (M7), and approximately 4% of the solutions were mistakes caused by an incorrect interpretation of the problem statement (M1).

On the other hand, there were hardly any mistakes in order and repetition when the operations were identified (M2 and M3), and almost no mistakes related to the incorrect use of formulas (M9 and M10), tree diagrams (M11) or the property of the binomial coefficient (M12). The mistake of excluding some elements to form the configurations (M5) did not appear.

Discussion

The students in our study underwent an intervention on combinatorics, in which problem solving and identification of isomorphic problems were emphasised, and formal terminology and formulas were subdued. The idea was to present combinatorics with understanding and prevent students' overreliance on formulas. The study focused on mistakes students made after this intervention.

We will compare our results with Batanero et al.'s (1997) comprehensive overview of mistakes. The mistakes they identified for the students *before* learning combinatorics (M6 and M14), caused by non-systematic listing or forgetting some types of partitions (in 72 out of 273 incorrect solutions) were made more frequently by our students *after* the intervention. The most common error, M6 (in 40 out of 273 incorrect solutions), was caused by a low ability to enumerate systematically (English, 2005). Thus, the ability to make systematic lists needs more attention in the intervention. Zooming in on this, we find out that almost half of the occurrences (19) of this error are from one group of students taught combinatorics by a beginning teacher just before the final state exam at the faculty.

On the other hand, mistakes related to formulas (M2, M3, M9, M10), which accounted for approximately 60% of all incorrect solutions of Batanero et al.'s students *after* the instruction on combinatorics, rarely occurred among our students. This difference may be partially explained by the nature of the intervention, which encouraged the students to use various solving strategies (including systematic listing and strategy of identifying isomorphism) and subdued formulas as a solving strategy. The deliberate suppression of combinatorial formulas probably prevented students' overreliance on formulas identified in previous research (Batanero et al., 1997).

Our study also revealed differences in the success rates for problems with different characteristics. In agreement with Batanero et al. (1997) and Lamanna et al. (2022), the students were most successful in solving problems with the selection model, followed by problems with the distribution model. The

problem with the arrangement operation had a higher success rate than the problems with combination operations did, which agrees with the results of Fischbein and Gazit (1988).

The problem of *Obraz* is unique, not fitting into combinatorial models and operations. It had the lowest success rate and was often unsolved. Unlike typical combinatorial problems, it does not focus on the number of possibilities. Students had not faced such a problem in the intervention, making it less suitable for the final test. Nonetheless, De Chenne and Lockwood (2022) suggest that such problems enhance the understanding of list formation and organisation. Our future intervention should include problems like Obraz as students struggled to apply their combinatorial knowledge when solving it.

Finally, we added error M15 to the classification of mistakes to Batanero et al.'s list of 14 mistakes. In M15, the student incorrectly determines the number of natural numbers in a given interval. This occurred mainly in *Code*, and, to a lesser extent, in *Obraz*. It did not occur in any other type of problem, which explains why it was not part of the original Batanero et al.'s list.

Conclusions

The main conclusion of our study is that our intervention prevented the students in our sample from over-relying on formulas yet did not provide them with enough opportunity to use the strategy of systematic listing effectively. This aspect needs more attention in the intervention's teaching plan. The main limitation of our study is that we treated all the students together without looking at results from each of the four classes and without connecting them with other data from the intervention, mainly with the data showing the fidelity of the intervention – to what extent it was implemented as designed and how it could have influenced the impact of the intervention. This remains to be done.

Second, we confirmed that the characteristics of combinatorial problems impact their difficulty and added one more mistake type to the existing classification of mistakes. Yet, our results must be considered in light of the small sample in terms of both the number of students' solutions and the number of problems with the same characteristics used in the test.

Computational thinking in mathematics problem solving: interplay between context, mathematics and computer science

Valérie Batteau[1], Jana Trgalová[1] and Sébastien Jolivet[2]

[1]University of Education, Lausanne, Switzerland; [2]University of Geneva, Switzerland;
valerie.batteau@hepl.ch, jana.trgalova@hepl.ch, Sebastien.Jolivet@unige.ch

This research aims to explore the links between the mathematical content and the computer science content in the implementation of a sequence prepared collectively by secondary mathematics teachers and researchers. This contribution reports on a sequence of lessons about approaching the measurement of area of irregular surfaces from a probabilistic perspective at grade 7 (students of 12-13 years). Scratch was used to program a simulation to estimate the area of irregular surfaces.

Keywords: Computational thinking, mathematical problem solving, Scratch.

Strong links between computational thinking (CT) and solving problems in mathematics are recognized (for example, Barcelos et al., 2018). Recently, the Swiss education policy (Conseil d'État, Octobre 2019) considers the teaching and learning of CT as a school priority and sets it as a transversal topic in mathematics as well as in other disciplines. Our research (Batteau & Trgalová, 2023) aims at investigating the links between mathematical and computer science content in the implementation of a sequence of lessons prepared collectively by mathematics teachers and researchers. More precisely, we explore how teachers make visible different transitions between the context of a mathematical problem, the mathematical content and the computer science content. This sequence was based on solving a problem mobilizing mathematical and computer science content.

Kallia & al. (2021) propose a conceptual framework of CT in mathematics, that aims to investigate the interplay between the context, mathematical and computer science content.

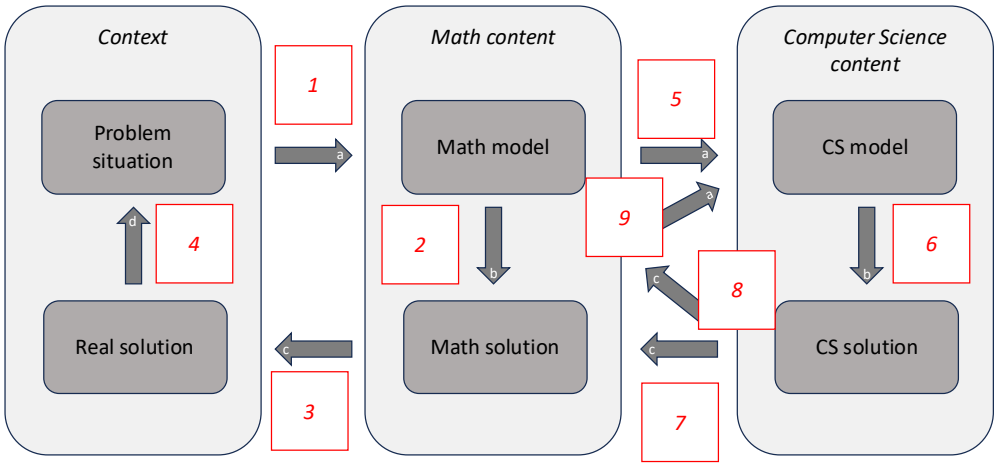

Figure 1: Computational thinking in mathematics based on Kallia et al. (2021, p. 3)

The model (Figure 1) constitutes our conceptual framework. Borrowing the concepts from the didactic engineering research method (Artigue & Perrin-Glorian, 1991), we realized an *a priori* analysis of the task to bring to the fore knowledge and reasoning at stake in the situation (context),

the mathematical and the computer science contents at stake and the transitions between these. Then, we confront this *a priori* analysis with *a posteriori* analysis (based on collected data) aiming at identifying in the students' and teacher's activity the differences between both, that highlight the critical points to be considered in the implementation of a problem-solving lesson involving computational thinking**.** Our aim is to show how the conceptual framework can be exploited to identify critical points in the implementation of a problem-solving lesson involving computational thinking where difficulties linked to transitions between real-life situation, mathematical and computer science content can be expected.

We address the research question: what are the critical points in the different transitions between context, math and computer science contents that need to be handled by the teacher to help students progress in solving the proposed problem?

The main task implemented during the sequence invites the students to measure the area of irregular plane surfaces. Three approaches lead to solving the task: break down the surface into smaller surfaces whose areas can be calculated; tile the surface with unit surfaces (conventional or not); probabilistic approach with simulation using Scratch.

By comparing *a priori* and *a posteriori* analyses, we have identified several critical points situated at these transitions that require specific attention in the design and implementation of mathematical problems, such as making explicit links between mathematical and CS models for example.

An initial attempt was made to use Kallia & al.'s (2021) model as an analytical framework. The aim now is to continue to use this framework, although not exclusively, and if necessary to develop it further. It is this perspective that will guide the rest of our work. This initial use of Kallia et al.'s (2021) model also opens up the prospect of using it in teacher training, or even by the teachers themselves, as a support for designing problems.

Connections between discrete mathematics and other mathematical topics in Hungarian curricula

Bernadett Szakácsné Györey[1] and Katalin Gosztonyi[1]

[1]Eötvös Loránd University, Budapest, Hungary; szgyoreyb@outlook.com

Keywords: Theory of conceptual fields, curriculum, textbooks, discrete mathematics.

Introduction

Combinatorics, discrete mathematics is of great significance in Hungarian mathematical culture. It is marked by names such as Pál Erdős, Pál Turán, Vera T. Sós, Endre Szemerédi, László Lovász. Discrete mathematics plays an important role in Hungarian mathematical research as well as in mathematics curricula of Hungarian public education. Several discrete mathematical topics appear in the curriculum as combinatorics, mathematical logic, sets, number theory and graph theory.

A characteristic of the Hungarian curriculum is its spiral structure. Mathematical topics are built in parallel, and connections between different mathematical domains are encouraged to reinforce deeper understanding of mathematical notions (Gosztonyi, 2020). These connections can be conceived in different ways while implementing the curriculum. In my ongoing PhD research, I investigate opportunities offered by the curriculum to integrate discrete mathematics with other mathematical topics and how this contributes to the emergence and development of mathematical knowledge.

In the first part of my poster, I will give a curriculum analysis. At the level of intended curriculum (Schmidt et al., 1996), I examine what connections are explicitly required by the Hungarian curriculum between discrete and other mathematical topics. However, these connections are not explicit in the text of the curriculum. Textbooks provide more information concerning possible connections. For this reason, my research is currently focused on the potentially implemented curricula (Schmidt et al., 1996), more particularly on textbooks.

The research question discussed on my poster is: What opportunities do Hungarian textbooks in mathematics provide for connections between discrete mathematics and other mathematical topics, in link with the Hungarian curriculum?

Theoretical framework and methods

I rely on Vergnaud's Theory of conceptual fields (2009, 2013). According to him, a concept is formed through a set of different situations, highlighting different aspects of the concept. At the same time, several concepts are encountered in a situation. This approach is very adequate to describe dynamics between different mathematical domains I am investigating. Furthermore, I rely on Vergnaud's distinction between operational and predicative form of knowledge, the first providing means to do and succeed, the second consisting in the linguistic and symbolic expressions of knowledge.

In the case study presented in my poster, I investigate a learning unit in a geometry chapter of a 6th grade textbook. My research question specified for this case: what opportunities are provided by the situation described in this learning unit for the development of students' operational and predicative knowledge both in geometry and in discrete mathematics?

Results

The learning unit in question introduces the chapter on quadrilaterals (Csahóczi et al., 2021). In this situation, students have to construct quadrilaterals from 2, 3, then 4 isosceles right triangles, then from equilateral triangles, and finally from isosceles non-right triangles joined by whole edges.

Reviewing the possibilities for 2 triangles is not difficult. However, in the subsequent problems, using 3 or 4 triangles, it is necessary to systematize the cases to find all solutions. The systematization is determined by the known properties of the triangles used. In my analysis, I identify preliminary (operational and predicative) knowledge necessary to deal with the situation; opportunities to build new operational knowledge and opportunities for transition between operational and predicative form of knowledge, both in the domains of geometry and discrete mathematics. I particularly investigate mutual role of these two domains in the construction of knowledge in the other domain. For example, the symmetries of the triangles can lead to symmetries in a combinatorial sense. Also, the solution process highlights the importance of the parity of the total number of sides of the triangles used. This can provide operational knowledge of parity, which is a typical invariant in discrete mathematical problem solving.

Conclusion

In the presented case, the situation has strong potential to improve knowledge in both domains. Working in both domains can lead to more complex knowledge than if students only apply preliminary knowledge from one of the topics.

In the continuation of my research project, I will analyse further situations, and I will investigate through experimentation how students mobilise operational knowledge for topics that are not discrete mathematical topics but can be approached in a discrete mathematical way, and how these situations contribute to the development of their knowledge concerning both domains.

Analysis of students' self-written combinatorial word problems

Charlott Thomas[1] and Birte Pöhler[1]

[1]University of Potsdam, Germany; charlott.thomas@uni-potsdam.de

Keywords: Combinatorics, arrangement, word problems, counting problems.

Theoretical background

The present study attempts to investigate students' understanding at the end of their school career by analysing self-written word problems, which are discussed in the context of the model of combinatorial thinking (Lockwood, 2013). It provides a framework for analysing difficulties in understanding combinatorial problems with three central components: *Formulas/expressions*, *counting processes*, and *sets of outcomes*. *Formulas/expressions* are mathematical calculations that represent a particular outcome or a number of possible combinations. *Counting processes* describe the mental or practical steps, such as the multiplication principle or the systematic division of a task, that lead to the solution. *Sets of outcomes* include all possible combinations or results of a counting task and help to visualise its structure. These three components are in a dynamic relationship: a counting process can lead to the development of a formula, while a formula can be a counting process. Similarly, counting processes can generate or structure sets of results, and conversely, understanding sets of results can contribute to the selection of an appropriate counting process. Mistakes often occur when students mechanically apply formulas without understanding the underlying counting process, which can lead to logical misunderstandings. The ability to switch flexibly between these components is crucial for understanding and solving combinatorial problems. A lack of understanding of these relationships can lead to results being overlooked or counted twice (Lockwood, 2013).

Research question and methodical approach

This poster aims to answer the following research question: *What understanding do students show of the combinatorial operation arrangement without repetition when formulating their own word problems?* In a test, 161 students (aged 17 to 18) were asked to formulate a word problem for the given equation ($\mathbf{6 \cdot (6-1) \cdot (6-2) = \frac{6!}{(6-3)!} = 120}$) to investigate their understanding of the formula. Thereby they should transfer from a formal representation into a concrete everyday situation. It required them to recognise that the formula calculates the number of ways to select three objects from six options in a specific order (arrangement without repetition). The data was analyzed using qualitative content analysis and a category system was developed ($\boldsymbol{\kappa = 0.72}$ (substantial)). The **deductive categories** were adapted on the basis of the study by Thomas and Pöhler (2024), in which permutation word problems were formulated, and on the basis of implicit combinatorial models (Dubois, 1984): Students can therefore formulate a word problem for arrangement without repetition *(arrangement word problem C1)* based on the combinatorial model *selection (C1.1)* or the *distribution (C1.2)*. The combinatorial model partition is not possible here because there is no division of the basic set *n* into distinguishable classes. It is also possible to formulate the equation according to the *product rule/multiplication principle (C2)*, so that a word problem can be formulated for the equation that is combinatorial, but in which different objects with different cardinality are arranged. Furthermore, students can also write a word problem for *multiplication (C3*) that fits the equation but

is not combinatorial. The **inductive categories** were formed on the basis of the data: *Combinatorial word problems that cannot be clearly assigned to an arrangement (without repetition)* are assigned to category *C4*, in which either a word problem was written in which the elements are partially identical *(C4.1)* or a word problem was formulated in which the elements are partially identical and no selection is made *(C4.2).* There were also *probability word problems (C5)* in which a probability was asked for and not the number of possibilities. There is also the category where *no concrete answer* was given *(C6)*, e.g. the box was left blank, a dash was drawn, or no word problem was written. Finally, there is the category *other (C7)* with answers that do not clearly fit into one of the other.

Results and discussion

Only the most common categories *(C1 and C4)* are presented here. *C1* includes problems where three objects of the same cardinality are selected or distributed from six different objects: *Three marbles are selected from an urn containing six different marbles. How many different combinations can be made? (C1.1)* and *Six athletes are running a race. How many different arrangements are there on the winners' podium? (C1.2).* These problems illustrate two combinatorial models: selection *(C1.1*), because three marbles are *selected* from an urn and distribution *(C1.2),* because athletes are *distributed/placed* on the podium. Applying Lockwood's (2013) model, these word problems demonstrate understanding of the set structure and arrangement process. Students grasp that the number of arrangements decreases step by step, aligning with the formula's logic. Conversely, *C4* problems, such as *Three balls are drawn from a bowl containing three white and three black balls. How many different combinations are possible? (C4.1)* and *Find the number of ways to arrange the letters in the name HANNAH (C4.2),* show challenges in recognising identical elements and applying formulas correctly. In C4.1, students misinterpret the influence of identical elements, while in C4.2, they apply the formula mechanically without understanding the conditions. These difficulties indicate that students do not fully understand the counting process behind the formula and do not always correctly recognise the influence of order. In summary, although students contextualise the formula, they have difficulty interpreting it correctly and recognising the conditions for its application (Lockwood, 2013). Based on this study, there should also be a focus on fostering students' conceptual knowledge (e.g. by formulating word problems) to gain a deeper understanding of combinatorial operations, which ultimately supports students' success in more advanced areas of mathematics and provides opportunities for rich mathematical thinking.

Introduction

Since its rejuvenation, computational thinking (CT) has been argued to be an essential skill, such as reading, writing, and arithmetic, which everyone needs to possess (Wing, 2006). However, there are several CT definitions, and they are not yet univocal (see Lodi & Martini, 2021). In this poster, by following Lodi and Martini (2021) suggestions, we defined CT as a way to access knowledge by using problem-solving skills to get solutions with or without the help of an information processing agent.

Realising the importance of CT skills, some European countries and institutions have initiated operationalising CT in compulsory education (Bocconi et al., 2016). Moreover, international organisations such as the Organisation for Economic Cooperation and Development (OECD) and the International Association for the Evaluation of Educational Achievement (IEA) have attempted to make international assessments of CT. Therefore, we are also motivated to contribute to the movements by proposing some CT activities.

CT can be fostered in informatics subjects or related subjects such as mathematics or sciences (Bocconi et al., 2016). Ye et al. (2023) have shown that students' CT skills could co-develop with their mathematics understanding. However, few studies utilised mathematics tools or software in the integration of CT into mathematics lessons (Chan et al., 2022). Therefore, this poster will present the integration of CT into mathematics lessons utilising mathematics software. We raised two research questions: What are the challenges that students face in approaching our designed tasks? And how can computational thinking be supported when engaging in our tasks?

Proposal

Chan et al. (2022), in their literature study, revealed software or tools used in the CT integration into mathematics education, and rarely has mathematics software been utilised, such as spreadsheets. Van Borkulo et al. (2023) utilised spreadsheets in the integrated CT into mathematics lessons and showed students' CT development on computational concepts. However, their study has not provided evidence of how students utilised spreadsheet formulas and fixed them when errors occurred. We then propose the use of Google Sheets (GSheets) to track the inputted and deleted formulas.

This study employed the educational design research (EDR) by McKenney & Reeves (2018); its iterations or cyclical features allowed us to improve our design and understand how our design innovation works. We developed Math+CT lessons (can be accessed at https://bit.ly/CTGSheet) by referring to the Shute et al. (2017) CT framework when incorporating CT components (decomposition, abstraction, algorithm, debugging iteration, generalisation) into the central tendency

tasks. We collected the data from students' work on GSheets and recorded some students' computer screens. The data would be analysed using content analysis following steps by Krippendorff (2004), which consist of making, categorising, and concluding codes that emerge from our data.

Our study has presented the struggles that students face when working on our Math+CT tasks and the CT skills that students have engaged with. Moreover, other topics should be investigated to understand how to optimally utilise GSheets for integrating CT into mathematics lessons.

Introduction

In their introduction to the papers presented at CERME6 in Lyon in 2009, the joint chairs stated that "the working group has no tradition in CERME" (Furinghetti et al., 2010, p. 2679). More than 15 years have passed. This is the ninth consecutive edition of CERME in which this thematic working group has been organized, and the previous statement no longer applies. In fact, although not too large (Figure 1), the presence of this working group at the conference has remained quite stable over time. Table 1 shows the evolution of the number of works published in the proceedings since 2009.

Table 1: Evolution over time of TWG12 papers

CERME6	CERME7	CERME8	CERME9	CERME10	CERME11	CERME12	CERME13	CERME14
13	14	15	16	18	15	13	16	12

One more paper was initially accepted for CERME14. However, the presenting author, who was born in Ecuador, was not granted a visa in time to enter Italy. It is unfortunate that, even in 2025, a lack of visa can prevent researchers from presenting their work at an international congress. Even more unfortunate is the fact that this problem affects researchers from less affluent countries more often. As co-leaders of this thematic working group, there is little we can do. However, we can publicly express our discomfort through these lines.

Figure 1: Participants of TWG12 at CERME14

Overview of the papers presented in Bolzano

The following is the list of possible topics that was provided in the call for papers:

1. Design of teaching/learning materials using history of mathematics, preferably with conclusions based on empirical data.
2. Research on the existing or possible uses of history or epistemology in curricula, textbooks, and/or classrooms practice.
3. Research on the history of mathematics education and/or the relevance of mathematics education in society at the time.
4. Connections and interplay between mathematics education and history of mathematics: theoretical and methodological issues.

This list of topics captures the key areas of research currently being explored within our field at an international level. However, it should be noted that not all topics receive the same level of attention, which is reflected in the uneven distribution of the presented papers across the topics. In particular, the most part of the papers (eight) were related to Topic 3. Of the remaining papers, two addressed Topic 2, while one each addressed Topics 1 and 4 (see Table 2).

Table 2: Distribution of papers among the topics from the call for papers

Presenting author	Topic	Strongly related TWGs	Weakly related TWGs
De Bock	3		
Goemans	3	2	13, 24
Oller-Marcén	3		7
Opsal	3	23	
Pinto	3	1	4
Piña-Aguirre	2	14, 25	24
Rodrigues	3	22	4
Schmidt-Thieme	3	24	
Segev	1		2, 3, 8
Smestad	3	22	
Thomsen	4	17	20
Watford	2	14	8, 17, 22

Most of the papers presented at the conference are potentially related to other thematic working groups (see Table 2). We note that roughly half of all the thematic working groups (14 out of 29) have some relation to the papers presented. Naturally, some of these links are stronger than others, as indicated in Table 2. It is also noteworthy that some papers can potentially be related to many different groups. This is the case with Mark Watford and Kathleen Clark's paper "A transformation of perception in calculus: An exploration of barriers and outcomes through transgressive actions," which is strongly related to TWG14 (University Mathematics Education) as well as TWG8 (Affect and the Teaching and Learning of Mathematics), TWG17 (Theoretical Perspectives and Approaches in Mathematics Education), and TWG22 (Curricular Resources and Task Design in Mathematics Education). Conversely, some papers have a less clear link with other thematic working groups. Some of these papers (such as De Bock and Goemans' paper "Mathematics education in Belgium inspired by Decroly's pedagogy") cannot easily be related to any group.

However, this should not be used as a measure of the paper's interest or quality. In fact, it is beneficial for our group to have both types of paper. Papers with strong links to other thematic working groups demonstrate our belonging to the mathematics education community, while papers with weaker or no links highlight the specificity of our research field.

The workshops

Since CERME12, that took place online, some of our presentations have been given in the form of workshops. This is not uncommon in the HPM (History and Pedagogy of Mathematics) community, and the European Summer University on the History and Epistemology in Mathematics Education (ESU) always includes a good number of workshops. Furthermore, in 2021, the new format was deemed enjoyable, and it was agreed that it should be retained (Chorlay et al., 2022). For this edition, two papers have been adapted for presentation as 90-minute workshops.

In the first workshop, based on the paper by Segev and Elitzur "Using word problems from the 16th century in teaching mathematics", we analyzed some word problems coming from a Jewish math book from the beginning of the 16th century. We attempted to solve them by ourselves and learnt about an experiment conducted with 20 students from an Israeli teachers' college. The results of the experiment indicated an impact on the positive attitudes of the students, as well as some gender differences. The second workshop, based on the paper by Schmidt-Thieme and Hamann "Iconic representations in Renaissance reckoning books – on the way to a table of classification", focused on iconic representations in ancient arithmetic textbooks. We analyzed and classified several such representations excerpted from the *Rechenbuch auff Linien und Ziphren* (1574) by the German Adam Ries. As a result, we reflected on what to understand by 'iconic representation', and we discussed our classification criteria in comparison with those of the paper's authors. The discussion also raised interesting methodological questions and suggested further lines of research.

Another paper, "Papy's minicomputer" by Wendy Goemans and Dirk de Bock, was presented in a hybrid format, combining elements of a traditional presentation with those of a workshop. The authors introduced the so-called Papy's minicomputer, a conceptual, non-mechanical, two-dimensional abacus that was initially intended by its creator for teaching the number system. We were shown how to use it in practice, and we were even able to manipulate some original material from the 1960s.

Group discussions and challenges for the future

CERME conferences usually provide a venue for fruitful conversations, within the thematic working groups, and in more informal situations. During this week of intense work, several discussion topics arose, some of which were addressed as a group during our final session. Here, we briefly report on two topics that were mentioned repeatedly in several of the papers presented: theoretical frameworks in our field and methodological challenges in the history of mathematics education.

Throughout the presentations, various theoretical frameworks and constructs were employed to either provide a foundation for the research or serve as an analytical lens through which to understand a phenomenon or interpret data. These include the theory of didactic situations, the concept of mathematical transgressions, didactic transposition, socioepistemology, the different curriculum levels, the notions of foreground, and Jankvist's hows and whys. Some of these ideas originate from mathematics education and have been adapted to a certain degree for use in a historical context; others are specific to our field. Regardless of their origin or role, they can and should be employed to communicate our findings in a manner that highlights the significant impact that some of our research can have on the broader field of mathematics education. Another issue relates to the multiple methodological challenges that arise in research in the history of mathematics education. Some of these challenges are related to the use of novel technological tools, such as AI, in data analysis, particularly when a quantitative approach is adopted. Others consider the variety of sources that may be relevant to a given research question, or the challenges of making comparisons between different countries. Finally, we consider the possibility (or necessity) of connecting our findings with contemporary mathematics education.

These two issues are related to overarching ideas introduced earlier: the concern for our mutual relationship with mathematics education as a discipline, and for the role, impact and applicability of our research results in this context. In the near future, we need to reflect on these issues, not only to gain visibility, but especially to be able to exchange theoretical approaches and methodologies that could benefit both fields.

Acknowledgment

We thank all the members of the TWG12 for their active participation and the superb working atmosphere throughout the whole conference. See you in Bratislava!

Mathematics education in Belgium inspired by Decroly's pedagogy

Dirk De Bock[1] and Wendy Goemans[1]

[1]KU Leuven, Faculty of Economics and Business, Leuven, Belgium; dirk.debock@kuleuven.be

After WWI, the New School movement flourished, mainly in Europe and the US. The movement proposed a child-centered pedagogy and sought a more just society. In this paper, we focus on the influence of Decroly on mathematics education in Belgium. Before WWII, this influence was limited to primary education (with new curricula starting in 1936). After WWII, mainly under the influence of the École Decroly*, there was an impact on secondary education. In this, the Brussels professor of geometry Paul Libois and his wife Lucie Libois-Fonteyne played a prominent role. The mathematical exhibitions organized by Libois and the students of the* École *drew international attention, for example, from Emma Castelnuovo and Italian teachers. But in the 1960s, Georges Papy's modern mathematics was dominant in Belgium; Libois' ideas could not penetrate widely. In the 1980s, however, ideas similar to Decroly's were revived in the model of realistic mathematics education.*

Keywords: École Decroly*, mathematical exhibitions, New School movement, Ovide Decroly, Paul Libois.*

Introduction

The New School is an international educational movement that emerged around 1890, had its heydays during the Interwar period, but remained influential in many countries after WWII. Other designations are: *Reformpädagogik* (in Germany), *éducation nouvelle* (in France), and Progressive Education (in the US). The movement aimed to "improve education" and it was assumed that therefore children and their (spontaneous) interests should be placed central in the learning process, which implies more attention to the individual learner. Learning also needed to be strongly linked to "real life" (in Decroly's words, "une école pour la vie par la vie" [a school for life through life[1]]). The school should not separate itself from the community in which it is embedded, so community projects and activities were favored. The movement also promoted a meritocratic educational system: social-class differences should not play any role; instead, school should become a vehicle for social progress.

Main protagonists of the movement were John Dewey (1859–1952), Maria Montesorri (1870–1952), Ovide Decroly (1871–1932), Édouard Claparède (1873–1940), Roger Cousinet (1881–1973), Célestin Freinet (1896–1966), among others; the work of 18th century Geneva philosopher Jean-Jacques Rousseau is widely regarded as a common inspiration for the New School reformers. In 1919, schools that endorsed New School ideals united in the New Education Fellowship (NEF) (Clews, 2009). It became a strong network of progressive and experimental education; in several countries national NEF branches were established (see, e.g., Beckers, 2023).

An extensive literature on the New School movement exists today: research on the work of key representatives of the movement (e.g., Depaepe et al., 2003), on national implementations of the reform (e.g., Pozo Andrés, 2021), and comparative studies (e.g., Van Gorp et al., 2017). Mostly,

[1] All translations were made by the authors.

however, research on the New School movement was conducted by general education historians and the influence of the movement on mathematics teaching is discussed marginally at best. At CERME13, following the paper presentation by Carrillo Gallego and Ginés Espín Buendía (2023), the possibilities of research on the influence of the New School movement on aspects of mathematics education were discussed. This discussion prompted the present study.

The purpose of the current study is to examine the influence of Decroly's pedagogy on mathematics curricula and practices in Belgium, both at the primary and at the secondary level. How did Decroly's ideas influence the mathematics curriculum for primary schools implemented in Belgium beginning in 1936? And how did they nourish the debate that began after WWII about reforming mathematics education at the secondary level? To answer these questions, we analyzed pre and post WWII documents, testimonies of those involved, and confronted our findings with the results of other research on the New School movement.

Decroly's views on mathematics education

Given the extensive literature available on Decroly's life, work, and views on child psychology and pedagogy in general (see, e.g., Depaepe et al., 2003; a pedagogical-historiographic "standard article" about Decroly), there would be little point in discussing these issues at length in this paper. Therefore, we will mention only a few key biographical facts and then elaborate on Decroly's views on mathematics education (which are, of course, in line with his general views on education).

Ovide Decroly (Figure 1), born in Ronse in 1871 and died in Uccle (Brussels) in 1932, studied medicine at the University of Ghent, where he graduated in 1896. Through his work with mentally "retarded" children, he became interested in psychology and pedagogy. Soon he became the figurehead of the New School movement in Belgium. In 1907, he founded the *École Decroly* in Uccle (originally named *École de l'Ermitage*), a school for pupils aged 3 to 18 where his pedagogical principles were uncompromisingly put into practice. Decroly was a Freemason, president and co-founder of several pedagogical organizations, including the Belgian NEF branch, and responsible for the chair of child psychology at the *Université Libre de Bruxelles* [Free University of Brussels] (Libois, 1971).

Figure 1: Ovide Decroly at work with children, n.d. (Centre d'Études decrolyennes)

As mentioned, Decroly's views on mathematics education cannot be separated from his broader educational philosophy. A fundamental principle in that philosophy is what he called "globalization" (Decroly, 1928). Children first understand their world in a holistic way. When brought into contact with an object or phenomenon, the child will spontaneously examine it as a whole, in its totality. As unanalyzed totalities, various notions penetrate the child's mind. But gradually, according to their needs and interests, they would continue to analyze, to revisit these notions, and to discover and understand different aspects of the investigated realities, including mathematical ones. The principle of "globalization" has an important didactic implication: to develop children's intellectual faculties at school, it is recommended to start from total realities rather than individual subjects. Already in the early 1900s, Decroly advocated reducing the number of school subjects and avoiding unnecessary subject divisions. "Do everything possible to ensure that the number of subjects is reduced and that the subject matter itself is designed to avoid arbitrary and artificial divisions" (Decroly quoted in Libois, 1962, p. 6). Applied to mathematics, he wanted to prevent young children from learning mathematics as a stand-alone subject; instead, mathematics education should focus on gaining an understanding of mathematical concepts and acquiring mathematical skills from a broader reality. Also, teaching the various sub-disciplines of mathematics (arithmetic, algebra, geometry, trigonometry, etc.) separately was best avoided as much as possible (Libois, 1962).

A second key idea of Decroly was to concentrate the teaching of subject matter around central themes that correspond to dominant interests of the children, the so-called "method of centres of interest". "Interest should be at the heart of everything we [teachers] impart to the children. We have to bow. We have to concern ourselves with their interests, techniques will come later" (Decroly, 1974, p. 14). In mathematics, this means that concepts should be introduced through activities that are meaningful and relevant to the child's everyday life. For example, children might engage in counting, measuring, collecting data or problem solving as part of an interdisciplinary project or activity, such as building something or exploring nature (Decroly & Hamaïde, 1932).

Third, Decroly emphasized the role of children's personal activity in learning, "learning by doing". He recommended to "stimulate a taste for observing, experimenting, questioning facts, expressing thoughts, creating and inventing" (Decroly quoted in Libois, 1962, p. 7). Learning mathematics by doing translates into activities in which children manipulate real objects, construct geometrical shapes, explore patterns and so can discover mathematical principles. It assumes the availability of concrete models and other aids that the child can "see and touch", as well as the necessary time to adapt to each child's individual learning pace. Decroly advocated giving children the time and materials they need: "provide them with the time, space and material opportunities to translate and control through assemblies or objective creations" (Decroly quoted in Libois, 1962, p. 7).

The 1936 curriculum reform at the primary level

In 1936, a new curriculum for public primary education was introduced in Belgium (Ministère de l'Instruction Publique, 1936). The curriculum, signed by liberal minister François Bovesse (1890–1944), was a major innovation compared to the previous one, which dated from 1922. It bore Decroly's stamp.

> It's in the immediate environment that the teaching material is to be found, and it can scarcely be found elsewhere. […] The study of the environment through active observation is at the heart of the program. […] The teacher will draw inspiration from observable things, draw the child's attention to what is around him, interest him in the phenomena unfolding before his eyes and constantly appeal to his immediate experience. (Ministère de l'Instruction Publique, 1936, p. 23)

Catholic schools, which before 1936 applied the same curriculum as public schools, did not follow suit. Catholic leaders could not agree with the purely "scientific" approach of the official curriculum, in which "reality" was reduced to the "concretely observable", and developed their own curriculum.

For the teaching of arithmetic/mathematics, the general tenor of the curriculum was continued and a "realistic" approach was advocated. Calculation should not be a goal in itself, but should be linked to concrete reality. Teaching had to be maximally based on observations and the children's environment. Long and abstract computations had to be avoided. Word problems were not allowed to be abstract, but had to be grafted on the students' activities and interests. In the domain of "measurement", the curricula called for using only the measures that the children would use in everyday life. Yet there were also some elements that were hardly consistent with the general principles. For example, it was stated that learning to calculate quickly and precisely was a main goal of the curriculum, and there was a plea for perfect mastery of the calculation tables and automation of the main arithmetic operations. The authors of the new curriculum recognized that "in the teaching of arithmetic, as in any teaching, there is a routine and mechanical part which must be accepted" (Ministère de l'Instruction Publique, 1936, p. 11).

In a general study of the 1936 curriculum reform in Belgian primary education, Depaepe et al. (1991) have shown that, for various reasons, educational practice did not change fundamentally in those days. This also applied, at least in part, to the teaching of arithmetic/mathematics. The word problems in the new textbooks appeared somewhat more realistic and "taken from life". Regularly, (functional) charts, tables and drawings that came directly from the children's world were used. Also, for the first time, a distinction was made in the difficulty level of the exercises (by designating the difficult exercises with a particular sign). In classroom practice, this probably amounted to tempo differentiation: after classroom instruction, all children made the same basic exercises. Children who were ready could then start on the more difficult exercises.

Most commonly used textbooks continued to pay a lot of attention to long series of bare sums, without "meaning" and unconnected to any applied context (De Bock & Vanpaemel, 2019). Quite deliberately, by the way, as evidenced in the preface of the manual by De Cock and De Vos (1938) for the fifth year:

> Many schoolteachers now reasoned as follows: the main operations have been sufficiently practiced in previous years, and each time the word problems offer, in one form or another, a repetition of the art of cyphering. So it seemed unnecessary to them to add many purely cyphering exercises. In this they wandered. Common experience should have made them sufficiently aware of this. How many word problems had a wrong solution because the ciphering was wrong. (p. 4)

A revised curriculum for public primary education in Belgium was introduced in 1958, but the underlying philosophy did not change substantially (Noël, 2022).

Call for reform at the secondary level after WWII

In Belgium, as in several other European countries, a debate on educational reform flared up toward the end of WWII. The main themes were democratization of education, cultural modernization, and pedagogical innovation (Noël, 2022). A protagonist during that period was the mathematician and communist politician Paul Libois (1901–1991), professor of geometry at the Free University of Brussels (De Bock & Vanpaemel, 2019). As a mathematician, Libois had been educated in part by Frederigo Enriques and Guido Castelnuovo (father of Emma Castelnuovo), figureheads of the Italian school of algebraic geometry. From his Italian masters, he had inherited a predilection for intuitive thinking in mathematics. Libois showed himself to be a fervent supporter of the Decroly's comprehensive child-centered pedagogy. In 1936, he married Lucie Fonteyne (1897–1980), a teacher at the *École Decroly* and later its director.

One of the first post-War initiatives was the founding in January 1945 of the *Comité d'Initiative pour la Rénovation de l'Enseignement en Belgique* (CIREB) [Committee of Initiative for the Renovation of Education in Belgium], a think tank that emerged from resistance circles and strived for a global and democratic reform of the Belgian educational system. The *Comité* was chaired by the physicist Frans Van den Dungen, vice-rector of the Free University of Brussels. Most of the other members of the CIREB were also free-thinking leftist intellectuals affiliated with or graduated from the Free University of Brussels, among them also Paul Libois. In an introductory manifesto *L'École de 6 à 16 ans* [The school for 6- to 16-year-olds] (CIREB, 1945), the *Comité* proposed extending compulsory education, which in Belgium at that time was limited to 14 years, to 16 years. To that end, the manifesto insisted, an entirely new type of school had to be created, a school for all, a synthesis of the existing school systems. "Schools whose task would be not only the teaching of some basic skills (reading, writing, calculating), but the entire formation of the future citizen" (p. 3).

The project of the CIREB was clearly influenced by the views of Ovide Decroly, "the great Belgian psychologist and pedagogue, whose ideas and achievements have largely inspired the current work" (CIREB, 1945, p. 2). In particular, in its call for pedagogical innovation, the "method of centres of interest" was promoted: "All activities are grouped around a central theme, the **Centre of interest**, which corresponds to a dominant interest of the children" (CIREB, 1945, p. 14, bold in original). To help schools implement the proposed reform, between December 1945 and February 1951, the CIREB published the magazine *L'École* which provided several detailed dossiers on cross-curricular themes that could be chosen as "centres of interest" for the various age levels between 6 and 16. Most of these dossiers were prepared by scientists from the Free University of Brussels and dealt with topics such as the "weather", "labor", "housing" and "nutrition".

Following the general principles, the CIREB (1945) also proposed a basic program for each subject. It is a comprehensive program intended for all pupils between the ages of 6 and 16, not divided into ability groups. For mathematics, the CIREB proposed a fairly concise program, organized into five sections: numerical calculations, geometrical figures, transformation of figures, spatial representations, and functions. Interestingly, in geometry, the emphasis was on an intuitive approach to geometrical objects. With the "transformation of figures" section, the program introduced a dynamic element to the teaching of geometry, which could be regarded as an innovation over

traditional approaches. Despite its brevity, it reflects some key ideas of Libois, who certainly had a hand in it.

In May 1945, the CIREB project was presented to the then Belgian Minister of Education, the liberal Auguste Buisseret (1888–1965), but the *Comité* did not wait for political approval of its reform proposals. The CIREB considered that its proposals did not conflict with existing legislation and therefore schools were invited to implement the program directly if they wished. Given the general nature of the program and the lack of precise guidelines, however, it is unlikely that many schools accepted the invitation of the CIREB (Noël, 2022).

In 1948, under the impetus of one of Buisseret's successors, the socialist Camille Huysmans (1871–1968), a major democratic reform of the education system in Belgium was initiated. Huysmans, who himself had worked as a teacher for several years, warmly welcomed the ideas of Decroly and the CIREB. Huysmans' reform led to new curricula for public secondary education, including for mathematics (Bosteels, 1950). The new mathematics program for the first year of secondary education (12-year-olds) mandated a course in intuitive geometry, as advocated by Libois. Catholic schools followed suit. Intuitive geometry was intended as a bridge between the elements of geometrical practice that students had learned in primary school, and the "rational" geometry that started in the second year of secondary education. Intuitive geometry aimed to familiarize students with the properties of basic geometrical shapes on which they could make practical measurements. Much emphasis was placed on actively manipulating real objects to develop students' sense of observation and to induce an "appetite" for learning geometry.

An alternative for Papy's modern mathematics?

In the early 1960s, modern mathematics, say basing mathematics education on set theory and structures, was prepared in Belgium and internationally. After the famous Royaumont Seminar in 1959, a "group of experts", including Paul Libois, met in Zagreb-Dubrovnik to develop a modern program for teaching mathematics in secondary schools. The outcome for geometry was an ambiguous compromise. In the early years (12–15-year-olds), the emphasis was put on an intuitive approach. This attention was largely due to Libois' intervention. For the final years of secondary education (16–18-year-olds), geometry would be replaced with the study of algebraic structures, as advocated by participating mathematicians such as Gustave Choquet and Emil Artin.

The resolutions of the Zagreb-Dubrovnik meeting were to the liking of the teachers of the *École Decroly*. In 1962, a few months after the publication of the official proceedings *Synopses for Modern Secondary School Mathematics* (OEEC, 1961), a pedagogical conference was organized by the Belgian Ministry of Education at the *École*. In her opening speech, Libois-Fonteyne proudly announced that the main conclusions of Zagreb-Dubrovnik corresponded perfectly with Decroly's pedagogical principles, which had already been formulated in 1907 (Libois, 1962). She selected as main conclusions the unity of mathematics, the coordination of the teaching of mathematics with the teaching of other subjects (especially physics) and the personal activity of the student.

Meanwhile, from 1959, Georges Papy (1920–2011), a professor of algebra at the Free University of Brussels, had started experiments with the teaching of "his" modern mathematics at the secondary level (De Bock & Vanpaemel, 2019). Papy's experimental trajectory would expand year after year.

Papy developed a pioneering series of textbooks entitled *Mathématique Moderne* and organized large-scale in-service training for teachers every year. Papy's approach to modern mathematics was innovative, yet from the beginning based on axioms and in many ways opposite to what Libois stood for. Soon Papy's modern mathematics became the leading model for a reform of mathematics education in Belgium. It would lead to a generalized introduction of modern mathematics in secondary schools (from September 1968 on) and, about ten years later, in primary schools.

At that same period, Libois continued working closely together with the *École*'s secondary section, both by advising the team of mathematics teachers and acquainting its members with new mathematical ideas. He also helped the students prepare annual exhibitions on mathematical themes. The alternative "experiments" of Libois continued to attract the attention for several years of a number of Belgian and foreign circles. Until the mid-1970s, Emma Castelnuovo (1913–2014) and many young Italian mathematics teachers came regularly to Brussels to visit the mathematical exhibitions prepared by Libois' students (De Bock & Vanpaemel, 2019). Libois' ideas, however, would not penetrate widely.

In conclusion

Before WW II, Decroly's views on mathematics education were quite influential in Belgian publicly-run primary schools, as they were in secondary schools in the 1950s. From the 1960s this influence waned as Papy's modern mathematics became dominant. However, in the 1980s, after the fall of modern mathematics, realist/constructivist ideas made their entrance (again) in Belgian primary and secondary schools (De Bock et al., 2020a, 2020b). These ideas had much in common with those of Decroly, but were then attributed to the Dutch model of realistic mathematics education.

Papy's minicomputer

Wendy Goemans[1] and Dirk De Bock[1]

[1]KU Leuven, Faculty of Economics and Business, Leuven, Belgium; wendy.goemans@kuleuven.be

Georges Papy and Frédérique Papy-Lenger are well known for their involvement in the Belgian and international modern mathematics movement from the late 1950s to the early 1970s. Less well known is a teaching aid invented by Papy and disseminated by Papy-Lenger: Papy's minicomputer. In this paper we present Papy's minicomputer, how it was created and how it works, and we illustrate its reception and use by teachers and teacher trainers in the 1970s. We consult sources authored by the Papys and by contemporaries. Moreover, we discuss recent literature on Papy's minicomputer and link it to the concepts of computational thinking and gamification.

Keywords: Frédérique Papy-Lenger, Georges Papy, minicomputer, modern mathematics.

Introduction

From the late 1950s to the early 1970s, Georges Papy and Frédérique Papy-Lenger were two of the most important Belgian protagonists in the modern mathematics movement. The Papys played a major role in the introduction of modern mathematics into the Belgian school curriculum by conducting classroom experiments, by (co-)organising meetings and training courses for teachers, and as authors of textbooks and as (co-)founders and/or active participants at meetings of national and international organizations. For extensive information on the Papys, their achievements and their detailed role in the Belgian and international modern mathematics movement, see De Bock (2022, 2023) and De Bock and Vanpaemel (2019).

At the end of the 1960s, when modern mathematics was introduced into the secondary school curricula in Belgium, the Papys' attention shifted from secondary to primary education. It is in this context that Papy provided young students with a teaching aid that allowed them to perform large number calculations almost effortlessly: minicomputer. G. Papy (1968) explains how he was inspired by the numbers of Mgr. Georges Lemaître for the construction of his minicomputer[1]. Papy's minicomputer is a non-mechanical two-dimensional abacus based on a binary number system combined with a decimal position system. Paraphrasing Papy, Jean-Claude Matthys stated, "PAPY has invented Minicomputer. He has also composed some of its major masterpieces. FREDERIQUE was the privileged and most inspired interpreter" (Kennes, s.d., no pagination, capitals in the original)[2].

In this paper, we present Papy's minicomputer and how it was used in mathematics education in the 1970s. We also outline how Papy's minicomputer relates to current research in mathematics education. More specifically, Bell and Hickman (2025) promote the teaching of binary numbers

[1] Mgr. Lemaître (1894–1966), a Belgian physicist, posthumously called the father of the Big Bang theory, proposed in 1955 new numbers and rules to perform effortlessly calculations, see e.g. G. Papy (1968).

[2] All translations are made by the authors.

because, according to them, these are the atoms of the digital world. They write mainly about how teaching binary numbers can explain the limitations of technology, but they also refer to how it exercises aspects of computational thinking. Although computational thinking is often associated with solving problems in computer science, it is also intertwined with mathematical thinking. Chan et al. (2023) conducted a literature review on the integration of computational thinking in mathematics education. They identify games as an important tool for computational thinking. Therefore, we mention how Papy's minicomputer was used by Papy-Lenger in gamification in the 1970s and how it can be related to the concept of computational thinking.

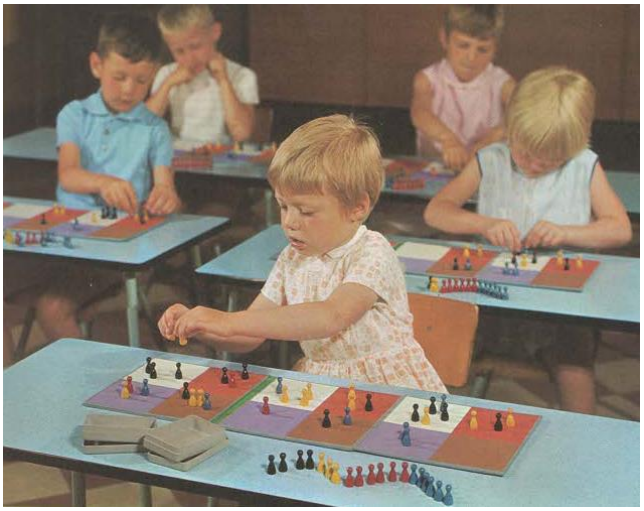

Figure 1: Children at work with Papy's minicomputer (G. Papy, 1968, p. 9)

Theoretical framework

To study the early years of Papy's minicomputer, we first consult documents authored or co-authored by Papy or Papy-Lenger. In addition, we check *Nico*, a journal for teachers which was published by the *Centre Belge de Pédagogie de la Mathématique* (CBPM) and edited by Papy-Lenger (De Bock & Vanpaemel, 2019). The references in these primary sources, as well as additional sources found via the online database GoogleScholar using the keywords 'Papy' and 'minicomputer', are then studied. In doing so, we aim to answer the following research questions: What is Papy's minicomputer? How was Papy's minicomputer received and used?

At the same time, recent literature on Papy's minicomputer is found by searching the online database GoogleScholar. Although scarce, these sources allow us to explore what remains of the potential uses of Papy's minicomputer. We also link Papy's minicomputer to the concepts of computational thinking and gamification. Chan et al. (2023) point out that there is no single definition of computational thinking, but that a definition of computational thinking depends on the subject in which it is integrated. Broadly speaking, computational thinking is the process of thinking required to arrive at a solution to a problem that can then be executed by an information processing agent such as a human, computer or machine. According to Chan et al. (2023), the most assessed computational thinking competency in mathematics education is algorithmic thinking.

Papy's minicomputer

Papy's minicomputer is not an electronic device, but a conceptual, non-mechanical, two-dimensional abacus. F. Papy (1969) describes Papy's minicomputer as a two-dimensional abacus that harmoniously uses the binary number system internally on plates that are organised according to the decimal position system. Papy's minicomputer consists of sequentially arranged square plates divided into four equal, coloured, squares, see Figure 1.

From right to left, the different plates represent the digits of a number, as in a decimal position system. Within each plate the binary number system is used, the white square at the bottom right represents $1 = 2^0$, the red square at the bottom left represents $2 = 2^1$, the purple square at the top right represents $4 = 2^2$, and the brown square at the top left represents $8 = 2^3$. A number is represented by placing a pawn on the correct squares, see Figure 2, which shows the number 697 represented on Papy's minicomputer.

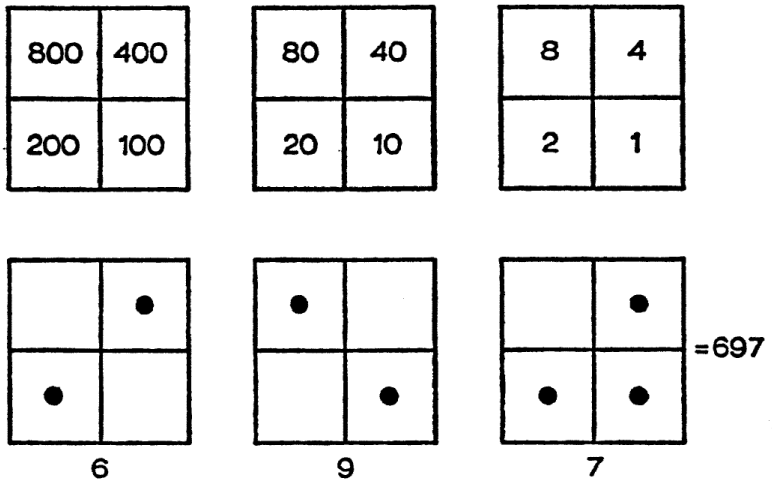

Figure 2: Representation of the number 697 on Papy's minicomputer (F. Papy, 1969, p. 333)

Some may immediately associate the colours of Papy's minicomputer with the corresponding Cuisenaire rods, a teaching aid consisting of blocks of different length and colour, representing the numbers 1 to 10, see for example De Bock and Vanpaemel (2019). This link is justified, as Papy used the same colours in his minicomputer as the corresponding Cuisenaire rods to honour Georges Cuisenaire, see G. Papy (1968, 1975). The first reaction F. Papy (1969) reports on when presenting the results of an experiment that she carried out with Papy's minicomputer in 1967 with 6-year-olds, is "– OH! CE SONT NOS COULEURS!" [Oh! It are our colours!] (p. 333, capitals in original), the child expressing his recognition of the correspondences of the colours with those of the Cuisenaire rods. However, Christiane Vandeputte (personal communication, August 22, 2024), who was for many years a close collaborator of the Papys, stresses that both she and Papy-Lenger observed that the introduction of Papy's minicomputer was easier without the reference to the Cuisenaire rods.

If the binary number system is used purely, then on one square plate subdivided in four equal squares one can represent the numbers 0 to 15, that is, $16 = 2^4$ numbers in total. See for example Figure 3 (left) for a representation of 12 on one plate. As can also be seen from Figure 3 (left), the

representation of a number on Papy's minicomputer is not necessarily unique. Therefore, G. Papy (1968) introduces two definitions. Firstly, every disposition of pawns on Papy's minicomputer represents a number. Secondly, a formation is a disposition that allows the number it represents to be read immediately. For example, the first two lines in Figure 3 (left) are a formation of the number 12, while the other four lines are dispositions but not formations. Figure 2 shows the formation of 697.

Under the title "Secrets of minicomputer" (G. Papy, 1968, p. 53), Papy states that "A disposition is a formation if and only if on all the plates: 1 - never more than one pawn per square, and, 2 - if there is a pawn on the brown, then there is no pawn on the red and no pawn on the purple" (p. 54). G. Papy (1968) continues with "If, for every disposition you are able to find the formation that is equal to it, Then you are able to perform any calculation on MINICOMPUTER" (p. 54, capitals in original). To transform a disposition into a formation, one can apply four reduction rules, see Figure 3 (right). G. Papy (1968) points out that, if a child applies the reduction rules correctly, then it will always have a disposition on its minicomputer that represents the same number, regardless of how many steps forward or backward, even useless steps, the child applies. In this respect, the only really important strategic rule is to apply reduction rule R4 as soon as possible.

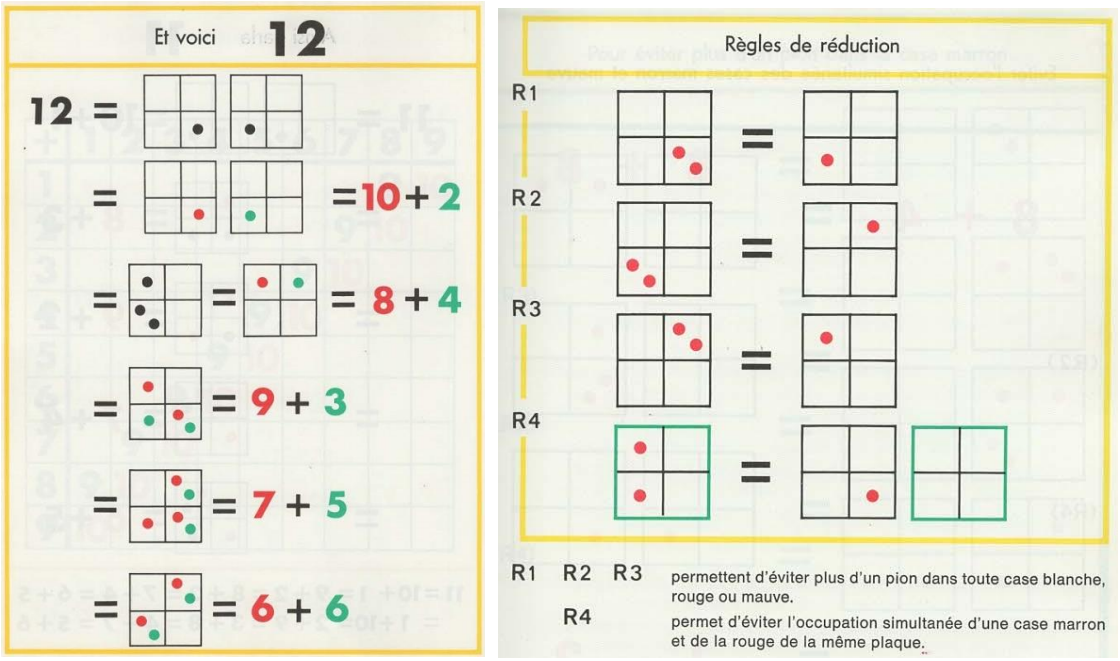

Figure 3: Reduction rules on Papy's minicomputer (G. Papy, 1968, pp. 44 and 55)

Once you know the reduction rules, you can start calculating with Papy's minicomputer. For an explanation on how to add, multiply, subtract and divide two natural numbers using Papy's minicomputer, see e.g. Herbert (1984), G. Papy (1968), Quevedo et al. (2017), Socas Robayna and Espinel Febles (1989), or Van Arsdel and Lasky (1972).

Papy's minicomputer during its first three decades

After F. Papy's (1969) presentation of Papy's minicomputer at the First International Congress on Mathematical Education (ICME-1) in Lyon, France, in August 1969 and on the 48th annual meeting

of the NCTM in Washington, DC, in April 1970, Papy's minicomputer attracted the attention of several teachers, teacher trainers and education specialists. For example, Van Arsdel and Lasky (1972) explain how to calculate using Papy's minicomputer and stress the correspondence of the colours with the Cuisenaire rods. They consider Papy's minicomputer to provide an answer to Jerome Bruner's appeal for "a skill as a tool" (Van Arsdel & Lasky, 1972, p. 451).

Steiner (1974) on his turn, presents Papy's minicomputer as a grouping concept in the sense of Piaget. He applies Erich Wittmann's definition of a grouping, combining a group and a lattice[3] in a hybrid way, see Steiner (1974) and the references therein. Steiner gives some models of a grouping among which one that plays a role in the representation of numbers by means of the Cuisenaire rods, one that is involved in the pedagogical application of Dienes' blocks, one of linear equations that is linked to solving linear equations with Papygrams, and one considering the set of all dispositions of n for $n \in \{2, \ldots, 99\}$ on Papy's minicomputer.

Lots of the promotion of, and experiments with Papy's minicomputer took place in the large, but inner circle of Papy. One finds for example a dozen of articles on (experiments with) Papy's minicomputer in different volumes of *Nico*. We mention Dieschbourg (1974), who reports on his work with mentally handicapped children in primary schools and Vandeputte (1974), who discusses her experiences with cerebral paralyzed children. Both authors explain how the ideas of the Papys about Papygrams, arrow representations for relations, sets and Papy's minicomputer for the representation of numbers and calculations are applied to teach mathematics to children with special needs.

At ICME-1, Papy-Lenger also drew the attention of co-workers of Burt Kaufman, director of the Comprehensive School Mathematics Project (CSMP), see De Bock (2022). The New Math project CSMP aimed at modernizing both the content and the teaching methods of mathematics. From 1973 till 1978, Papy-Lenger was director of research of the CSMP (De Bock, 2022). In the final evaluation report of CSMP, Herbert (1984), we read that "the minicomputer, string pictures, and arrow diagrams" (p. i) [4] make up three representational languages that are used frequently throughout the program. Herbert (1984) gives also examples of the CSMP teacher's guide. These include two games invented by Papy-Lenger to get children to do arithmetic in a playful way using Papy's minicomputer. By playing these games, *Minicomputer Golf* and *Tug of War* (rope pulling), individually or in competing teams, children do arithmetic and develop computational skills while playing a game, which is now called gamification (Quevedo et al., 2017).

Herbert (1984) reports on the development of CSMP, its content and organization, training and coordination and on CSMP materials. The latter were in 1974 sent to five academical reviewers, of which three were positively impressed by most of the content and the applied representational languages, except about Papy's minicomputer. As a matter of fact, all five reviewers expressed a negative opinion on the use of Papy's minicomputer, with the worst quotes being "a horrible

[3] A lattice is an ordered set in which there exist specific least upper bounds and greatest lower bounds, see Steiner (1974).

[4] String pictures are Venn diagrams.

aberration" and "a disaster of the first magnitude" (Herbert, 1984, p. 30). In the summary of these external reviews, one reads "All five reviewers are dubious to very negative on the minicomputer's mixture of a binary and decimal base" (Herbert, 1984, p. H-1, underlining in original).

The negative opinion of the five CSMP reviewers is the only documented unfavourable perception of Papy's minicomputer that we could find. However, from the interview with Papy that is available on Kennes (s.d.), we deduce that, in Belgium, critical voices about the price of Papy's minicomputer existed, as well as about the necessity to retrain teachers. Both arguments are rebutted by Papy, one can use paper and pawns to fabricate one's own cheap minicomputer, see also G. Papy (1975), and experiences in CSMP show that only a few hours are needed to initiate teachers to use minicomputer.

Compared to the sources discussed so far, Socas Robayna and Espinel Febles (1989) take the use of Papy's minicomputer to a higher level. On the one hand these authors do not limit themselves to the basic calculations of addition, subtraction, multiplication and division, but also show how to calculate powers, square roots, and logarithms with Papy's minicomputer. On the other hand, they present the corresponding algorithms in the form of flowcharts and make explicit reference to what is now called computational thinking, "developing one's own strategy and stimulating creativity" and "the use of flowcharts is a means of telling a machine how to operate, which allows the development of fundamental programming skills" (Socas Robayna & Espinel Febles, 1989, p. 60).

Recent research on Papy's minicomputer

Recent literature on Papy's minicomputer is scarce and almost exclusively found in languages other than English. An interesting example is provided by Dassie and Costa (2020), who describe the Brazilian production of Papy's minicomputer, and, using press articles and records of Papy's visit to Rio de Janeiro in 1971, link this to a discussion of the modern mathematics movement in Brazil. For additional information on the latter, we also refer to chapters 19 and 20 in De Bock (2023).

From Soares Silva Teixeira (2017) we learn that Papy's minicomputer is still being used in the first cycle in some primary schools in the greater Porto area in Portugal. Two teachers who use Papy's minicomputer describe how their students love this teaching aid and how it helps them to become fluent in mental arithmetic. They emphasize that Papy's minicomputer is very useful in teaching the place value system and that it increases the student's awareness of the structure of numbers (e.g. $7 = 1 + 2 + 4$). During classroom observations Soares Silva Teixeira (2017) witnessed the ease with which the students manipulated Papy's minicomputer, it was not quiet in the classroom, but the students were all actively participating in the mathematical activity. Finally, an intervention study with Papy's minicomputer was carried out with a group of 12 students. Afterwards, in a survey, they reported an overall very positive attitude towards learning with Papy's minicomputer.

Quevedo et al. (2017) first present Papy's minicomputer and its reduction rules and then describe the Minicomputer Golf and Tug of War games we mentioned earlier. Similarly, Mladinić (2020) presents arithmetic problems on Papy's minicomputer. However, the reduction rules are not explained, so part of the original design of Papy's minicomputer and its goal of performing large number calculations almost effortlessly, are lost in this way. Similar remarks apply to the games Minicomputer Golf and Tug of War, which were extensively implemented in the CSMP material (Herbert, 1984). In

retrospect, one can wonder if this was the reason for the negative reception of Papy's minicomputer by the reviewers of the CSMP material. If Papy's minicomputer is deprived of its reduction rules and its goal of obtaining a formation, all that remains is a rather cumbersome notation for a number.

Conclusion

We have presented an overview of how Papy's minicomputer was constructed and how it works. Additionally, we provided some examples of experiments that were carried out with Papy's minicomputer. Due to space limitations, we could not discuss all sources on Papy's minicomputer, so we encourage the interested reader to consult the bibliographies of the references. However, to the best of our knowledge, we believe to have touched upon a broad range of aspects of Papy's minicomputer and to have discussed the key references. It is remarkable to see in how many different countries Papy's minicomputer has appeared as a teaching tool and we were surprised to learn that it is still used nowadays in for example some schools in Portugal, see e.g. (Soares Silva Teixeira, 2017).

We believe it might be interesting to consider the use of Papy's minicomputer as a gamification tool to evoke or train computational thinking. However, one should be careful not to use Papy's minicomputer in a way which was perceived unfavourably in the past. Moreover, keeping in mind Bell and Hickman (2025), if one would apply Papy's minicomputer, then its internal binary number system should be stressed more.

Acknowledgment

The authors are very grateful to Francis Lowenthal and Christiane Vandeputte for their warm hospitality and for their donation of several documents and materials, among which a copy of G. Papy (1968) and a version of Papy's minicomputer by Ivac. Many thanks also to Antonio Oller-Marcén and Alexandra Sofia Rodrigues for bringing under our attention and providing us with a copy of (Socas Robayna & Espinel Febles, 1989) and (Soares Silva Teixeira, 2017), respectively.

The study researches how geometry proofs were approached in Brazilian educational regulations and textbooks between 1930 and 1970, focusing on 13-year-old students. Comparing two modern periods, the first influenced by CIEM in 1908 and the second by the Modern Mathematics movement in 1959, four representative textbooks of the period are analyzed. The results reveal that, despite the reforms proposing more intuitive approaches, the traces of practices remained centered on deductive geometry with an emphasis on memorizing theorems until the 1950s. Only with the insertion of Modern Mathematics, especially in Sangiorgi's book in the 1960s, there was an attempt to break with traditional practices, introducing more experimental and innovative methods. This situation highlights the resistance and adaptations of Brazilian school culture in the face of international movements for pedagogical renovation.

Keywords: Demonstrations, Intuitive Geometry, Deductive Geometry, Two-column proofs, Secondary education.

Introduction

The study in question aims to analyze how geometry proofs, introduced to 13-year-old students, were approached in educational regulations and textbooks, between the years 1930 and 1970, firstly in the Brazilian context in general and, later, focusing on the state of São Paulo, in the southeast area of the country. Two ideas of international scope circulated in the period examined: the first, represented by the creation of the Commission Internationale de l'Enseignement Mathématique (CIEM) at the IV International Congress of Mathematicians, held in Italy, in 1908; and the second, promoted by the Organisation for European Economic Co-operation (OEEC), Royaumont Seminar, in France, in 1959. In Brazil, these movements were characterized as modern initiatives in mathematics teaching, bringing together representatives from different countries, producing curricular guidelines, and being appropriate to the Brazilian educational context, both in regulations and textbooks. The aim is to answer – how do international movements contribute to the introduction of the study of proofs? What changes can be observed during this period regarding introductory proofs exercises?

The theoretical and methodological contribution of this study is based on research on the international circulation of pedagogical ideas, which since the 19th century has created a vast system of exchanges and mutual observations, structured by pedagogical missions (Matasci, 2016). From the 20th century onwards, international scientific congresses and the creation of commissions to discuss new Mathematics teaching programs enable the continuity of cultural transfers, covering the circulation

of educators, experiences, books and knowledge between different countries. Although the centrality and relevance of European culture is recognized in these two international movements, led by influential mathematicians, the debates and recommendations formulated in these spaces gained global visibility, crossing the Atlantic and becoming important references for Brazilian educational reforms. It is important to highlight, however, that these guidelines were adapted to the local context, considering that, as Chartier (2009) argues, the reception of dominant cultural models does not negate the negotiation with deeply rooted shared traditions, even when new disciplines or norms are introduced.

The present study aims to understand the process of appropriation (Chartier, 2009) of two modern ideas by Brazilian school culture, separated by an interval of 50 years. The focus of the analysis is on the proofs processes in geometry, which throughout this period were introduced in secondary education, starting at 13 years old.

1st modern movement – 1908

Schubring (2003) points out that the official from CIEM guidelines, led by Felix Klein, proposed the inclusion of basic notions of variable quantities and functional dependence on mathematical concepts, in addition to a methodological reorientation with an emphasis on intuition and practical applications. Although Brazil did not participate in the IV Congress of 1908 in Rome, teacher Eugênio de Barros Raja Gabaglia (1862-1919), from Colégio Pedro II (founded in 1837 and a reference in the constitution of Brazilian secondary education), represented the country in the V International Mathematics Congress, in England, in 1912 (Schubring, 2003). However, it's possible that Gabaglia did not bring international discussions and proposals for reforming mathematics teaching to the Brazilian community, as no significant changes were incorporated into the programs at Colégio Pedro II in the 1910s and 1920s (Valente, 2003). It was necessary to wait until 1930s for the proposals of 1st modern movement were inserted in the official program of secondary school through the Francisco Campos Reform, in 1931. This happened through another teacher at Colégio Pedro II, Euclides Roxo (1890-1950), who, for the first time, introduced the subject of mathematics as an integrated unit, bringing together arithmetic, algebra and geometry, aligned with the recommendations that:

> Starting from the living and concrete intuition, the logical feature will grow, little by little, until it gradually reaches formal exposition; [...] knowledge will be acquired, at first through experimentation and sensory perception and then, slowly, through analytical reasoning. Thus, regarding geometry, the formal demonstrative study must be preceded by a propaedeutic course, aimed at intuitive teaching, of an experimental and constructive nature (Bicudo, 1942, p. 157).

The 1931 Reform didn't last long and was replaced in 1942 by the Capanema Reform, keeping the division between intuitive and deductive geometry. In 1951, through the Simões Filho Reform, geometry teaching was reduced to the final school years. The three reforms prescribed deductive geometry, that is, the introduction to the study of proofs in geometry for 13-year-old students, as shown in Table 1. The analysis of this table indicates the sign of deductive geometry, preceded by an intuitive preparation, aligned with the modern movement, in the reforms of 1931 and 1942; however, in 1951, geometry loses space in the program and in the intuitive approach.

Table 1: Geometry in programs prescribed for students aged 11 to 14 (1931-1951)

Reform	Geometry organization	Instructions
1931	*Geometric Initiation Geometry*	- Starting from intuition to **gradually reach** formal exposure: from experimentation and sensory perception to analytical reasoning
1942	*Intuitive Geometry Deductive Geometry*	- Intuitive geometry as a **smooth transaction** between experiences with shapes and deductive conception of Geometry
1951	*Geometry* (13 and 14 years old)	- **Gradually awaken** the feeling of the need for justification and proof

2nd modern movement – 1959

According to Kilpatrick (2012), between 1950 and 1970, there were several attempts to change mathematics teaching under the name "Modern Mathematics" (MM) or "New Mathematics", with the aim of aligning school mathematics with scientific mathematics of the 20th century. The creation and elaboration of textbooks by the School Mathematics Study Group (SMSG), in 1958, in the United States of America (USA) and the holding of the Royaumont Seminar, organized by the Organisation for European Economic Co-operation (OEEC) and held in 1959, in France, followed by the publication of the modern program for secondary education, are important milestones for Brazil. The teaching of geometry was the subject of intense debates; at least two trends can be mentioned. The first one, prepared by Birkhoff, proposed the change of Euclid's axioms, preserving Euclidean geometry. The second trend recommended the development of geometry through geometric transformations, that according to our understanding, is related to Klein's ideas.

In 1960, teacher Osvaldo Sangiorgi (1927-2017), author of widely circulated textbooks in Brazil, completed an internship in the USA. Upon returning, in 1961, he created the Mathematics Teaching Study Group (GEEM), in São Paulo, in the southeast area of the country, inspired by Birkhoff. The first collection of textbooks published with a modern approach was prepared by Sangiorgi, having great repercussion, especially in the state of São Paulo (Valente, 2008). On the other hand, the second trend of geometry through geometric transformations (GT) is also gaining space in Brazilian textbooks. The study by Leme da Silva and Jahn (2024) analyzed four textbooks by authors considered leaders in MM in Brazil and concluded that there was a diversity of approaches: two of them included GT in the appendix, one presents a complete and formal treatment of GT (with one of the main authors having made visits to several European countries in the 50s), and a fourth one includes only symmetry and homothety, aiming to integrate it with Euclidean geometry, as these transformations facilitate the study of the notions of congruence and similarity of figures.

Still in 1961, the Brazilian National Education Guidelines and Bases Law (LDB 4,024/61) decentralized national programs, allowing each state to develop its own programs. In this way, the state of São Paulo was a pioneer in incorporating MM ideas into its program published in 1965, which was the subject of discussion within the scope of GEEM. The 1965 program resumed the intuitive study of geometry only in the 1st grade of secondary education and kept deductive geometry in the 3rd grade, for 13-year-old students.

To compare with the normative guidelines, we analyzed four textbooks representative of the period, all aimed at the 3rd year of secondary education (for 13-year-old students), in which the study of proofs in geometry was introduced. The first two books are part of the collections "Curso de Matemática" (Roxo et al., 1936) and "Matemática Ginasial" (Roxo et al., 1944), both prepared by Euclides Roxo, Júlio Cezar de Mello e Souza, and Cecil Thiré, all teachers from Colégio Pedro II, which makes the collection a reference for the period. The other two books make up the collections “Mathematics curso ginasial” (Sangiorgi, 1958) and “Matemática curso ginasial” (Sangiorgi, 1967), both authored by Osvaldo Sangiorgi, equally representative in the 1950s and 60s. In methodological terms, we analyzed the content of the textbooks, focusing on the criteria: how deductive geometry is introduced, which proof methods are used, the language applied, how the proof of base angle of isosceles triangles theorem is carried out and the exercises proposed to students.

Analysis of introductory proofs exercises

We present a study that examines the approach to proofs in two sets of textbooks by different authors, which were designated according to the decades of publication. The first set is made up of textbooks by Roxo et al., which we call Book 01 (1930s) and Book 02 (1940s). These texts allow us to understand how the authors integrated the proofs exercises into the regulations of the 1st modern movement. The second set analyzes Sangiorgi's textbooks, called Book 03 (1950s) and Book 04 (1960s). The first set represents the pre-modern period and the second one allows us to examine the appropriation of 2nd modern movement by the author. Our goal is to identify possible changes in the introduction to deductive geometry and how geometric properties are justified or validated.

Proofs exercises – 1st modern movement – 1930s and 1940s

Books 01 and 02 have many similarities in their approach to geometry, the authors present an introduction to the study of deductive geometry, consisting of an explanatory text containing definitions and principles of a deductive axiomatic system for geometry. The terms "proposition", "axiom", "postulate", "theorem" and "definition" stand out. The exercise of proving is understood as "proving the proposition, showing, through a chain of reasoning, that the thesis necessarily results from the hypothesis" (Roxo et al., 1936, p. 202).

In Book 01, the authors warn that "it is not possible to establish a general method for demonstrating all geometry theorems" (Roxo et al., 1936, p. 206), and promise to present different forms of proof in subsequent chapters, and thus promote deductive thinking. In Book 02, two additional topics on mathematical validations are introduced: "Proof methods", which covers direct and indirect proofs, and "Reduction to absurdity", with examples of proofs. A comparative analysis reveals the primary distinction between the two books lies in the significant expansion in the number of proposed exercises, especially those involving proofs; this difference may stem from Book 01 being seemingly aimed at teachers, while Book 02 more explicitly targets students. In Book 02, the terms “demonstrate”, “prove” and “show” are used as synonyms in the statements of the proof exercises.

Due to space limitations in this article, we focus our detailed analysis on triangles, which correspond to the first topic that approaches proofs in geometry. In the study of triangles, the notion of congruence is introduced, along with the cases of congruence of triangles presented as theorems, all demonstrated

in both books. Other properties of triangles are presented, all involving the application of congruence cases to their respective proofs. Figure 1 illustrates the proof of the property of equality of the base angles in an isosceles triangle in Book 01 (on the left) and 02 (on the right).

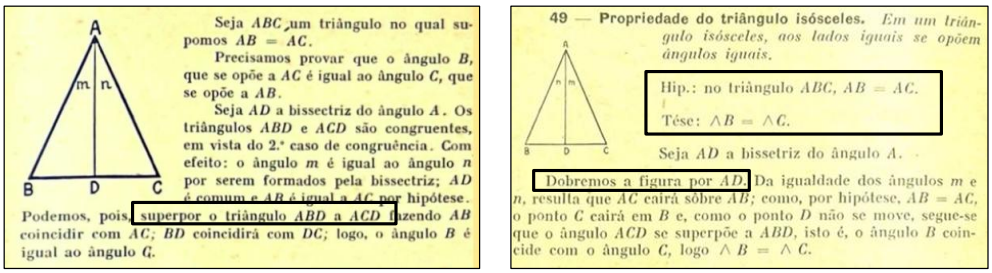

Figure 1: Proofs of property of isosceles triangle (Book 01, p. 235; Book 02, p. 168)

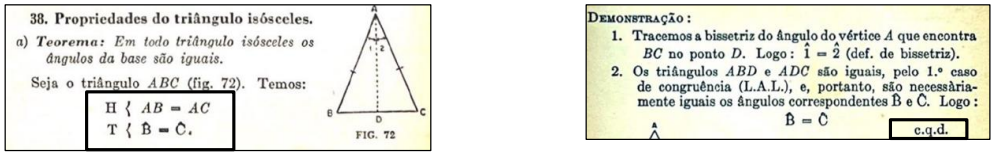
Some differences are noted between the proofs. In Book 01, the authors write in natural language, explaining the starting point and what they want to prove. The proof is justified by mobilizing the 2nd case of congruence, but appeal is also made to the superposition of triangles. In Book 02, the terms hypothesis and thesis, absent in Book 01, are clearly explained, and the proof is inserted in a more concise language, for example, to indicate the angles, the congruence of triangles is not used, the justification is supported by intuition and use of action resources, as in the expression "Let us fold the figure" (Roxo et al., 1944, p. 168). In the exercises in Book 02, before students are asked to do proofs, exercises are proposed such as "Separate the hypothesis and thesis into each of the following propositions, translating them symbolically when possible" (Roxo et al., 1944, p. 138), reinforcing the starting and ending point and the mathematical language.

Proofs exercises – pre-modern and MM – 1950s and 1960s

The regulations of the 1950s restrict the teaching of geometry to the final two grades of secondary school. In Book 03, Sangiorgi announces that experimental geometry was created in the primary course and that, for the secondary course, a deductive geometry is reserved. The emphasis on the exposed theorems and exercises for students to do the proofs follows the approach of Book 02, the terms "intuitive and deductive propositions", "axiom or postulate", "theorem and proof" are introduced (Sangiorgi, 1958, p. 85), reducing the appeal to intuitive aspects. However, the mathematical language used in the hypothesis and thesis is even more concise, the proof process is justified by numbered steps. The term "Let's fold the figure" (figure 1, on the right) is replaced by "Let's draw the bisector of the angle of vertex A" (figure 2, on the right), the justifications are done in parentheses and, at the end, there is the acronym c.q.d (as we wanted to demonstrate). The appeal to the movement and superposition of the obtained triangles cannot be further highlighted, the justifications highlight definitions and properties already stated.



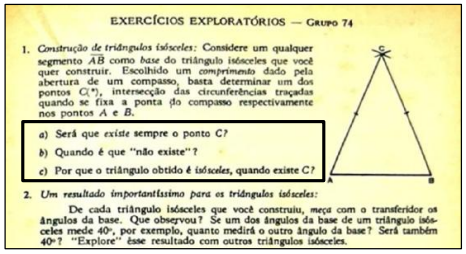


Figure 2: Proofs of property of isosceles triangle (Book 03, p.119-120)

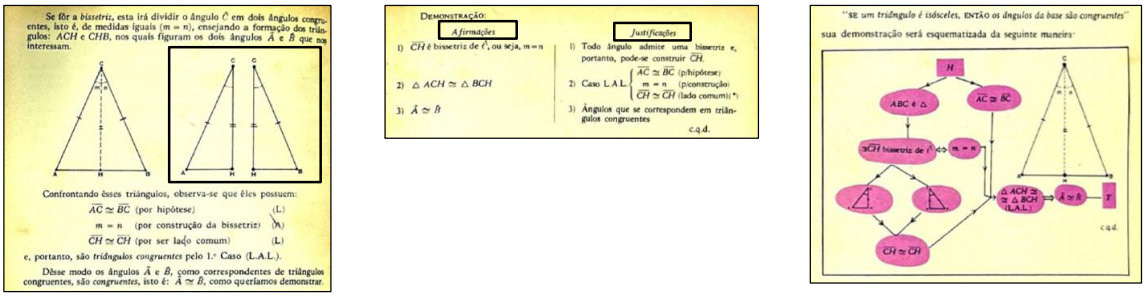
We can identify, in Book 03 (1950s), that the evidence is presented using symbolic language, containing more formal aspects in terms of its content. Certainly, such aspects must have contributed to the debate about students' difficulties in understanding geometry proofs getting more space at the National Congress of Mathematics Teaching, in 1957, reporting a practice of "memorizing theorems" used by students to obtain a grade in evaluations (Búrigo, 2015).

Jahn & Leme da Silva (2023) carried out a comparative study of Sangiorgi's Books 03 and 04 and indicated a significant difference between them. Book 04 brought an innovative proposal for the treatment of proofs in geometry, reduced the number of theorems demonstrated, inserted exploratory exercises, as well as new representations used in the proofs. We can realize that, in Book 04, the study of triangles is carried out before the introduction of deductive geometry, in a previous chapter, aimed at intuitive and experimental geometry. There are no proofs of theorems, but a predominance of "exploratory exercises", such as the construction of the isosceles triangle and the exploration of its existence and the measurements of the base angles (cf. figure 3) so that the student "figures out" (or conjectures) experimentally the properties involved.

EXERCÍCIOS EXPLORATÓRIOS — GRUPO 74

1. *Construção de triângulos isósceles:* Considere um qualquer segmento $\overline{AB}$ como *base* do triângulo isósceles que você quer construir. Escolhido um *comprimento* dado pela abertura de um compasso, basta determinar um dos pontos C(*), intersecção das circunferências traçadas quando se fixa a ponta do compasso respectivamente nos pontos A e B.



a) Será que *existe* sempre o ponto C?
b) Quando é que "não existe"?
c) Por que o triângulo obtido é *isósceles*, quando existe C?

2. *Um resultado importantíssimo para os triângulos isósceles:*
De cada triângulo isósceles que você construiu, meça com o transferidor os ângulos da base. Que observou? Se um dos ângulos da base de um triângulo isósceles mede 40°, por exemplo, quanto medirá o outro ângulo da base? Será também 40°? "Explore" êsse resultado com outros triângulos isósceles.

Figure 3: Exploratory exercise on isosceles triangles (Book 04, 1967, p. 207)

The demonstration of the base angle theorem of an isosceles triangle illustrates well the changes proposed by Sangiorgi in Book 04. Only after having proposed several exploratory exercises, involving the construction of isosceles triangles, the cases of congruence, and encouraging students to look for a valid property in all of them, is that the proof is presented. The cases of congruence, proven as theorems in Books 01, 02 and 03, are considered postulates in Book 04, after having been studied in exploratory exercises.

In addition to the introductory study, the author uses new methodological strategies for the proofs, such as the proof on the left of figure 4 that separates the triangles, organizes the justifications and at the end writes "how we wanted to demonstrate"; two columns proof (statements and justifications, see figure 4, central) and the proof through drawn schemes (figure 4, right).

Se fôr a *bissetriz*, esta irá dividir o ângulo $\hat{C}$ em dois ângulos congruentes, isto é, de medidas iguais ($m = n$), ensejando a formação dos triângulos: ACH e CHB, nos quais figuram os dois ângulos $\hat{A}$ e $\hat{B}$ que nos interessam.

Confrontando êsses triângulos, observa-se que êles possuem:

$\overline{AC} \simeq \overline{BC}$ (por hipótese) (L)
$m = n$ (por construção da bissetriz) (A)
$\overline{CH} \simeq \overline{CH}$ (por ser lado comum) (L)

e, portanto, são *triângulos congruentes* pelo 1.º Caso (L.A.L.).

Dêsse modo os ângulos $\hat{A}$ e $\hat{B}$, como correspondentes de triângulos congruentes, são *congruentes*, isto é: $\hat{A} \simeq \hat{B}$, como queríamos demonstrar.

DEMONSTRAÇÃO:

Afirmações	*Justificações*
1) $\overline{CH}$ é bissetriz de $\hat{C}$, ou seja, $m = n$	1) Todo ângulo admite uma bissetriz e, portanto, pode-se construir $\overline{CH}$.
2) $\triangle ACH \simeq \triangle BCH$	2) Caso L.A.L. $\begin{cases} \overline{AC} \simeq \overline{BC} \text{ (p/hipótese)} \\ m = n \text{ (p/construção)} \\ \overline{CH} \simeq \overline{CH} \text{ (lado comum)} \end{cases}$
3) $\hat{A} \simeq \hat{B}$	3) Ângulos que se correspondem em triângulos congruentes

c.q.d.

"SE *um triângulo é isósceles*, ENTÃO *os ângulos da base são congruentes*" sua demonstração será esquematizada da seguinte maneira:

Figure 4: Proofs of properties of isosceles triangles (Book 04, 1967, p. 240-241)

The way in which Sangiorgi (1967) proposes the study of proofs for 13-year-old students is unprecedented in Brazil and, most likely, was conceived based on the contact he established in the USA with study groups, with North American textbooks and with researchers involved in Modern Mathematics. Herbst (2002) reports that, in the USA, two column proofs became a common practice among textbook authors since the beginning of the 20th century, remaining present for a long period in North American textbooks.

Sangiorgi also highlights in Book 04: "Don't 'memorize' proof of theorem! Value yourself, using any of the methods presented. Do it your way, using to these methods and you will be accomplishing in mathematics!" (Sangiorgi, 1967, p. 258). Certainly, the call for the student to do their own proof means explaining that the student can create personal ways of proving theorems, other than those carried out in books or presented by teachers.

Final considerations

Although regulations from 1930 onwards record the appropriation of the first modern movement, highlighting the need for an introductory intuitive study, at the end of the 1950s, secondary education was still dominated by deductive geometry. There is evidence that students memorized theorems, with almost no prior intuitive and experimental study. The analysis of textbooks also reveals a significant number of geometric proofs in Books 02 and 03, in addition to many exercises for students to do proofs. In summary, geometry teaching in the late 1950s and early 1960s was characterized by a strong emphasis on the logical-deductive process, resulting in students memorizing theorems.

The 2nd movement, referring to the ideology of the MM, seems to have had different appropriations. Regarding the introduction of proofs in geometry, they are not highlighted in the 1965 regulations, nor in the need to insert intuitive geometry, nor to emphasize changes in geometry validation processes. On the other hand, Book 04, which announces the modern approach, clearly indicates an attempt to break with sedimented practices of reproducing countless theorems, without prior experimentation, without meaning or understanding by students, and being translated by memorization of theorems.

When we analyze the period in question, we notice the persistence of traditional practices in teaching geometry, in which Euclidean proofs are considered standard of accuracy and, even though they are included in the regulations, they provoke reactions from teachers, book authors and students. It took a 2nd movement, perhaps Sangiorgi's closest contact with North American culture, to present different proposals for teaching proofs, at least in textbooks.

Mathematics for all, but what mathematics? Comparing the overlap of three coexisting curricula in the mid-20th century Spain

Antonio M. Oller-Marcén

Departamento de Matemáticas - IUMA, Universidad de Zaragoza, Zaragoza, Spain; oller@unizar.es

In Spain, primary and secondary education were not consecutive until the reform that took place in 1970. After the Spanish civil war (1936-1939), education was mandatory (on paper) for children until the age of 12. The 6-10 years period corresponded to primary education but, after that, students from 10 to 12 years old could follow three different itineraries: They could continue and conclude their primary education studies, they could shift to the so-called 'bachillerato universitario' [university baccalaureate] that eventually could lead to higher education, or they could join the so-called 'bachillerato laboral' [working baccalaureate] that was supposed to provide training for different types of jobs. In all cases, mathematics had an important role in the curricula. Here, examining textbooks and official documents, we show similarities and differences in the weight and intentionality given to the mathematics that were taught in these itineraries to students of the same age.

Keywords: Curricula, primary education, middle school, professional education, 20th century.

Introduction

According to Schubring (2015, p. 248): "true universalism can only then become effective when primary and secondary school levels became consecutive". In Spain, despite some previous advances in that direction, this condition for universalism was reached only in 1970. Until that reform, Spanish primary and secondary education overlapped in the 10-12 years period. Moreover, in the case of secondary education, two different itineraries existed, each of them aiming at students with different profiles and eventually leading to different specializations.

Mathematics was present and played a central role in primary education and in both secondary education itineraries. Considering their different goals and orientations, it can be relevant to compare the presence of mathematics in those three curricula, especially in the overlapping grades. Thus, we aim to answer the following research question: What were the differences in the treatment of mathematics according to the itinerary?

We will approach this question by considering different levels of the curriculum and, in particular, the intended and the implemented curriculum (Van den Akker, 2003). From the point of view of the intended curriculum (in official documents), we can focus on the weight of mathematics in the whole program, on the selection and sequencing of contents, on the methodological orientations provided to teachers, etc. On the other hand, from the point of view of the implemented curriculum (particularly in textbooks) we can focus on the treatment of topics and their relative importance, on the number and context of problems, etc. In this paper, we will pay especial attention to the grades corresponding to ages 10-12. This choice is motivated by the fact that this time interval corresponds to the overlapping of curricula taking place in the mandatory schooling period (ages 6-12). As we will see, between ages 6 and 10 there was a common primary education curriculum, and at the age of 10

children had to choose among three itineraries. Since age 12 was the upper bound for mandatory education, we believe that this 10-12 period gains particular interest for comparative purposes.

To carry out this research, we consider different sources of information. Regarding the intended curriculum, we have analyzed some of the official programs and syllabi which were in effect in Spain between 1950 and 1970. Regarding the implemented curriculum, here we have compared textbooks published by the publishing house Bruño, which was directly related to the De La Salle Brothers (officially Institute of the Brothers of the Christian Schools), a religious congregation that played an important role in the Spanish education at that time (Dávila & Naya, 2013).

Some background. Spanish primary and secondary education by 1960

In Figure 1 we provide a slightly simplified overview of the situation of Spanish primary and secondary education by the middle of the 20th century.

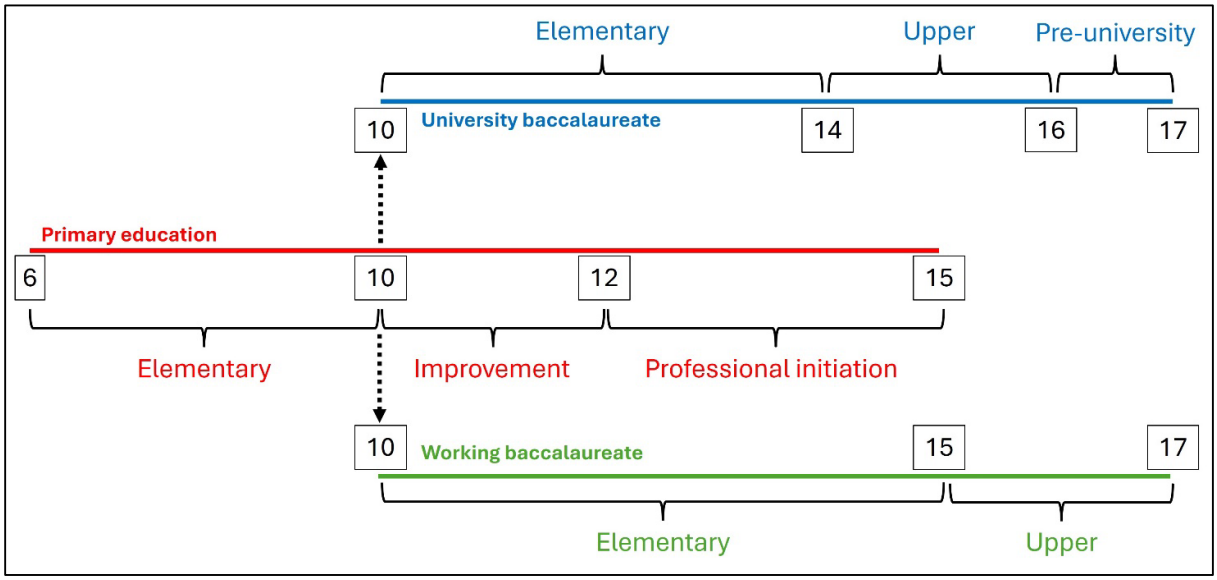

Figure 1: Spanish primary and secondary education by 1960

Education was mandatory for children between 6 and 12 years old. At the age of 10, they could decide whether to continue and conclude their primary education or to switch to any of the two possible itineraries of secondary education: university baccalaureate or working baccalaureate.

The students that continued their primary education could continue it past the age of 12, following the so-called grade of professional initiation that was supposed to provide useful knowledge to carry out certain jobs. After that, they could also enroll in industrial vocational learning util the age of 17 (to become an officer) or 19 (to become a master).

University baccalaureate, as its name suggests, was intended to be the itinerary for those students that wanted and could attend university or to special schools (architecture and engineering). The elementary period was common, and in the upper period the students could choose between a sciences or humanities specialization. Working baccalaureate was intended to provide specialized training for different activities such as agriculture, mining, secretariat, etc. In this baccalaureate there were

common subjects, while others depended on the chosen specialization. After completing their elementary grade, both baccalaureate itineraries could be left to enroll either into the Trade school (to follow studies roughly related to modern economy degrees) or into the Normal school (to become a primary education teacher).

Table 1: Number of students and gross enrollment ratio in Spain (Núñez, 2005)

	1950	1960	1970
Primary education	3,202,915 (66.9%)	4,033,592 (75%)	4,632,253 (74.1%)
Secondary education	214,874 (4.1%)	448,316 (8.77%)	1,286,335 (22.41%)

It is clear, then, that the itinerary followed by the students had a great impact on their future. Furthermore, for many years secondary education was only followed by a minority of students. Table 1 provides some illustrative data about this issue. As we can imagine, the path that a child followed was very often determined by sociological and economic reasons, and not by merit or ability. In fact, even if sometimes there existed mechanisms that connected some of the different itineraries, it was not very usual to move between them so that social mobility was not particularly easy.

Various official syllabi were published between 1950 and 1970. In the case of primary education, the first official syllabi were published in 1953, and they were later reformed in 1965 (Oller-Marcén, 2022). For university baccalaureate, official syllabi with different approaches were published in 1954, 1957 and 1967 (Ausejo, 2010). It seems that the case of working baccalaureate has not been addressed in the literature yet. As far as we know, the first complete official syllabi for this itinerary were published in 1956. Over time, new specializations for the upper period were approved, and their syllabi published (secretariat in 1958, horticulture in 1961, etc.).

The intended curriculum: presence and weight of mathematics

Mathematics was present as a mandatory subject in the nine grades (4 of the elementary period, 2 of the improvement period, and 3 of the professional initiation period) that constituted the primary education itinerary. In the case of university baccalaureate, mathematics was a mandatory subject only during the 4 grades of the common elementary period, while in the 3 remaining grades it was mandatory just for those students following the science option. Finally, in the case of the working baccalaureate, mathematics was a mandatory subject in the 7 grades (5 of the elementary period, and 2 of the upper period). However, the contents of grades 5, 6 and 7 were different according to the chosen specialization.

Regarding the weight of mathematics, in the case of primary education, the official documents from 1953 did not give any number of weekly hours to be devoted to teaching mathematics. According to Galera Pérez (2018) this number traditionally varied among schools, with a likely range of between 3 and 5 hours per week. Later, the 1965 reform established 3 weekly hours in grades 1 and 2, 4 weekly hours in grades 3 to 6, and 6 hours in grades 7 and 8. In the case of university baccalaureate, the official documents of 1953 stipulated 3 weekly hours during all the elementary period, then 6 weekly hours in grade 5, and 3 in grade 6 and pre-university. Finally, in the case of working baccalaureate,

official documents of 1956 stipulated 6 weekly hours of mathematics in grade 1 and 4 weekly hours in grades 2 to 5. During the upper period the number of weekly hours greatly varied according to the specialization.

The intended curriculum: methodological orientations

Official curricula were always accompanied by rather detailed methodological orientations. Sometimes they give indications to the teachers about how to treat certain particular mathematical topics. In other cases, and more interestingly, they provide more general observations about methodological approaches, providing some connections, elaborating on the purpose of teaching mathematics, etc.

In Table 2 we give some excerpts dealing with logical reasoning and abstraction in the different itineraries. We see that, in primary education, the orientations talk about "reasoning well" and there is no further mention of logical reasoning. In fact, the orientations for ages 10-12 explicitly recommend that teachers "avoid difficult proofs". In the case of the working baccalaureate, cultivating logical deductive reasoning is overtly rejected as a teaching goal. These statements contrast with the situation in the university baccalaureate, where logical reasoning is presented as one of the goals of the stage.

Table 2: Logical reasoning and abstraction in the different itineraries

Primary education (MEN, 1953)	**Working baccalaureate (MEN, 1956)**	**University baccalaureate (MEN, 1954)**
"From the earliest years, it is advisable to accustom the child to reason well, step by step" (p. 63).	"The purpose of the teaching of mathematics in the working baccalaureate should not be […] the cultivation of logical deductive reasoning" (p. 561).	"…with it the students must begin logical reasoning, which is one of the purposes of the teaching of mathematics in the baccalaureate" (p. 56).
"Children must acquire the habit of generalization; they must gradually detach themselves from the material and reach the abstract" (p. 63).	"…reasoning should be based on concrete things and images, within the child's reach, using facts and examples from daily life and models made by the students themselves in the handicraft class or in the workshop" (p. 562).	"It must be pointed out to the students that the figures they draw are only approximate, for example, the lines they draw are crude images of those conceived in Geometry […] when introducing the student to the idea of the ratio of two homogeneous quantities, the abstract nature of the ratio must be emphasized" (pp. 55-56).

In the case of abstraction, the orientations of the three itineraries try to avoid an excessive degree of abstraction. However, we see that the working baccalaureate emphasizes the use of concrete things

and images, while the university baccalaureate seems to pursue a higher degree of abstraction and metamathematical reflection when dealing with certain mathematical objects.

The intended curriculum: mathematical contents

In this paper, we are going to restrict ourselves to the case of geometry for students of age 10-11 years. This corresponds to grade 5 in primary education and grade 1 in any of the baccalaureate itineraries. Table 3 shows the contents exactly as described in some of the official published syllabi. We have tried to group the different contents to highlight the existing similarities and differences.

Table 3: Geometry for age 10-11 in the different itineraries

Primary education (MEN, 1953)	**Working baccalaureate (MEN, 1956)**	**University baccalaureate (MEN, 1954)**
Geometry: notion and division. Lines: their classes. Recognition and tracing exercises. Use of the ruler and compass, measurement and operations with segments. Plane angles: classes and properties. Measurement of angles. Exercises. Construction of equal angles. Perpendicular and oblique angles. Use of the bevel and the square in exercises on them.	Elementary movements and constructions in the plane.	Body, surface, line and point. Rectilinear segment and straight line. Measurement of segments. Plane surface. Angles. Perpendicular lines. Mediatrix of a segment and bisector of an angle. Parallel lines.
Polygon in general: classes and properties. Triangles: their classification. Value of its angles. Exercises and problems. Quadrilaterals: their classes. Special study of parallelograms. Exercises and problems. Regular and irregular polygons. Recognition and tracing.	Triangles and polygons.	Triangles: Classification and first properties. Quadrilaterals; parallelograms: Classification and immediate properties. Polygons: Classification. Convex polygon.
The circumference and the circle. Properties. Length of the circumference. Exercises and problems. Relative positions of two circles. Length of the line of the centers.	Empirical measurement of the circumference.	Circumference and circle; first properties about radius, diameter, chords and tangents. Sexagesimal division of the circle. Measurement of angles and arcs.

Similar figures. Proportional lines. Construction of similar polygons.		
Area of plane figures. Area of the triangle, parallelogram and regular polygon. Same for the circle and circular figures. Formulas. To find in them the value of any of its elements.	Area of elementary plane figures. Area of the circle.	Expressions of the areas of polygons and the circle.
	Initiation to the geometry of space with the analysis of the most common corporeal shapes. Volume of the orthohedron.	

We see that the degree of detail is rather different in the three official documents. The primary education syllabus provides a more detailed description of the contents than the other two. For some topics, the differences are quite remarkable, such as in the case of polygons.

When there are more detailed descriptions, other interesting differences arise. Again, for polygons, we see that the primary education syllabus seems to suggest beginning with polygons in general to later particularize to 3 and 4 sides, while the university baccalaureate syllabus seems to suggest the other way round. We also point out that some topics, such as geometrical proportionality or three-dimensional geometry were explicitly mentioned only in some of the itineraries.

The implemented curriculum: the definition or circumference

We present here a small example of how a particular mathematical object was treated slightly differently in two of the itineraries. We focus on the notion of circumference that, as we have seen in Table 3, was part of the geometry contents for age 10-11.

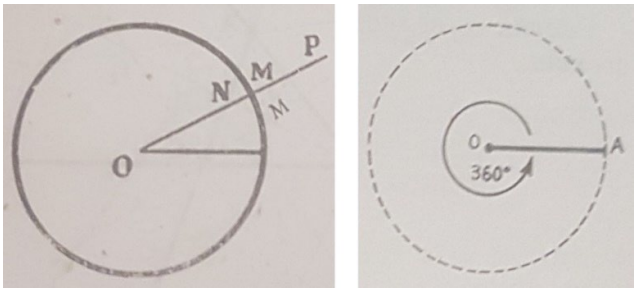

Figure 2: Illustration accompanying the introduction of the notion of circumference in primary education (left) and in university baccalaureate (right)

The following definition has been taken from a book addressed to students in the 10-12 period of primary education (Bruño, 1959, p. 78): “A circumference is a closed plane curve whose points are at the same distance from a point in the same plane”. On the other hand, the following excerpt comes from a book addressed to grade 1 of university baccalaureate (Bruño, 1962, p. 175): “If we rotate a

line segment OA, in a way such that it remains in a plane and the point O is fixed, the point A will follow a closed plane curve such that all of its points are at the same distance from O. This curve is called circumference". In Figure 2, we see the drawings that accompanied these definitions.

Both definitions share a common part, but the one addressed to university baccalaureate students introduced a dynamic approach including the notion of rotation (briefly presented earlier in the book) that makes it richer and more modern than the one for primary education students which is a static more classical definition.

Some final remarks

In Spain, until 1970, students of ages 10-12 had to attend to mandatory education. However, three different itineraries coexisted, each with a different aim. Although mathematics was present in all of them, its weight, contents, and treatment varied. In this paper we have given the first steps towards a systematic comparison of this situation which, as far as we know, has not been addressed in the existing literature.

Mathematics was present practically every year of every possible itinerary. However, its weight was different and somewhat erratic. For example, and for ages 10-12, primary education students received 4 weekly hours of mathematics each year, university baccalaureate students received 3 weekly hours each year, and working baccalaureate students received 6 and 4 weekly hours, respectively. From the point of view of the mathematical contents, even if there were differences (recall Table 2) they might not have been that big. Nevertheless, if we combine the lists of topics with the different workload, it seems rather obvious that the treatment of those topics should differ. This is made even clearer when we have a look at textbooks. Methodological orientations also show the intentionality in giving to each itinerary a more practical, applied or scientific approach.

All the previous observations need to be further explored. To do so we need to globally compare the three itineraries, and not only the overlapping ages 10-12, as well as the different specializations. In doing so, we think that we will contribute to illustrate how mathematics was – and is – concerned not just about educational issues, but also with shaping different types of people (Valero, 2017).

New Math: A comparison of the NKMM's curriculum with Norwegian and Swedish curricula

Hilde Opsal[1] and Bjørn Smestad[1,2]

[1]Volda University College, Norway; hilde.opsal@hivolda.no

[2]OsloMet – Oslo Metropolitan University, Norway

In this paper we compare the content in three curricula, one written by the Nordic Committee for the Modernization of School Mathematics (NKMM) in 1967, one curriculum from Sweden in 1969 and a temporary plan from Norway in 1971. Both the Swedish and the Norwegian plans are said to be based on the NKMM's plan. There are large similarities between these plans, yet there are also some interesting differences: the Norwegian plan goes further than the Swedish plan when it comes to set theory while it has omitted some of the more advanced mathematical topics.

Keywords: Comparative research, curriculum research, educational history, mathematics education.

Introduction

Two of the goals of New Math were to move mathematical concepts from higher grades to lower grades and "to bring school mathematics closer to the academic mathematics of the twentieth century" (Kilpatrick, 2012, p. 563). The foundation of modern academic mathematics was set theory. According to Kilpatrick (2012), one cannot transfer from one country to another how school mathematics should be taught because every country has "a unique school mathematics – a product of its history, culture, and tradition, and conforming to its social, political, and educational systems" (p. 569). De Bock (2023, p. 2) states that New Math appeared differently in the various countries "but in general, the emphasis shifted from developing technical-computational skills to insights into mathematical structures, often but not exclusively pursued by the study of abstract concepts such as sets, relations, algebraic structures, number bases other than 10, etc".

In the Nordic countries, there were several major changes in the school systems that happened around the same time. Norway and Sweden went from a seven-year school (seven to fourteen years) to a nine-year school (seven to sixteen) at the same time as the introduction of a comprehensive school. In Norway, experiments with nine-year *Grunnskolen* started in 1960 to replace seven-year *Folkeskolen* and the schools building on that; *Framhaldsskolen* and *Realskolen*. In 1969, nine-year school was mandatory for all. In Sweden, a reform in 1962 replaced *Folkskolan* and *Realskolan* with *Grundskolan*. It took ten years to implement the reform fully. In addition, the governments both in Norway and Sweden wanted to introduce New Math (Smestad & Opsal, 2023).

At the seminar in Royaumont in 1959, often viewed as the starting point for New Math in Europe, there was a call for regional cooperation in the work to reform mathematics education (NKMM, 1967, p. 6). In 1960, the Nordic Committee for the Modernization of School Mathematics (NKMM) was established by the Nordic Council with members from Denmark, Finland, Norway, and Sweden. The task of NKMM was to develop preliminary plans for mathematics to be tested in schools, and ultimately this work was to result in a report with proposed measures to be handed over to the

authorities in the four countries. The final report included, among other things, a proposal for a curriculum for students from first to ninth grade.

Bjarnadóttir (2023) has studied the work of NKMM and what was the driving forces behind it. “The question is to which degree four independent states with some heritage in common, but different situations in other respect could create a common policy in the field of mathematics education, in particular at the compulsory school level” (Bjarnadóttir, 2023, p. 240). Bjarnadóttir describes the committee’s work as contentious, marked by various interests, perhaps especially among those committee members who were to work with mathematics on the primary level. One of the members of the committee, Norwegian Torgeir Bue, was member of the working team for grade one to six. According to Bjarnadóttir, he wrote an appendix to the main document from this group where sets were not mentioned. Bue left the committee in 1963 (NKMM, 1967).

The secretary for NKMM was Matts Håstad. From the beginning, he was also leading the group responsible for the mathematics curriculum in Sweden in 1969, but left the group “due to conflicts within the group and other people at the National Board of Education” (Prytz, 2018, p. 201). According to Prytz, with references to Kilborn et al. (1977), the use of terms and symbols from set theory was reduced by the new members of the curriculum group.

In Norway, New Math was introduced in the experimental plan of 1971. In the guidelines for the committee working on mathematics, there were clear directions for a transition to New Math as proposed by the NKMM report. Since there were likely several schools and teachers who were not ready for this transition, two proposals for curriculum were made, a traditional one like the experimental plan from 1960 (alternative 1), and one with New Math (alternative 2) (Gjone, Part III, p. 37). During a transition phase, schools could choose between alternative 1 or alternative 2. Sweden was ahead in introducing nine-year compulsory education, as early as 1962 (Prytz, 2015). The 1969 curriculum in Sweden was based on New Math and “included new pedagogical principles on how to introduce and explain concepts” (Prytz, 2021, p. 1038).

In an earlier study we conclude that “While the expansion of obligatory schooling seems to have eased the transition to New Math in Sweden, it also complicated the transition in Norway” (Smestad & Opsal, 2023, p. 172). In both countries, new curricula for obligatory nine-year school provided opportunities to include New Math, but in Norway, complications concerning whether all students should have mathematics in grade nine, slowed down the process. In the end, in Sweden, the teachers were encouraged to choose teaching methods freely from 1973, the national approval of textbook series were removed in 1974, and in the new curriculum of 1980 most of New Math had been removed. In Norway, the final curriculum of 1974 already included far less New Math. Since both the Swedish and Norwegian curricula where New Math was introduced are based on the same plan from the NKMM, it is interesting to see how similar/different the plans are compared to the NKMM plan. Our research question is: How do the Swedish curriculum of 1969 and the Norwegian curriculum of 1971, compare to the curriculum proposal of the NKMM?

Method of analysis

To compare the two curricula with the NKMM proposal, we performed content analysis of the three curricula. Inspired by a framework for analysing mathematics textbooks from Charalombous et al. (2010) and using their concepts, we did a curriculum analysis in two parts: horizontal and vertical. In the horizontal analysis, we established how the plans were developed, by whom and when and in which context. Moreover, we noted the structure of the plans, the number of pages as well as the place the subject of mathematics had in the respective school systems. In the vertical analyses, we focused on one aspect of the curriculum, in our case on the stipulation of content to be covered. The rationale for dividing the analysis in two parts in this way, is that characteristics of the curriculum documents, studied in the horizontal analysis, may well be relevant to interpret the findings of the vertical analysis.

In the vertical analysis, we first created a table with the list of contents from the NKMM's plan (Table 1, column 1). Then we each studied the Norwegian and Swedish curriculum and analysed whether the NKMM contents were represented in these plans, and under which main level (column 2 and 4) and suggested grade levels they were placed (column 3 and 5). We also noted contents that were mentioned in the Norwegian and/or Swedish curriculums that were not mentioned in the NKMM curriculum. When we had finished the analyses individually, we compared the result, discussed and agreed upon those we had analysed differently.

Table 1: Analysis table, the first contents from first grade[1]

NKKM's annual plan	Norwegian, main level (L-M-H)	Norwegian, annual plan Grade	Swedish, main level (L-M-H)	Swedish, annual plan Grade
Grade 1				
1.1 Set, element, member of, subset, empty set	L1	1-1, 2-1, 3-1		1
1.2 Concept of numbers	L1, L2	1-2, 2-2	L	1
1.3 Natural numbers 0-100	L2 (without limit)	1-2, 2-2	L (without limit)	1

[1] In the second and fourth column, the letter refers to main level (L for first to third, M for fourth to sixth, and H for seventh to ninth). The number in the second column and the number after the hyphen in column three refers to the number of the mathematical themes in the Norwegian plan. For example, the number 2-1 in the third column refers to grade 2 and mathematical theme 1.

Result of horizontal analysis

The development processes of the three curricula were different. As mentioned in the introduction, the NKMM was established in wake of the Royaumont seminar to experiment and develop a common curriculum. The committee had members from four countries, and the experiments were international. The work lasted from 1960 to 1967 (Bjarnadóttir, 2023).

As early as 1963, an informal group, with varying members, was established in Sweden by The National Board of Education to follow the development of mathematics education and participate in the discussion about changes in the mathematics subject. In connection with this work, a new group, with some of the same members, was set in 1967 to develop the new curriculum in mathematics. (Kilborn et al., 1977, p. 11). The work stopped for half a year from October 1968 to March 1969 and was only picked up after Håstad and Magne left the group. According to Kilborn et al., Sandström, a chemist, did major edits to the curriculum in the final stages. Magne claimed that "In fourteen days, Sandström rewrote what we had worked on for a couple of years" (Kilborn et al., 1977, p. 23). The curriculum was finished by the end of 1969.

In Norway, a committee began work on a new mathematics curriculum in 1968, where the plan was to be based on NKMM's work. The members of the committee had advanced knowledge of New Math and created a proposal in 1969. Afterwards, the Normal Plan Committee (Normalplanutvalget) took over to adapt the mathematics plan to the other school subjects. There were several changes, both organizational, academic, and methodological. Parts of the changes were done to assure that the curriculum was workable for all students (Gjone, 1985, Part III). An interesting subject-related change was that "set theory" was changed to "basic concepts from set theory" and logic was almost completely omitted. After the Curricula Committee had submitted its proposal, this was to be processed by the Elementary School Council (Folkeskolerådet). The final version of the temporary plan was published in 1971.

The forms of the three curricular documents analysed here are comparable. The NKMM's curriculum proposal in the report first contains the background for the proposal, seven main areas in mathematics that all start with "All students should" (Alla elever bör), and then a description of the content for grades one to nine. In list form, the plan first describes the content for each grade (see Figure 1 grade 1) and then a description of what each theme in the list entails. A total of 27 pages are analysed (NKMM, p. 177-203). The seven main areas in this plan are number area, geometry, measurement, probability, table and diagram, problem solving and the nature of mathematics. The description of the main areas ends with a paragraph that tells what must be fulfilled for this to be carried out.

The 1969 curriculum in Sweden consist of a general part with goals and guidelines, schedules and plans for each level, low (grade one to three), medium (grade four to six), and high (lower secondary), where the subject is included (Skolöverstyrelsen, 1969b). In addition, there are also instructions and comments for the teachers. The structure of the mathematics section of the plan is similar to the structure of the other subjects in the plan and here we have the main elements for low, medium, and high level. A total of 4 pages described mathematics. There is also an appendix for each subject, in which mathematics was treated in 24 pages, with complementary instructions, comments and examples of annual plans in the subject (Skolöverstyrelsen, 1969a).

Årskurs 1

1.1 Mängd, element, tillhör, delmängd, tom mängd
1.2 Antalsbegreppet
1.3 De naturliga talen 0—100
1.4 Större än, mindre än, lika med, inte lika med (symbolerna $>$, $<$, $=$, $\neq$)
1.5 Union, addition (symbolen +). Den kommutativa lagen
1.6 Subtraktion (symbolen −)
1.7 Den associativa lagen för addition
1.8 Verksamhet med material av geometrisk natur
1.9 Enheter

Year 1

1.1 Set, element, belong, subset, empty set
1.2 The concept of quantity
1.3 The natural numbers 0-100
1.4 Greater than, less than, equal to, not equal to, (the symbols >, <, =, ≠)
1.5 Union, addition (the symbol +). The commutative law
1.6 Subtraction (the symbol -)
1.7 The associative law for addition
1.8 Activity with geometric nature material
1.9 Units

Figure 1: Grade one in NKMM's plan (NKMM, 1967, p. 180) to the left, our translation to the right

The Norwegian temporary curriculum from 1971, alternative 2 in mathematics, first gave the goal of the subject, then a list of 10 mathematical themes, what the students should work with at the various levels and finally guiding annual plans (Midlertidig mønsterplan, 1971, pp. 130-137). In addition, there are 30 pages with the headings "working methods" and "symbol list" which we have only included in the analysis for clarification and exemplification. In the NKMM, no details were given on the number of lessons expected for the subject of mathematics. In Sweden, mathematics was given on average 4.4 lessons per week in grades 1–9. Each lesson was 40 minutes, apparently. In Norway, mathematics was given on average 3.5 lessons per week in grades 1–8, with lessons lasting 45 minutes each. Mathematics was an elective subject in the ninth grade with 3 lessons per week. Thus, the Swedish subject had about 15 percent more time than the Norwegian one when the elective subject in Norway is included. Further in this work, we have included the mathematics in the ninth grade in Norway.

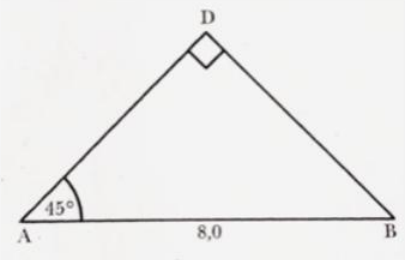
Result of vertical analysis

As both the Norwegian and the Swedish plans are based on NKMM, there are many similarities. We will therefore focus on the differences.

Set theory is an important part of New Math and is treated differently in the three plans. The first content mentioned in the NKMM's plan for first grade is "sets, elements, belong, subset, empty set". Furthermore, the students will also be introduced to the commutative and associative laws of addition. Logic is introduced in the third grade. It is also claimed that: "In order for the above program to be implemented successfully, mathematics should be presented in a modern spirit" (NKMM, 1967, p. 179, our translation). In this context, set theory is stressed. We see a greater emphasis on sets in the Norwegian plan than in the Swedish plan – both in the work with geometry, functions, and algebraic expressions. For example, in geometry at the intermediate level in the Norwegian plan, it states "Use of set terminology in the description of points, line segments and polygons" (Midlertidig mønsterplan, 1971, p. 131; our translation), while in the Swedish one it states: "Simple geometric concepts and correlations", without mentioning sets (Skolöverstyrelsen, 1969b, p. 137; our translation).

To exemplify how far the Norwegian plans went in using set notation as a tool in other areas of mathematics, in Figure 2, we give an example of how the plan expects the students to analyse a construction using sets.

In addition, the Norwegian plan has more set algebra, includes number sets (**N**, **Z** and such), and there is more emphasis on the laws. The Swedish plan, unlike the Norwegian one, lacks some logic and set



concepts (e.g. open statements, and/or, and intersection) and set symbols. For instance, sets are not included for students at the intermediate level (grade four to six). Also, the Swedish plan lacks some logical concepts such as implication and negation.

Example 1: A triangle ABD is to be constructed.

The side $AB = 8.0\ cm$, $\angle A = 45^\circ$ og $\angle D = 90^\circ$.

Construct the triangle and give a complete solution to the task.

1. *Auxiliary figure*

Measuring unit: cm.

2. *Analysis*

Start with a line *l* and mark $AB = 8.0\ cm$ on *l*.
The point *D* is given by:
1) $\angle A = 45^\circ$
2) $\angle D = 90^\circ$

We use the sets:

1) $V = \{P | \angle(AP, l) = 45^\circ \wedge A \in l\}$
2) $R = \{P | AP \perp BP\}$

$D \in V \wedge D \in R \Leftrightarrow D \in V \cap R$

Then follows the construction.

Figure 2: Example from the Norwegian curriculum (Midlertidig mønsterplan , 1971, p. 159), translation from Opsal and Smestad (2023)

According to the NKMM plan, the first-grade students will work on "Greater than, less than, equal to, not equal to (symbols >, <, =, ≠)" (NKMM, 1967, p. 180). The same wording is also verbatim in the Swedish suggested study plan for the first grade, but here without "not equal to" and the symbol for this. In the Norwegian plan, it says both under level grade one to three and for first grade: "Quantitative concepts in concrete and abstract contexts". In this plan, it includes what is in the NKMM plan but goes beyond this content.

The division algorithm is not mentioned in the Norwegian plan, while in the NKMM, students will work with it in the fourth grade and according to the Swedish plan in the fourth to sixth grade. Neither is the calculator mentioned in the Norwegian plan. According to NKMM, students will use a calculator in the fifth grade. In the Swedish plan, students will use a calculator in lower secondary school and a computer in ninth grade.

Other topics that are treated differently are probability and statistics. In NKMM's plan, probability is one of the seven main areas, and it is one of the points in the list for ninth grade. In the Swedish plan, probability is included, but it is not mentioned in the Norwegian plan. Although statistics is included in all plans, the choice of grades varies. In the NKMM's plan, descriptive statistics first come in the grade eight while in the Norwegian plan this is introduced gradually from fourth grade, and in the Swedish also gradually from second grade.

Vectors and introduction to derivation were two mathematically advanced topics that were included in the NKMM's plan. Derivation is not included in either the Norwegian or Swedish plan. For vectors, Norway and Sweden chose different solutions. While vectors are not included in the Norwegian plan, they are placed in grades 7-8 in the Swedish plan. It is stressed that while most students should be able to add vectors and show that vector addition is commutative, fewer students will be able to subtract vectors or calculate using vectors in coordinate form.

Discussion

To answer our research question: How do the Swedish curriculum of 1969 and the Norwegian curriculum of 1971, compare to the curriculum proposal of the NKMM, we have conducted a horizontal analysis and a vertical analysis of the three plans.

The structure of the NKMM plan is not followed in the Norwegian and Swedish plans. In the NKMM, they first introduce the main area and then what the different classes should contain. It is not divided into levels as we find in both the Norwegian and Swedish plan, where annual plans are just suggestions. The reason for this may be that there is ideally a common structure on how the various subjects should be described in the different curricula, and we see both in the Norwegian and the Swedish plan that the various subjects have the same structure where it is divided by levels and not grades. Even though the structure of the NKMM's plan and the Norwegian and Swedish plan is different, it is still interesting to discuss what is included in all three, and what is emphasized in one or two of the plans and not in the third one something that emerges in the vertical analysis.

Given the much larger amount of classroom time for the subject of mathematics in Sweden, it is not surprising that the Norwegian plan is missing some topics from the NKMM plan, which are included in the Swedish plan. Probability and vectors are two prominent examples of this. It is more surprising that the Norwegian plan goes a lot further in using set terminology in the treatment of other mathematical content, such as geometry. Given that both plans were based on the NKMM plan, this must have been a conscious decision based on different priorities for the subject. Norway introduces set theory as a "tool" in mathematics but does not introduce parts of the more advanced mathematics where this tool is needed. On the other hand, Sweden introduces some of this more advanced mathematics, such as vectors, but not the tool of set theory. It may be that a reason for this was the extensive rewrite of the Swedish plan by a non-mathematician in the final stage.

As Kilpatrick notes, it is not possible to transfer school mathematics materials and practices from country to country, due to each country's unique social, political and educational systems. In our case, several countries with rather similar systems cooperated to create a common curriculum, but still the national curricula ended up differently. Whether this is because of the systems or also individuals' influence, is another story. As De Bock states, there are differences between countries: In Norway, there is more focus on the mathematical structure than in Sweden and less on computational skills – as exemplified by the absence of the division algorithm in the Norwegian plans.

No matter what the background for this difference was, the difference seems to be important when discussing why New Math had such an abrupt end in Norway, at least in the sense that the New Math alternative 2 was abolished already in 1974. The Norwegian way of including set theory must have influenced the whole subject of mathematics more profoundly than the Swedish way, possibly eroding support.

The use of two-dimensional figures as means of mathematical justification in complex analysis

José Gerardo Piña-Aguirre[1] and Rosa María Farfán Márquez[1]

[1]Center for Research and Advanced Studies (Cinvestav), México; gerardo.pina@cinvestav.mx

To have a better understanding of how different ways of doing mathematics employed by historical subjects are nuanced in contemporary complex analysis scenarios, in this study we present some results of how two participants in a pilot study used two-dimensional figures (without prior instruction on how to use them) as means of mathematical justification when they engaged in a series of tasks based on two problems that Cauchy and Goursat had to face. To carry out the analysis of the mathematical activity used by the participants in the study, we relied on the socioepistemological theory, which allowed us to understand that figures, without homologous representation in an algebraic setting, were used in two different ways: to compare in order to find upper bounds for the modulus of integrals over closed curves, and when the participants felt the need to supplement the algebraic apparatus to give a meaning to purely algebraic expressions.

Keywords: Use of figures, mathematical justification, original sources, complex analysis, history of mathematics.

Introduction

Chorlay et al. (2022) acknowledge that a line of research that has developed in mathematics education over the last 20 years is concerned with how the history of mathematics can become a resource for didactic intervention. Studies such as those of Clark et al. (2022) contribute to this line of research by reporting on three research initiatives that developed during the TRIUMPHS project; a project that aims to teach mathematical topics based on a series of tasks that require university students have to engage with, interpret, and explore the mathematics of primary source excerpts. We envisage that our ongoing doctoral research also aligns with this line of research reported by Chorlay and others. However, before configuring didactic material with the intention of teaching, we decided to explore how the history of complex analysis can enrich didactic research by understanding how the use of two-dimensional figures, that we unveiled in the analysis of original mathematical works, is nuanced in contemporary complex analysis scenarios.

Specifically, in a previous study (Piña-Aguirre & Farfán, 2023a), we conjectured that to develop complex analysis historical subjects had to complement their purely algebraic procedures through the gradual incorporation of two-dimensional figures. In Piña-Aguirre and Farfán (2023b) we illustrate this by means of two problems that historical subjects had to face. On one hand, Cauchy (1825) had to give a meaning to the concept of integral comprised between complex numbers, and to do so he had to complement his purely algebraic procedures with the use of figures accompanied by algebraic expressions. Later on, Goursat (1884) had to use figures, that were not represented by algebraic expressions, in order to find

upper bounds to the modulus of complex integrals over closed paths to prove what we know as Cauchy's integral theorem.

The previous results allowed us to show evidence (Piña-Aguirre et al., 2024) that the use of figures in modern complex analysis textbooks differs from the way in which historical subjects used them to deal with the complex integral concept and to prove Cauchy's integral theorem. Therefore, to give an answer to the question, how do undergraduate mathematics students use figures when facing some of the problems that historical subjects affronted in the development of complex analysis?, we designed a series of tasks (see the next section of the paper) based on original mathematical works, with the particularity that, in order to solve them, students will gradually incorporate the use of figures to their algebraic arguments as evidenced in our historical reconstruction of the development of complex analysis. Nevertheless, before applying the set of tasks with undergraduate mathematics students, we conducted a pilot study to see if the tasks would evoke what we wanted them to evoke, and in this paper we present some results of this pilot study.

The tasks sequence

By relying on Cauchy's memoire (1825), we configured tasks related to the concept of complex integration. Meanwhile, Goursat's (1884) proof of Cauchy's integral theorem allowed us to design tasks that require finding upper bounds for the modulus of integrals around closed curves. Space does not permit us to present the full set of tasks, but we do present one task related to Cauchy's work and one task related to Goursat's work (in which the pilot study participants used two-dimensional figures), accompanied by a brief description of the other tasks that make up the whole set of tasks.

In order to attend to the complex integral concept, we first present a couple of tasks designed to reproduce the type of mathematical activity that was predominant when dealing with complex quantities up to 1825. These tasks require to compute the four algebraic operations with complex numbers, as well as real integrals of real-valued complex functions. In task three, we ask to compute the value of an integral by relying on an excerpt of Cauchy's memoire that deals with a specific definition of real integration. Then, in the next task (which we will call task A), we present the following excerpt from Cauchy's memoir.

> Task A: Therefore, in order to embrace the same definition of integrals between real limits for integrals between [complex numbers] it is appropriate to represent by the notation
>
> $$\int_{x_0+iy_0}^{X+iY} f(z)\,dz$$
>
> the limit [to which is directed] the sum of the products of the form
>
> $$[(x_1 - x_0) + i(y_1 - y_0)]f(x_0 + iy_0)$$
> $$[(x_2 - x_1) + i(y_2 - y_1)]f(x_1 + iy_1)$$
> ...
> $$[(X - x_{n-1}) + i(Y - y_{n-1})]f(x_{n-1} + iy_{n-1})$$
>
> When each of the two sequences

$$x_0, x_1, x_2, \dots, X,$$

$$y_0, y_1, y_2, \dots, Y$$

are made up of ever increasing or decreasing terms from the first to the last, infinitely close terms, whose number increases more and more.

We then asked the participants to express, in terms of a limit and a sigma notation, Cauchy's definition of integrals comprised between complex numbers. The following tasks were configured to present a contemporary definition of complex integration via integration paths connecting two different points in the complex plane. Then, we presented tasks related to the concept of simple closed curves. This in turn allows us to present the following task based on Goursat's proof, which we will call task B.

Task B: Consider curve C in Figure 1, oriented counterclockwise, which is made up of sections of the following five curves

$$y_1 = -x + 2;\ y_2 = x + 2;\ y_3 = 0;\ y_4 = -\frac{1}{8}sin\,(31.2x) + x + \frac{1}{2};\ y_5 = -\frac{1}{8}sin(25x) - x + \frac{1}{2}$$

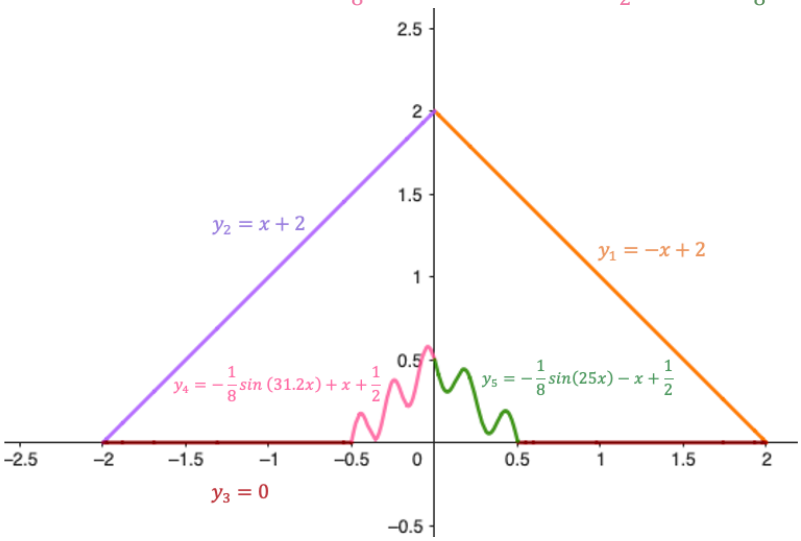

Figure 1: Closed curve C

If it is desired to traverse the entire curve C through 3 or more auxiliary curves C_i dividing the region bounded by the curve C in such a way that the following two conditions are satisfied:

(i) $\int_C f(z)dz$ can be written as the sum of integrals over closed curves γ_i (traversed counterclockwise) composed of sections of curve C and auxiliary curves C_i.

(ii) The distance between any two points in or on the curves γ_i can be bounded by a positive quantity.

Which auxiliary curves would you use?

The final task of the design is identical to task B, the main difference being that the curve C is a freehand drawing similar to an ellipse.

The socioepistemological theory of mathematics education

Since our objective is to understand how the participants of the study use figures to solve the sequence of tasks, we relied on a framework that studies the production of situated mathematical knowledge,

known as the Socioepistemological Theory of Mathematics Education (Cantoral, 2020). According to Torres-Corrales y Montiel (2019), one way in which this theory has analysed how individuals use and do mathematics is through the analytical questionings: *what does he/she do?* and *how does he/she do it?* In this research, we adapted these questions and analysed the mathematical activity of the participants in the pilot study by answering the questions: *what do they do in order to give an answer to the tasks?* and *how do they do what they do?* The second question allowed us to detect the emergence of figures as a means of mathematical justification, which led us to answer the following two questions: *what type of figures are they using?* and *what are the purposes of these figures?*

Following the work of Tournès (2012), we considered that the answers to the question *what type of figures are they using?* could be of two types. If the figures were accompanied by algebraic expressions, we classified them as *quantitative* figures. If the figures were freehand drawings without them being described through algebraic expressions, we catalogued them as *qualitative* figures. Meanwhile, the answers to the question *what are the purposes of these figures?* helped us to identify what these figures enabled the study participants to do.

Method for the recollection of data

Apart from the fact that we wanted to know if the design induced the use of figures, we also considered that it could be an opportunity to get feedback on the design itself (redaction, sequencing, and difficulty of the tasks, etc.). For this reason, the pilot study was carried out with four postgraduate students in mathematics education, with a bachelor's degree in the teaching of mathematics from three different universities in Latin America, who had not previously taken a course in complex analysis, but who were familiar with the four algebraic operations of complex numbers. The reason for looking for participants who had not previously taken a course in complex analysis was that we believed that if the participants had previously worked with the concept of complex integration, the process of discovering how to give a meaning to the complex integral (elicited by the task sequence) would not emerge. In this paper we report some of the responses of the participants called Alejandra and Manuel (both pseudonyms).

We conducted the pilot study using task-based interviews (Maher & Sigley, 2020). One of us (first author of the paper) met with each participant individually in a classroom in the Department of Mathematics Education at Cinvestav. We provided them with pencils, sheets of white paper and an eraser. Each participant was given the following task of the design after completing the previous task. There was no time limit; it was up to each participant to decide how long they wanted to engage with the tasks each day, with the commitment that they would complete all the tasks. The interviews were semi-structured in the sense that we made general comments linking the tasks, any doubts arising from the wording of the tasks were clarified, and if what the task required was uncleared, we rephrased what the task was asking for. As the participants completed the tasks, as they moved from one task to the next, and at the end of the sessions, notes were made about their mathematical work, about errors in wording of the tasks, and about the participants' comments on the tasks. In this sense, we claim that the interviews were also exploratory because they allowed us to provide a basis for a more detailed design.

The mathematical activity of the participants

Our intention with task A was that the participants obtained a symbolic expression that allowed them to attend to the concept of integral comprised between complex numbers. We hoped that the participants extended Cauchy's definition of integral presented in the previous task without the need to rely on the use of figures. However, this is not entirely what happened, as described in Alejandra's mathematical activity below.

What does she do? She obtains a symbolic expression for the concept of complex integration. *How does she do it?* She conceives that the points $x_k + iy_k$ behave in the same way as real numbers, in the sense that they can be arranged in a straight line (see Figure 2). By operating the particular case of $(x_1 + iy_1) - (x_o + iy_o)$, she convinces herself that the general form of these elements is $[(x_{k+1} - x_k) + i\,(y_{k+1} - y_k)]$.

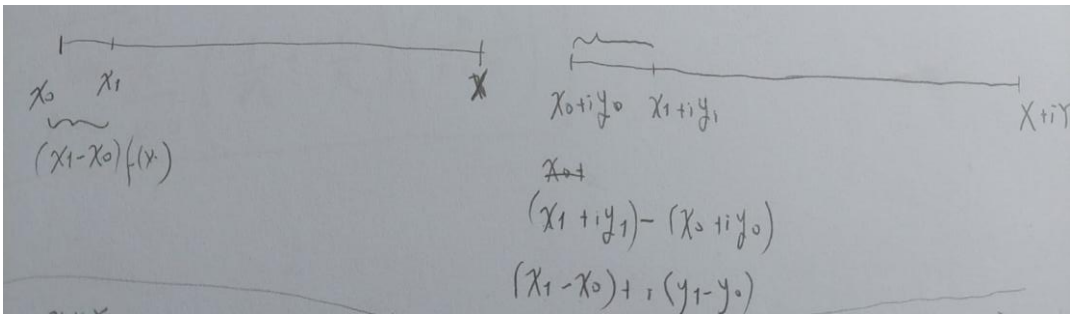

Figure 2: Alejandra's array of complex numbers in a straight line

What type of figure did she use? A qualitative figure. *What are the purposes of the figure?* It allows her to make sense of Cauchy's mathematical activity by imagining that sequences of points in $\mathbb{C}$ behave in a similar way to sequences in $\mathbb{R}$. Unlike Alejandra, Manuel compared the two definitions proposed by Cauchy and realised that what was different in the case of complex integration was that there was an iy accompanying the real expressions denoted by x.

On the other hand, task B was designed with the intention that the participants used figures to divide the inside of curve C. Specifically, Manuel did the following.

What does he do? He obtains the greatest distance in each of the regions delimited by the γ_i curves. *How does he do it?* He divides the region comprised inside the curve C by four γ_i curves. Two of these curves are triangles (yellow triangles in Figure 3) made up of sections of the curves y_1, y_2 and y_3. The other two γ_i curves delimit two regions (whose interior points are marked by green points in Figure 3) that are contained in two triangles (red triangles in Figure 3) that contain sections of the curves y_4 and y_5. Manuel conceives that the four triangles are right-angled triangles.

For the yellow triangles, Manuel states that the greatest distance between any two points within these regions are the lengths of the line segments represented by y_1 and y_2. He argues that these are the greatest distances by comparison. Manuel selects two points inside the yellow triangles and connects them with straight lines, then he uses these straight lines to form right-angled triangles (see white triangle in Figure

3). The two sides of the white triangle are then compared to the sides of the yellow triangle. Since the white sides are always shorter than the yellow sides, because they are contained in the region bounded by the yellow triangles, the greatest distance inside the yellow triangles is the length of the line segments represented by y_1 and y_2.

Then, Manuel states that the greatest distance in the γ_i regions, whose interior points are denoted by green points in Figure 3, are the hypotenuses of the red triangles. Manuel knows that the hypotenuses of the red triangles represent the longest distance between any two points inside or in the red triangles, then the greatest distance between any two points inside the two γ_i regions cannot exceed this hypotenuse, because the γ_i curves are inside the red triangles. That is to say, Manuel obtains upper bounds by comparing the regions delimited by the γ_i curves with the regions delimited by the red triangles.

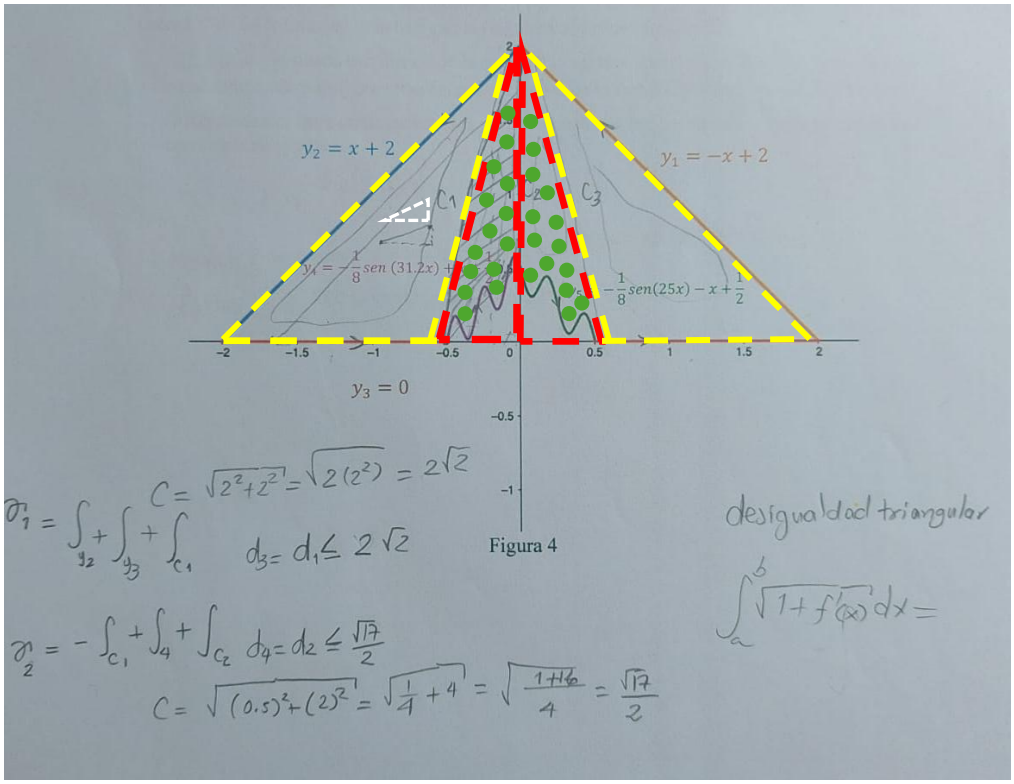

Figura 4

Figure 3: Manuel's use of figures

What type of figure did he use? Although some of the sides or the yellow triangles are represented by algebraic expressions, we argue that Manuel used qualitative figures, because the arguments he used did not involve the algebraic expressions that were already part of the task. *What are the purposes of the figures?* They were used to compare the γ_i figures with known triangular figures. Manuel compares the distance between any two points in or on the γ_i curves with a given distance, which he identifies as the greatest distance in the γ_i region.

It should be noted that in task B Alejandra also used figures to compare. However, Alejandra used rectangles instead of triangles to delineate regions within the curve C.

Conclusions

We argue that the results presented in this paper have allowed us to have a better understanding of how our theoretical results, reported in Piña-Aguirre and Farfán (2023a, 2023b), "live" in contemporary complex analysis scenarios. In the sense that both Alejandra and Manuel used figures, without homologous representation in an algebraic setting and without prior instruction on how to use them, in two different ways when dealing with some of the problems that historical subjects faced in developing complex analysis. Alejandra used them to give a meaning to a purely algebraic expression. Meanwhile, both of the participants used them to compare in order to find upper bounds for the modulus of integrals over closed curves.

In terms of the design, we would like to note that the configuration of the whole set of tasks shares some of the benefits reported by Barnett et al. (2014) when students engage with primary sources. For example, in task A, we hoped to bring the pilot study participants closer to the experience of *mathematical creation* by presenting Cauchy's proposal for complex integration. However, in light of Alejandra's response, we modified this task by removing Cauchy's excerpt in which he gives a meaning to complex integration. We believe that by not presenting the excerpt from Cauchy's memoir, we will give more freedom to the participants of the study to come up with a definition that allows them to deal with this concept. In particular, in Piña-Aguirre and Farfán (2024) we present these modifications to task A (accompanied by the way we designed the whole set of tasks), which in turn allowed us to configure more tasks that will enable us to study in more detail the use of two-dimensional figures. On the other hand, the answers to task B made us realise that all the closed curves that we presented in the set of tasks always delimited convex regions. Therefore, we decided to add a final task involving a non-convex figure, in order to find out what kind of figures the study participants use and how they use them when dealing with non-convex regions.

As our research develops, we hope we can understand in more detail how to transpose scholarly historical knowledge in complex analysis (in this case related to the use of figures) that, as shown in Piña-Aguirre et al. (2024), has not been entirely considered in contemporary complex analysis textbooks.

Acknowledgements

We would like to thank the four participants in the pilot study. Their feedback allowed us not only to modify the content of the tasks, but also to improve the structure of the tasks to make them more accessible to understand.

In this paper, we analyse a textbook from 1906, written by Joaquim d'Azevedo Albuquerque, intended to teach geometry to VI and VII classes of liceus in Portugal. Based on the prescribed curriculum and the one presented to teachers, this article aims to i) compare the prescribed curriculum with that presented to teachers and ii) analyse a proposal for teaching geometry in the final two years of liceus. Using content analysis techniques based on seven categories, we concluded that although the textbook transcribed the programme to be taught in both classes, in the final year of liceus, the author added a chapter on transformation methods, which was not indicated in the official syllabus. Furthermore, the didactic proposal of the school textbook is rather formal, lacking a contextual introduction and providing few application exercises.

Keywords: Curricular development, textbook content, mathematics education, geometry.

Introduction

In developed countries, textbooks are part of the daily routines of students and their parents. They are also an important resource for teachers. Analysing old textbooks reveals, among other things, the objectives to be achieved in past school classes (Nietz, 1941). For example, studying prefaces may allow us to understand how the authors relate to the educational context: the subject matter, teaching values, other educators, etc. Also, how authors choose to present content gives clues to their educational perspectives. Schools reflect and shape society's values, language, processes, etc., and textbooks, in particular, are pervasive cultural artefacts (Burke, 2016). The analysis moves away from Julia's (2001) perspective, for whom the textbook is defined essentially on its use. Textbooks are resources consciously designed to assist instructional objectives both from the student's and the teacher's perspective (Chopin & Bastos, 2009). This broader perspective for the study of school textbooks will be used in this text. Historians struggle to distinguish the different facets of this extremely complex object that is the textbook (Choppin, 2004). Its didactic function intends to convey knowledge, skills, and cultural and social perceptions to younger generations and, as with all curricular productions, mirrors the conflicting forces that shape curricula. Textbooks shape curricula, and we use this term from a wide-ranging perspective, encompassing several levels of decision resulting from pressures of distinct social and cultural forces (Gimeno, 2000). We specifically distinguish between the prescribed and the presented curriculum: the former, the program, usually determined by school authorities and the latter, the one that is printed in textbooks (Gimeno, 2000). Examining the curriculum presented in textbooks cannot fail to consider the programme. The success or failure of "divergent" textbooks may provide insights into the inner workings of curricular change and stability. Furthermore, textbooks are under the technical constraints of their time and participate

in an economic system whose rules and uses, both in production and consumption, necessarily influence their design and material realisation.

This text is part of a broader research program aiming at understanding how school mathematics curricula changed through time as a means to apprehend the broader role of social and cultural forces in forming contemporary curricula. This text focuses on a specific textbook for the upper classes of secondary school that strikes us as distinct from previous and later textbooks for the same classes. *Geometria* is the title of a school book written by Joaquim d'Azevedo Albuquerque and published in 1906, aimed at VI and VII classes of Portuguese *liceus* (current 10th and 11th grades, designed for students with 15-16 years). The author, Joaquim de Azevedo Sousa Vieira da Silva Albuquerque (1839–1912), graduated in Civil Engineering from the Polytechnic Academy of Porto, where he was born. He began his professional career at the *Liceu do Porto*. His intellectual merit earned him, a few years later, a position as the third former student of the Polytechnic Academy of Porto to join its teaching staff [1876/77 academic year]. He was also involved in politics and was a candidate for parliament during the monarchy. He retired in 1910 due to the age limit (Sigarra, 2011). This intellectual was a member of the Lisbon Geographical Society, where he served as its first secretary in Oporto's section. He authored several scientific and educational works in Mathematics, such as "Is the principle of universal gravitation sufficient to explain celestial phenomena?" (1876). He also wrote many mathematics textbooks, some of which became the standard books for teaching arithmetic and geometry in secondary schools. He was an important member of the Porto Instruction Society, where he delivered three lectures between 1884 and 1885 under the theme "The Machine and the World", which introduced a new method of studying kinematics (Guedes, 2004).

This analysis of the textbook aims to i) compare the prescribed curriculum with that presented to teachers and ii) analyse a proposal for teaching geometry in the final two years of *liceus*. To achieve this, we closely examine the *Geometria* textbook, integrating two methodological frameworks: one proposed by Lisa Okeeffe and the other by Jenneke Krüger, combined and applied previously by Almeida and Rodrigues (in press) and Rodrigues (in press). This article focuses on analysing the content, structure, expectations, and language used by Okeeffe (2013) while considering the coherence, visualisation, and context usage more broadly (Krüger, 2010).

The textbook indicates on the first page that it follows the programmes of the 1905 reform for secondary education (Portugal, 1905). The educational system in Portugal includes four years of primary education, followed by secondary education, which consists of a General Course in *liceus* lasting five years (currently covering the 5th to 9th grades), divided into two cycles of three and two years, respectively, and a two-year complementary course. In the final two years, there were two branches: science and humanities. Mathematics was taught only in the science branch, with a workload of four hours per week. Secondary education was aimed at the elite, and illiteracy rates were around 80% of the Portuguese population (Carvalho, 2008).

The 1905 programs (Decreto n.º 3/1905) introduced a key textbook change. In 1895, authorities decided on one, and the same textbook was chosen for all schools (unique textbook). Under the new reform, the unique textbook regime ended, and the production of textbooks was liberated (Carvalho, 2008). The new program also explicitly stated which textbooks were admitted for each grade. For

example, VI and VII classes should have an arithmetic book, an algebra book, a trigonometry book, and a geometry book (Portugal, 1905). Although the first three had similar counterparts in the 1895 reform, as the programs did not change much in these topics, the geometry book did not. Consequently, "older" books on those three topics could still be used, but there was no option for the geometry book, which should contain conic sections, geometric methods, and plane analytical geometry. Previously, Joaquim Albuquerque's textbooks were unique textbooks for the first five years of secondary school but not for the last two years of *liceus*. There is no other textbook for geometry in this specific prescribed curriculum, so Albuquerque's approach to the methods is the only one that is known. Therefore, the 1906 geometry book we are discussing is an attempt to shape the new curricular topics and also an attempt of Albuquerque to extend the range of his collection.

Methods and Theoretical Framework

Methodologically, the text conducts a documentary analysis (McCulloch, 2004) of the curriculum presented to teachers through the *Geometria* textbook without losing sight of the official programme. Document analysis involves representing a document's content in a distinct form to facilitate research and referencing. It is primarily executed through classification, indexing, and transformation procedures to analyse and condense information from documentary sources. Considering the political, social, and economic context of the time, a content analysis (Cohen et al., 2007) was conducted based on examining the school textbook and the official programme. This approach ensures the study's relevance, providing a comprehensive analysis of curriculum documents, school textbooks, and other curricular materials.

Due to the role that textbooks have in the context of teaching and learning, their content and structure are very important for promoting specific visions of curriculum. In this case, a content analysis is performed under two complementary frameworks: one by Lisa Okeeffe (2013) and another by Jenneke Krüger (2010), both used by Almeida and Rodrigues (in press) and Rodrigues (in press).

OKeeffe (2013) established a framework for analysing mathematics textbooks that comprise four primary elements: content, structure, expectation, and language. The content elements include value formation, motivational factors, accessibility, illustrations, and study guides, among others. The structural dimension encompasses how the textbook is organised, the distribution of content, the connections between different subjects, knowledge and information, and the construction process. The expectation dimension is present in all textbooks and can influence how students engage with the topics presented. "For example, if the focus of a mathematics textbook is on repetition and practice, then a student will subconsciously look to replicate a previous method as soon as he/she encounters a question, without attempting to use any problem-solving skills" (Okeefe, 2013, p. 7). The language dimension encompasses features such as the type of discourse (narration, description, etc.), connectors between sentences, and semantic structures; for more refined analyses, the author provides three subtitles: word signifiers, notational signs, and graphic signs (Okeeffe, 2013).

In turn, Krüger (2010) analyses lessons from the early 17th century, using three categories: coherence, visualisation, and use of contexts. Coherence refers to the consistent application of previously taught, aimed at reinforcing skills through practice that can be utilised in more complex situations or diverse contexts. Visualisation pertains to the layout of the textbook, the illustrations, and the contexts

depicted in these illustrations. This category also encompasses the artistic quality of the images and their role in facilitating the content or mathematical problems. Lastly, the contexts are typically drawn from practical or professional situations, relating mathematics to its applications within the students' environment. In this article, Krüger's (2010) framework will be employed to conduct a meta-analysis of the curriculum presented under study.

This text examines the *Geometria* textbook, concentrating on its suitability for the prescribed curriculum. In particular, it analyses two topics: the "Reduction to the absurd method", as Albuquerque chose to explain it without illustrations of the proofs of the theorems, and the "Possibility of solving geometry problems using only a ruler and compass." This presentation, derived from the author, begins the section with a question reinforcing the next content.

Description of the textbook

Considering the *structure*, Albuquerque's textbook (1906) is 156 pages long, with the index at the end. It does not have methodological suggestions, just a description of the methods. It is printed in black ink, with no colour highlights in the titles or figures. The cover states that the school textbook follows the programs published in 1905 and is directed to the VI and VII classes of *liceus*.

The textbook is divided into two main parts, one for each grade. The first part covers the content to be taught in VI class. It begins with the programme's transcription and is followed by four chapters on conic sections: introduction, ellipse, hyperbola, and parabola. These conic sections are those recommended in the official programme, which outlines some properties of these sections and defines the conic sections based on those properties, as illustrated throughout the book's chapters related to geometry for VI class. The second part includes the *contents* for grade VII. This part of the textbook also begins with a transcription of the program, followed by four chapters. The first three explain the methods, while the last focuses on plane geometry. For the VII class, the program prescribes the teaching of elementary contents of plane analytical geometry, which comprise:

> Elementary notions of analytical geometry in the plane – Equations of a point in a rectangular coordinate system. Line equation; angular coefficient. Determine the coordinates of the intersection point of two straight lines; condition for lines to be parallel. Find the equation of the line determined by two given points. Find the acute angle of two straight lines; condition of perpendicularity. Determine the distance between two given points.
>
> Equation of a geometric locus; equation of curvature referred to two perpendicular diameters; equation of the ellipse and hyperbola referred to the axes; equation of the parabola referred to the axis and the tangent at the vertices. Graphical representation of circular functions[1]. (Decree no. 3/1905, p. 489)

The last chapter introduces, in the order in which they appear in the prescribed program, the geometry topics planned for the VII class. Along the chapter, there are sections with exercises, allowing

[1] All translations were made by the authors.

students to practice. The author's choice to dedicate the three previous chapters to exploring the methods stands out since the methods are nothing more than the observation of the programme.

> Observation. - During the review of the doctrines of geometry, attention must be paid to the general methods (analysis, synthesis, reduction to absurdity) and particular methods (geometric places, inversion and algebraic) ((Decree no. 3/1905, p. 489, p. 489)

In the first three chapters of the second part of the textbook, alongside the recommended methods for observing the prescribed programme, the author also includes a section on transformation techniques: multiplication of curves, similar figures, inverse problems, transformation by translation, abstraction or generalisation, algebraic techniques, and the possibility of solving problems using only a ruler and compass. This aligns with the author's pedagogical perspective of teaching different methods, an approach not present in previous or subsequent geometry textbooks.

The figures throughout the textbook either depict a construction or represent graphs of functions, such as the sine and cosecant graphs. The figure is introduced as "The continuous line curve is the graph of the function $y = sin\alpha$, without any other contextualisation of the sine function and introducing $y = cosc\ \alpha$ noting that the ordinates for the same abscissa are the "reciprocal numbers of the corresponding numbers of the function $y = sin\alpha$, since $cosc\alpha = \frac{1}{sin\alpha}$", indicating that it is represented in dashed lines (Albuquerque, 1906, p. 105-106), as Figure 1 shows.

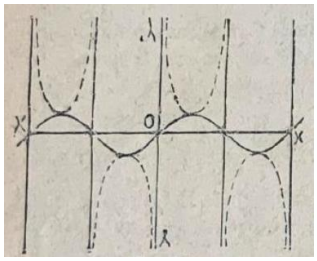

Figure 1: Sine and cosecant graph. (Albuquerque, 1906, p. 150)

There are no motivational elements or indications to guide students' learning. The exercises proposed in the last chapter lack solutions or resolution proposals. The book is highly theoretical, featuring a sequence of methods, definitions, and theorems, and presents the contents in a very formal way. This student-directed organisation fosters a passive *expectation* of learning grounded in a theoretical explanation of the mathematical content to be learned. The student is not encouraged to engage, complete reasoning, or solve exercises when reading the textbook.

For example, in the section where the author introduces the Reduction to Absurd Method, the author begins by explaining what it consists of

> This method consists of demonstrating that the *denial* of the theses, stated as true, evidently leads to absurdity (*ad absurdum,* [sic]), that is, to consequences incompatible with the hypothesis of the proposed proposition or contrary to already established truths, or in themselves absurd (translated from Albuquerque, 1906, p. 53, italic in the original).

The author illustrates the application of the method by proving two theorems: i) If two triangles have equal sides from side to side, the triangles are equal, and ii) The shortest segment that joins a point

outside a straight line to a point on that line is the perpendicular dropped from the point to the straight line. The author demonstrates theorems without any illustration. The lack of illustration makes it difficult to interpret the proof presented by the author, as it stands out in the following example.

> We can always make two equal sides [of the triangles] coincide: let's suppose that the triangles do not overlap (negation of the thesis), that is, that the third vertices do not coincide. Then, these non-coincident vertices form, with each vertex that coincides with direct application, two isosceles triangles with a common base, the segment determined by the non-coincident vertices. The perpendicular raised through the middle of this base must pass through the apex of each of the isosceles triangles, which is absurd (Albuquerque, 1906, p. 53).

Chapter III presents "Transformation methods", a topic not specified in the official program. It includes multiplication of curves, similar figures, contrary problems, transformation by translation, abstraction or generalisation, algebraic, and the possibility of solving problems using only a ruler and compass. The author begins with the question: "How may the possibility or impossibility of a geometrical construction of a problem with the restriction as mentioned earlier be recognised?" (Albuquerque, 1906, p. 110). It then considers the impossibility of solving simple geometry problems using only an unmarked ruler and an Euclidian compass, indicating three famous examples of this impossibility: the duplication of the cube, the trisection of an arbitrary angle and the squaring of the circle. The author answers the question posed at the beginning of the chapter using Petersen's formulation, which ends this section:

> The necessary and sufficient condition for a problem to be solved using a ruler and compass is that the quantities sought are expressible by the quantities given through rational operations or using square roots within a finite number (Albuquerque, 1906, p. 112).

Regarding *expectations*, this book offers a theoretical approach, featuring few exercises, and presents a collection of mathematical methods and concepts. Albuquerque describes mathematics as he perceives it. He employs elaborate formal mathematical *language* to prove results and does not accommodate the textbook for students' independent learning. It's possible to characterise *language* as elaborate by contemporary standards, with little regard for the reader's understanding.

A broader perspective of the textbook

Carrying out a meta-analysis with the categories proposed by Krüger (2010), *coherence*, *visualisation*, and *use of contexts*. It appears that the textbook has a theoretical nature without the *use of contexts* to illustrate what it is intended to teach. Contents are formally exposed using definitions, theorems, corollaries, and demonstrations. Very few examples are given, and the book lacks exercises as a form to allow students to practice.

Regarding *visualisation*, this is a geometry book, so figures appear regularly, especially to illustrate the mathematical content. The book is dense and difficult to read. The contents are organised according to the prescribed program and numbered sequentially throughout the chapters.

Regarding *coherence*, it appears that it exists within the textbook itself, where the teaching of methods for solving geometric problems is privileged. Throughout its 156 pages, the textbook presents a coherent structure, with formal mathematical language constantly used and addressed to the third

person. Although the author did not follow a strict axiomatic approach, arguments for constructing the content almost always follow a rationale supported by logic. The author follows the program's suggestions for revisions of general and particular methods provided for in VII class but introduces a section with a set of methods before geometry in the plane, found in the last part of the textbook.

Final considerations

This article aims to i) compare the prescribed curriculum with that presented to teachers and ii) analyse a proposal for teaching geometry in the final two years of *liceus*.

The fact that there was no unique book during this reform does not allow us to determine whether this would be the only textbook intended for teaching geometry in science courses in the last two years of *liceus*, although we did not find a competing textbook in PORBASE (https://porbase.bnportugal.gov.pt/), the national library database. We also do not know the extent to which teachers using this particular textbook would follow the abstract approach it implied or if they would choose to include illustrative examples and exercises. Also, we do not have data on the number of teachers who used this textbook in their geometry teaching, and we do not know whether they followed the adopted school textbook. However, comparing this textbook with those from previous and subsequent reforms suggests a novel approach to introducing mathematics into the last two years of *liceus* science courses, particularly in teaching plane geometry. According to the 1905 program—or at least Albuquerque's interpretation—geometry takes a secondary role, with the main goal being to develop students' appreciation for specific methods of reasoning.

Drawing a parallel between the prescribed curriculum and that presented to teachers, it is not known what led the author to choose to structure the textbook, including some methods that are not listed in the official program prescribed in the Government Gazette. Due to the lack of a preface, we don't know the sources or the intentions of Joaquim Albuquerque. However, the study of this textbook allows us to look at a set of methods used to prove geometric results with an approach to teaching geometry that is innovative due to the differences found.

The proposal for teaching geometry in the last two years of *liceus* is very formal, and the *Geometria* textbook does not have a didactic nature but is rather a theoretical book due to the lack of exercises, their solutions or resolution proposals, the language used, and the lack of use of contexts, which could make it easier for *liceus'* students to learn plane geometry. However, it is interesting to note that the formal proposal for teaching geometry introduces a series of methods into the curriculum, which allow the teaching of geometry to be systematised. This proposal differs from previous and subsequent proposals for teaching geometry in the last two years of *liceus*.

Iconic representations in Renaissance reckoning books – on the way to a table of classification

Barbara Schmidt-Thieme[1] and Tanja Hamann[1]

[1]University of Hildesheim, Germany; barbara.schmidt-thieme@uni-hildesheim.de

In this paper, we present a first step of a research project aiming at developing a scheme for the didactical description and analysis of textbooks from the early modern period. The first design feature we take a closer look at are iconic representations and as a first source, we choose a reckoning book by famous German "Rechenmeister" Adam Ries. Within a qualitative approach, we categorise the representations and describe their function in order to find out what we can tell about Ries' didactical intentions that the figures are based on.

Keywords: Textbook research, history of mathematics education, numeracy, Adam Ries

Introduction

When it comes to research on mathematical education in Renaissance Europe, reckoning books written by *Rechenmeister* serve as our main sources for elementary, for the most part arithmetic education. We can rather easily derive from them *what* was to be taught, while the books tell us hardly anything about *how* things were meant to be taught, at least from a strictly methodical perspective. Yet, it is quite clear that these books can tell us something about their authors' didactical principles and intentions. As we see a rather broad agreement on the mathematical subjects of teaching, we need to have a closer look at the differences between the books in presenting their content. Wishing to do that, we found we are missing criteria to describe and compare Renaissance reckoning books in more detail. This paper marks a starting point of a long-term project aiming at developing a scheme for the didactical description of textbooks from the early modern period.

The long-term aim of the project is to find out about didactical concepts respectively communication patterns in mathematical learning situations between around 1500 and 1800. This requires a thorough description of the fundamental database, i.e. persisting reckoning books, in regard to contextual as well as textual aspects. While contextual aspects like "addressers and addressees, […], the physical and social setting of text production and text reception, and the goal(s) of the text" (Jacobs & Jucker, 1995, p. 11) might be extracted directly from the book's surface or introductory parts, an account of textual aspects – i.e. symbolic and iconic representations – requires further differentiated criteria.

For a start, we chose to describe and categorise iconic representations in the 1574 edition of Adam Ries' *Rechenbuch auff Linien und Ziphren* (Ries, 1574; so called *Zweites Rechenbuch*). We use a qualitative approach, characterising pictures and figures first by their components and surface features and secondly by their functions for acting mathematically. From these descriptions, we inductively derive different types of figures and – after considering the text they are embedded in – deduce statements about Ries' didactical intentions. These findings will be used as a base for the analysis of what we find in comparable books, e. g. the one by Johannes Widmann (1526), and will serve as a step on the way to coming up with a table of classification of iconic representations in Renaissance textbooks.

State of research

Considering the methodological perspective, Karp (2014, p. 12, in reference to Schubring) notices a "lack of worked-out theoretical categories for analysis" of sources concerning the history of mathematics education in general. We have reason to believe that this is still true ten years afterwards. Schubring (2022) himself has rather recently devoted a whole book on the question of analysing historical textbooks and ascertains "enormous methodological problems" (p. 3) in this area of research. His main focus, though, is on the "contextual analysis of historical textbooks" (p. 7), referring here to the socio-cultural context of the textbook work. In his own research on Lacroix's textbooks he works out three dimensions of analysis: comparison of consecutive editions of the same textbook, comparison of contemporaneous textbook series and establishing relations between (changes in) textbooks and (changes in) underlying external conditions (e.g. curricula). All of these dimensions of analysis require detailed description of a corpus of textbooks first to allow systematic comparisons at all. However, this problem is not addressed by Schubring. He gives an account of documentation of and research on mercantile arithmetic books – meaning what we call reckoning books in this paper – in different European countries, but does not go into methodical detail here.

Regarding existing research on Renaissance textbooks, especially arithmetic and reckoning books, from Germany, one needs to mention the *Adam-Ries-Bund*. The proceedings of their regular conferences (for an example see Gebhardt, 2023) contain numerous accounts on these, but for the most part this research is limited to the description and analysis of single books and their authors, lacking both a systematic review and a didactical perspective, not considering the teaching context (in the sense of Jacob & Jucker, see above). Holl (2023, pp. 35-42) recently presented an outline of a systematic description of arithmetic books including a categorisation of content-related elements. His work shall serve as a valuable tool when it comes to analysing *what* the author of the textbook wanted his pupils to learn. Didactical features are lacking in his collection, though. Linguistic surveys on reckoning books are rare, as well. Gärtner's (2000) edition of Widmann's book is accompanied by an etymological study on reckoning books being regarded as a specific text type but does not focus on further didactical aspects. Gabriel's (2010) work is the only one known to us to describe Ries' *Zweites Rechenbuch* from a didactical perspective using linguistic methods. He compares Ries' work to Widmann's book focussing content, language issues and notations and therefore analysing the representations that are covered. His work is limited to this particular example; nevertheless, it should be of good guidance for our own purpose in the long-term. Schöneburg (2007) performs a methodical-didactical analysis of the textbook on military mathematics from 1631 by Ambrosius Rhodius, especially regarding addressees, language use and the author's intentions. For this purpose, she analyses the book's content, style, figures and methodical features. The work is limited to a particular example, though, as well.

Analysis of iconic representations in Adam Ries' *Rechenbuch auff Linien und Ziphren*

Types of iconic representations

Before one speaks about iconic representations, it is necessary to make a clear distinction between symbolic representations, i.e. text, and iconic representations, i.e. figures. By figures, we understand

those parts of the written or printed matter that do not only consist of letters, but comprise numbers, lines, operators etc., as well, and that are two-dimensional or offset.

Ries' book contains about 150 figures, and in a first step, we characterised them according to their constitutive parts. We found that the majority of them (about 90%) only consists of numerals/numbers, lines (in different arrangements), dots, brackets, single words (meaning that they are not part of a sentence) and abbreviated notations for units (e.g. currencies). Beyond that, one of these examples also shows a pointing hand and six examples display jettons as part of depictions of a counting board.[1] All of these figures clearly represent mathematical items. Of the remaining figures, one only consists of lines, this one can be easily characterised as an ornament, and ten are made up of pictorial elements, depicting persons in certain contexts from everyday life. While the image on the title page apparently shows a situation inside a reckoning school and by that tells us about the context of use of the whole book, the others each depict the everyday context taken up in the following chapters, in the most part trading scenes (e.g. the trading of cattle). So, this first step, in which we describe iconic representations by their surface features, already allows us to distinguish two categories of figures: those that display **mathematical** items and those that display only **non-mathematical** items. We will call the latter **pictures** and they can again be divided in two sub-categories, **ornaments** and depictions of everyday life situations. As we are interested in Ries' views on the teaching and learning of mathematics, it is obvious that we do not learn enough about the ideas behind the figures of mathematical items from only describing their external characteristics. We need to pose further questions to enable a more sophisticated categorisation of the iconic representations in Ries' book.

In the second step, we strove to ascertain the function of the figures. At this point, we are not yet talking about didactical functions as we seek to deduce these from the more detailed categories later on. The focal question here is: What is it that the figure "does"? As for the ornament, it is clear that it has a purely decorative function and is therefore not of further interest in regard to teaching and learning situations. We will hence exclude this type from our upcoming considerations. The images of everyday life situations illustrate the paragraphs to come; we will therefore call them **illustrations**. Regarding the mathematical items, we find different types. One type of figures **introduces** terminology and notations like numerator and denominator or the names of the place values. Another one **presents** calculations with concrete numbers that are complete in the sense that the given numbers as well as the results are presented. Examples for this type are a multiplication table and images of fully conducted written calculations. These presenting figures differ in how far intermediate results of the calculation process are visible and replicable. Apparently, those presentations may be introductions of calculation methods, as well, but we cannot tell by looking at the figure in isolation. We find that to make further statements and describe the presenting figures more thoroughly, we need to consult further features and integrate the position of the figure within the book. Therefore, the first appearance of a presenting figure is likely to have an introductory function, as well. Furthermore, we

[1] In this book, Adam Ries introduces Arabic numerals and methods of written calculation using the decimal system. Before the introduction of these methods, though, he teaches how to do calculations using the counting board.

find a third type of mathematical figure, which appears numerously. This type consists of numbers and is sometimes complemented by abbreviated units. The numbers are arranged in a certain, often two-dimensional manner, sometimes lines are added. These figures are not self-explanatory when they are looked at in isolation. Again, we need to consult further features, and this time we find that the surrounding text is necessary to make statements on the function of this type of figures. These examples are either part of proofs or part of the presentation of the diverse *regulae* that are typically found in Renaissance reckoning books. The figures do not present the full calculation itself but they provide a scheme how to arrange the given data and intermediate results in such a way that the calculations can easily be carried out in mind. One can say that these figures **structure** the given numbers and data.

Up to this point, we find five types of iconic representations within the second reckoning book by Adam Ries that we can assign all the figures to:

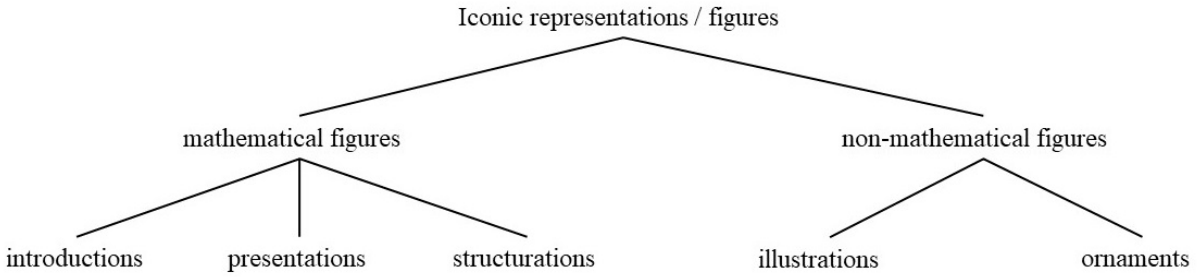

Figure 1: Types of iconic representations in Ries' second reckoning book

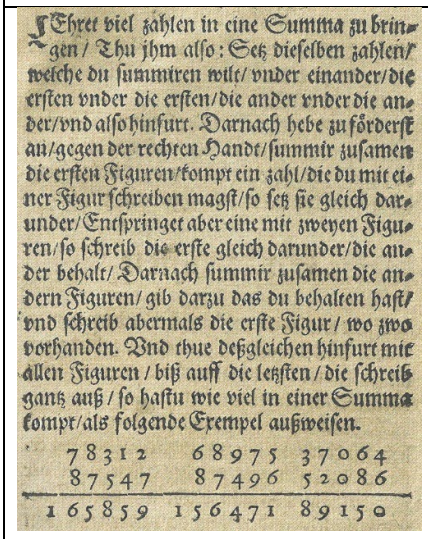

Didactical function of iconic representations

In order to be able to express assumptions about Ries' didactical intentions behind his use of figures, we need to work out their functions in regard to their recipients first. That is, we need to ask next: What is it that the addressee is supposed to do when he or she sees this figure? Starting with the illustrations, being non-mathematical figures they do not aim at a mathematical kind of action. They establish an everyday context for the reader and by doing that they enable the recipient to familiarise with the situation presented. The alleged didactical function of this is identification with the upcoming problems and showing their relevance to practical application. However, we do not know whether Ries himself wanted to include these illustrations at all. Earlier editions do not contain any so it is quite probable that it was the publisher who inserted them of his own accord.

Considering the mathematical figures, we find that it is again not sufficient to look at them separately to work out what mathematical action is supposed to be induced. We need to consider the surrounding text and its relation to the figures. For those figures that introduce terminology and notations it seems clear that they present knowledge that must be grasped and learned by heart. As for presentations and structurations, a closer survey is necessary. In the following, we examine the text-figure relations for two mathematical examples. One of them is the introduction of written addition, which we allocate to presentations; the second one is a part of the paragraph on the *regula falsi*, which can be assigned to the structuring type. We will describe them on a formal (i.e. surface) as well as on a substantive

level. For the latter we compare the content of the accompanying text with the content of the figure itself.

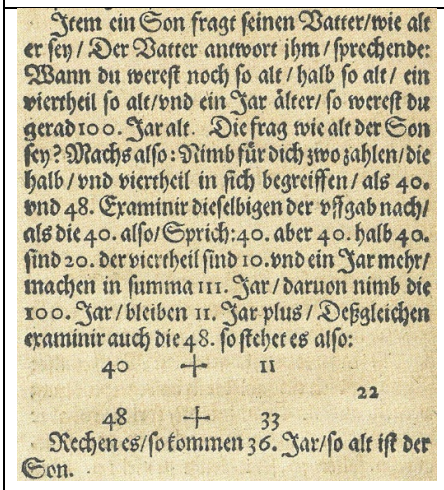

Table 1: Description of text-figure relation in Ries (1574, p. 10r)

Example 1: presentation	Text	Figure
	Stepwise description of the written addition procedure for general numbers: • how to write and arrange the given numbers (one above the other) • how to add up the place numbers • how to write the intermediate sums and how to proceed in case of a carry • how to read the sum	Three examples of fully conducted written addition with concrete numbers: • five-digits summands written one above the other • six-digits sums beneath lines that divide them from the summands
	The text shows direct reference to the figure by saying "as the following examples reveal" (*als folgende Exempel ausweisen*)	

The reference shows that Ries wanted his readers to use both, text as well as figure, so the whole paragraph should be seen as a unit. Consequently, when we wish to work out the figure's function we must analyse its function within this unit.

Ballstaedt (1997, pp. 251-254) names three possible characteristics of text-figure relations that usually appear in combination. Relations may be congruent (meaning that the figure represents the same content as the text), complementary (meaning that the figure fills blank spaces that are left by the text or vice versa, so that comprehension requires to consider both) or elaborative (meaning that the figure presents information beyond the original content of the text or vice versa). The table shows that in the figure information from the text gets lost as generality of application is not visible in it and not every single step described is shown separately. Nevertheless, there are congruent parts, namely the objects mentioned, the notation and the procedure itself as results from intermediate steps are visible. On the other hand, the figure shows concrete examples with numbers that are not mentioned in the text, establishing a clear complementary relation. The function of the figure as part of the text-figure unit is to complement, augment and concretise the text and by this to complete the unit. Ries invites the addressees to use the figure in such a complementary way. They are supposed to reproduce the steps that the text describes for general numbers with the aid of the concrete examples, either mentally or by writing down the calculation stepwise themselves. The didactical function of this intended mathematical action is to reproduce procedural knowledge, possibly in order to gain the ability to applicate this procedural knowledge to other given numbers.

Table 2: Description of text-figure relation in Ries (1574, p. 58v)

Example 2[2]: structuration	Text	Figure
 Item ein Son fragt ſeinen Vatter/wie alt er ſey / Der Vatter antwort jhm / ſprechende: Wann du wereſt noch ſo alt / halb ſo alt / ein viertheil ſo alt/vnd ein Jar älter/ ſo wereſt du gerad 100. Jar alt. Die frag wie alt der Son ſey? Machs alſo: Nimb für dich zwo zahlen/die halb / vnd viertheil in ſich begreiffen / als 40. vnd 48. Examinir dieſelbigen der vffgab nach/ als die 40. alſo/ Sprich: 40. aber 40. halb 40. ſind 20. der viertheil ſind 10. vnd ein Jar mehr/ machen in ſumma 111. Jar / daruon nimb die 100. Jar / bleiben 11. Jar plus / Deßgleichen examinir auch die 48. ſo ſtehet es alſo: 40 + 11 22 48 + 33 Rechen es/ſo kommen 36. Jar/ſo alt iſt der Son.	Exemplary task consisting of problem and incomplete solution: • verbal description of situation • question to be answered • detailed description of first step of solution procedure, applied to number 40, giving 11 as positive (*plus*) intermediate result • request to apply first step of procedure to number 48 • solution 36	Numbers and lines arranged in a certain schematic order: • numbers 40 and 11 in a row, symbol + in-between • numbers 48 and 33 in the row below, symbol + in-between • number 22 on the right between the rows
	The text shows direct reference to the figure by saying "so it says:" (*so stehet es also:*)	

Again, the reference suggests that text and figure form a unit and that the recipient is supposed to consider both. Comparing this example with the first one, we see some differences, though, already from a formal typographic perspective. While in the first example the figure follows the text, the number scheme in this example has accompanying text above as well as below it. It is immediately apparent, that the figure is an essential part of the unit completing the text parts and vice versa. The substantive perspective supports this. While in example 1 text and figure might stand for themselves, this is not the case here. The figure is lacking information that is crucial for its understanding, and so is the text, neither of them would be comprehensible if they stood for themselves. There is some congruency, namely the numbers 40, 48 and 11 as well as the word and sign for "plus", but this overlap is very limited. For the rest we can see no content-wise congruencies, the text-figure relation is clearly complementary, and the function of the figure within the unit is to complete it. The mathematical action that the reader is supposed to conduct is to understand the task's solution and in order to do that, it is necessary that they carry out parts of the calculation by themselves with the aid of the number scheme. Apparently, the whole example is missing detailed guidance on the solution procedure, so that the text-figure unit is still incomplete. The necessary instructions can only be found on some prior page, so we have yet another example where not only the accompanying text but the figure's position in the book respectively the paragraph is crucial for its analysis. The didactical

[2] "A son asks his father how old he was. The father answers: If you were twice as old, half as old, a quarter as old and one year older, then you would be 100 years old. The question is how old is the son?"

intention of the text-figure unit is to repeat and practise the *regula* to incorporate procedural knowledge and to gain the ability to apply the rule to other given situations and numbers.

Conclusion and outlook

By describing and categorising the iconic representations in the second reckoning book by Adam Ries, we were able to work out the figures' functions whereupon we could deduce some didactical intentions that Ries built his work on. We found that the mathematical figures' surface characteristics are in line with their functions for the most part. Introductions provide terminology and notations that must be memorised; therefore, they provide learnable knowledge. Presentations and structurations show sections of algorithmic calculations, which are supposed to be retraced and understood in order to enable the addressee to perform the calculations themselves. Hence, these kinds of figures aim at imparting procedural knowledge and abilities. In all cases, it is not intended to lead the reader to a deeper comprehension of the calculation methods.

As this paper is only a first small step in a bigger project there are many steps laying ahead. A first one would be to apply our findings from Ries to other reckoning books as well as textbooks from other subjects (geometry, architecture…) from Renaissance times to see whether the categorisation and the assumed connection to the functions of the figures fit other sources, too. A first glance at the reckoning book by Johannes Widmann shows resemblance concerning the types of figures but reveals that we would have to enhance our categories, as well. It looks like it could be a more promising approach to replace the fixed categories by criteria and to establish a set of characteristics relevant for determining the figures' didactical functions. While keeping the number of criteria to a manageable size, this approach, at the same time, allows combining the criteria in diverse ways enabling a more precise description of the types of figures and leading to more flexibility when selecting categories fitting a research question.

When analysing figures, we also noticed, that in most cases, it does not suffice to look at the figure in isolation. As a second step, the accompanying text respectively the text-figure relation has to be considered, too, as well as the figure's position within the book or within the paragraph. A comparison of Ries and Widmann also suggests that it may be crucial for a didactical analysis to consider whether a figure is part of a sequence of figures, e.g. with increasing difficulty.

So, analysing and categorising further textual aspects and connecting them to contextual aspects has to be done to find out more details about the didactical intentions of the authors.

Using word problems from the 16th century in teaching mathematics

Stela Segev[1] and Tsurit Elitzur[1]

[1]Herzog College, Jerusalem, Israel; stela.segev@gmail.com

Word problems in mathematics is a topic that has received a lot of research interest, mainly because of the difficulties it poses during teaching. In this study, we tried to check what the contribution of bringing such problems from a Jewish math book from the beginning of the 16th century to teaching students could be. The results of the study showed that dealing with these problems and their solution as they appear in the 16th-century book can lead to positive attitudes in the students both in terms of getting to know Jewish mathematicians and in terms of exposure to new ways of solving.

Keywords: History of mathematics, mathematics education research, primary historical sources.

Introduction

The integration of historical content in mathematics teaching has been widely discussed in recent years. For the idea to become a reality, it is necessary, among other things, to introduce the subject into the curriculum of preservice teachers **(**Furinghetti, 2007). In this study, we planned a study unit that exposes the students to the historical content of a specific topic in teaching mathematics: word problems in an arithmetic Hebrew book from the beginning of the 16th century.

Theoretical background

In his 2009 article, Jankvist (2009) proposed a new way to organize the discussion about using the History of Mathematics (HOM) in teaching by answering the questions of "why" and "how" and the interrelation between them.

The "why" refers to the causes of using HOM, and according to Jankvist's opinion, all the arguments for integrating the history of mathematics in teaching can be attributed to one of the following two: arguments referring to history as a tool and as a goal. When we use the history of mathematics to motivate our students, to lower their anxiety, and to improve their cognitive processes, we use the history of mathematics as a tool. When we speak with our students about the evolution of mathematical concepts in time or the development of mathematics in different times and cultures, we refer to mathematics history as a goal.

The "how" refers to the different ways of integrating HOM in teaching. Jankvist classified them into three major categories: Illuminate approaches (short historical notes, mainly about mathematicians, essential events, and famous problems), modules approach (study units are dedicated to the history of mathematics), and history-based approaches (when historical considerations guide how the mathematical subjects are written).

Using primary sources in teaching mathematics

Using primary resources is an obvious choice when we refer to HOM as a goal and want to design an appropriate teaching module. However, the expected difficulties in bringing primary sources to the students must be considered: understanding old texts' language, different terms, and different cultural contexts. However, as Jahnke stated:

> The study of original sources is the most ambitious of ways in which history might be integrated into the teaching of mathematics, but also one of the most rewarding for students both at school and at teacher training institutions. (Jahnke, et al., 2002, p. 291)

Word problems in Elijah Mizrahi's "Book of Number"

The problems were chosen from Elijah Mizrahi's "Book of Number", written in Hebrew in Constantinople at the beginning of the 16th century. This book is particularly relevant because it addresses the didactic aspects of learning mathematics, such as the importance of understanding beyond performing the algorithms for the solution. The book contains various arithmetic topics, such as calculations with integers, simple fractions, and sexagesimal fractions, a chapter on proportions and roots calculations, and a chapter with 100 word problems. In this chapter, each problem is explained in detail; sometimes, more than one solution is given. The problems deal with various subjects from everyday life, such as inheritances, partnerships, shared work, and more, but there are also theoretical problems (Mizrahi, 1534).

Rationale and objectives

In this research, we chose to refer to HOM as a goal and design a teaching module about word problems in Mizrahi's book (16th century). The study unit was designed to give future teachers a broader concept of mathematics and its development process, focusing on Jewish mathematicians. We chose to focus on word problems because this is a mathematical topic relevant to students and their (future) students—a common topic in the grades 7-10 curriculum.

The mathematics department at Herzog College trains mathematics teachers for the 7th - 10th grades. As part of their degree, they study at least one course on the history of mathematics. However, in these courses, there is little reading of original texts and only sometimes discussion about the possibilities of integrating the content into teaching in schools. Beyond the general goal formulated earlier, we set ourselves some more focused goals:

- Learn the solution methods in historical sources and compare them to today's methods.
- Check how these problems can be integrated into teaching in grades 7 to 10.
- Deepen the students' connection to Jewish heritage in a lesser-known field by getting to know prominent figures in the scientific-mathematical context.
- To arouse their awareness and generate a positive attitude toward integrating historical content in mathematics teaching.

Beyond learning the mathematical texts, their content, and the ways of solving the presented problems, the students enrich their background about mathematical knowledge in the early 16th century. For example, they can understand how to do mathematics without negative numbers and some advantages of working without algebra (Heeffer, 2014).

Method

The research was carried out in two classes (20 students) studying a course on different strategies for solving mathematical problems. This course exposes students to diverse and unconventional strategies and solution methods.

In planning the research, we followed the hermeneutic approach.[1] (Glaubitz, 2010). During the study, the students were exposed to other solutions that are common today and methods that were used in the past and "forgotten." They were exposed to non-algebra solutions to problems they are used to solving using algebra. We raised whether there is any added value to these solutions found in historical sources.

In addition, they received some information about Elijah Mizrahi and his book. Some students (mainly the men) were familiar with Mizrahi's halachic writings and did not know he was also a mathematician. Others heard about Elijah Mizrahi for the first time in these lessons.

During the unit's planning, we tried to anticipate difficulties that may arise: The students can read the original book written in Hebrew, but they have to overcome linguistic difficulties originating from the medieval language and the different terminology. They also must be able to understand the cultural environment of the author, Mizrahi, and the stage of development of mathematics at that time.

Participants

The students at Herzog College are primarily religious or traditional Jews with a strong orientation to Jewish tradition. The 20 students who participated in the study are in a program for teaching mathematics in grades 7 to 10 (ages 12-16) and studied in two classes: a women's class (12) and a mixed-gender class (8). Most women's class students were young women who had just graduated from high school and were going on to college, and they were usually without teaching experience. In the mixed group, there were six men and two women, most of whom were older and usually had been working in teaching for several years[2]. So, this was a heterogeneous group that could provide information on different sections of the population.

Research questions

1. What are the students' views about word problems?
2. What are the students' opinions on integrating historical sources in teaching mathematics, particularly word problems?
3. What are the students' opinions on pedagogical aspects of teaching word problems: teaching more than one solution to a problem, solving problems without algebra, and more?

Research design

We chose seven problems from Mizrahi's book: problems that use the rule of three or the false position method, two motion problems (one involving using arithmetic sequences), one inheritance problem, and one dealing with integer division and their remainders.

The subject was taught in two consecutive lessons. The first lesson provided background on Mizrahi's life, work, and cultural environment. Two problems were then presented. First, the students solved the problem the way they wanted (usually using algebra), and then Mizrahi's solution was presented.

[1] This approach concerns local and episodic historical interventions and serves as a means of deepening and reflecting.

[2] Of the 20 students, there were 7 students who worked as teachers and 13 students who were not yet working as teachers.

In the second lesson, the class was divided into groups of 2-3 students, each receiving 1-2 problems from the book. They were required to decipher the problems and Mizrahi's solutions and then present them to the class. We helped the students understand medieval language when necessary. We also had to draw the students' attention to the mathematical content known in Mizrahi's time (without using negative numbers and algebraic tools, but on the other hand, knowledge of the formula for the sum of an arithmetic series).

Table 1: The problems in the research

	The Problem	**Comments on the content and solution method**
1.	If 4 of Constantinople are equal to 6 of Bursa and 9 of Bursa are equal to 3 of Adrianople, how many of Constantinople are 7 of Adrianople?	Rule of three
2.	We added the ninth and tenth to an amount of money, and the result was 50. How much was the amount of money?	False position method, rule of three
3.	A master sent a messenger running 29 miles a day. After ten days, he sent another messenger running 35 miles a day. When will the second messenger catch up with the first one?	Motion problem
4.	Someone swore that each day God doubled his money, he would donate two pešuṭim to the poor. For four consecutive days, God doubled his money, and he gave two pešuṭim each day and ran out of money. How much was his amount of money?	Recursive problem (from the end to the beginning)
5.	If the king sends a messenger to a place, who walks ten miles every day and immediately sends another messenger after him, who walks one mil on the first day, two miles on the second day, three on the third day, four on the fourth day, and so on, when will he catch up with him?	Motion problem, arithmetic sequence.
6.	Someone divides his property among his sons. He instructs that the first will take one zahuv (gold coin) of his money first, then a tenth of the remainder; the second will take two zehuvim of what remains from the first, then he will take a tenth of the remainder; the third will take three zehuvim of what remains from the second, then he will take a tenth of the remainder; so on by this order; the last of his sons will take all that is left from the former ones. We find that all took the same according to this arrangement. How much is the money, and how many are the sons?	Inheritance problem
7.	If one asks: what is the number that when counted by twos - one remains; by threes - 2 remains; by fours - 3 remains; by fives - 4 remains; by sixes - 5 remains; and by sevens - nothing remains.	Integers division and their remainders

After these two lessons, we asked the students to answer a short feedback questionnaire. The questionnaire included 16 questions[3]. There were three open questions and the rest closed questions, in which they had to rate claims/ statements from 1 to 5.

The questionnaire dealt with attitudes and thoughts towards:

a. Word problems in mathematics.
b. Different ways of solving problems.
c. Teaching mathematical content written by the sages of Israel.

Results

Below, we will first present the conclusions regarding all participants. Later, we will focus on the characterizations of different sections of the group.

Most participants expressed positive attitudes towards word problems: They like the topic and think of them as nice puzzles, yet they believe that they are challenging for middle school students and that it is difficult to succeed without algebraic tools. (see Table 4)

Also, on integrating word problems from Jewish mathematicians from the Middle Ages and the importance of knowing Jewish mathematicians, the participants expressed positive opinions despite their difficulty, even though they would not necessarily contribute to raising their students' motivation. The following are some of the reasons they gave for their positive opinion:

Student: As Jews, knowing about Jewish mathematicians is exciting and important.
Student: I think it connects the material taught to us and gives it more meaning when it is connected to Jews and thus also connects to Judaism
Student: I love the Jewish head, and it's nice to see the Jews' wisdom also in real life.

Some students thought it was important to know HOM regardless of the mathematicians' national identities. Other students talked about the connection between the sacred and the profane, especially when the Jewish mathematician is also a halachic, rabbinic authority.

Student: Because it shows that mathematics is not profane and has spiritual and divine creation, and the sages of Israel also dealt with it.
Student: I think there is a mistaken belief that there is a separation between profane and sacred studies.

We also found significant differences between students who are not yet teaching and those already working in teaching. The students already working as teachers tend to attach more importance to content related to Jewish mathematicians (Table 2, Figure 1).

Table 2: Attitudes about integrating HOM in teaching

Statement	Mean (scale 1-5)	Pre-service teachers	Students who are teaching
7. It is important to know word problems that appear in the books of our sages.	3.7	3.4	4.3

[3] The questions were numbered 5-20, while the open questions were no. 9, 19, and 20.

8. I think it is important to know Jewish mathematicians.	4	3.4	4.4
12. Word problems from our sages are more interesting than those in regular textbooks.	3.45	3.2	4.1
15. Word problems from historical sources are too difficult for high school teaching.	2.85	3.2	2.3
17. Teaching word problems from historical sources increases students' motivation to study mathematics	2.85	3	2.7

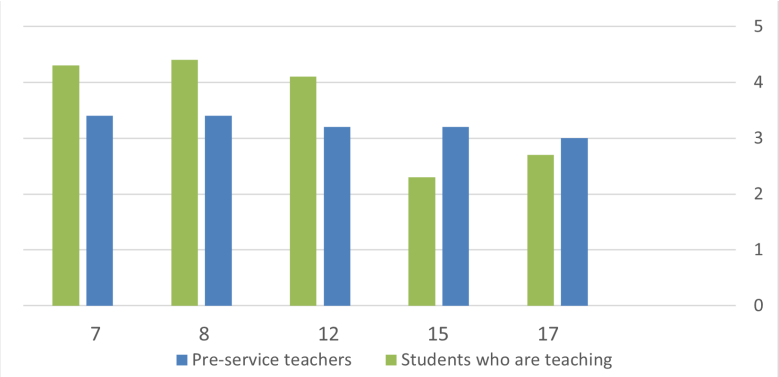

Figure 1: Attitudes about integrating HOM in teaching

Below (Table 3) is a summary of the students' opinions on several didactic issues that emerged during the discussion of Mizrahi's word problems:

Table 3: Attitudes about didactic aspects of teaching word problems

Statement	**Mean** (scale 1-5)
14. It is important to teach solving word problems also without algebra.	4
16. There is no need to teach multiple methods to solve problems.	1.65
18. I like to know different methods of solving problems.	4.1

We see great openness among the students on the subject of various solutions to given problems, including non-algebraic solutions, and also in the answers to the open questions of the questionnaire. Here are some of their answers to the question**,** "Write some new things you learned in these lessons"**:**

Student: I felt I used a way of thinking I usually don't use.
Student: It is incredible how algebra is a narrow way of thinking about problems.
Student: To me, problem-solving in multiple ways develops thinking and creativity.

The attitude to word problems in different genders

Various studies have investigated gender differences in mathematics learning. Most studies dealt with students' cognitive and behavioral differences while studying different mathematical contents, including solving word problems (Zhu, 2007). However, gender differences in teachers' attitudes to

mathematics have been studied less. In this study, although we did not set out to investigate this question, we noticed differences in the students' attitudes towards solving word problems: the men like the subject more than the women; they see the problems as nice puzzles. On the other hand, they estimate that the subject is not too complex for their students. They also think it is not necessarily more challenging to solve problems without algebra than the women who believe there are more difficulties here (Table 4, Figure 2).

Table 4: Attitudes about word problems

Statement	Mean (scale 1-5)	Mean men	Mean women
5. I like to solve word problems.	3.5	4.1	3.2
6. It is difficult to solve word problems without algebra	3.7	3.3	3.9
10. Word problems are a difficult subject for most students.	3.8	3.4	4.0
11. I see word problems as nice puzzles.	3.95	4.4	3.7

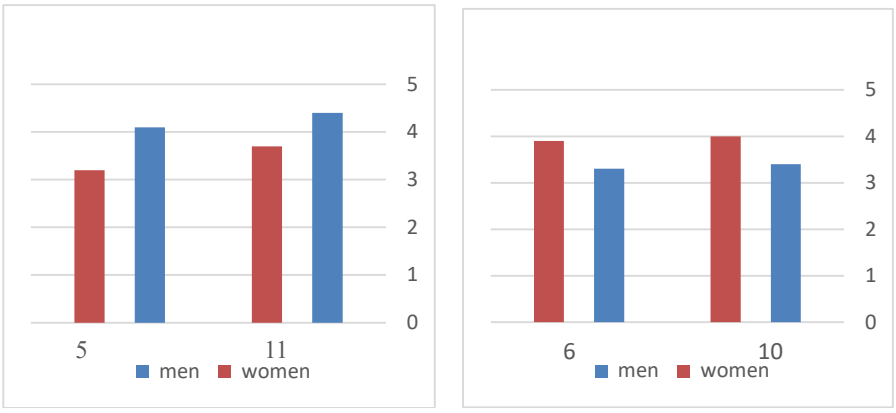

Figure 2: gender differences in attitude to word problems

Discussion and conclusions

The students in this study mainly expressed positive opinions about word problems, similar to the results in Shirvani and Garcia (2014). However, in the same study, gender differences were reported to be insignificant. We can assume that the different results are related to the cultural differences of the study population.

The differences in opinions regarding integration in teaching between students who teach and those who do not can be explained by the fact that only after several years of teaching do they feel the need to do things beyond the daily routine.

The students' positive opinions about word problems or alternative ways of solving, besides algebraic ways, can also result from all the topics taught in this course, which emphasized different, creative, non-standard ways of solving. On the other hand, knowing the solutions of well-known and respected personalities gives additional appreciation to these solutions.

Further and more extensive research can lead to the development of a more comprehensive study unit on word problems from Elijah Mizrahi's book, which is suitable for future teachers. Using word problems from Hebrew books written by prestigious rabbinical figures can also be helpful in curricula aimed at an Orthodox audience that usually avoids non-religious studies.

In his article, Moyon (2019) describes an experiment in which a word problem from Fibonacci's "Liber Abaci," like problem 4 in our study, was presented to secondary school students (aged 14-16). We tried something similar but with prospective teachers in the hope that this activity would change the students' perceptions regarding the importance of integrating the history of mathematics in teaching and that it would continue during the work of these students as teachers.

Studying curricular reform through a full-text database of Norwegian textbooks: Findings and methodological considerations

Bjørn Smestad[1,2] and Hilde Opsal[1]

[1]Volda University College, Volda, Norway; smestadb@hivolda.no

[2]OsloMet – Oslo Metropolitan University, Oslo, Norway

When studying curriculum reforms, it is of interest to investigating when and how key concepts have been included in textbooks. In this paper, we investigate how 390 mathematics textbooks for compulsory school in Norway from 1930 to 1986 treated selected concepts that are usually connected to New Math. We also discuss methodological considerations arising from our study. We use a full-text database of Norwegian books and compare our findings with previous research from Iceland and Norway. We demonstrate that many concepts associated with New Math were included in Norwegian textbooks prior to the 1971 "New Math curriculum", contrasting with the situation in Iceland, and provide a more detailed account of their inclusion. We also discuss how automatic searches can help (and when it does not) in historical research on mathematics education, pointing to some affordances and limitations.

Keywords: Textbook research, mathematics education, history of education.

Background

When new curricula are introduced by governments, policy documents often emphasize the innovations and departures from past practices. However, curricula do not necessarily work according to the plan. Textbooks serve as a bridge between the intended curriculum (the curriculum document) and the implemented curriculum (classroom practice), and can thus be considered part of "the potentially implemented curriculum" (Valverde et al., 2002). Textbooks should therefore be studied as part of a study on the effects of new curricula.

Within the field of history of mathematics education, the reforms under the heading of New Math constitute a particularly interesting case. New Math is often connected to the concept of *set*, but other parts of mathematics, for instance the number line, equations, vectors and statistics, also tended to enter curricula as part of New Math reforms. New Math was based on years of research efforts, was actively promoted through study conferences and international cooperations, and inspired curriculum reforms in many countries (De Bock, 2023). These circumstances created fertile ground for comparative research on curriculum reforms. For instance, Smestad and Opsal (2023) have studied why New Math fared so differently in countries that are often considered to be similar.

Bjarnadóttir (2017) studied textbooks in Iceland before, during and after New Math. Her study shows that set theory concepts were not the only concepts introduced to Icelandic students with New Math. Some of the novel concepts also remained in textbooks after New Math. We replicated Bjarnadóttir's method for the situation in Norway (Opsal & Smestad, 2022). One key difference was that in Iceland, no new textbooks had been published for decades before New Math, while in Norway, several textbook series had been developed in every decade, gradually introducing concepts that in Iceland

co-occurred with set theory. On the other hand, in Iceland there were some topics that only appeared in the 1970s, after New Math had waned there, which in Norway had appeared with New Math.

Both Bjarnadóttir (2017) and Opsal and Smestad (2022) were done by painstakingly studying page by page of textbook after textbook. As we explored the possibilities of expanding our research to include earlier textbooks and more textbook series, we became aware of the possibility of using tools from the National Library of Norway to do searches in a corpus of mathematics textbooks. While corpus-based studies is well known in research on language textbooks to study the vocabulary used (Yang & Coxhead, 2022), we have not found such examples in research on historical mathematics textbooks. This paper therefore has two research questions. The first concerns the content of textbooks, and the second concerns the affordances of full-text searches in databases in historical research on mathematics textbooks.

Our research questions are:

- RQ1: How has the treatment of some key concepts (distributive law, associative laws, the number line, odd and even numbers and equations) changed in Norwegian mathematics textbooks in the period 1930–1986?
- RQ2: What advantages and disadvantages do full-text databases have for historical research on mathematics textbooks?

Norwegian curricula and languages

For context, we will give some background on Norwegian mathematics curricula in the 20th century. At the beginning of the 20th century, curricula from 1889 were used. New curricula appeared in 1922 and 1925, for the countryside and for cities respectively, both for grade 1–7 (ages 7–14). They were replaced in 1939 with new plans, which we will denote N39. In 1960, experiments with nine-year compulsory schooling got its own experimental plan (F60). During the 1960s, there were also experiments with New Math materials produced by the Nordic Committee for the Modernization of Mathematics Education (NKMM). Then, in 1971, a temporary new curriculum, for nine-year compulsory schooling, was published. This included two alternative plans: a traditional Alternative 1, and an Alternative 2 which was close to the NKMM suggestions. However, when a final new curriculum was published in 1974, Alternative 2 was abolished and New Math went back to having a small place in Norwegian curricula. After 1974, there has been new curricula in 1987 and 1997, as well as 2006 and 2020 in the 21st century, but these are not relevant for this article.

As we will study textbooks, we need to give a brief explanation about the official languages of Norway. The Norwegian language has two official written standards, bokmål and nynorsk. From 1974, all students have the right to get textbooks in the standard they use. Sámi is also an official language of Norway.

Methods

To answer RQ1, we will examine when and to what extent the selected concepts are emphasized in textbooks for relevant curricula, supplemented by an analysis of which concepts are closely linked to certain other concepts in the textbooks. RQ2 will be answered by reflecting on the difference between Opsal and Smestad (2022) and this present study.

In Norway, the National Library aims to digitalize all Norwegian books. It also has apps available to do different kinds of analyses, the relevant ones we will describe below. We have developed a corpus that includes all (as far as we have been able to establish) Norwegian mathematics textbooks published from 1930 to 1986. Opsal and Smestad (2025b) describes the development of this corpus in some detail. The corpus included student textbooks, exercise books, teachers' guides etc, in two languages (bokmål and nynorsk) and in all editions (see Opsal & Smestad, 2025b).

For the current project, we have developed subsets of this main corpus for each of the relevant curricula of the period (N39, F60, NKMM, M71, and M74). These subsets include only the first available edition in bokmål of all the student textbooks for each of the curricula. We focused on student textbooks, as those are books used by students where mathematics is explained, as opposed to exercise books (where mathematics is usually not explained) or teacher guides (that students do not use). We chose books in bokmål as the inclusion of both languages would complicate the textual analyses. We chose the first available edition because the inclusion of several editions of some books would skew the results. We ended up with a total of 390 textbooks in the subsets (see Table 1).

Table 1: Number of textbooks included in the subsets

Curriculum	N39	F60	NKMM	M71	M74
Number of books	67	68	10	116	129

The concepts chosen were the distributive law of addition, the associative law of addition, the number line, even/odd numbers and equations. These concepts were chosen since they were shown in Opsal and Smestad (2022) to be part of Norwegian textbooks before 1971, thus making it possible to track them over time. In Iceland, the first three of these concepts entered textbooks from 1966, even and odd numbers had been in textbooks since the 1910s, while equations entered textbooks in the 1970s.

When looking for instances of a concept in a textbook, an operationalization is needed. For instance, the number line can be referred to both as a phrase ("number line") and as an image of a number line. Concepts can also be evoked in other ways, as when the set of even numbers can be written as $\{2n: n \in N\}$. When using automatic text searches, we are limited to searching for particular words or phrases in the textbooks. This limitation needs to be considered when analysing the results, as we will discuss below.

To search for words in textbooks for different curricula, we used the National Library app Word Frequencies (Ordfrekvenser). This app simply counts the occurrences of words throughout the corpus. The words chosen were *distributiv* (distributive), *assosiativ* (associative), *tallinje/tallstråle* (number line), *partall/oddetall* (even/odd number) and *likning/ligning* (equation), and variants of these words, such as tallinjer (number lines).[1] The app includes the possibility of using a grouping variable. In our

[1] The complete list of variants searched for is: distributiv, distributive, assosiativ, assosiative, tallinje, tallinja, tallinjen, tallinjer, tallstråle, tallstrålen, tallstråla, tallstråler, partall, partallene, oddetall, oddetallene, likning, likninga, likningen, likninger, likningene, ligning, ligninga, ligningene, ligninger.

case, we used grade as a grouping variable, to get an overview of which grades words occurred in. The analysis of these tables consisted simply of comparing the tables, individually and together, to point out trends in when and to what degree concepts were stressed.

There is no one-to-one correspondence between a concept and a word. Firstly, a concept may be treated in a textbook without being named (or by using another word). Therefore, we cannot claim that a word search will find all occurrences of a concept. Secondly, the word may be used without referring to that exact concept. However, some mathematical words are exclusively or predominantly used for the concept, and in other cases, each occurrence of a word can be checked. An additional issue is that we have no exact knowledge of the accuracy of the digitalization, so some words may be misspelled leading to the app not finding them. Again, this means that the method may miss some instances of a concept, but probably not lead to extra, erroneous instances. Word searches are therefore more suited to establish that concepts are treated than to establish that they are not.

We do not search for phrases such as “associative law of addition”, as there would be too many alternative phrases (“addition’s associative property” etc.). The downside of searching just for the word associative, is that we don’t know which operation it concerns. To clarify this, we used the app Concordances (Konkordanser), which gives the context of every occurrence of a word in the corpus, by providing extracts of up to 25 words surrounding the search word from the paragraph where the word is used. We used this app in the case of “associative” and analysed the resulting concordances. In many cases, the app returned a text not indicating which operation was discussed. It would be possible to find these paragraphs in the respective books, but that was outside the scope of this article.

Another option for the same goal, would be to use the National Library app Collocations (Kollokasjoner) with the word “associative”. This app does a rather more advanced analysis, as it for a given word (“associative”, for instance) finds words that are more often included near the given word than it is in a general text. For reasons of space, we did not include this in the present article.

To answer RQ2, we compared the kinds of findings we obtained in the present study with similar findings in Opsal and Smestad (2022). In one instance, we also did a quick look at the textbooks in question to supplement the automatic searches. We noted instances where the automatic analyses of full-text databases gave additional insights or, to the contrary, failed to give insights.

Results

We begin with an overview of the word frequencies (Table 2). Most of the selected words are not used in N39, while the words “even” and “odd” number can be found, but rarely. However, all our selected words were much more frequent in the F60 textbooks. They have stayed in textbooks throughout the period we look at, except “equations”, which were not included in NKMM textbooks. When comparing curricula, it is helpful to look at the “words per book” numbers. These show, for instance, that our words (except “equations”) were mentioned far more often (per book) in NKMM textbooks than in F60.

The result for “equations” was somewhat surprising, so we had a quick look through the NKMM textbooks. We did not find the word “equations”, but we did find tasks such as this “What operations

do you use to find n in these true mathematical statements? […] 5 + n = 6" (*Matematikk for 4. klasse: forsøkstekst. Del I*, 1966, p. 93), showing that the concept of equations was touched upon.

Table 2: Word frequencies (words per book in parenthesis)

	N39	F60	NKMM	M71	M74
distributive		22 (.3)	16 (1.6)	53 (.5)	59 (.5)
associative		46 (.7)	45 (4.5)	69 (.6)	31 (.2)
number line		517 (7.6)	175 (17.5)	491 (4.2)	452 (3.5)
even number	7 (.1)	83 (1.2)	52 (5.2)	55 (.5)	197 (1.5)
odd number	6 (.1)	92 (1.4)	51 (5.1)	50 (.4)	194 (1.5)
equation		1959 (28.8)		750 (6.5)	1622 (12.6)

Table 3: Word frequencies for even and odd number – grouped by grade level (words per book in parenthesis)

	N39	F60	NKMM	M71	M74
1				4 (.3)	10 (1.0)
2	12 (1.2)	9 (2.3)		34 (2.6)	27 (3.0)
3		51 (17.0)		13 (1.3)	23 (2.3)
4		12 (3.0)	80 (26.7)	1 (.2)	36 (4.0)
5	1 (.2)		18 (6.0)	21 (10.5)	28 (2.0)
6		4 (1.3)	5 (1.3)	7 (3.5)	22 (1.6)
7		2 (.2)			180 (15.0)
8		15 (2.1)			32 (2.5)
9		2 (.3)			10 (1.0)
more than one		48 (2.3)		2 (.0)	23 (.8)

We have also run these analyses while grouping for grade level. We find the results for even and odd numbers particularly interesting (Table 3). Even and odd numbers have been included in all the

corpuses, and an analysis by grades can disclose whether their placement in grades have fluctuated. Some textbooks are written for more than one grade, and these are coded as “more than one” in the corpus and in the table.

It is striking that the position of the words even and odd numbers varies so much between curricula. For instance, in the F60 textbooks, there were most mentions in grade 3, while from M74, a large part of the mentions was in grade 7. The striking number of mentions in grade 7 could be investigated further – could it be that even and odd numbers had a particular role in grade 7 in M74 that it did not have in other grades or curricula? A quick use of the Concordances app would give a view of how the words are used in sentences, which could give ideas of what role they play. We will not go into that here.

The contexts of the word “associative” (assosiativ/assosiative) (Table 4) gave some surprises. Although aware that the associative property is relevant for a whole range of binary operations, we imagined that the associative laws for addition and multiplication would be the ones mentioned. However, textbooks also asked whether (or stated that) the associative law holds for subtraction, translation, potentiation[2], addition of vectors and an unknown operation (called “operation quadrilateral”). In M74, however, only associative laws of addition and multiplication are mentioned. The app does not always give enough context – in a large part of the cases, the “associative law” is mentioned without enough information from the app to decide which associative law it is.

Table 4: Contexts (binary operations) of the word “associative”

	N39	F60	NKMM	M71	M74
addition		18	12	36	14
multiplication		13	24	29	9
subtraction		1	1		
division					
translation				2	
potentiation		4			
addition of vectors				1	
the operation quadrilateral			1		
not possible to determine		13	13	18	14

[2] Potentation is the operation of raising something to a power.

Discussion

Broadly speaking, our answers to RQ1 confirm the findings of our manual searches for when concepts were introduced in textbooks in Opsal and Smestad (2022): The concepts distributive law, associative law and number line, which in Iceland entered into textbooks with New Math (Bjarnadóttir, 2017), in Norway were present in textbooks for the F60 curriculum, long before set theory took the stage in what has long been considered the "New Math curriculum" of 1971. The current analysis includes more textbooks, and therefore strengthens the findings in Opsal and Smestad (2022). It also includes the frequency of certain words, and not only first inclusion of a concept. This provides more nuance, as it gives indications of the prevalence of a concept through the grades.

These findings will in turn inform comparisons between Iceland and Norway. As Bjarnadóttir (2006) points out, in Iceland new textbooks with novel ideas were welcome. In Norway, new textbooks were frequent, leading to a more gradual introduction of New Math concepts. When considering the reception of the "New Math" curriculum (M71) in Norway, this fact is relevant. However, other analyses (Opsal & Smestad, 2025a) suggest that the M71 (alternative 2) went further in the incorporation of set concepts than for instance Sweden. Such detailed studies are valuable when studying and comparing curriculum reforms across countries.

Our further analyses, concerning even and odd numbers and the associative laws, rather give inspiration for further detailed analyses than conclusive results. Such future studies could include comparisons with curriculum documents.

Regarding RQ2, we conclude that the use of a corpus, a full-text database and apps has some potential. In our case, the books were already digitalized, but it was still time consuming to create and ensure the quality of a corpus. Once the corpus is established, the analyses can be run quickly, and some hypotheses can be raised which can later be studied in more detail. A traditional textbook analysis of 390 textbooks would be painstaking. Our previous analysis included far fewer textbooks and was content with finding the first inclusion of a concept, instead of all mentions. Thus, the finding above about the apparent differences in use of odd and even numbers in grade 7 in 1960 and 1974 (as judged by word frequencies), would not be found as easily in our manual research.

However, our analyses in the current article are simple. We search only for words, and some concepts are difficult to research in this way. Already, we have not been able to distinguish between the associative law for addition and the associative law for multiplication. Searching for phrases such as "associative law of addition" would risk losing other phrasings (such as "addition's associative law"). The use of other apps gave some more, but still limited, information. Searching for "the role of 0 in multiplication" would probably not give any results, even though we know from Opsal and Smestad (2022) that textbooks do indeed point out what happens when 0 is used in multiplication. Likewise, equations can be found in the NKMM books, even though the word equations is not.

In Opsal and Smestad (2022), we also included implicit inclusion of concepts. The best example is implicitly including the commutative law of multiplication by giving many tasks where the factors are toggled, such as $3 \cdot 6 =$, $6 \cdot 3 =$, $5 \cdot 4 =$, $4 \cdot 5 =$, and so on. There is currently (at the time of writing) no artificial intelligence in the apps to identify such implicit inclusion of concepts.

Automatic searches should be used with care. When specialised mathematics words are found, the corresponding concept is probably included, and this can be checked manually. On the other hand, when words are not found, the concept may still be there. Surprising non-findings should therefore be checked carefully. Used well, we believe such technology will provide good opportunities for textbook research. Simple searches can give preliminary overviews that can spur new studies. Of course, such methods can also be used by researchers who digitalise a small number of books on their own. We are eager to hear of researchers doing such research in this area – as well as to hear of other countries in which the national library or other entities have digitalised all textbooks. This could provide a great arena for detailed, comparative textbook research.

Historical awareness and foreground in idea generation processes

Marianne Thomsen[1] and Inge Marie Lyngsø Olsen[2]

[1]University College Copenhagen, Teacher education, Copenhagen; Mart@kp.dk

[2]University College Copenhagen

Abstract *In this paper we give a suggestion for how historical awareness and the concept of foreground can be a springboard to create a didactical frame, which supports pre-service teachers' possibilities to engage in collaborative teacher communities about idea generation processes of their own teaching and learning modules. First, we emphasize points from literature and the Danish curricula for mathematical education for primary and lower secondary school as well as for pre-service teacher education. On this we base our argument for including history of mathematics in such processes. Then we present and connect the theoretical terms we use in the paper. Finally, we discuss and reflect about how to include history of mathematics to support students to engage in idea generation processes.*

Keywords: Historical awareness, foreground, engagement, collaborative teacher communities, idea generation processes.

Introduction

The purpose for the subject mathematics in the curricula for primary and lower secondary school in Denmark among other things emphasize, that it must "contribute to the pupils' experience and acknowledge of the role of mathematics in a historical, cultural and society context" (our translation, Børne og undervisningsministeriet, 2019, p. 7). To prepare the future teachers to support that, we must include the historical context in the pre-service teacher education as well. The curricula for teacher education part 3—the local subject description—among other things says, that the "students participate in collaborative teacher communities about developing their own teaching in mathematics and contribute to the development of mathematical education in lower and secondary school" (our translation, Læreruddannelsens studieordning [Curriculum for teacher education] 2024/2025, part 3, p. 85). To prepare the future teachers to do that, the pre-service teacher students can be supported in developing, expressing and discussing their ideas, of what they find important in their own education. This can be a way of letting them connect their reflections on their own role as future math teachers and being pre-service teacher students. The teachers of pre-service teachers can orchestrate processes, where the students get the possibilities to express and discuss their ideas of, what they find important. Thereby the students participate in a collaborative students' community, where their ideas contribute to the development of their own local teaching modules. In this paper we use the term idea generation processes as a description of such processes. These idea generation processes of course must be seen in connection with the curriculums for both the teacher education and the national curricula for primary and lower secondary school.

In this paper we focus on a more general view on, how the history of mathematics and different mathematicians' views of mathematics can be a starting point to engage pre-service teachers in common idea generation processes. You might say that we take the perspective of Jahnke's et al.

(2002) description of Freudenthal's (1986) view on using history in mathematical education. Freudenthal among other things:

> took the view that historical interventions in mathematics teaching at schools should contribute more to comprehending the general history (of culture) than to comprehending mathematics. (Jahnke et al., 2022, p. 1430)

Fried (2001) points out, that there is no reason to think, that the techniques and approaches, which we use in nowadays' classrooms, always will be the most powerful ways of using and teaching mathematics in the modern world. To us that is also an argument for why it must be important to let the students meet different perspectives from historical mathematicians. This can give them the experience that mathematics and perspectives on mathematics changes. We consider that the terms *historical awareness* (Jensen, 2010) and *foreground* (Alrø et al., 2009; Skovmose, 2011) can be a springboard to support pre-service teachers' possibilities to engage in common idea generation processes. We unfold these two terms and relate them to Jankvist's (2009) description of *whys* and *hows* in the next section of the paper. The following describes the question we seek to answer from a theoretical perspective:

How can the terms *historical awareness* and *foreground* be a springboard for constructing a didactical setting and a theoretical construct, which support pre-service teacher's possibilities to engage in collaborative teacher communities about idea generation of their own teaching and learning modules?

In the next section we present the theoretical terms we use. Then we describe, how these can be implemented and can interact with each other in an appropriate way to support collaborative idea generation sessions. We have piloted some of the elements in our own teaching of pre-service teachers, but we did not collect data except our own planning of the sessions. Based on this, we keep this as a theoretical paper. In our didactical setting we, among other things, focused on the differences between Poincaré's and the Bourbaki group's view on mathematics and organizing of mathematical working processes. Poincaré's "ideas of teaching and education were closely linked to the roles he attributed to intuition and logic in mathematics" (Jahnke et al., 2022, p. 1422) and Bourbaki's group had a structuralist view on mathematics (Jahnke et al., 2022, p. 1421). Our choice of these different perspectives was inspired by Lindenskov (2009). We also used that text in the didactical setting, where we tried to orchestrate a common idea generation process. This is one perspective of how to use historical mathematicians in idea generation processes. We could also have included other historical mathematicians' views or original sources, which we discuss and reflect on later in the paper.

Theoretical terms

Kjeldsen et al. (2022) introduce Jensen's (2010) terms *historical awareness* from didactic of history and combine it with didactics of mathematics. *Historical awareness* includes what Jensen (2003) coined as a multiple perspective approach. It is both observer and action-oriented and "both the past and the future are present in the present: the past as recollection and interpretations of the past and the future as a set of expectations" (Kjeldsen et al., 2022, p. 46). According to Kjeldsen et al. (2022)

the term *historical awareness* has some resemblances with what Skovsmose (e.g. 2011) call *foreground*. They elaborate as follow:

> In this respect, the notion of historical awareness has some resemblances with Skovsmose's (e.g., 2011) notion of "foreground" within critical mathematics education. Yet, Skovsmose's notion of foreground is embedded in a social context involving students' hope, despair, uncertainty, etc., whereas historical awareness has to do with the students' academic foreground. (Kjeldsen et al., 2022, p. 47)

We interpret this as Kjeldsen et al. (2022) distinguishing between *historical awareness* and *foreground* by emphasizing, that *historical awareness* has an academic *foreground*, and Skovsmose's (e.g. 2011) use of *foreground* is related to students' lives and social contexts. Kjeldsen et al. (2022) found that "the construct of *historical awareness* is well suited to articulate students' academic *foregrounds* in the discipline of mathematics—that is, their potential future lives with mathematics" (p. 65). In this paper we also include the term Skovsmose (e.g. 2011) calls *foreground*. We consider that pre-service teachers' "hope, despair, uncertainty, etc." about being math teachers, both are about an academic *foreground* and a social *foreground*. It is about mathematics itself, mathematics as a subject, and about their personal reasons and visions about being math teachers. That is why we focus on the intersection between, what Jensen (2010) define as *historical awareness*—an academic *foreground*, and what Skovsmose (e.g. 2011) define as *foreground*—a more social *foreground*. We see both *historical awareness* and *foreground* as ways to enlarge and qualify students' possibilities to engage in collaborative idea generation processes of their own pre-service teacher's teaching and learning modules. This, of course, must be within the frame of the educational curricula.

Jankvist (2009) divides the motivations for using history in mathematics educational contexts in two categories: *Whys* and *hows*. The *whys* are argument for using history, which is characterized as history-as-a-goal arguments (meta-issues) and history-as-a-tool arguments (in-issues). Here "the learning of developmental and evolutionary aspects of mathematics either serves a goal in itself or serves to illustrate other historical aspects of the discipline" (Jankvist, 2009, p. 239) and human being is a part of "the developmental and evolutionary aspects of mathematics as a discipline" (p. 239). Using history-as-a-tool "contains the arguments concerning how students learn mathematics" (Jankvist, 2009, p. 237) and can also include, that history has the potential to be a motivation factor for the students and make the mathematics less frightening, by giving the mathematics a more human face (Jankvist, 2009). The *hows* are about approaches to teaching. Jankvist (2009) describe three categories of approaches: illumination, modules and history based (we return to the illumination approach and module approach later). Jankvist (2009) points out, that these distinctions can be used to analyze teaching materials applying history, and that they can be "useful when making decisions about content, form of presentation, and organization concerning the use of history for teachers as well as material designers" (p. 236). We think that the distinction between *whys* and *hows* can also be useful when teachers engage the students in previous described idea generation processes with a starting point in the history of mathematics. Common for both the term *historical awareness* and *foreground* are, that their turning point is about how student's awareness supports their possibilities to act in the present, in the light of both the past and the future. This also relies on their way of

understanding the evolution of mathematics, the subject of mathematics, and the educational systems as a result of human beings taking part in it (see also e.g. Jankvist, 2009).

The *goals* and *tools* argument can be seen as arguments for including history of mathematics in common idea generation processes. It has a concrete role in the design of a didactical setting, which support students' common idea generation processes. Here history-as-a-goal can support, that the students get an understanding of the developmental and evolutionary aspect of mathematics. Furthermore, it can support the pre-service teachers in seeing themselves and their future pupils as a part of this. That is one reason for, why it is important, that they as pre-service teachers participate in collaborative communities, where they discuss and reflect on, what they find can contribute to the development of their own mathematical education and mathematics education in general. In the didactical setting we focus on in this paper, you might say, that using history-as-a-tool on the one hand are about motivating the students to engage in the idea generation processes. On the other hand, they are also about giving the students insights into different views on working with mathematics, give the mathematics a more human face, so to speak. When the students get the possibilities to also engage in discussions about e.g. the mathematical content, they find important to be taught in and how to teach this as future math teachers in primary and lower secondary school, we see this as both *whys* and *hows* perspective.

The didactical setting and theoretical construction

In this section we will try to explain some elements of, how we as teachers for pre-service teachers have tried to form a session, where we could engage the students in an idea generation process for planning some of their own teaching and learning modules at the teacher education. We do not think this as a concept of how to engage students in such processes, but as a concrete example of how we find, that the theoretical term, we have presented in this paper, can interact together in an appropriate way. We finish this section of the paper by giving a visualization of how, we in this example see the theoretical terms are related.

To support the students in sharpening their awareness of their own *foregrounds*, we asked more open questions about e.g. how they see mathematics, how it contributes to their own lives and how they would like to teach mathematics as future teachers. These questions were asked to give the students' a possibility to express and discuss their own connection to math, and their hopes connected to be a math teacher. This is a way to activate their social *foreground* related to their personal academic *foreground*.

Then we used Lindenskov (2009) as a starting point to introduce the students to different historical mathematicians' perspectives of why mathematics is important, their view of mathematics and working processes related to that. Lindenskov (2009) describe Henri Poincaré's (1854-1912) and the group of Nicolas Bourbaki's ideas of mathematics, their perspective of how to work with mathematics and organizations hereof. The idea of presenting different perspectives of historian mathematicians to the students, was to support them in getting an understanding of the developmental and evolutionary aspect of mathematics, and in seeing themselves and their future pupils as a part of this. Here the argument to bring this into play is a *why-goal* perspective. This can be a way to support students in developing a *historical awareness*—a more academic *foreground*. We also found that

Lindenskov's (2009) presentation of these two historical mathematicians' perspectives of mathematics could qualify the students' possibilities to develop their awareness of their own views of mathematics—why it is important from a personal, educational and society perspectives. That was also a *why* perspective related to support the students' awareness of their *foreground*—a more social *foreground* to be a future math teacher. Finally, we found that presenting these two historical mathematicians' perspectives of mathematics to the students, would be a way to motivate the students. It might also have the potential for the students to identify with some of the views. These different views could thereby contribute to give math a more human face, which can be characterized as a *why-tool* argument. Therefore, we found, that this text could be an outset for the further idea generation process.

Poincaré (1854–1912) see mathematics as much more than logic, it is also intuitive and connected to the real world, it can be seen as art, where e.g. numbers and symbols are interrelated in a harmonious way (Lindenskov, 2009). Poincaré's way of working with mathematics was not making a full plan, but starting and seeing where it goes, stopping if the work becomes heavy, because most of the essential ideas comes, when you are not concentrating on the problem (Lindenskov, 2009). Nicolas Bourbaki is a pseudonym for a collective of mathematicians started of six French mathematicians in 1934. The group of Bourbaki found Poincaré's intuitive and non-logical way of looking at mathematics confusing and elitist (Lindenskov, 2009). They wanted more people to be more educated (Lindenskov, 2009). The Bourbaki group was a strong professional and social community, where all the members of the group worked with the tasks, the proofs, and the descriptions, both by writing to each other and by physically meeting (Lindenskov, 2009). Lindenskov (2009) use among others Poincare and Bourbaki to describe, why it might be important to have an aesthetic perspective of mathematics, and how to work with mathematic in an aesthetic way. Based hereof Lindenskov (2009) defines seven keys to open aesthetic aspects of mathematics. We will not go further into the seven keys, neither focus particular on the aesthetic aspects of mathematics. We found, however, that this presentation of different historical mathematicians is a way to support students impression of e.g.: 1) mathematics is created by human beings, and thereby it changes over time, 2) working with mathematics can be seen both from a more intuitive and a more logical perspective or from both perspectives, and 3) you can work and create mathematics, mathematical problems, and mathematical solving using different working strategies. As stated above, we found, that these different historical perspectives could support the students in developing their *historical awareness*. They could e.g. have a *why* discussion related to respectively Poincaré's and the Bourbaki group's view of why mathematical education is important and for who.

We also think it could be a good idea to present the pre-service teachers for the concept of *foreground*. We took our outset in Alrø's et al. (2009) text to introduce the concept of *foreground* to the pre-service teachers. Thereafter we asked them questions divided into the categories: past, present and future. An excerpt of these sounded like: What kind of math did you find important, when you were children? (past); What have been the most important experiences from your own practical experiences of teaching throughout your studies? (present); How will your praxis as a math teacher look like in ten years from now? (future). How do you imagine, we can work with math in the next module/the next year to support you to become math teachers? Try to give some concrete examples (*foreground*

-> present). Here the students could get the possibilities to specify and discuss their *foreground*, their reasons for working with mathematics, and ideals for being math teachers—their social *foreground*. Here they also got the possibilities to use their knowledge of both Poincaré's and the group of Bourbaki's perspectives of mathematics, the different ways they worked with it, and their ideals related to mathematical education. We will characterize our *how* approach to work with history in this case as an illumination approach, because in our didactical setting history was used as a supplement and that agree very well with Jankvist (2009) description: "One way to think of these smaller supplements in the illumination approaches is to think of them as "spices" added to the mathematics education casserole" (p. 246).

These different steps in an idea generation process could lead to more focus on the specific content, that the pre-service teachers found important to work with. This was also related to the curriculum for primary and lower secondary school. Questions that could support this part of the process could e.g. sound like: Which subject areas do you want to work with? Which mathematical didactical perspectives do you want to know more about? Which working methods do you prefer?

These different steps presented above could be characterized as a beginning process of engaging the students in idea generation processes. These could be revisited consecutively throughout their study as pre-service teachers.

A visualization of the interaction between the theoretical terms is presented in Figure 1.

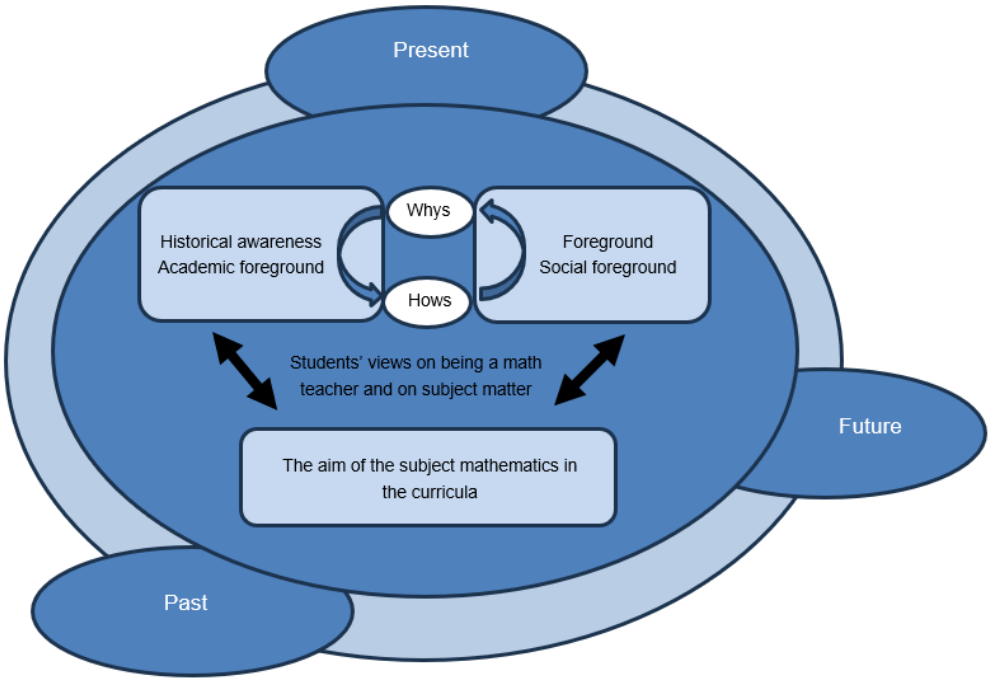

Figure 1: To support idea generation processes—the interaction between the theoretical terms: Historical awareness (Jensen, 2010), foreground (Skovsmose, 2011) and the distinction between whys and hows (Jankvist, 2009)

Reflections

We have presented an example of how teachers for pre-service teachers can focus on the term *historical awareness* and *foreground* as central terms to engage the students in idea generation processes related to their own local teaching and learning processes in mathematics. In this paper we focus on a Danish educational context, but we find that, the terms *historical awareness* and *foreground* can be used broader in other mathematical educational contexts for pre-service teachers. This could also include Jankvist's (2009) description of the *whys* and *hows* for using history in mathematical education. In this paper our concrete historical input were Lindenskov's (2009) description of respectively Poincaré's and the group of Bourbaki's view of mathematics and how to organize working with it. Here we could have used other perspectives or historical mathematicians as well. We could e.g. have used primary historical sources to focus more on supporting the students in developing their *historical awareness* (inspired of Kjeldsen et al., 2022). This could have the benefit which Barnett et al. (2014) emphasizes by referring to Jahnke et al. (2002): "the educational value of original source readings in any discipline lies in their ability to promote "thinking into other persons and into a different world" (Jahnke et al. 2002, p. 299)" (p. 12). Furthermore, they refer to Barbin (1997):

> the educational value of the reorientation (or dépaysement) which reading historical texts can effect in our view of mathematics by "making the familiar unfamiliar" requires a reading which seeks always to understand, rather than judge, the content of those texts (Barbin 1997, p. 24). (Barnett et al., 2014, p. 12).

We think that giving the students the possibilities to engage in situations, which include "reorientation", and the ability to "thinking into other persons and into a different world", have the potential to support pre-service teachers in developing a more reflective awareness of their own *foreground.* In such situations, they might have the possibilities to get insights into other perspectives on mathematics and mathematics education. Kjeldsen et al. (2022) stresses, "that using primary historical sources in mathematics education has potential to develop students' historical awareness" (p. 63). If primary historical sources become a part of such idea generation processes, we think that it would requires another *how* approach, namely the module approach, where more time is used on the historical aspect and the math within the source to support the students in getting insights into the *whys* and thereby supporting them in developing an *historical awareness* to support them in reflecting on their own *foreground*.

In this paper we aimed to focus on how the terms *historical awareness* and *foreground* can be seen as central parts of a didactical setting and a theoretical construct, which has the objective to support pre-service teachers to collaborate in teacher communities about idea generation processes of planning their own teaching and learning modules. This will hopefully also strengthen their abilities to collaborate in such processes in their future life as math teachers.

A transformation of perception in calculus: An exploration of barriers and outcomes through transgressive actions

Mark Watford[1] and Kathleen Michelle Clark[2]

[1]Florida State University, USA; mark.watford@fsu.edu

[2]The University of Alabama at Birmingham, USA

Research on learning undergraduate mathematics via primary historical sources has been investigated for over a decade, and much of the available research has focused on, for example, aspects of students' learning of metadiscursive rules or the reorientation students experience when learning typical mathematical concepts from unfamiliar primary source materials. In our research we employ the lens of transgressions to explore links among transgressive actions, barriers, and outcomes. We present an illustrative example for Simon (a student in a Calculus III with Engineering Applications course), and we highlight the relationship between a barrier and its associated outcomes resulting from engaging in discourse with an instructor and engaging with curriculum materials utilising primary historical sources in the learning of mathematics as transgressive actions.

Keywords: Teaching and learning of analysis and calculus, Undergraduate mathematics education, Primary historical sources, Primary Source Projects, Transgressions.

Introduction

For decades, the role of history of mathematics in the teaching of learning of mathematics has been investigated (Clark et al., 2018). More recently, researchers have paid increasing attention to drawing more explicitly on theoretical frameworks (both within and from outside mathematics education). In doing so, such research has more frequently appeared in the mainstream mathematics education literature, including contributions in a variety of top-tier peer-reviewed journals (e.g., Agterberg et al., 2022; Jankvist et al., 2020).

The focus of our work is to investigate students' learning experiences when primary historical sources (PHS) are used. Researchers have examined students' learning of mathematics via primary sources from different theoretical perspectives, including commognition (Sfard, 2008). For example, Kjeldsen and Blomhøj (2012) illustrated how the use of primary sources promoted students' learning of metadiscursive rules. Additionally, Barnett et al. (2021) used a detailed case study to highlight one student's "figuring out" of metadiscursive rules in the discourse of mathematical analysis through the use and study of curriculum materials drawing upon PHS, called Primary Source Projects (PSPs), in an undergraduate analysis course. Recently, we (Watford et al., 2025) trialled a lens relatively new to mathematics education research (*transgressions*; Kozielecki, 1986) to explore the *transgressive actions* students employ to cross *boundaries* they may have experienced while studying abstract algebra via PSPs[1]. In this paper, we build on our previous work to investigate students' experiences with studying PSPs in a Calculus III course focused on engineering applications. The goal of the investigation was to explore the link between barriers and outcomes related to students' perception

[1] We expand upon these components of transgressions (boundaries, transgressive actions, outcomes) in the "Theoretical background" section.

of mathematics and to determine what actions may have contributed to students' change in perception.

Literature and theoretical background

In the last two decades or so, several experts—particularly within the domain of history and pedagogy of mathematics (the HPM domain)—have discussed claims for the potential effects of students' learning of mathematics via PHS. Pengelley (2011) identified nine reasons motivating the use of original (primary) sources in teaching undergraduate mathematics. Of these, Jankvist (2014) noted several are associated with in-issues (e.g., "participating in the process of doing mathematics") and several with meta-issues (e.g., "understanding origins and discovery"), and most may be subject to interpretation (e.g., "understanding essence"). The most prevalent among Pengelley's reasons is that the use of original sources allows for what is known as *dépaysement* (Barbin, 1997)—which can be thought of as a form of disorientation, cognitive dissonance, or providing multiple points of view for the same idea or concept. The notion of dépaysement was reconceptualised by Jahnke et al. (2000) and became one of three ideas that they proposed as replacement, reorientation, and cultural understanding.

Additionally, Barnett et al. (2014) provided theoretical grounding for teaching undergraduate mathematics via PHS, as well as a discussion of their guided reading approach, which is the primary design tool of the PSPs developed as part of the TRansforming Instruction in Undergraduate Mathematics via Primary Historical Sources (TRIUMPHS) project. The TRIUMPHS project developed, disseminated, and field-tested PSPs, which were designed to teach topics in the undergraduate mathematics curriculum. Each PSP includes author commentary, pertinent primary source excerpts, student tasks, and notes for the instructor. To date, TRIUMPHS has produced some 100 PSPs, which are freely available (via Creative Commons licence) from the grant project website[2].

Within the context of learning mathematics using history and especially learning via PSPs, potential learning outcomes are common among the literature, such as meta-issues (Jankvist, 2014) and instructor perceived benefits (Barnett et al., 2016). Potential barriers to learning mathematics via history and PSPs infrequently appear throughout the research (commonly, a language barrier); however, very few studies have attempted to explore specific barriers and how students overcome barriers to reach outcomes. We found a productive solution in the framing of *transgressions* by Jozef Kozielecki (1986), in which barriers are connected to "new havings or beings" through *transgressive actions*. Such actions are defined as "a purposeful action that leads to an outcome exceeding the boundaries of the individual's past achievements" (p. 89). Although the typical connotation attached to anything transgressive is negative, this is not the case in the context of the theory of transgressions. The conceptualisation of a transgressive action allows for a medium of travel beyond boundaries[3] of limited perception to an expanded perception, which we situate as outcomes often associated with surprise and perceiving what seemed impossible as now possible (Pieronkiewicz, 2015). Additionally, Semadeni's (2015) operationalisation of a boundary, associated with transgressive

[2] The PSPs can be found on the TRIUMPHS website: https://blogs.ursinus.edu/triumphs/

[3] In this paper, we use forms of "barrier" and "boundary" interchangeably instead of the term, "obstacle." We do so to remain consistent with Kozielecki's (1986) use of the same terms.

actions, as a "previously non-traversable limit of own mathematical knowledge or… deep rooted convictions" (p. 27), fits well with our experience with students who study mathematics using PHS.

Initial investigation: Linking transgressive actions, barriers, and outcomes

Possibly due to the original context of transgressions (situated within psychology), the framework has only recently been recognised in the mathematics education research community. We conjecture there are valuable possibilities that the theory affords when studying the mathematics learning process. Recently, we were part of a research team who explored transgressive actions of Abstract Algebra students (also studying via PSPs) based on survey responses; however, the development of the survey instrument was not informed by a transgressions lens. To remedy this limitation, Watford (2022) developed and piloted an interview protocol with the purpose of exploring transgressive actions, outcomes, and barriers identified in Watford et al. (2025). Particularly, Watford's (2022) report demonstrated that engaging in discourse constitutes a transgressive action. In its multiple forms, discursive transgressive actions overcame barriers students encountered in a "Calculus and Its History" course, which was taught primarily with PSPs. Based on that work, we sought to investigate how transgressive actions may have manifested in a different learning context. We draw upon Watford (2022) to situate discourse with the instructor as a transgressive action as well as claim that engagement with the PSP (via reading primary and secondary source material and working through tasks) also constitutes a transgressive action because of the students' purposeful interaction with the PSP and the existence of barriers and outcomes surrounding their interaction.

Methods

The setting for this study is a two-year college located in the western United States. The college boasts three dozen career and technical programs and has 29 academic programs from which students can earn two-year degrees and if desired, they can then transfer to public four-year university or college programs. The course, *Calculus III with Engineering Applications* (or, Calc III-EA), with 12 students enrolled was taught in Spring 2022 (January–May) by Dr. Leaf (all names in this paper are pseudonyms). Dr. Leaf has been affiliated with TRIUMPHS since Spring 2017 as both a site tester and author of PSPs. In the Calc III-EA course, Dr. Leaf implemented two PSPs, approximately one month apart. For the purposes of this paper, we discuss findings for the implementation of the first PSP, "The Radius of Curvature According to Christiaan Huygens" (Lodder, 2022), which students studied for 2.5 class sessions with the focus of instruction being the PSP.

Participants and data sources

Data sources included a 17-item instructor implementation report, in which Dr. Leaf detailed how the PSP was implemented to all students in the course. The report also asked for instructional goals and perceived benefits and obstacles (that Dr. Leaf described for himself, as well as his perceptions of these for students). Interviews with three student participants comprised the second data source. The interviews lasted approximately one hour and were held within a week following the PSP classroom instruction.

Preliminary data analysis

Transcripts were coded using a combination of inductive and deductive coding methods partially informed by previous analysis regarding transgressive actions (e.g., Watford, 2022; Watford et al.,

2025). We searched for instances when a student mentioned they felt limited or unable to do something before performing an action. These actions led to some new insight or state of being. Respectively, clusters of coded data illuminated a *barrier*, *transgressive action*, and an *outcome*, based on Kozielecki's (1986) characterisation of transgressive actions. The implementation report was coded in the same manner. For the purposes of this paper, we highlight the relationship between a barrier and its associated outcomes resulting from engaging in discourse with an instructor and engaging with the PSP as transgressive actions. Engaging in discourse with the instructor fits well with Kozielecki's notion of transgressive action because of its potential to enable students to overcome obstacles leading to outcomes. For the same reason, engagement with the PSP constitutes a transgressive action. The outcomes, which result from these transgressive actions, extend beyond simply learning calculus content. That is, we report on students' ability to connect present mathematical content to previous calculus learning, as well as demonstrating an awareness of the evolutionary aspect of mathematics.

Findings

To depict a student's distinct story while highlighting transgressive components common to all three interviews, we present an especially illustrative example from one participant, Simon, who provided rich responses to interview questions. We begin with a barrier that appeared in each of the three interviews, *Perception of Mathematics*. To account for the unique and personal nature of outcomes, we then discuss a complex assemblage of Simon's outcomes that resulted in his "new having/being" from overcoming the barrier. Finally, we highlight the transgressive actions *Expert/Instructor Discourse* taken together with *Engagement with the PSP* which also appeared in all three interviews. The excerpts on which we focus were prompted by the interview question: How do you feel that your connection to mathematicians and mathematical ideas has changed throughout the course, and what has promoted this change?

Perception of Mathematics as a barrier

Because of the mutually dependent relationship of a barrier to one's new having or being (Semadeni, 2015), we feel it would diminish the importance of the transgressive action if we were to discuss the barrier apart from the outcome. Therefore, we focus on the barrier, *Perception of Mathematics*, in conjunction with its crossing to a complex array of outcomes which generally revolve around meta-issues of mathematics.

A recurring phenomenon in the data was centred around how students' own perception of mathematics defined the scope of their mathematics learning experience. Students' learning experiences were bounded such that, to them, mathematics consisted of a small portion of the vast mathematical landscape. Specifically, students viewed calculus and geometry as two distinct domains with no connection. This concerned Dr. Leaf, who wrote in the implementation report:

> Students often see calculus and Euclidean geometry as two completely separate subjects that have nothing to do with each other beyond that one related rates problem that used similar triangles that one day. I think it is a crime to let them leave the calc[ulus] sequence believing this, and I can't imagine any learning object[ive] more effective than this particular PSP for correcting that misconception, showing how calculus was a method that very directly grew out of Euclidean geometry!

Here, Dr. Leaf demonstrated awareness of a barrier to student learning so endemic to his students that it became a specific learning objective for implementation of the Huygens PSP. Although Dr. Leaf listed other goals more closely related to mathematical content, such as understanding and calculating the radius of curvature, his primary goal was aligned with students understanding certain meta-issues of mathematics.

In what follows, we present the case of Simon, who previously perceived calculus and Euclidean geometry as being two separate mathematical domains. Additionally, Simon viewed calculus as being created by two "insanely intelligent" (i.e., Leibniz and Newton) men who had an "abstract thought that came out of the blue." We show that by Simon's own account of engaging with the PSP and through discourse with the instructor, Simon formed a connection from calculus to Euclidean geometry and now sees mathematics as much more realistic, beautiful, and possible.

Simon revealed his previous perception of mathematics in the following transcript excerpt. He hinted about why he thought calculus and geometry may have been two separate mathematical domains by alluding to Newton and Leibniz as the architects of calculus, implying that Simon may have regarded modern infinitesimal calculus as the authentic calculus. Additionally, Simon imbued the two mathematicians with exceptional qualities such as being "insanely intelligent" people who "randomly think" of great mathematical innovations. This conception of mathematical thought may have limited Simon in viewing others as thinkers, doers, and creators of mathematics, especially himself. In fact, Simon's reference to the previously perceived impossibility of such thought is suggestive of a lack of confidence to think the way Newton and Leibniz thought.

Simon: I remember even in class I said to Dr. Leaf, "that's really wild" because he mentioned before we started the PSP that Leibniz and Newton studied what Huygens was doing… it's just like, yeah, that's infinitesimal calculus. They're … we're creating tangent lines; we're doing this and that, and it was just like, "yep that's exactly it." It was the limit... where we had to actually create the limit. And, it was… one of those mind-blowing moments because … we get it; we're taking a limit, and we get how to do the algebra, but now, that's where that came from! Although Newton and Leibniz were insanely intelligent, … these guys didn't just randomly think of that; this is what they were staring at when they're like, "oh, this is how we're going to now create limits," and it makes it a lot more... realistic and a lot more beautiful.

Mark: How does it make it more realistic to you?

Simon: The way math is always presented is either some crazy calculations that people will magically just know, or it's some very weird abstract thinking that you're just like, "how would somebody think that abstractly, …what would you be thinking about to be able to create the limit as x goes to zero of something? How do you even establish that kind of thought process?" You think it seems impossible, and then you get something like this, and this is how they did it. It's not that it's impossible; it's just that these guys were insanely intelligent, and they… had something to reference so they had something they were trying to solve. They had a problem at hand. It wasn't just abstract thought that came out of the blue.

Not only did Simon have a narrow vision of who was capable of mathematical thought, but he was bound by his previous perception of how innovative mathematical thought occurred. Innovative thinking appeared distant to Simon and out of the scope of his own capabilities. Simon implied that he would never be able to think in such a way, a marker of a boundary (Kozielecki, 1986; Pieronkiewicz, 2015), as he expressed the theoretical impossibility of duplicating a similar thought

process. Simon's narrow perception of (who does) mathematics contrasts greatly with his expanded perception, presented as outcomes.

Outcomes: An attempt to capture the essence of a complex melange

Although we highlighted a clear barrier to Simon's relationship with mathematics via his own perception of mathematics, we found it difficult to clearly define the outcomes associated with the transgressive actions and barriers. Kozielecki (1986) alluded to this obstacle of describing outcomes characteristic of transgressive actions as "more complex and less well-defined" (p. 102) than those of other types of actions. Therefore, we contrast Simon's previous perception of mathematics to Simon's present thinking, which we situate as consisting of outcomes.

In Simon's present thinking, he perceives the possibility of innovative mathematical thought, and he attributed the knowledge of the context of mathematical innovation to be key in establishing the possibility of such thinking. Simon realises "these guys" were not producing random thoughts; instead, he sees the potential connection that Leibniz and Newton could have made while studying Huygens' writing, indicating a more evolutionary aspect of mathematics. Simon's revelation in reference to people "creat[ing] limits" supports this evolutionary perspective. We cannot be certain to whom Simon was referring, but the data suggest a resulting perspective which allows Simon to visualise mathematicians "staring at" and being influenced by Huygens' work. Additionally, Simon can now establish a purpose for innovative mathematical thought saying, "these guys… had something to reference" and acknowledging they were trying to solve a problem.

Simon's revelations of who is capable of mathematical thought and how mathematical innovation occurs is evidence that he was also able to make connections to previous calculus learning. Through his conversation with Dr. Leaf, Simon related what he was doing in the PSP to infinitesimal calculus, and specifically to calculus concepts including limits, tangent lines, and derivatives. Simon even indicated an instant of surprise with the "mind-blowing moment" that he realised what could be a potential origin of infinitesimal calculus. According to Kozielecki (1986), transgressive actions may "culminate in surprise" (p. 102), further supporting the presence of transgressive actions.

Transgressive actions in tandem

Kozielecki (1986) characterised transgressive actions as "every kind of purposeful action that leads to an outcome exceeding the boundaries of the individual's past achievements" (p. 89). In addition, he stated that transgressive actions may often be accompanied by positive emotions, complex outcomes, and surprise. With the evidence presented above, Simon surely engaged in some transgressive action. From his own words and that of the instructor, the actions which brought about the outcomes exceeding the barrier of Simon's own perception of calculus were two-fold. First, *Instructor/Expert Discourse* was necessary for Simon to expand his perception of calculus; without conversing with Dr. Leaf about Newton and Leibniz studying Huygens' work, Simon may not have made a connection from whom he considered the architects of infinitesimal calculus to those that influenced them. However, instructor discourse was not enough to expand Simon's perception of calculus. Simon also needed the transgressive action of *Engagement with the PSP* to add context to what was discussed with the instructor. This included not only reading through the PSP, but also working through the exercises to see primitive notions of limit and derivative comprised engagement with the materials. Although we view the transgressive actions as being distinct (each action appeared

elsewhere in the data without an obvious dependence on another action), we feel the combination of the two was instrumental in assisting Simon over the barrier of his own perception of calculus.

Discussion and future directions

Initial analyses of survey data collected as part of the TRIUMPHS project were focused on students' identification of benefits and obstacles to learning mathematics via PSPs. This initial work fell short of any true explanatory power of what PSPs offered about the learning experience using such an innovation. We found that the theoretical lens of transgressions provided a tool to understand students' experiences with using PSPs in undergraduate mathematics classrooms; moreover, the framework allowed us to link barriers with outcomes through the transgressive action medium, an enlightening relationship we had yet to discover. However, employing this lens with our existing data at the time (survey items that prompted students to discuss benefits and obstacles) was inadequate. A pilot of the interview protocol in Spring 2021 enabled us to explore transgressive actions, outcomes, and barriers, and the current study presents excerpts from our implementation of the refined interview protocol within a content course (Calc III-EA) as opposed to a history course. The transgressions framework provided a valuable lens to describe the link from student barriers to outcomes through transgressive actions, yet these actions remain vague possibly due to the anecdotal nature of interview responses. Therefore, our next step is to more deeply explore transgressive actions through additional in-the-moment data via classroom observations along with other data sources. Our goal is to discover nuances of these transgressive actions which help move students beyond a barrier.

TWG 13: Early Years Mathematics

Introduction to TWG13: Early years mathematics

Introduction

In CERME14, presented research about Early Years Mathematics has concerned the mathematics education of children 1 year old (e.g. see the contribution by Björklund & Palmér) up to 7 years old (e.g. see the contribution by Benz et al.). Researching mathematics education during the early years is a complex endeavour and depends on several cultural and institutional constraints. In many European countries, children attend early childhood education, yet the conception of schooling and mathematics in early years varies significantly across different countries as it is testified by the 22 contributions in our group, presented by authors from 14 different countries in the European area (Czech Republic, Denmark. Germany, Greece, Israel, Italy, Latvia, Norway, Portugal, Spain, Sweden, UK) and outside of Europe (Australia, Jamaica, South Africa). Furthermore, transition from childcare to more formal schooling may differ across countries. In TWG13, contributions pay attention to how mathematics is approached more or less explicitly by children, teachers, and other caregivers. The studies within this working group show that mathematical learning occurs in various settings, including kindergarten, preschool, primary school, as in informal environments.

Overview

During CERME14, the 22 contributions (20 research reports and 2 posters) published in the proceedings were presented in seven thematic sessions and were discussed between the participants. A wide range of topics was covered: different areas of mathematical teaching-learning are addressed, and different theoretical and methodological approaches are adopted. In the following, we summarize the wide variety of topics addressed in TWG13 by clustering the contributions presented in CERME14 proceedings.

Numbers and structure

This section examines how young children develop structural awareness in early mathematics, particularly in relation to number concepts. Lindgren and colleagues explore part-whole relationships through a playful distribution task, demonstrating how artefacts become mathematically meaningful when structured with verbal communication, gestures, and finger representations. Sprenger and

colleagues investigate how children describe quantities using ten-frames, identifying four distinct descriptive strategies and highlighting the role of peer interaction in shaping mathematical language and understanding. Elofsson and colleagues focus on children's reasoning with repeating patterns, showing how systematic variation in unit size and repetition—carefully guided by teachers—supports generalization and the development of early multiplicative thinking. Their work underscores the importance of strong pedagogical content knowledge. Together, these studies provide complementary perspectives on structural thinking in early mathematics—through number decomposition and recomposition, visual structuring and peer interaction, and pattern-based generalization—emphasizing the richness of young children's mathematical experiences when instruction is intentional, well-designed, and responsive to their ways of seeing.

Additive problems

Research about additive problems highlighted that tools, gestures, and language support early mathematics learning, hence children often struggle to apply part-whole concepts to arithmetic. Young children verbalise their reasoning inconsistently, and research is needed to understand their cognitive processes. In a study conducted in Germany, Benz and colleagues explored how word problem features—like structure, unknown elements, and visual representations—affect how young children solve addition and subtraction tasks in an online assessment. The results suggest that spatial reasoning consistently emerges as a key factor in problem-solving.

Seo, with colleagues, examined whether spatial abilities—specifically spatial visualisation and visuospatial working memory—help predict how well six- to seven-year-olds in England solve one-step addition word problems. Findings suggest that spatial visualisation plays a role in tackling more complex, dynamic problem types, highlighting a spatial-mathematical link in early arithmetic learning.

Roesch and Hartmann presented a study about children's use of their fingers for addition and subtraction tasks. Although, the sample was small, the results showed that finger use was more common when manipulatives were not provided and particularly beneficial for subtraction tasks.

Multiplicative problems

All studies highlight the role of language, manipulatives, and structured activities in supporting early multiplicative thinking. They collectively suggest that multiplicative reasoning can emerge before formal instruction, but is shaped by age, context, and language. These findings have implications for curriculum design and teacher training in early mathematics education.

Pitta and colleagues demonstrate that structured interventions can support children in kindergarten in transferring multiplicative strategies to novel contexts. Björklund and Palmér identify developmental shifts in toddlers' partitioning strategies, highlighting the emergence of unitizing and equal distribution. Downton and colleagues reveal that linguistic background significantly influences children's interpretation of multiplicative comparison tasks.

Mathematical learning within child and care-givers interactions

Within the 'Early years mathematics' TWG, there are contributions paying attention to how mathematics is approached more or less explicitly by children in informal contexts and in relation with their parents and other caregivers. Graven reports about parents' confidence within the Family Maths Storytime Programme (FMSP), designed for providing opportunities for play-based home numeracy learning among South African children. Voutsina and colleagues present the 'Written Numbers in Everyday Life' project, implemented with families of 3–5-year-old children in the UK and Jamaica. Both contributions provide insights into the wide-ranging opportunities for learning that arise when parents are prompted and supported.

Learning difficulties and disabilities

Research under this theme underlines the importance of family-school partnerships for supporting the early mathematics development of children with intellectual disabilities and specific learning difficulties.

Charitaki and colleagues describe profiles of home numeracy support for preschool children with intellectual disabilities in Greece and underscore the importance of communication and reciprocal support between parents and educators, particularly for families who face systemic barriers that can affect the level of home numeracy support that they can offer. The importance of parent-teacher collaboration is also emphasised by Helmane and colleagues who reveal variations (both similarities and discrepancies) in parents' and teachers' evaluations of the mathematics skills of 4–6-year-old children with and without specific learning difficulties, in Latvia.

The role of play

Two studies, conducted in the context of preschool education in Sweden, contribute to current debates about the role of play in mathematics learning in the preschool years.

Lundvin and colleagues analyse preschool teachers' talk about play and mathematics teaching through the lens of Play-Responsive Teaching theory (PRT). Discrepancies between teachers' talk and PRT, but also teacher's alignment with the position that play and teaching are 'going into one another', emphasise the need for developing shared understandings in relation to play and mathematics teaching within preschool education practice and policy. Comparing instructional sequences that integrate play and mathematics with sequences where mathematics teaching is separated from play, Karlsson highlights the benefits of combining both approaches, for supporting children's exploratory as well as structured learning of mathematics, within a balanced learning environment.

Digital tools and technology

Three papers directed specific attention to digital tools and technology in early mathematics education. Walla and colleagues presented a study on guardians' views on digital tools in Swedish preschools, while Vee and colleagues presented a study on Norwegian preservice teachers' views on the use of digital technology in early childhood institutions. Both of these presentations initiated a discussion on observed differences between countries regarding if and how to use digital tools and

technology and whether and how digital competence is part of mathematics curricula in early childhood education.

Nogueira and colleagues added to the discussion their study on robot programming, concluding that robot programming activities can be used in early childhood education to develop children's itineraries and map-reading skills through activities that not only are highly motivating but also stimulate both cognitive and social skills.

All three papers were further discussed in terms of the risk of digital tools becoming "just play"; raising the question how teachers are supported to use digital tools and technology for mathematics education. A conclusion was that more research is needed and pre- and in-service preschool teachers need professional development regarding digital tools and technology, to be prepared to meet parents, pre-service teachers and children.

Other topics

The topics mentioned above do not comprehend all the numerous issues addressed within the group. Other relevant examples are given by contributions about first graders' mathematical creativity described by Cohen and Levenson in terms of fluency, flexibility, and originality, and younger children's argumentation by Nosrati and colleagues who investigated the factors that may aid or hinder the development of an argument. TWG13 also included contributions about kindergarten teachers, such as their mathematical awareness investigated by Bundgaard, and teachers' level of professional readiness as investigated by Nováková.

Conclusion and future perspectives

The collection of studies presented in TWG13 during CERME14 emphasizes how young children develop mathematical understanding through structured, playful, linguistic and socially rich experiences.

In the last editions of CERME we have registered an increasing number of studies about parental involvement. Home numeracy environments appear to play a relevant role, especially (but not only) for children with learning difficulties. The role of the cultural and linguistic background as embedded in the home, kindergarten, and school environments should remain central in future research about the development of structural thinking, spatial reasoning, and initial arithmetical learning.

The discussion about play-based learning-teaching is ongoing and more theoretical and empirical contributions might fuel it in the future. Digital tools show promise but require clear educational aims and teacher preparation. Future research should explore how to better support teachers and families, integrate play and digital tools effectively, and tailor learning for diverse developmental needs.

Performance on addition and subtraction word problems in an online assessment

Christiane Benz[1], Axel Schulz[2], Sebastian Wartha[1]

[1]University of Education Karlsruhe, Germany, christiane.benz@ph-karlsruhe.de
[2]University of Bielefeld, Germany

Word problems operationalize different semantic characteristics of addition and subtraction. Often, they are used to assess knowledge of addition and subtraction before written numerals and operation signs are introduced. Earlier research shows that the semantic structure, the unknown set and the use of iconic representations of quantities influence children's performance. To address different requirements of difficulties in an online assessment of children starting school concerning word problems, the problems were varied due to different criteria. However, considering the solution frequency of different problem types, our findings are not completely in line with earlier results. This leads to open questions.

Keywords: Early mathematics education, word problems, arithmetic, assessment.

Theoretical and empirical background

Different addition and subtraction word problems

Informal methods to solve simple arithmetical (word) problems by direct modeling with objects such as counters or fingers constitute an important aspect of children's mathematical competencies before formal schooling. These competencies are seen as "the best predictors of mathematical disabilities/difficulties and later achievement in […] mathematics" (Clements et al., 2020, p. 638). For this reason, in assessments addition and subtraction word problems often are used to assess children's knowledge of addition and subtraction before written numerals and operation signs are introduced. Moreover, word problems operationalize different semantic characteristics of addition and subtraction as operations. This means, different one-step addition and subtraction word problems are also used to assess which semantic characteristics can be understood and solved by children.

Riley et al. (1983) and Carpenter and Moser (1984), distinguish four semantic structures or characteristics of problem types (*change, combine, compare, equalize*) for addition and subtraction. In that vein, two aspects are discerned: The first aspect distinguishes whether the situation is static or dynamic. The second aspect focuses on whether a set is described in a part-part-whole-relation or two disjunct sets are described.

Table 1: Different semantic structures of word problems

	dynamic	static
Part-part-whole	***change***	***combine***
Two disjunct sets	***equalize***	***compare***

Some authors combine the two dynamic situations and, thus, distinguish only three types: combination, change or comparison of sets (Stern 1993, p.7). Furthermore, Clements et al. (2020)

distinguish four types: they merge *change* and *equalize* and they discern change problems into *add to* and *take from* problems.

In addition to the semantic structure of word problems, a further distinction can be made (Verschaffel, 2020; Gabler & Ufer, 2021): additive and subtractive wording. Examples for additive wording in dynamic situations are *she gets* or *she buys*. Examples for subtractive wording in dynamic situations are *she gives away*, *she lost*, *she sells* – the wording describes a dynamic increase or decrease. In *static* situations, the wording does not describe an increase or decrease. In static compare situations, additive and subtractive wording can be expressed by using the terms *more than* and *less than*. In combine situations there are sometimes hints that focus on the whole (*altogether)* or on one part (*out of, of them, of which*). In literature, however, these hints are often not referred to as additive and subtractive wording (Radatz et al., 1996; Gabler & Ufer, 2021). In each of these word problems, three quantities play different roles, any one of which could be the unknown quantity. In dynamic situations the quantities of start, change, and result can be unknown. In compare problems the reference, difference, or compare quantity can be unknown (e.g., Stern, 1993). In combine problems one part or the whole can be unknown. Four different dimensions or "organizing criteria" are therefore used to categorize word problems. The combination of these four dimensions results in a total of 20 possible situation types (Table 2). Table 2 is the extension from two dimensions in Table 1 to four dimensions (Radatz et al., 1996). The four dimensions are:

- Does the situation involve a change (dynamic) or a status (static) (see, two right columns in Table 2)?
- Does the situation involve a part-part-whole relationship or two independent, disjunct sets (see two wide rows in table 2)?
- In which direction does a change or comparison take place? Is the change increasing or decreasing, is a comparison regarding more or less required (see fields marked in light grey, Table 2)? What is given, what is unknown? In other words: Which of the three quantities can be determined by the other two (see fields marked in dark grey, Table 2)?

Table 2: Different problem-types due to semantic structure, wording and unknown quantity

		dynamic						static					
part-part-whole		***change***						***combine***					
	additive/subtractive wording	increase			decrease								
	unknown part	st	ch	res	st	ch	res	whole			part		
two disjunct sets		***equalize***						***compare***					
	additive/subtractive wording	increase			decrease			more			less		
	unknown part	st	ch	res	st	ch	res	ref	dif	co	ref	dif	co

st=start, ch=change, res=result, ref=reference, dif=difference, co=compare

Influence of problem-types on performance

Surveys revealed that the *semantic structure* influences children's performance (Stern, 2009; Riley et al., 1983; Clements et al., 2020). For example, all studies indicated that young children had greater difficulties solving compare tasks (especially when a relation between quantities is described) than solving dynamic tasks like change or equalize tasks. Stern (2009) explained these difficulties (that are independent to the linguistic challenges) by the (missing) idea of a relational understanding of quantities: If the given information does not describe a concrete existing quantity, but the relation between two quantities, the children must activate "a mental image abstracted from concrete things" (Stern, 2009, p. 155; translation by the authors). However, Gabler and Ufer (2021) could not confirm these results for second graders at primary school (average age 7,56 years).

Besides the influence of the semantic structure, studies also revealed that the *unknown quantity* in word problems influences children's performance. In this vein, it was shown that word problems with an unknown reference or start set are more challenging than those with an unknown compare or result set (Riley & Greeno, 1988; Stern, 1993; Gabler & Ufer, 2021). Clements and colleagues describe "Find Results Problems" with an unknown result in their learning trajectory two levels before the level of "Find Change Problems" (Clements et al., 2020, p. 640).

Another factor influencing the difficulty of word problems is the use of *additive or subtractive wording*, especially in combination with the aspect of the unknown quantity: "Word problems in which the directly applicable mathematical operation is inconsistent with the wording are usually harder than consistent word problems" (Ufer & Gabler, 2024, p. 3; Fuson et al., 1996; Lewis & Mayer, 1987). Examples for inconsistent word problems are: "Julie had some cookies. Then she gave 3 cookies away, now she has 2 cookies. How many cookies did she have in the beginning?" (subtractive wording "she gave away", required operations is addition 3+2=5); "Julie has 7 cookies, that is 3 cookies more than Jane has. How many cookies has Jane?" (additive wording "has more than", required operations is subtraction 7-3=4). In Stern's study (1993), the word problems with an unknown reference and an inconsistent formulation were the most difficult.

Also, other aspects, like number range or consistent or inconsistent presentation of quantities can influence children's performance (Fuson et al., 1996). An overview about research concerning different aspects can be found in Daroczy et al. (2015).

Influence of iconic representations on performance

Theoretical considerations and empirical findings indicate that the use of iconic representations for given quantities in oral text problems influences the solution frequency. This is because children do not need to know the quantity only by the number word, they also can see the number of objects corresponding to the number words. This has been confirmed for diagrams (Diezmann & English, 2001), visual presentations of divisions problems (Matalliotaki, 2012) and compare problems in the number range up to 20 (Múñez et al., 2013). Nevertheless, studies investigating performance on written text-problems (especially change problems) also revealed that iconic representation is not always helpful (Van Lieshout & Xenidou-Dervou, 2018; Elia et al., 2007), for example when the whole situation of a *dynamic* problem is represented in one or several pictures. The reported studies

were mostly conducted with children who already received mathematics teaching at school. Thus, it is not clear, whether these results can be transferred to early mathematics education in the absence of formal schooling. However, in an exploratory study in kindergarten, Elia (2020) investigated, the influence of visual representations of quantities in change, combine and equalize problems. The tasks were distinguished in three groups: Tasks with visual representations of two quantities (groups of illustrated objects), tasks with visual representations of one quantity and tasks only with numerals representing the quantity. For the change problems an increase and decrease problem with unknown result was chosen. Moreover, or the combine problems the unknown quantity was once the part and once the whole. Children's performance in problems with two iconic representations was higher for combine and compare problems than for equalize problems. Also, children's performance with two iconic representations was higher in the subtraction combine problems (with the unknown part) than in the subtraction change problems (Elia 2020, p 26).

Despite different results from all studies about representations, it can be concluded: The role of representation seems to influence children's performance on addition and subtraction word problems.

Study

In an online assessment of children's arithmetical performance at the beginning of primary school, the role of situation types and the use of iconic representations of quantities on situation types was varied. The following research questions were raised concerning the word problems:

1. Does the frequency of solving addition and subtraction tasks depend on the situation type?
   Hypothesis: Our findings will confirm the findings of previous studies (e.g. change tasks and combine tasks with unknown results were solved more frequently than compare tasks).
2. To what extent does the use of iconic representations of quantities influence the frequency of solutions within a situation type?
   Hypothesis: The more iconic representations of quantities are given, the higher the correct results.

To standardize software-supported assessment procedure (ILeA Plus), about 2900 children participated in a computerized online interview during the first six weeks of the first school year (age range 5 to 7 years). For this analysis of word problems only children who solved all word problems were considered (N=2275), so that a quantitative comparison over all word problems is possible without missing data. The goal of the online assessment (ILeA Plus) is to assess children's mathematical competencies at the beginning of school. This is done not for labeling children's competencies, but for indicating in which area children should be assessed more differentiated and probably need individual support. As part of the software-supported assessment, numerous aspects of mathematical competencies of each child were documented.

Eleven word problems with different semantic structures, different use of iconic representations of quantities and different unknown quantities were presented acoustically (see table 3, for examples see figure 1). When a new task appeared, the acoustic task was presented automatically. All children could listen to the tasks as often as they wanted by clicking on the speaker symbol. The results of word problems could be selected by clicking on a number field. Only children who showed

knowledge of numerals were considered in the analysis. The number range of all word problems was within the number range of six, to minimize the influence of numbers. At least two tasks per situation type were given. Tasks were constructed for the sematic structures *change combine, compare* (Stern, 1993). We also differentiated for the change problems between *increase* and *decrease* and if the result or change is unknown (Clements et al., 2020, see table 3).

	*Compare*, difference unknown, two numbers represented as quantity Acoustic task: "Ben has 4 stickers. Isa has 5 stickers. How many more stickers has Lisa?" [Wie viele hat Lisa mehr?]
	*Change*, increase, change unknown, one number represented as quantity Acoustic task: "2 stickers are in the box. 5 stickers shall be in the box. How many stickers do you have to add?" [Wie viele Sticker musst du noch dazulegen?]
	*Combine*, whole, no number represented as quantity Acoustic task: "Carla has 2 Stickers. Tom has 4 Stickers. How many stickers do they have together? [Wie viele Sticker haben sie zusammen?]"

Figure 1 Task presentation in the online assessment (Benz et al., 2019)

Results

Tasks of the type *change with unknown result* and *combine unknown whole* were solved more frequently (solution rate more than 50%) than tasks of the type *change with unknown change* and the *compare with unknown difference* (solution rate less than 50%). These two groups of tasks were compared statistically (paired samples t-Test). The difference in students' performance is significant ($t(2274)=5.248$, $p<0.001$) between the group of tasks *change with unknown results* / *combine unknown whole (*M=.63, SD.29) and the group of tasks *change with unknown change* / *compare with unknown difference* (M=.30, SD.39).

At first glance this result is in line with earlier studies, because the tasks *change with unknown result*s / *combine unknown whole* were solved most frequently. However, considering the group of tasks *change with unknown change* / *compare with unknown difference,* the results contradict the results of Stern (2009). Here compare tasks with unknown difference were scored as more difficult tasks than change tasks with unknown change.

The following analysis concerning iconic representations of quantities is based on frequencies of only one item per situation type and representation level (the limitation will be discussed). Therefore, only a descriptive analysis of frequencies was performed. For change tasks with unknown result and combine tasks with unknown whole, the solution frequency was higher the more numbers were represented as quantities. However, the use of iconic representations of numbers in compare tasks with unknown difference and change tasks with unknown change did not lead to a consistent increase of the solution frequency.

Table 3: Frequency of correct solutions

Representation of quantities	*Change* increase, result unknown	*Change* decrease, result unknown	*Change* increase, change unknown	*Combine* whole	*Compare* more, difference unknown
2	72%		40%		28%
1		75%	18%	62%	
0	60%	56 %	29%	53%	35%

Discussion

The first hypothesis can essentially be confirmed. Nevertheless, it is surprising that *change tasks with unknown change* were solved less frequently (except the change tasks with two representations) than *compare tasks with unknown difference.* What aligns with findings is that change tasks are solved correctly more often than comparison tasks. Stern's (1993) study in particular, in which these two types of tasks are directly compared, is repeatedly cited as a reference here. One explanation for this apparent contradiction may be that these two types of tasks have rarely been directly compared with each other in the recent past (for example, Elia (2020) only used change task with unknown result). However, in the learning trajectory of Clements et al. (2020), within the level called “Find change” also compare tasks with unknown difference are mentioned. One possible conclusion from these considerations could be that different word problems should be compared again and, above all, systematically in preschool institutions. Such studies could then examine whether Stern's findings can be confirmed or whether children's understanding of word problems has changed in the past 30 years.

The presence of two iconic representations of numbers does not seem to be helpful for the compare situations and one iconic representation does not seem to be helpful for the change task with unknown change. One possible explanation could be that the unknown quantity cannot be identified easily in the picture – it even leads to wrong solutions (for example, when two numbers were presented as quantities, the presented objects were added).

The second hypothesis could not be completely confirmed. The question remains as to what role iconic representations of numbers in word problems play in performance. Also, in this context the

question remains, what differences can be observed, if the word problems are introduced as enactive representations with concrete objects and actions. However, it became clear that the role of iconic representation cannot be unambiguously clarified. Further research should systematically consider the different semantic types as well as whether the unknown number can be seen in the iconic representation.

Because the items in the online diagnosis were originally not constructed to investigate differences in solution frequencies between task types and representation levels, the analysis shows limitations with only one item per situation type and representation level. Thus, a controlled study is needed in which the unknown part of the problems is considered. Further research questions can be raised, like how the chosen context of word problems or how a presentation of numbers in word problems with concrete objects influences the solution frequency. Finally, another question which also remains is to what extent the digital setting did influence the solution frequencies.

Cookies on plates – toddlers' partitioning strategies

Camilla Björklund[1] & Hanna Palmér[2]

University of Gothenburg, Faculty of Education, Gothenburg, Sweden;
camilla.bjorklund@ped.gu.se

[2]Linnaeus University, Sweden

This paper presents a study of toddlers (1- to 3-year-olds) development of number knowledge in general and partitioning strategies in particular. We investigate changes in toddlers' ways of experiencing numbers as expressed through actions and utterances when encountering the same task over a prolonged period of time. In this paper, we present the partitioning strategies of these toddlers when engaging in a preschool game, "sharing cookies with Kitty's friends". We identify the strategies used and the meaning of numbers these strategies entail. Further, we present an overview of their progression in number knowledge. The results add to the current knowledge of what it means to develop number knowledge in general and partitioning strategies in particular.

Keywords: Partitioning, toddlers, number knowledge, units, equal distribution.

Background and aim

In situations like play and everyday tasks such as setting the table or sharing objects with peers, young children engage in partitioning activities using different strategies (Björklund, 2010). Partitioning could, in this sense, be considered an intuitive action to solve everyday problems. Partitioning (or "splitting", as Confrey, 1994, terms it) is also known to be a basic feature of mathematical knowledge – one that is foundational for conceptual knowledge of numbers and arithmetic skills, including multiplication, proportional reasoning, and exponentials. Research that focuses on partitioning most often refers to the mathematical content of division and mainly includes school children, even though partitioning is also an aspect of additive tasks. Studies with younger children often emphasize unitizing abilities and are based on theoretical assumptions about how development towards more advanced arithmetical reasoning occurs. Therefore, we consider that there is a need for empirical studies on emerging understanding of partitioning among the youngest learners.

In the project DUTTA, for two years we followed toddlers' (1- to 3-year-olds) ways of reasoning about numerical situations. Play-based interviews were conducted with the toddlers on five occasions. One task in the interview focused on partitioning. In this paper we present the partitioning strategies expressed by the toddlers. The strategies are understood as expressions of the toddlers' ways of experiencing number, in line with the variation theory of learning (Marton, 2015). The research questions are: RQ1) What meanings of numbers are expressed in the strategies enacted by the toddlers in a partitioning task? RQ2) What strategies for partitioning numbers are observed among toddlers over a prolonged period of time?

Conceptual framework and research on partitioning

Partitioning is an aspect of number knowledge that is foundational for multiplicative reasoning and understanding of proportions and fractions. According to Lamon (1996), "Partitioning is an operation that generates quantity; it is an experience-based, intuitive activity that anchors the process of

constructing rational numbers to a child's informal knowledge about fair sharing" (p. 171). Partitioning is, however, a complex skill that involves not only fair sharing but both additive and multiplicative relations. It includes the action of splitting a set of items into smaller units of equal or unequal size (emphasizing an additive part-whole relation), and it also includes switching the focus from individual items to groups of items as composed units that can be compared, or making a one-to-one correspondence with other units, such as when partitioning cookies on a number of plates to make a fair share (equal-sized groups in a multiplicative relation). When partitioning, or exploring different ways to partition a set, a flexible understanding of "unit" is essential because, depending on the number of parts needed, the set sizes (units) will differ. For example, the number six can be split (in an additive sense) into two and four or five and one, but also (in a multiplicative sense) into two threes as well as three twos. Consequently, how children encounter a partitioning task depends on their way of understanding the idea of "unit" and the part-whole relationship of numbers. In agreement with the above-described complexity, Hunting (2003) found in a study of partitioning that children's ability to change focus from counting individual items to identifying the structure of a group was fundamental to the development of their number knowledge.

As partitioning is considered foundational for more advanced mathematical areas, efforts have been made to conceptualize the knowledge that partitioning constitutes. In a study on young students' perceptions and representations of structure, Mulligan et al. (2006) found a high positive correlation between children's structural development (pre-structural, emergent, partial, and structural) and the use of multiplicative structures including unitizing and partitioning.

In a study by Lamon (1996), the partitioning strategies of students (grades 4–8) showed that, at each grade level, a greater percentage of students used more effective partitioning strategies, shifting from the distribution of single units towards the use of composite units. It was also found that the students' strategies were more influenced by the commodity being shared than the numerical portion. Kim (2012) investigated partitioning related to equal sharing situations presented in contextual or symbolic forms of division. The children were found to develop partitioning strategies stepwise with two pre-stages of partitioning for equal sharing: 1) an unequal sharing strategy where children exhaust the whole shared quantity but distribute unequal quantities; and 2) a sorting-out strategy where children distribute equal amounts of shared objects to parts but do not exhaust the whole shared quantity.

To summarize, research on partitioning and structural reasoning provides many examples of strategies, and some studies try to conceptualize learning trajectories (e.g., Kim, 2012) based on empirical observations. There are also studies aiming to describe the conceptual growth behind the development of partitioning strategies, but these concern primary school children (e.g., Castro-Rodríguez et al., 2022; Hurst & Huntley, 2020), leaving a significant gap in the field of knowledge regarding the emerging knowledge of numbers and the idea of partitioning among the youngest learners.

Theoretical framework

The study is based on the variation theory of learning (Marton, 2015), which provides analytic tools to interpret knowledge as different ways of experiencing numbers. According to variation theory, learning the meaning of numbers means discerning necessary aspects of numbers, such as cardinality,

ordinality, part-whole relations, and representations (Björklund et al., 2021). The more aspects discerned, the more advanced the way of experiencing numbers, allowing for more proficient strategies and the use of numbers and numerical features in problem-solving activities. The way a child handles a task is thereby interpreted as an expression of his or her ways of experiencing essential features of the task, which is explained in terms of discerned and undiscerned aspects.

Method

The sample for this paper is 17 toddlers for whom we have interview data from three interview occasions when they were 1, 2, and 3 years old. For the interview to make sense to the toddlers, each interview task was embedded in a meaningful activity or a game. Manipulatives were used partly to engage the toddlers' interest and partly to make possible different kinds of expressions, for example, gestures and actions (Aubrey & Dahl, 2005). Further, the tasks were based on the theoretical framework of variation theory (see above), whereby the use of variation-invariance made it possible to act upon different aspects of numbers in different tasks.

One task was to set the table for Kitty the cat and her friends who are coming to her birthday party. This task is a kind of "distribution problem" where objects (cookies) are to be distributed to a number of recipients (plates). There were always 12 cookies, but as new friends arrived, the number of plates varied. The task included five steps of increasing number of plates. At step 1, there were two plates; at step 2, three plates; at step 3, four plates; at step 4, six plates; and at step 5, six plates in a different setup (Figure 1). For each step, the interviewer first arranged the plates according to the pictures in Figure 1. After that, the 12 identical cookies were placed in front of the child in a pile. Then, the interviewer said, "Can you help Kitty put the food on the plates?" The children were not told to divide the cookies, for example, to distribute them evenly among the plates. Instead, the intention with the task was to explore whether the children would interpret this as a mathematical task, and if so, whether they could discern some structure of numbers and, for example, try to partition the cookies evenly among the plates. The validity of this task is elaborated on in Palmér and Björklund (2024).

The cookies were circular, made of wood, and approximately three centimetres in diameter. The plates were 15 cm in diameter made of plastic.

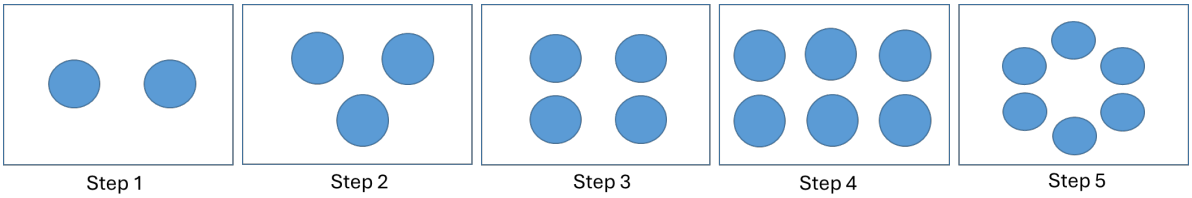

Figure 1: The setting of the plates in the interview task

Toddlers' expressions can be very subtle and demand exclusive knowledge of the individual child's ways of expressing him/herself. Therefore, we involved the toddlers' preschool teachers in conducting the interviews. The preschool teachers were given training in how to conduct interviews with a research purpose. Based on their knowledge of the toddlers, they could be sensitive to the toddlers' responses in the situation (Palmér & Björklund, 2022). The interviews were conducted in a room at the preschools, with one child attending each time. All interviews were video recorded, with

the written consent of the toddlers' legal guardians. All interviews were then coded in NVivo. The analysis of the video recordings of the interviews was inductive, where seven different strategies were identified and then categorized based on the mathematical aspect foregrounded. According to variation theory, a child acts in accordance with how he or she experiences a phenomenon, which opens up for analysing children's strategies as expressions of their knowledge and, in particular, what aspects they discern in a specific situation that guide their actions.

To answer the research questions, we produced an overview of the strategies enacted when the children were 1, 2, and 3 years old. This gives a comprehensive view of the progress on a collective level. To illustrate children's ways of experiencing numbers and numerical features of partitioning, we present one child's progress of partitioning strategies, discussing what it entails for her learning partitioning.

Results

Sometimes, the children were satisfied playing with the toy cat or feeding the cat with cookies. These observations were coded as not attending to any numerical feature of the task and are not included in this overview. We found six strategies for partitioning numbers used by the toddlers. Even though differences in performance can be observed, three different ways of experiencing the numerical feature were identified (see Table 1).

Table 1: Identified strategies and the mathematical aspects foregrounded, PS = Partitioning Strategy

Code	Strategies	Aspects foregrounded
PS1	a) Some cookies on some of the plates	Cookies as quantities (not relating to the fixed set)
	b) All cookies on one plate	
	c) Cookies on some of the plates	
PS2	a) One or more cookie on each plate	Unequal units relating to the fixed set
	b) Approximate equal distribution	
PS3	a) Starts systematic partitioning but loses track on the way	Equal units relating to the fixed set
	b) Systematically partitioning equally onto each plate	

Children who put some of the 12 cookies on some of the plates or all cookies on one plate were interpreted as engaging in completing the task and to some extent attending to numerical features because they were *experiencing cookies as quantities (PS1).* That is, the toddlers were composing units of different kinds, seeing it as possible to combine the single cookies into composed units. However, these units varied in number and did not relate to the fixed set of plates.

Other toddlers were foregrounding the set of plates as an important part of the task and partitioning the 12 cookies onto the plates, although as units of unequal size. A significant difference from PS1 is that these children were *experiencing unequal units relating to the fixed set (PS2)*.

Some of the toddlers made efforts to connect the fixed number of plates to equal-sized sets of cookies. This way of experiencing the numerical feature of the partitioning task was expressed in the toddlers' attempts to partition the cookies in a systematic manner. The toddlers who acted, for example, by putting the same number of cookies onto each plate, were expressing an awareness of units (groups

of cookies) to be connected to other units (the plates). The number of cookies, however, was large (not possible to perceive in an instant), and the toddlers may have made several attempts by trial and error. Nevertheless, this qualitatively distinct way of acting in the partitioning of the cookies is interpreted as the toddler *experiencing equal units relating to the fixed set (PS3).*

The above-described qualitatively different ways of experiencing the numerical features of the partitioning task emerged from the empirical observations of the toddlers' enactment in the interview. The progression in terms of observed strategy use is shown in Figure 2. Among the 1-year-olds, there are only a few observations of toddlers attending to the plates as a significant feature of the task and acting by putting cookies on the plates unevenly distributed. Among the 2-year-olds, we observe a growing awareness of units (cookies) that are to be connected to another kind of unit (plates), both evenly and unevenly distributed. It is among the 3-year-olds where we see a strong tendency among the toddlers to also discern the equal size of the units as a feature to account for in their partitioning.

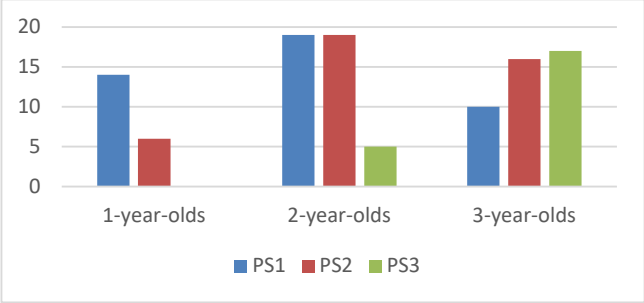

Figure 2: Number of observations across different partitioning strategies at different ages[1]

The progression of the toddler Ester

The toddler Ester has been chosen as a typical example of the progression in partitioning strategies observed among the toddlers in our study.

Table 2 shows that, as a 1-year-old, she makes some attempts to put cookies on the plates. Her strategies include putting only a few cookies on some of the plates and sometimes putting cookies on all of the plates (Excerpt 1).

Table 2: Observed partitioning strategies when Ester was completing the task

	PS1	PS2	PS3
1 year old	x	x	
2 years old	x	x	
3 years old		x	x

Excerpt 1

Ester has two plates in front of her and all 12 cookies on the right side of the plates. She grabs one cookie at a time, putting four on the right plate, then two at a time, and continues one at a time until three are left on the table. Ester then takes one cookie in each hand and moves them to the

[1] The number of observations differs between interview occasions because of varying number of steps that the toddlers were presented with and responded to.

other plate. She moves them back again to the right plate and adds the remaining three cookies to the plate with the other cookies. Ester moves three cookies to the left plate and repeats moving cookies back and forth a few times.

In the excerpt, Ester is fully engaged in the partitioning of cookies onto the plates. However, there are no observations of her trying to be systematic in partitioning the cookies, and therefore our interpretation is that any relationship between the 12 cookies and the number of plates is not discerned; rather, she composes and decomposes units made of the cookies. Her way of experiencing numbers is regarded as seeing the cookies as quantities but these are not relating to the fixed set of plates (PS1).

At 2 years old, Ester seems to attend to number as she more often puts cookies onto each plate (Excerpt 2). This indicates her awareness of some relation between the cookies (as units) that are to be related to the fixed set of plates (PS2). No cookies are left on the table; all of them are used in the partitioning act.

Excerpt 2

Ester has three plates in front of her and 12 cookies to her left. She puts four cookies, one at a time, on the left plate, the rest of the eight cookies on the right plate. Ester suddenly stops, looking at the third (middle) plate for a few seconds, then moves three cookies from the right plate to the empty one, thereafter looking satisfied.

Ester's actions and reactions when completing the task show her intention to compose units of the cookies and these are to be connected to a plate. However, her surprised look when all the cookies have been used to compose units on the two plates while one plate remains empty can be interpreted as indicating that the number of plates is not experienced as a composed unit to which the cookies are to be related.

In the last interview, being 3 years old, Ester acts in more systematic ways to partition the cookies on the fixed set of plates (Excerpt 3).

Excerpt 3

Ester has six plates in an array (level 4) in front of her and 12 cookies to her right. She rapidly puts one cookie at a time onto each of the six plates, then says "no more" and takes all the rest of the cookies in her hands "No more cats; we save the rest."

Ester seems to focus on partitioning one cookie to each cat or plate but without discerning how cookies can be composed into units that in turn can be partitioned as units-to-units. This means she does not yet experience the cookies as something to be composed into units, to be related to other units (plates) in a relationship that may be characterized as multiplicative (units made up of a smaller number of objects are to be connected to a unit of different objects). This indicates that Ester experiences equal units relating to a fixed set (PS3) but does not yet discern the full complexity of this part-whole relationship.

The difference between a child's ways of partitioning the cookies to the varying number of plates can be interpreted as different aspects being discerned; in particular, the relation to the fixed set of plates (constituting an invariant composed whole) is critical, as is how units composed of cookies can be related to the fixed set. When this is not discerned, the child may put a random number of cookies onto the plates and look around for more cookies, surprised that all 12 have already been used. The

advanced way of experiencing numbers in this task is to adhere to the wholeness of the 12 cookies and the wholeness of the set of plates and to understand that there needs to be a relation between the plates and the units composed of the cookies. How this relation looks is for the children to figure out, which some of the 3-year-olds do as they systematically partition the cookies into smaller portions and make changes between number of cookies on each plate to make the units equal in size.

Discussion

Earlier research has often observed strategies that students act out when solving a partitioning task, resulting in descriptions of whether students partition items one by one or in "chunks" (e.g., Lamon, 1996). This presupposes that the children already have an idea of the relationship between units in the task. What our study contributes is empirical observations and interpretations of how children at a very young age experience numerical features (that direct their intentional actions) of a partitioning task. For example, Kim (2012) provides an interesting schema of the development of partitioning strategies among primary school children, but our toddlers also act out one-to-one partitioning (see Ester's attempt in excerpt 3), as Kim observed among primary students. However, a significant difference is that the toddlers may not yet experience the task as constituting a part-whole relationship to be attended to. The primary students likely have more experiences of fair sharing and may even have learnt some strategies, such as procedures connected to certain kinds of tasks. Our investigation of partitioning strategies may therefore provide important insights on the need to look beyond the executed strategies by taking the child's perspective, interpreting *the meaning of the numerical features* embedded in a task.

Some might consider partitioning into equal-sized units evenly distributed across a fixed set to be more advanced than doing so across irregular-sized sets. In a mathematical sense, this may be accurate when highlighting the need to simultaneously consider the number of cookies in each cookie-unit and how many plate-units there are to connect each unit (that is, a multiplicative reasoning of units-within-a-unit related to a different kind of unit). Partitioning in unequal sets only requires relating the number of cookies (12) to be partitioned into parts (in an additive relation), which of course is less complex. Taking the child's perspective, it may, however, be equally relevant to give unequal shares to the birthday guests. This must be considered when trying to implement mathematical reasoning and ideas about partitioning in early childhood education.

Methodologically, it is challenging to do research with the youngest children. Most tasks build on verbal instruction, or a narrative (story) presented to the child, who is expected to respond in some way. Even though the present study takes the approach that any response is of qualitative interest, the children's response is highly dependent on their interest in interacting with the teacher or interviewer at that specific moment and how the child interprets the verbally presented task.

A following step in the analysis process would be to investigate the variety of strategies used by the individual toddlers with differently positioned plates to further explore the essence of the different ways of experiencing numbers' part-whole relationships connected to partitioning.

Collaborating on researching mathematical awareness in kindergarten class

Mette Amalie Bundgaard

Aarhus University and Copenhagen University College, Denmark; mafb@kp.dk

In Denmark, mathematical awareness is a competency area in kindergarten class (ages 5-6 years). This study explores the competency area and its development in collaboration with kindergarten class teachers, applying a critical research perspective to identify potentials and challenges across three collaborative processes: pedagogical imagination, practical organisation and explorative reasoning. The study shows that knowledge from both the kindergarten class teachers and the researcher affects the collaboration, but the way it is expressed varies across the three processes.

Keywords: Critical research, kindergarten class, collaboration, mathematical awareness.

Introduction

In Denmark, children start kindergarten class (KC) in the year they turn six. As a transition year, KC has its own pedagogical approach and competency areas, distinct from the rest of compulsory schooling, though it is legally and often physically part of the compulsory school system. In 2014, mathematical aspects were incorporated into KC through the competency area *Mathematical Awareness* (MA). This addition to the curriculum expanded mathematical perspectives in KC, while also distinguishing it from first-grade mathematics. These changes pose didactical challenges in practice for three reasons: (1) MA is a completely new mathematical competency area that is not well-defined in the curriculum or founded in existing practice, (2) the curriculum and supplementary materials provide little concrete guidance on implementing MA, and (3) MA and mathematics are only sparsely covered in KC teacher education, as a bachelor's degree in social education does not qualify teachers to teach mathematics. Additionally, KC's position as a transition year means that MA is not only a mathematics-related competency area but is also expected to foster coherence in students' mathematical learning across different pedagogical contexts. In summary, integrating MA into the curriculum is challenging due to the shift in content and perspective for KC teachers.

A three-year PhD project was launched to investigate and develop MA in collaboration with six KC teachers from two schools. The project follows the critical research (CR) approach (Skovsmose & Borba, 2004). Here, the researcher and practitioners collaborate to explore a practice that does not yet exist but is considered desirable, through three iterative processes: pedagogical imagination, practical organisation and explorative reasoning (Skovsmose et al., 2004). Since collaboration is central to all three processes in CR, this framework positions the KC teachers as active participants in the study of MA. However, the specific circumstances related to MA influence the collaboration. Therefore, this paper addresses the following research question: What challenges and potentials are revealed when conducting critical research on mathematical awareness in collaboration with KC teachers?

This contributes to knowledge on collaboration between a researcher in mathematics didactics and an early-years practitioner with no mathematical background, while also informing the methodological approach of CR when studying an unfamiliar concept like MA.

Background

Collaboration between practice and research has long been a focus in mathematics education research, taking various forms (Robutti et al., 2016). Ponte, Segurado and Oliveira (2003) argue that successful collaboration requires a common goal and meeting participants' diverse needs. While research has explored teachers' collaboration with peers, educators and researchers, theoretical frameworks remain limited (Robutti et al., 2016). In educational design research, close collaboration is emphasised, and the diverse perspectives and expertise of participants are valued (McKenney & Reeves, 2019). Furthermore, practitioners can take on roles as co-designers, implementers or co-explorers (Gundersen, 2021).

CR shares this emphasis on collaboration, focusing on conducting research *with* practitioners rather than *on* them. However, CR does not emphasise the different roles but instead explicates how collaboration occurs through three different processes: pedagogical imagination, practical organisation and explorative reasoning (Skovsmose et al., 2004). In CR, collaboration within pedagogical imagination is shaped by negotiation and deliberation, involving both critical reflection on the *current situation* and envisioning possible alternatives (Skovsmose et al., 2004). Ultimately, this process leads to a description of an *imagined situation*. Wright (2021) highlighted the role of participant agency in this phase, noting that his conceptualisation of the imagined situation prompted critical reflections from teachers. Wright (2021) also found collaboration beneficial in the practical organisation phase, which involves preparing an arranged situation to be carried out in the classroom. Here, the collaboration is pragmatic, focusing on determining and planning the feasibility of an *arranged situation* (Skovsmose et al. 2004). Negotiation is still essential, and structural constraints must be considered. The explorative reasoning phase is an analytic process (Skovsmose et al. 2004). Here, collaboration involves practitioners and the researcher reconsidering the imagined situation alongside an analysis of the arranged situation. Wright (2021) found that this process involved contributions of expertise from both practitioners and the researcher. Andersson (2011) noted that collaboration provided the researcher with valuable insights into pedagogical practices and emphasised that meaningful change requires time and strong participant ownership throughout the process. This reveals elements to consider regarding collaboration in CR.

However, both Andersson (2011) and Wright (2021) demonstrated how CR transformed pedagogical practices in secondary mathematics classrooms. Thus, collaboration in CR has not yet been explored when the participants are a researcher and non-specialist mathematics teachers in an early-years setting. While some early-years studies have involved teachers in designing and implementing interventions (e.g., Sæbbe & Mosvold, 2020), research on collaboration itself remains rare, particularly in the context of developing learning situations during a transitional stage of learning. Therefore, CR serves both as a framework for collaboration in research and as an analytical tool for investigating the collaboration.

The study

Preliminary observations of the current situation revealed that KC teaching closely resembled first-grade instruction, prompting the need for change. This led to the introduction of CR as the research approach, as it is driven by a desire to create change, while also enabling the investigation of a practice

that does not yet exist. Following the three processes, an imagined situation was formulated through *pedagogical imagination*. This process began with the researcher's interpretation of MA, which was discussed during a four-hour workshop with the KC teachers, followed by a preliminary questionnaire. The *practical organisation* of an arranged situation took place during the workshop, focusing on discussing and developing a concrete teaching design. The teaching design was subsequently changed based on the discussion before being executed as the arranged situation. Afterward, a conversation between the KC teachers and the researcher framed the *explorative reasoning*, incorporating both critical reflections on the intervention and forward-looking considerations. Along with the researchers' analysis of video recordings of the arranged situation, this led to a revised understanding of the imagined situation and informed the subsequent intervention. Over two years, two iterations of the three CR processes were completed.

Method

In this paper, purposively selected examples from each process in the second iteration are analysed to reveal potentials and challenges during the collaboration. The analysis focuses on the situations that Skovsmose et al. (2004) characterise as determining the collaboration during the specific process.

The pedagogical imagination is informed by questionnaires from the first iteration, results from the first explorative reasoning and transcripts of conversations with KC teachers following the first arranged situation. The analysis includes situations and statements where the perspectives of the KC teachers and the researcher led to negotiation and deliberation regarding the imagined situation. In the practical organisation, the researcher formulated three guiding principles based on the imagined situation: 1) The mathematical content should be recognisable to the KC teachers, 2) it should be framed by an engaging, realistic context that students can relate to, and 3) students should engage in mathematical inquiry. Subsequently, the researcher designed teaching material centred around a fictional story, where questions within the story engaged students in mathematical inquiry about repeating patterns. The teaching material was explored, discussed and negotiated at a workshop as part of the practical organisation. The practical organisation is documented through video recordings and transcriptions. Situations in the data where structural constraints or other pragmatic considerations are discussed or negotiated are selected as examples of collaboration. The explorative reasoning draws on field notes, transcripts of interviews with the KC teachers and the researcher's observations of the arranged situation. In this process, the concrete experiences of the KC teachers and their reflections in response to the researcher's question, "If you had to do it again, what would you change?" are analysed. Situations from the explorative reasoning where the process resulted in either deliberation or renegotiation of the imagined situation are analysed.

Analysing the collaboration in the three processes

The following examples are from the pedagogical imagination in the second iteration.

As part of the pedagogical imagination, MA had to be established. From the researcher's perspective, this was informed by publications on MA, which, among other things, explicate how MA differs from mathematics in a school setting. In the questionnaire, the KC teachers were asked about their experience teaching MA. KCT4 stated: "I'm new to the world of mathematics". This indicates that

KCT4, to some extent, perceived MA as being equivalent to mathematics as an academic subject. Thus, the pedagogical imagination of MA is disrupted because the KC teachers do not consider MA to be unclear. For them, MA is mathematics as it is taught from first grade onwards, while from the researcher's perspective, MA is something different from school mathematics. At the same time, the statement also reveals KCT4's insecurity about her relationship with mathematics. Some KC teachers describe themselves as novices in mathematics and express feelings of inadequacy in the subject. During the first explorative reasoning, when asked about the mathematical aspects, KCT1 said: "I mixed the tasks as I stood there because I also found it hard to teach". In the teaching situation, KCT1 had difficulty distinguishing between decomposing and composing the number 5 as the sum of two natural numbers. When asked what the mathematical content in the next iteration should be, KCT1 said: "You decide", leaving the decision completely to the researcher. This and other utterances indicate that the KC teachers' main concern regarding MA is their own understanding of the mathematical content, and that they did not want to engage in negotiation about it. This limits the collaborative elements of negotiation and deliberation about the mathematical aspects of the imagination process to the researcher's perspective. Thus, the examples reveal challenges in the pedagogical imagination concerning critical reflection, deliberation and negotiation.

In the first pedagogical imagination, both the researcher and the practitioners contributed an inquiry perspective to teaching, making it a mutually agreed-upon pedagogical approach. In the second pedagogical imagination, this shared understanding of using inquiry as an approach was not re-deliberated. As such, it remained a key element in the imagined situation, demonstrating that when two different professions contribute the same perspective, and this is confirmed during an arranged situation, no re-deliberation is necessary.

The imagined situation that emerges through pedagogical imagination cannot be directly translated into teaching, as the constraints arise from the current situation. I will not delve into the constraints affecting the practical organisation. The following examples are drawn from the practical organisation of teaching material during the second iteration.

As noted in the pedagogical imagination, the KC teachers initially felt insecure about their own mathematical understanding and did not express any opinions on the mathematical content. In the second iteration, the researcher introduced repeating patterns, which KCT1 remarked would be "not just easier for the children to access, but also for us". The suggested content was therefore quickly accepted and recognised by KCT1. During the workshop, there was no didactical discussion on the practical organisation of the content, although the mathematics itself was discussed, such as clarifying what a "unit of repeat" is. While the content seemed familiar, and the KC teachers were engaged, the workshop held greater potential for professional development in the mathematics itself, rather than in evolving the practical organisation of the arranged situation.

The teaching material featured a story about a toy dragon. The KC teacher read a paragraph of the story aloud, ending with an engaging question. The students were then asked to answer the question related to the paragraph. The subsequent paragraph included both a recap of the previous question and an introduction to the next one. At the workshop, the implementation of the designed teaching intervention was negotiated. KCT5 suggested reading the entire story before addressing the questions

one at a time. The researcher supported the KC teacher's reflection, saying: "If it makes sense for you and your class… you can do it… It's not how it's meant to be read… but I also think you can try it". KCT4 then added: "I think someone would only pay attention to the last part" – a point later endorsed by KCT2. In this situation, KCT5 proposed a concrete change, which the researcher was receptive to, while other KC teachers critically reflected on it. Despite these discussions on how to read the story, no compromises were made, thus preserving the KC teacher's agency and expertise in KC practice. Here, the negotiation of the practical organisation regarding a pedagogical aspect is not between the researcher and the KC teachers, but among the KC teachers themselves.

The KC teachers' expertise in KC teaching was also evident in another situation. When asked about challenges in implementing the teaching sequence, KCT1 expressed a concern: "So there is something about following each other's pace and waiting for each other," a concern shared by all KC teachers. The concern was that some students would just sit and wait with nothing to do. This was not something the researcher had considered beforehand. Therefore, a fourth guiding principle was added: 4) The design should be flexible and not too compact, allowing students to work at their own pace while still following the same progression. This led to modifications in the teaching material from a pedagogical rather than a mathematical perspective, such as describing when to start a classroom discussion, even if not all students have finished, and giving quick finishers related tasks.

In these last two examples, the KC teachers apply their specialised pedagogical knowledge regarding KC practice. This sparks deliberation and negotiation of certain pedagogical aspects, which would not have occurred without the KC teachers' involvement in the practical organisation.

The following examples are drawn from explorative reasoning in the second iteration.

Despite recognising repeating patterns, KCT1 still expressed mathematical insecurity when asked about the teaching: "I probably would never, because it's difficult for me, so now, based on myself, …, because I'm in deep water myself regarding all this." In situations like this, the conversation often focused on the KC teachers' learning rather than the students' learning, as when KCT1 said: "I also learned a lot." All KC teachers acknowledged that the students had learned some mathematics, but did not elaborate further on what they had learned. Engaging KC teachers in reflecting on a specific teaching episode highlighted their concerns about their mathematical understanding once again. However, the focus on the KC teachers' learning was, in some ways, an obstacle to the process of reimagining the imagined situation. Additionally, the limited interest in exploring students' mathematical learning impeded the KC teachers' contributions to the process.

Initially, the fictional story was introduced by the researcher as part of the inquiry approach, relating it to the description of MA in the curriculum. This was not questioned by the KC teachers at that time. During this second explorative reasoning, KCT1 emphasised the story's value as an engaging context for the students, stating: "We could have done it in so many ways, where they wouldn't have felt the same ownership or had the same approach…". The main character of the story – the toy dragon – was sitting in the classroom during the teaching. During an observation, the researcher noted that at the end of the lesson, many students gave goodbye hugs to the toy dragon. This indicates that both the researcher and the KC teachers recognised the students' engagement in the story. Consequently, the purpose of the fictional story shifted as critical reflection led the KC teachers to reassess and refine

the idea, thereby enhancing the imagined situation. At the same time, by comparing the researcher's observations with the KC teachers' experiences from the concrete arranged situation, it is possible to also re-confirm elements from the first imagined situation, as seen with the fictional story. During the explorative reasoning, the KC teachers view the mathematical content as difficult but feel confident in the pedagogical approach. For example, KCT1 said: "This is new to me, not to teach this way [the inquiry approach], but the tasks [are different]". This reflection confirms once again the use of inquiry as an approach in the imagined situation, even though it does not address the mathematical content.

Findings

The analysis of the pedagogical imagination shows that negotiating a common understanding of MA is challenged by two main factors. First, differing views of MA and its relation to mathematics make it difficult to engage in creative, critical reflection. While the KC teachers see MA as already well-defined, the researcher seeks to explore its meaning. Thus, for the researcher, it is the understanding of MA that needs to be explored, whereas for the KC teachers, it is the teaching of mathematics that are to be explored. Second, when the KC teachers struggle not only with teaching the content but also with understanding it, engaging in a process of imagining how the current situation could be different regarding the content becomes challenging. However, as this was the second iteration, a potential is revealed in how elements from the first pedagogical imagination do not always need to be re-deliberated if there is already an agreement on them, as in the case of the inquiry approach.

Analysis of the practical organisation process shows that there was no discussion or negotiation regarding constraints or changes to the mathematical content in the teaching material. The KC teachers' focus on their own learning of mathematics, rather than on its teaching, hindered the negotiation of mathematical aspects. However, this created an opportunity for professional development, as engaging with the teaching material supported the KC teachers' mathematical learning. Furthermore, once the mathematical content was clear, the KC teachers began to question the pedagogical aspects of the researcher's teaching material. As a result, their experience and pedagogical knowledge were incorporated, revealing the potential for negotiating the pedagogical aspects of the teaching material through collaboration between practitioners and the researcher.

Explorative reasoning is challenged by the KC teachers' focus on their own mathematical insecurities, hindering their ability to reflect on their students' mathematical learning and limiting their analysis of the intervention, as well as their connection to the imagined situation. However, engaging KC teachers in reflecting on a specific teaching episode enables them to address concerns about their teaching of MA. At the same time, explorative reasoning reveals the potential to reassess and refine the purpose of ideas from the imagined situation, reinforcing the second guiding principle concerning the realistic context and reaffirming the inquiry element.

Potential and challenges in collaboration arise across all three processes, but they differ at each phase. However, collaboration is not simply collaboration; using CR as a methodology enables the exploration of how collaboration varies across the processes when developing a practice that does not yet exist. During the collaboration, the KC teachers are positioned as co-designers when engaging in the practical organisation, and as co-explorers during the pedagogical imagination and explorative reasoning. The challenges revealed show that, in these roles, the KC teachers are sometimes limited

by their mathematical insecurities. Conversely, the potential of collaboration lies in the diverse perspectives that emerge. This is evident when the pedagogical aspects are strengthened by the KC teachers' expertise. Additionally, during the second iteration, the KC teachers felt confident reflecting on another practice and, in relation to this, on their own mathematical understanding, which made them aware of their need for professional development.

Discussion

Ponte et al. (2003) state that two factors define successful collaboration: a common goal and the fulfilment of each participant's needs. In this project, the common goal is the exploration of MA, driven by the need to change the current situation. While KC teachers view MA as equivalent to mathematics and feel like novices in the subject, their challenge lies not in uncertainty about MA itself, but in their own insecurity regarding mathematics. From this perspective, a common goal may seem absent. However, in CR, a common goal can also be a shared desire for change and the recognition that change is necessary. Anderson (2011) highlighted that practitioners initiate change, while Wright (2021) emphasised that collaboration in CR is meaningful because everyone is committed to change. Thus, even in the absence of a specific common goal, the shared aspiration for change acts as the unifying factor. Unlike Anderson (2011) and Wright (2021), who worked with mathematics educators, the KC teachers in this study expressed a need to learn more mathematics, signalling that change was needed. However, addressing this need shifted the focus to the mathematical content itself rather than the exploration of MA as an area of competency.

The status of KC as a transitional year with its unique pedagogical approach emphasises the need to include the KC teachers' perspectives in the various phases. Here, the KC teachers provide pedagogical expertise on what characterises a good classroom environment in their practice. In line with Anderson (2011), this allows the researcher to gain deeper insight into practice, revealing a shared understanding and the potential to accommodate both professional roles during the pedagogical imagination. In this study, engaging in the pedagogical imagination during the second iteration becomes more comprehensive as the KC teachers critically reflect on their experiences from the first iteration, thereby engaging in the renegotiation of the researcher's perspective. Wright (2021) found that collaboration in the practical organisation enables practitioners to share and discuss different perspectives on teaching, as well as take joint responsibility for designing changes. In this study, while discussions on how to read the story did not change the teaching material, they were valuable in fostering critical reflection that might not have otherwise occurred. Moreover, another discussion led to the development of an additional design principle. Thus, collaboration within the practical organisation was not only inspirational but also contributed to expanding and modifying the teaching material, thereby affirming the role of KC teachers as co-designers. As Wright (2021) concluded, the opportunity for both parties to contribute their expertise is distinct in explorative reasoning. In this study, two different professions analysed the same arranged situation and noticed the same thing. Not only did both parties share their expertise, but they also contributed to the collaborative development of the imagined situation, particularly regarding the realistic context. As McKenney et al. (2019) express, this is one of the most valuable elements of collaboration – when different professions contribute their specific knowledge.

The potential for both researchers and practitioners to contribute their expertise in developing a shared understanding of MA is significant and should not be overlooked. These dynamics highlight how different areas of expertise shape the collaboration, demonstrating that both researchers and KC teachers bring unique and valuable resources to all three processes. Although professional development was not the primary aim of the study, it clearly occurred throughout all three phases. When two different professionals discuss and negotiate, mutual learning takes place; thus, it is not only the KC teachers who gain new insights, but also the researcher. However, more than one intervention is necessary for the KC teachers to engage in collaboration as more than implementers. For the KC teachers to actively participate in the development and exploration of MA through engagement in the three processes in CR, it seems they need to be involved in at least three iterations. The project will determine whether this is sufficient.

[3]University of Crete, Greece

Mathematics education during the early years involves researching the role of parental practices that could promote numeracy. This study aims to shed light on the individual differences in parental support for home-numeracy in pre-schoolers with Intellectual Disabilities taking into consideration the parent's expectations about his/her child's school readiness. We employed a two-step cluster analysis in a sample of n=374 parents. Statistical analysis yielded seven different profiles for participating parents, including profiles from (1) Moderate Expectations, Few Numeracy-Related Activities to (7) High Expectations, High Numeracy-Related Activities. Also, we examined the effects of activities that parents employ to assist their children during this critical developmental period and are related to direct literacy, fine motor, and general skills unrelated to mathematics or literacy that parents employ to assist their children during this critical developmental period.

Keywords: Home-numeracy, intellectual disabilities, early childhood, parental practices,

Introduction

A significant number of research efforts emphasize the importance of home-numeracy experiences for kindergarten readiness and the acquisition of early numeracy skills (Charitaki & Alevriadou, 2024; LeFevre et al., 2009). During early childhood, numerical concepts are taught through playing. Parents can foster a wide range of activities that can promote their children's numerical skills through a direct [Books with Numbers (e.g. "Using number activity books", "Reading number storybooks"), Counting Activities (e.g. "Using number or arithmetic flashcards", "Identifying names of written numbers")] or an indirect [Applications (e.g. "Measuring ingredients when cooking", "Playing with calculators"), and Games (e.g. "Playing board games with die or spinner", "Playing card games")] manner. Through their choices, parents create a home numeracy environment (Anders et al., 2012; Cannon & Ginsburg, 2008; Charitaki & Alevriadou, 2024; Elliott et al., 2021; LeFevre et al., 2009).

Readiness for the transition to kindergarten over years has gained much of research attention. Findings in the field suggest that the relationships between parental expectations, support, and kindergarten readiness are characterized by significant variability (Slicker et al., 2021). The phenomenon is characterized by such complicity that the best way to be illuminated is through a person-centred approach. Existing applications of person-centred approaches in populations of typically developing suggest that parental expectations demonstrate significant variability which may be attributed to family background factors (Barbarin et al., 2008; Miller & Kehl, 2019). Parental beliefs/expectations regarding their children's academic achievements (numeracy and literacy) are supposed to mediate the choices they make to create their home-numeracy environment (Bradley &

Corwyn, 2002; Charitaki & Alevriadou, 2024; Sy & Schulenberg, 2005) and their children's mathematical attainments (Puccioni, 2015).

Furthermore, existing findings in the field suggest significant variability in terms of early numeracy acquisition of young children with Intellectual Disabilities (Charitaki et al., 2024). Parental aspects seem to have a significant effect on this variability and the use of specific-oriented approaches to domains such as parental beliefs, attitudes, and expectations is considered to have a significant role in terms of enrichment of the home-numeracy environment (Sénéchal & LeFevre, 2002; Skwarchuk et al., 2014). Beliefs and expectations are psychological aspects of parents' personalities that formulate their actions sometimes consciously and some others unconsciously (Grusec & Danyliuk, 2007). Consequently, it is important to take into serious consideration parental beliefs. The population of children with Intellectual Disabilities is characterized both by uniqueness and variability. These parameters that should not be disregarded.

One study that has attempted to shed light on the phenomenon and explain existing variability is Slicker's et al. (2021) study. They employed a sample of 12.670 parents of typically developing children and revealed distinct parental profiles, entitled: (1) high expectations, fewest home activities; (2) high expectations, high activities; (3) very high expectations, moderate home activities; and (4) very high expectations, most home activities. This study suggested clearly that there is a clear effect of parental expectations on their choices to create a home numeracy environment. Though, parents of children with Intellectual Disabilities cope with significant restrictions in terms of functioning and choices to create their home numeracy environment (Greenway & Eaton-Thomas, 2020). Their psychological state of being is formulated in a complicated manner. Their children's functioning is a significant factor that affects their expectations for their children's academic achievements.

Moreover, existing theories related to children with Intellectual Disabilities numeracy acquisition (Burack, Hodapp & Zigler, 1998) suggest that in many cases they tend to follow the developmental pathways of typically developing children but in a slower rate and reach a lower level of achievements. They could be compared to their typically developing matched peers with the same mental age. Consequently, parental support for home-numeracy in pre-schoolers with Intellectual Disabilities could be equally of more complicated compared to analogous support in typically developing children. The significant shortage of person-centered studies in the case of children with Intellectual Disabilities stresses the need for research findings in the field.

The aim of this study

This study aims to gain insights into the individual differences in parental support for home numeracy in pre-schoolers with Intellectual Disabilities and seek evidence to build their specific profiles. Moreover, we intend to research the profiles' association with parental expectations and other parental support regarding direct literacy, fine motor, and general skills unrelated to mathematics or literacy. Consequently, this study aims to answer the following research questions:

1. What are the profiles of parental support for home numeracy in pre-schoolers with Intellectual Disabilities?

2. Are there qualitative differences within the groups of parents' distinct profiles related to parental expectations and other parental support regarding direct literacy, fine motor, and general skills unrelated to mathematics or literacy, and other demographic characteristics?

Method

A total number of 374 parents were enrolled in this exploratory study. The mean age for the mothers was formed at m=37.56 and s.d.=1.75 years, while the mean age for the fathers was formed at m=44.79 and s.d.=1.95 years. All of them had a child with Intellectual Disabilities (IQ scores ranged from 56 to 66) aged between 4 and 7 years old (m=5.33 and s.d.=.498). The data collection process was implemented through two different stages. The first one was implemented during the spring semester of 2022, while, the second one was during the fall semester of 2022 and the first term of 2023. All parents gave their informed consent, which was ensured by providing them with clear written and verbal information about the research and the planned use of data. Confidentiality and protection of data were also ensured for the archiving of recorded and written data.

Measures

Parents Questionnaire

Parents' Questionnaire (LeFevre et al., 2009) is a research tool designed to assess five district domains, including benchmarks (8 items) (e.g. "Count to 100."), direct literacy activities (3 items) (e.g. "Identifying names of written alphabet letters."), fine motor skills (10 items) (e.g. "Putting pegs in a board or shapes into holes, playing with puzzles."), general skills unrelated to numeracy (7 items) (e.g. "Playing store") and numeracy-related activities (20 items) (e.g. "Using number or arithmetic flashcards." or "Measuring ingredients when cooking."). Activities for fine motor skills were assessed through two separate subscales namely: Tasks / Daily life skills (tying shoes, buttoning buttons, tracing, puzzles), and Playing (Movement songs, musical instruments, clay, blocks). General activities unrelated to numeracy were assessed through two separate subscales namely: Role Playing, TV shows or educational software, and Arts and Crafts: Paper or Legos. Finally, the part of numeracy-related activities consisted of four subscales entitled: Books with Numbers, Counting Activities, Applications, and Games. The scale's scoring is made through a 5-point Likert scale. In the benchmark's case the Likert scale that is being used (1=not important at all to 5=very important). In the remaining domains, the Likert scale is being used (0=if the activity was not implemented at all to 4=almost daily).

Caregiver's / Parent's Attitudes Toward Mathematics and Reading

Caregiver's/Parent's Attitudes Toward Mathematics and Literacy (LeFevre et al., 2009) scale is a research tool, which consists of 9 items. The scale's scoring is made through a 5-point Likert scale (1=strongly disagree to 5=strongly agree). Specifically, a high score indicates positive attitudes toward mathematics.

Results

For the study, we employed segmentation analysis. More specifically, we used a two-step cluster technique, which suggested a seven-cluster solution for the description of the profiles of parental

support for Home - Numeracy in pre-schoolers with Intellectual Disabilities. Schwarz's Bayesian Criterion (BIC) was estimated and used to draw a decision regarding the appropriate number of clusters that should be used. We made separate assessments of the fit of all possible cluster solutions from one to seven-cluster solutions. The seven-cluster solution offered the most optimal and parsimonious fit (BIC was minimized at the value of 672.134). Moreover, the silhouette measure of cohesion and separation showed better cluster quality (>.7) in the case of the seven-cluster solution. A comprehensive interpretation of the suggested profiles is provided in Figure 1 and Figure 2.

The cluster analysis revealed seven distinct profiles of parental support for home numeracy among preschoolers with Intellectual Disabilities, each characterized by different levels of engagement, expectations, and educational focus.

Cluster 1, labelled the *Poor-quality Home Environment*, included 60 parents, this group demonstrated limited engagement in numeracy activities. Applications were used occasionally, while counting activities, books with numbers, and games were rare. Despite expressing moderate academic expectations, these parents prioritized non-academic activities such as arts and crafts. Cluster 2, the *Uninvolved/Neglectful Home Environment*, included 61 parents who also reported moderate expectations, but engaged even less in numeracy activities than Cluster 1. Applications and books with numbers were used infrequently, and games and counting activities were largely absent. Their overall activity pattern suggests minimal structured support and a lack of consistent educational engagement. Cluster 3, the *Socially Oriented Home Environment*, consisted of 20 parents in this cluster, numeracy engagement was almost exclusively limited to games. Other structured numeracy activities were seldom used. These parents held low academic expectations and focused primarily on social and play-based activities such as arts and crafts, movement games, and fine motor skill development.

Cluster 4, the *Frustrated Home Environment,* included 70 parents who reported moderate use of applications and games, but limited use of books with numbers and counting activities. Although their expectations remained low, some positive orientation toward numeracy was observed. Non-academic activities such as arts and crafts and limited use of literacy and multimedia tools were also present. Cluster 5, the Authoritative Home Environment, was the largest with 93 participants, this cluster emphasized structured numeracy support, particularly through counting activities and books with numbers. Applications and games were used less frequently. These parents expressed moderate expectations and engaged in a range of academic and creative activities, including music, movement, and literacy-related practices. Cluster 6, the *Demanding Home Environment*, comprised of 30 parents exhibited the highest engagement across all numeracy-related activities. Their home environments incorporated counting, books, games, and applications. High academic expectations were paired with consistent use of literacy, multimedia, and play-based activities, with less emphasis on arts and crafts. Finally, Cluster 7. the *Highly Demanding Home Environment*, included 40 parents, this cluster created rich and structured numeracy environments. All types of numeracy activities were employed frequently, along with strong support in literacy and creative domains. These parents maintained high academic expectations and provided comprehensive educational experiences across domains (Figure 2).

Characteristics	Cluster 1 (n=60)	Cluster 2 (n=62)	Cluster 3 (n=20)	Cluster 4 (n=70)	Cluster 5 (n=92)	Cluster 6 (n=30)	Cluster 7 (n=40)

Figure 1: Sample Characteristics within Clusters.

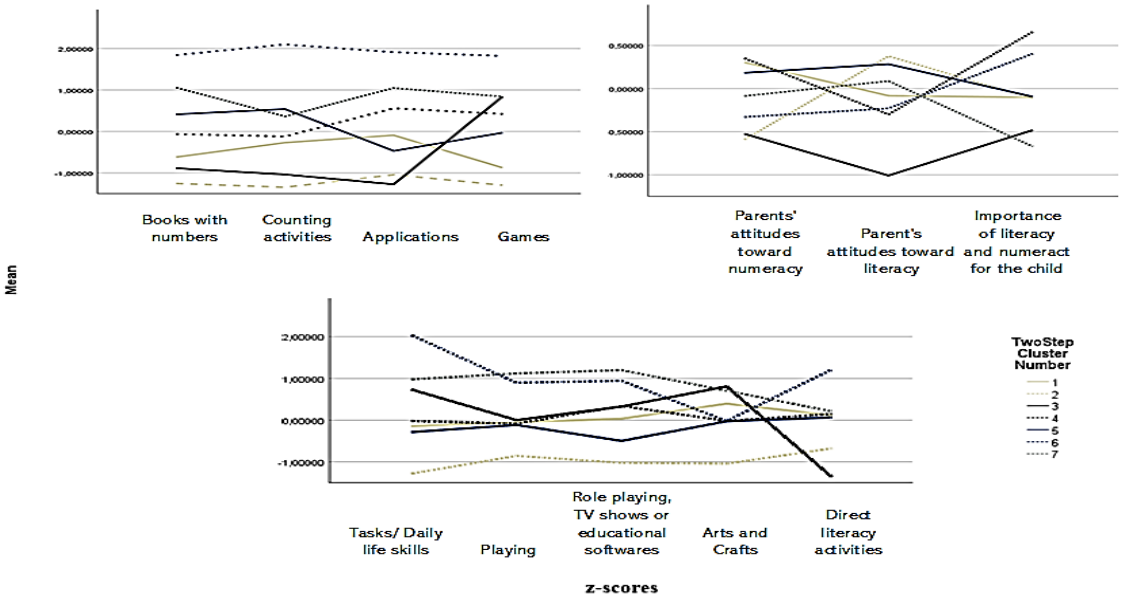

Figure 2: Profiles regarding parental support profiles in pre-schoolers with ID (seven clusters).

Internal Validity

Sensitivity analysis suggested that 87% of parents remained in the same cluster across clustering techniques. Moreover, the cluster solution was re-estimated using a random sub-sample comprising 70% of the entire sample and the solution indicated stability of the cluster solution.

Discussion

Early years of mathematics focused on the home-numeracy environment seem to have a significant impact on children's school readiness and later achievement when entering primary school (Charitaki & Alevriadou, 2024; LeFevre et al., 2009). Existing intra-individual differences across families of children with Intellectual Disabilities justify the need for person-oriented findings regarding the type

of parental support in terms of home numeracy. The present study identified a diverse range of parental support profiles for home numeracy among preschoolers with Intellectual Disabilities, reflecting substantial variability in both the quantity and quality of engagement. These profiles ranged from minimal, unstructured involvement with moderate or low academic expectations to highly enriched and structured numeracy environments aligned with high parental aspirations. Rather than listing each cluster individually, we emphasize the overall pattern: parents differed not only in the types of activities they used—such as counting, reading number books, or playing games—but also in their underlying expectations and priorities, which were often shaped by broader contextual factors, including socioeconomic status.

These profiles revealed a spectrum of engagement, from low-activity environments with modest academic expectations to highly enriched, structured home settings characterized by frequent numeracy activities and strong educational aspirations. Parental behaviour was not only defined by the type of numeracy activity, for example counting, using books with numbers, or playing math-related games, but also by parents' underlying expectations for their children's learning. Importantly, these expectations and support strategies were found to be deeply influenced by contextual and socioeconomic factors.

In line with prior research (Slicker et al., 2021; Bradley & Corwyn, 2002), our results confirm that parental beliefs and expectations are closely tied to the learning environment parents construct at home. Moreover, these beliefs are shaped by multiple factors, including the child's developmental challenges, the level of support and guidance families receive, and critically their socioeconomic background (Sénéchal & LeFevre, 2002; Skwarchuk et al., 2014). Families facing economic hardship and lower educational attainment often experience reduced access to resources and information, which in turn limits their ability to foster numeracy development effectively (Bradley & Corwyn, 2002; Charitaki & Alevriadou, 2024; Sy & Schulenberg, 2005).

Our findings reinforce the well-established association between lower socioeconomic status and reduced academic performance in early numeracy (Kluczniok, 2017; LeFevre et al., 2010; Xu, 2023), which is the case in pre-schoolers with intellectual disabilities (Szumski & Karwowski, 2012). Clusters characterized by minimal parental involvement and low activity levels were predominantly composed of families with limited income and education (e.g., Clusters 1 and 2). In contrast, clusters demonstrating structured and consistent numeracy practices (e.g., Clusters 5 through 7) were primarily composed of families with average to high socioeconomic status. This gradient underscores how economic and educational capital translate into differences in home learning quality, further compounding disparities for children with ID (LeFevre et al., 2010; Ramani & Siegler, 2011).

These findings are of considerable practical significance. Families from disadvantaged backgrounds, especially those who hold lower expectations for their children's academic potential, may be at significant risk of under-supporting their early numeracy development. These families often face systemic barriers to accessing specialized therapies or interventions. Therefore, tailored support strategies are essential. Strengthening family-school partnerships that promote reciprocal communication and shared responsibility between parents and educators could be beneficial for young children with intellectual disabilities. Additionally, low-cost, engaging activities such as

numeracy games can be an accessible and enjoyable way to stimulate early skills across all socioeconomic status groups.

Supporting collective mathematical creativity in first grade

Michal Cohen[1,2] and Esther S. Levenson[1]

[1]Tel Aviv University, Israel; michalc3@mail.tau.ac.il

[2]Oranim Academic College of Education, Israel

This paper describes observations of collective mathematical creativity among first-grade students. Three measures of mathematical creativity were analyzed: fluency, flexibility, and originality. Four groups of students engaged with four open-ended activities suitable for young children, designed to occasion mathematical creativity. Two groups received social support, and two groups received arithmetic support from the first researcher. The results show that these interventions fostered active listening, idea-sharing, mutual support, and diverse responses among students, helping them to exhibit mathematical creativity. Three episodes from two activities are presented here to exemplify how the different supports promoted students' fluency and flexibility as well as a moment of mathematical insight by a student.

Keywords: Mathematical creativity, social support, arithmetic support, first grade.

Introduction

The OECD has identified various skills that are foundational for students in the education system, including collaboration, interpersonal communication, problem-solving and creativity (Chu et al., 2016). Specifically, it is important to nurture mathematical creativity among students (Leikin et al., 2011). Regarding collective creativity, a review of the research literature reveals that most studies on that subject focus on older students (e.g., Molad et al., 2020), and there is a lack of studies involving first-grade students who are just beginning their journey in elementary school. This paper explores the possibility of promoting collective mathematical creativity among first-grade students, thereby highlighting the development of 21st-century skills of creativity and collaboration among young students.

Theoretical Background

What is creativity? According to Torrance (1988), creativity is defined as the process of sensing problems, deficiencies, gaps in knowledge, missing elements, or something that is not in harmony. This process requires individuals to evaluate, test, revise, and re-examine their work to present a final result. Torrance's tests for identifying creativity were based on four dimensions: fluency, flexibility, originality and elaboration. In mathematical education, creativity is typically characterized by three of the four dimensions: fluency, flexibility, and originality. The fluency dimension refers to the ability to generate many possible solutions and ideas to a given problem and is usually measured by the number of correct distinct solutions to a problem (Levenson et al., 2018). The flexibility dimension examines the different strategies students use to solve a problem, and is measured by sorting the responses into categories, where the number of categories represents the flexibility score. Originality refers to the provision of unexpected and unusual answers (Levenson et al., 2018; Leikin, 2009).

Mathematical creativity can be nurtured through specific activities known to foster creative thinking, including tasks that allow for multiple strategies, multiple outcomes, investigation tasks and sorting tasks (Klein & Leikin, 2020). These tasks may also involve deriving general formulas and recognizing

mathematical patterns. For example, open-ended tasks encourage divergent thinking and mathematical exploration (Tabach & Levenson, 2018). An open-ended task is a task with many solutions, allowing students to propose a wide variety of mathematical ideas (Molad et al., 2020).

Additionally, collective learning can promote and develop creativity. Sengil-Akar and Yetkin-Ozdemir (2020) demonstrate that collective creativity can thrive when students are given open-ended, real-world tasks that encourage exploration, discussion, and refinement of ideas. Furthermore, Levenson (2011) highlights a connection between the work environment, the actions of the teacher, and the promotion of creativity among fifth and sixth graders. The teacher's role is to legitimize innovative ideas presented by students, thereby encouraging them to present new ideas (Levenson, 2011). In a study by Gajda et al. (2017), it was found that the teacher's emotional support for his students is important for establishing creative learning environments. A creativity-supportive environment is characterized by an atmosphere of mutual respect between teachers and students and incorporates open dialogue and collaborative activities (Gajda et al., 2017).

There are two types of intervention in the study. The first type is when the researcher offers social support, therefore we call it social intervention. The second type is when the researcher offers arithmetic support, hence we call it arithmetic intervention. The current study explored the impact of these two types of researcher interventions on students' mathematical creativity, while working in groups on tasks designed to occasion creativity. In the social intervention, the researcher guided students to help, listen to, and encourage each other during the activity. In the arithmetic intervention, the researcher corrected mistakes, provided mathematical hints, and asked arithmetic questions related to the tasks. The students' mathematical creativity was assessed based on the three commonly accepted dimensions in mathematical education research: fluency, flexibility and originality. Specifically, we ask, (1) What is the level of mathematical creativity–in terms of fluency, flexibility and originality–among groups of first grade students receiving either type of intervention? (2) In what ways can each type of intervention support collective mathematical creativity?

Methods

The study involved 12 first-grade students, aged 7, attending elementary school. Ethical approval was obtained from the Chief Scientist of the Ministry of Education, written parental consent was obtained, along with the option to withdraw at any time, and all names in this paper are pseudonyms.

The students were divided into four heterogenous groups of three students each, such that each group included one academically advanced student, one average student, and one low achieving student, as based on the teacher's assessment and academic achievements in arithmetic. The research was conducted towards the end of the school year. The mathematics lessons up to that point covered recognizing natural numbers up to 100, as well as addition and subtraction, including chain exercises with two or more operations. In the final months, students also began learning the fundamentals of multiplication and division up to 20.

Group meetings were held at the school, with each group having four sessions, spaced one week apart. The researcher met with each group in a quiet room, separate from the rest of the class. During each meeting, the students worked on a single task, following the sequence described later. All sessions were video-recorded and transcribed by the first author. The research tools included four tasks along with interventions, as well as observations. This paper will focus on two tasks.

The first task, 'Questions from a Picture', is rooted in the visual domain, where students are asked to look at a picture and generate as many mathematical questions as possible. Before beginning the task, the students were given a demonstration task to introduce the concept of formulating questions based on an image. The researcher presented the students with an illustration of two trees, one bearing three oranges and the other four lemons, and asked them to formulate relevant arithmetic questions (see Figure 1).

Once it was clear that the students grasped the concept of generating questions, the researcher introduced the image for the first task and encouraged the students to "be teachers" by generating as many questions as possible based on that picture (see Figure 2).

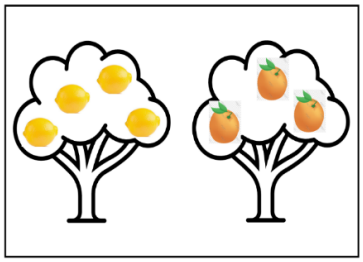

Figure 1: Demonstration Task

Figure 1: First Task

The second task, implemented one week after the first, titled 'Exercises for the Number 12', challenged students to generate as many arithmetic exercises as possible that result in the solution 12. To clarify the assignment, the task was preceded by a preparatory activity. The researcher wrote the number 3 on a sheet of paper, circled it, and asked the students to create exercises where the answer would be 3. Following this introduction, the students were encouraged to "be teachers" by inventing as many exercises as possible for their classmates, all leading to the answer of 12. It is important to note that both activities offer many possible solutions. In both tasks, the researcher handled the actual writing of the answers, as the students were in first grade, not yet fluent in writing.

The students' responses were analyzed using creativity measures, with each task evaluated separately for fluency, flexibility, and originality. For the first task, fluency was measured by counting the number of relevant mathematical questions based on the given picture. For the second task, fluency was measured by counting the number of arithmetic exercises that led to the solution of 12. For both tasks, if the same question or exercise was repeated more than once, it was only counted as one. Incorrect exercises, such as 10+3=12, were not counted. Each question or exercise earned the group one point. Flexibility was assessed by examining the variety of methods proposed by the students. The first author categorized the students' responses, which were then validated by the second author, with discussions held as necessary.

As demonstrated in previous studies (Levenson et al., 2018), the level of flexibility was set by categorizing the students' responses for each task (exemplified below, Table 1).

Task 1 - 'Questions from a Picture'		Task 2 - 'Exercises for the Number 12'	
Category	Example	Category	Example
Count	How many pancakes are on the tray?	Addition	3 + 9

Combining groups	How many apples and strawberries are there in total?	Subtraction	17 - 5
Subtraction	There were 15 balloons, and 4 of them popped. How many are left?	Multiplication	2 x 6
Comparison	How many balloons are there of each color, and which color has more?	Chain exercise	10 x 2 – 8
Inference	How old is Itai? (can be inferred from the number of candles on the cake)	Verbal problem	13 donuts minus one donut.
Measurement	What is the length of the table?	-	-

The number of categories indicates the level of flexibility. Originality in each activity was determined by identifying unexpected or novel solutions (Leikin et al., 2011). Due to the small number of participants, in this paper, we refer only to fluency and flexibility, as summarized in Table 2.

Results

This section begins by presenting the fluency and flexibility scores each group achieved in the selected two tasks. Three episodes were selected from the tasks to illustrate how the different types of interventions – social and arithmetic support – impacted on students' flexibility and fluency. Table 2 presents the measures of fluency and flexibility for each group in the two tasks, 'Questions from a Picture' and 'Exercises for the Number 12'.

Table 2: Measures of fluency and flexibility according to task and group

Group	Questions from a Picture		Exercises for the Number 12	
	Fluency	Flexibility	Fluency	Flexibility
Social Support A	9	3	27	4
Social Support B	11	3	26	4
Arithmetic Support A	13	4	22	5
Arithmetic Support B	14	5	19	5

In general, when it came to fluency, students found it more challenging to generate verbal questions than to create arithmetic exercises. Additionally, in the 'Questions from a Picture' task, the groups that received arithmetic support demonstrated higher fluency in their responses compared to those that received social intervention. Conversely, in the 'Exercises for the Number 12' task, fluency was higher among the groups that received social intervention. For both tasks, flexibility was slightly higher among those who received arithmetic support.

Arithmetic support leads to flexibility

During the 'Questions from a Picture' activity, the students from Arithmetic Support Group B primarily asked questions involving counting items. The researcher noticed a lack of variety in the types of questions being asked, so to encourage greater flexibility, she asked the students if they could think of other types of questions, not just those involving counting that begin with the word "how many". Following the researcher's prompt a student named Carmi asked a question that involved making an inference from the picture.

Carmi: How many children will come based on the number of chairs?

Carmi wanted to know how many children would attend the party based on the number of chairs arranged around the table.

Researcher: Wow, what a great question. So, if we count the chairs, we can guess how many children are expected to arrive. Well done.

It seems likely that Nurit was paying attention, because following Carmi and the researcher's comment, Nurit also proposed an inferential question based on the picture.

Nurit: How many hamburgers will be left at the end of the party?
Researcher**:** How can we know that?

Nurit's question directly followed Carmi's, referring to the hamburgers on the tray. Carmi's response to Nurit's question showed that he was paying attention to her.

Carmi**:** Because there are 12 children, and if they all want some...

It appears that Nurit was thinking about the sequence of events in the picture—specifically, what the children would do after taking their seats at the party.

It should be noted that flexibility in the 'Questions from a Picture' activity was measured by the variety of types of arithmetic questions the students asked based on their observations of the picture. Inference questions require understanding beyond what is immediately visible, as opposed to direct questions that could be asked simply by looking at the picture. This case illustrates how the researcher's intervention encouraged students to increase their cognitive flexibility, enhance their creativity, and collaborate with one another.

Arithmetic support leads to fluency and flexibility

At the beginning of the 'Exercises for the Number 12' activity, the researcher instructed the students to come up with as many exercises as possible that resulted in the answer 12. The students in Group A with arithmetic support, Ela, Miki, and Ronit, initially proposed one multiplication exercise and three different subtraction exercises, all of which were correct solutions for the task. They then attempted to create word problems with the answer of 12, but their questions were unclear and incorrect. For example, Ronit asked, "12 bananas times one apple". Possibly, they were recalling the image from the previous picture activity, leading them to try to invent similar questions. Miki stated, "I have nothing", but the researcher persisted and reflected to the students that while they had used multiplication and subtraction, they had not yet tried addition.

Researcher: I saw that you did multiplication and subtraction, but I don’t see addition.

Following the researcher's prompt, the children changed direction and turned to addition:

Ela: 10 plus 2.
Researcher: Wow. What else?
Ela: 9 plus 3.
Ronit: 8 plus 4.

A pattern can be observed in these three exercises. In each, the first addend decreases by 1, and the second addend increases by 1. In this exchange, it is evident that Ronit, (considered by her teacher to be a weak student), was listening to Ela (considered to be a strong student), which led Ronit to think of an additional solution. The researcher's arithmetic intervention motivated the students to come up with more exercises, thereby increasing the fluency, but not the flexibility, of their responses.

Social support leads to fluency and flexibility

During the 'Exercises for the Number 12' activity, Sagiv and Tamir (Social Support Group B) came up with two subtraction exercises that resulted in 12. Afterward, another student, Miri, repeated an exercise that had already been mentioned, 14 minus 2. Although she did not invent a new exercise, the researcher responded with a 'compliment': "We've already said that, but good job!". Immediately after, Miri began generating a stream of subtraction exercises.

Miri: 15 minus 3.
Researcher: Wow, 15 minus 3. No one has said that yet.
Miri: 16 minus 4.
Researcher: Wow, no one has said that either.
Miri: 17 minus 5.

Miri continued to create more exercises, consistently increasing both the minuend and subtrahend by 1 in each new exercise, maintaining the difference so that the result was always 12. It should be noted that Miri was considered an academically weak student by her teacher. It seems that she reached this mathematical insight during the activity, ultimately inventing 14 different subtraction exercises.

Miri: 21 minus 9.
Researcher: Wow!
Miri: 22 minus 10.
Researcher: Wow, Miri, you're doing great today!
Researcher: What do you think of Miri's answers? (asking the two other students.)
(The other students tap loudly and rapidly on the table signifying enthusiasm.)
Miri: 23 minus 11.
Researcher: Nice. What a creative child.

Throughout the activity, the other two students observed Miri, occasionally encouraging her, but did not participate in increasing the fluency of responses. Possibly, the researcher's interventions, such as asking for feedback on a peer's work and giving compliments during the activity, helped Miri generate a significant flow of exercises. Additionally, the non-verbal support from her peers might have also helped Miri find more correct exercises that met the task's requirements.

Up until that point, Miri had been quite passive. The compliments from the researcher appeared to encourage her to speak and motivated her to find more and more exercises. Miri smiled, clearly pleased with the attention and her success in generating a steady stream of exercises, contributing to the task's overall success. This example illustrates how the researcher's social intervention helped enhance fluency and foster mathematical insight during the "Exercises for the Number 12" activity.

Discussion and Conclusion

Qualitative research on this scale is limited and can only suggest possible directions and trends regarding how interventions can contribute to the development of mathematical creativity. In the current study, we found that the researcher's interventions helped students to express mathematical creativity. Regarding the level of creativity, no major differences were found in the measures of fluency and flexibility between the social intervention group and the arithmetic intervention group. Both tasks, 'Questions from a Picture' and 'Exercises for the Number 12,' are defined as open-ended tasks in which students were required to invent questions and exercises. It is important to note that this is a challenging task for young first-grade students. Yet, it also provides them with an opportunity to express creativity by "creating something". Additionally, first-grade students do not yet have fully developed social skills, and working together is not something that comes naturally to them (Veldman et al., 2020). Therefore, teacher intervention is important (Levenson, 2011).

Regarding the second research question, which explores how each type of intervention supports collective mathematical creativity, the findings from the three episodes described above show that both social and arithmetic interventions contributed to increased fluency and enhanced flexibility. In the third case, we also see mathematical insight following social intervention.

Reflecting on the researcher's approach to intervening during the students' work, the question arises: How feasible is it to separate social and arithmetic interventions? In Levenson (2011) the teacher indeed provided both type of supports. As researchers, we try very hard to adhere to the guidelines, in this case, implementing either social or arithmetic interventions. We had prepared in advance a set of questions for each type of intervention. However, there were situations where it seemed very appropriate to deviate from the planned intervention. Our conclusion is that in a regular classroom setting, it would be unnatural for teachers to separate the types of interventions, as some situations require a combination of social and arithmetic interventions to effectively support student work.

In conclusion, a significant contribution of this study is that first grade children, with support from a knowledgeable adult, can build on each other's ideas, support one another, and provide diverse responses to various tasks. This finding is in line with Levenson's research (Levenson, 2011) regarding the contribution of teacher's support to creativity. Although it requires investment from the teacher, this study showed that the effort is worthwhile. First graders can work together and can be mathematically creative. Teachers can show students how to work together, by providing them activities that encourage creativity and lead to teamwork and dialog. As demonstrated by Gajda et al. (2017), social support is important for creative learning environment. Teachers need to mediate the students' work—both social and academic—thereby "planting the seeds" to teach young children how to work together in the future. Students who learn to work together and collaborate are likely to enhance their creativity, both as individuals and as a group.

The study paves the way for larger and more comprehensive studies that also include control groups without intervention.

The influence of linguistic background on early representations of multiplicative comparison

Ann Downton[1], Esther Levenson[2], Andrea Maffia[3] and Nufar Tobal[2]

Linguistic aspects involved in young children's interpretation of multiplicative comparison situations are investigated by comparing the answers provided by children aged 5-6 years old from three different countries: Australia, Italy, and Israel. Two tasks with different wording are used to analyse how language differences affect children's performance in terms of number of correct answers and most common wrong answers. The study shows that the number of children who can provide correct answers to multiplicative comparison tasks before their formal introduction change significantly according to the linguistic background. Furthermore, the analysis of wrong answers suggests that several possible linguistic factors may intervene including vocabulary knowledge, familiarity with phrases, and differences in the way that languages convey multiplicative meanings.

Keywords: Kindergarten, language, multiplicative comparison, representations.

Introduction

There is a growing (but still scarce) body of literature about how young children represent intuitively multiplicative semantic structures before their formal introduction in school. Through an exploratory study, the first and third authors of this contribution found that by the age of 6, many children can represent correctly different multiplicative situations including equal groups, rectangular arrays, multiplicative comparison, and allocation situations (Downton & Maffia, 2023). In the context of that study, multiplicative comparison (MC) problems were more difficult for the children than the other multiplicative situations. The authors attributed this to children's lack of familiarity with the phrase 'times-as-many', which Nesher (1988) also found. Evidence of this was that the Italian children (for whom this phrase is very unfamiliar, see the Method section) found MC situations more difficult to interpret than Australian children. This observation may lead to the relevant educational implication that familiarity with the words used to describe MC could be a pre-requisite for accessing MC problems (Vanluydt et al., 2020), but this remains a conjecture.

Seeking to better understand this phenomenon, this contribution presents a study, which replicated interviews similar to those by Downton and Maffia (2023) but compared the Italian and Australian contexts with another linguistic background: the Hebrew language. Our research question is: To what extent do linguistic aspects influence young children's answers to MC word problems?

Multiplicative comparison and language

Multiplicative comparison, commonly referred to as 'times-as-many' in research undertaken in English, is a different application of multiplication from that of Equal Groups or Rectangular Array, as it refers to a comparison or an enlargement that may apply to either discrete objects or to a

continuous medium, rather than an iteration of equal groups (Anghileri & Johnson, 1992; Greer, 1992). In short, MC involves two different groups being compared to each other. For example, *John has 3 times-as-many apples as Mary. If Mary has 4 apples, how many apples does John have?* In this instance the number of apples Mary has is being compared to how many John has. In this instance the multiplicative factor (3) may be considered as the multiplier. In essence the MC relationship includes three elements that relate to each other: one quantity is a unit of measure (Mary's apples-4), another is the measured quantity (John's apples-12) and the third is the coefficient (the multiplied measure, which in this context is 3) (Polotskaisa & Savard, 2020). The same problem may also be viewed in terms of ratio or a many-to-one correspondence (3 apples of John's for every one apple of Mary's) which makes 4 the multiplier. Greer (1992) purported that *multiplicative comparison* or '*n times-as-many as'* to be a preliminary stage to ratio and has the advantage over the *groups of* aspect as it relates directly to the nature of multiplication.

While some studies found that young children (6 and 7 years old) had difficulty interpreting this semantic structure (Anghileri, 1989; Mulligan & Mitchelmore, 1997), Downton and Sullivan (2017) found that a high proportion (64%) of Grade 3 children (8 and 9 years old) successfully solved comparison problems using multiplicative strategies.

From a linguistic perspective, Nesher (1988) maintained that an understanding of the textural structure of word problems is critical to interpreting the underlying mathematical structure of the problem. From her analysis of the differences in the propositional structure of three types of multiplicative word problems, Nesher noted that for MC (scalar problems), both the order of the text and the language of 'times-as-many' must be considered. Further, the language of this phrase may confuse students (Anghileri, 1989; Nesher, 1988). Others suggested that it is not uncommon for students to add the two given numbers rather than multiply to solve one-step MC word problems (González-Calero et al., 2015; Nunes et al., 1993).

Several studies have shown that language development and numeracy development are related, and that language skills may account for variation when predicting early numeracy skills (Purpura & Ganley, 2014). This makes sense as understanding and "doing" mathematics necessitates the use of language, and specifically the use of mathematical terms such as more, less, and number names. Studies have also shown that different languages may assist or deter children from understanding number concepts. For example, Kung et al. (2019) found that structural language differences between Chinese and English provide different supports for learning mathematics in preschool, especially since numeracy-related words are embedded in Chinese natural language. Indeed, studies have shown that one of the challenges of teaching mathematics at all ages is bridging between natural, sometimes called informal, language, and the more formal, or technical, language of mathematics. For example, in Greek, the mathematical term for set can have three different meanings in their natural language (Antonopoulos, 2023).

Related to the linguistic perspective are the cultural differences, which also impact on children's interpretation of the phrase 'n times as many' in relation to MC. For example, in Spanish the translation is 'n times more than' (increasing comparison) and 'n times less' (decreasing comparison), which is the case for other languages (e.g., Hebrew, Czech, and Arabic) (Nesher et al.,

2003). These subtle differences indicate that MC is expressed by a different construction to that used in English. In fact, these alternative phrases would be considered grammatically incorrect or confusing to English speakers (González-Calero et al., 2015). Another issue related to the current study is that the same concept, in this case multiplication, may be expressed verbally using different terminology, giving rise to different meanings. Language such as 4 times 6 does not activate conceptual meaning, while saying instead, 4 groups of 6, infers the equal groups semantic structure of multiplication (Downton & Maffia, 2023). Hence, the available literature suggests that vocabulary and wording can affect young children's understanding of comparison tasks. In this paper we investigate to what extent such linguistic aspects influence children's responses to MC problems. We will ascertain this by comparing answers provided by children from three different countries to two different MC word problems.

Methods

We conducted the same interview in three countries: Australia, Israel, and Italy. The interview consisted of several tasks including different multiplicative semantic structures. In this report we will focus only on the MC tasks presented in Table 1.

Table 1: The two tasks in the three languages involved in the study

	English version	Hebrew version	Italian version
Apples task	Mary has 4 apples and John has **double** the amount. How many apples does John have?	לגל יש 4 תפוחים ולתומר יש כמות לתומר. כמה תפוחים יש **כפולה?**	Maria ha 4 mele e Giovanni ne ha il **doppio**. Quante mele ha Giovanni?
Towers task	Mary made a tower using three blocks. Max made a tower **three times as tall**. How many blocks did Max use?	גל בנתה מגדל באמצעות שלוש **פי** קוביות. דן, בנה מגדל בגובה יותר מגל. בכמה קוביות **שלושה** השתמש דן**?**	Maria ha fatto una torre usando tre blocchi. Max ha fatto una torre **tre volte più alta**. Quanti blocchi ha usato Max?

Both tasks present a MC situation but they differ in several aspects. Different numbers are involved and, while both situations involve discrete quantities, the Towers task can also be interpreted in terms of linear comparison (in terms of the height of the towers). In the Apples tasks, the word 'double' is used in all three languages; in the Towers tasks we did our best to translate the English 'times-as-many' into similar phrases in Hebrew and Italian.

Children in the study were aged between 5 and 6 years old. Convenience sampling was used to select the schools that already had been in contact with the researchers for past projects. Children for whom parent consent was provided were interviewed. The Australian sample consisted of 39 children, the Israeli sample 37 children, and the Italian sample 43 children. Each sample was coded according to the country in which they attended school and where English, Hebrew, and Italian are respectively – the language of teaching and the native language for most (but not all) children.

Australian children were interviewed during their Foundation year, the first year of school. Within Victoria children must turn 5 before April 30 of the year they start school. Multiplication is introduced in Year 1 (Grade 1) with a focus on equal group situations (Victorian Curriculum and Assessment Authority [VCAA], 2024). In Foundation the focus is on quantifying and comparing collections to at least 20, partitioning and combining collections up to 10 using part whole relationships and subitizing skills, and practical situations involving partition division. While multiplication is not formally taught in Foundation, children become familiar with the language of 'doubles' in the context of addition and may experience the language of 'times as many' in measurement contexts when comparing lengths.

Children in Israel were interviewed during the last months of Kindergarten. In Israel, there is a compulsory mathematics curriculum for children aged 4-6 years old (Israel National Mathematics Preschool Curriculum, 2010). While learning multiplication is not an explicit aim for kindergarten, the curriculum states that other numerical skills, such as skip counting and creating equal groups of objects, are a prelude to multiplication which will be learned later. The language of teaching is Hebrew, the first language of all children participating in this study. In Hebrew, the word 'times,' as in 'five times three,' is 'kaful.' However, in a different context, this same term could mean 'double,' or 'twice as many,' as in Esther has double ('kaful') what Ann has. There is no one term for triple or quadruple, and instead, those meanings must be said as 'three times (or four times) as many,' but here, the term for "times" is not the same 'kaful' as used above. Instead, there is another term which literally translates as 'bigger by 3'. Finally, when children are first introduced to multiplication in first or second grade, they learn to count the number of equal groups (harking back to kindergarten) and thus instead of immediately using the expression 'kaful' for 'three time five,' they use another term 'pa'amim,' which loosely translates as 'three repetitions of five'.

Italian children were interviewed during their last months of Kindergarten, which is not compulsory schooling in Italy. There is no subject-related teaching and the national curriculum for Kindergarten does not refer to Mathematics directly (Italian National Standards for K-8, 2012). There are recommendations for teachers to work on the procedures of counting and measuring as well on recognizing geometrical shapes. The language of teaching is Italian even if children from migrant families (mainly second generation) are present in almost all class-groups. The use of multiplicative numeral adjectives as 'doppio', 'triplo', etc. ('double', 'triple' in English) is common in the Italian language. In Italian grammar, the use of 'volte' (meaning 'times' as in 'two times' or 'five times') is considered more common than the corresponding multiplicative adjective only when the number is higher than five. Even in those cases, the phrase 'times-as-many' is still uncommon. The Italian word 'volte' has several meanings. In the most popular Italian dictionaries, the meaning as 'repetition' is never the first or second one presented and when examples using the word are provided, they include phrases such as "l'ho detto tre volte" ("I said that three times" in English), but the equivalent of the phrase 'times-as-many' (which would be 'tante volte quanto') does not appear in any of the dictionaries consulted by the third author.

During the interviews in all countries, a research assistant presented verbally the situation and asked the child to provide an answer. For each task half of the children were requested to represent the situation using manipulatives, while the other children were provided with paper and pencil and

prompted to draw the situation. In this way, we could avoid the effect of the means of representation (being a manipulative or a drawing, cf. Downton & Maffia, 2023).

Results

Results from the interviews are summarized in Table 2 indicating the number of correct answers for each task in the three samples.

Table 2: Correct answers in the three samples (corresponding percentages are indicated in brackets)

	Australian sample	Israeli sample	Italian sample
Apples task	14 (36%)	5 (13%)	3 (7%)
Towers task	16 (41%)	2 (5%)	1 (2%)

It is apparent, there is a strong difference: Australian children were able to answer correctly to both tasks much more frequently than Israeli and Italian children. Furthermore, the Apples task appeared more difficult for the Australian children than the Towers task, while this was not the case for the Israeli and Italian children. This is possibly because discrete quantities are involved and the word 'double' may be less familiar to the Australian children than the phrase 'times-as-tall'. As noted in the Methods section, the Israeli and Italian languages differ from English in how the phrase 'times-as-many' is presented, and those phrases may be less familiar for children aged 5-6 years old than the words equivalent to 'double'. Indeed, we had examples of children asking about the meaning of the words; in those cases, the interviewer asked the children what they thought. In some cases, the children replied that they just did not know the word.

For a deeper interpretation of these results, we analysed the most common answers provided by children when the given answer was incorrect. Table 3 summarizes the percentage of selection for the most common wrong answers to both tasks across the three samples. Again, we can observe different phenomena in the three samples: the most common wrong answer is not always the same. In the case of the Apple task, the answer 6 (corresponding to the sum of the involved numbers) was the most common for Australian children, but Italian and Israeli children opt more often for 4 (the first number mentioned in the task). Several children were able to represent the numbers 4 and 2 involved in the Apple task, but then they were not able to answer the question as expected; some of them merely counted all.

As in the Apples task, the first number involved in the Towers task (3) was a common incorrect answer (especially in the Israeli sample), but it was not the most common. For this task, the sum of the two involved numbers (3+3=6) was the most common answer not only for Australian children, but for Israeli and Italian ones as well. The language in the Hebrew and Italian translations of the expression 'times-as-many' directly implies that the second tower is taller than the first one. The necessity to increase the tower's height may have prompted the children to sum the two given numbers. This interpretation may explain also the presence of answers such as 4 and 5. Indeed, we have examples of children that, when asked to justify their answers, replied "because the tower is big" or "because 3 and another 1". Another explained, "I think it is 4 because it is more than 3".

Table 3: Relative frequency (over the total of each sample) for the most frequent wrong answers

	Apples task (correct answer 4×2=8)			Towers task (correct answer 3×3=9)		
	Australian	Israeli	Italian	Australian	Israeli	Italian
Answer "3"	0%	11%	7%	5%	16%	7%
Answer "4"	18%	19%	26%	8%	11%	9%
Answer "5"	10%	5%	9%	0%	11%	14%
Answer "6"	23%	14%	9%	36%	19%	14%

Discussion and Conclusion

We acknowledge that his task may be difficult for young children of this age, but the aim of this study was to investigate the extent to which linguistic aspects influence young children's answers to MC word problems. We compared the answers provided to two different word problems across three samples of 5-6 years old children from three countries with different languages: English, Hebrew, and Italian. The three languages differ in how multiplicative numeral adjectives are used. Furthermore, the three countries differ in how mathematics is taught to 5-6 years old children. These differences are reflected in the results.

Overall, the Australian sample performed much better than the other two. Furthermore, the analysis of most common incorrect answers provides hints about differences in children's interpretation of MC as presented in the two tasks. In particular, we noticed that Australian children tended to sum the two numbers involved in the tasks; this phenomenon may stem from the fact that addition is already introduced in Foundation year. In the case of Israeli and Italian children, adding was more common in the Towers task. This may be related to the fact that the presence of two numbers is more transparent in that task, whereas in the Apple task the number 2 is represented by the word 'double' in a less obvious way. Another explanation is that in the Italian and Israeli translation of 'times-as-tall' there is an explicit reference to the second tower being taller or bigger, as noted by some of the children when justifying their answers.

The general difficulty for Italian and Israeli students to provide a correct answer to these tasks may be explained by their lack of understanding of some words (e.g., 'double' for some Israeli children) or lack of familiarity with phrases such as 'times-as-many' (uncommon in Italian everyday language). Having an understanding of meaning of terms such as these is critical to interpreting a word problem (Nesher, 1988). We believe that linguistic aspects (as an expression of the more general cultural contexts) can explain most of the observed differences. Indeed, different languages have dissimilar features in addressing mathematical concepts that may, as a consequence, result in being more or less familiar to young children. For instance, in Hebrew there is a suffix that can be added to words to express the idea of two-ness (as being in a pair or couple) in the same way that in Latin the prefix 'bi' was used to make explicit the presence of two elements (as the word

‘binoculars’ which is composed of ‘bini’ and ‘oculus’, the Latin words for ‘two’ and ‘eye’). This kind of suffix is common in Hebrew everyday language, which is not the case for ‘bi’ in English or Italian. Furthermore, there are everyday words (like ‘pair’ or ‘couple’), which may express similar meanings but may be more or less familiar to young children according to their linguistic and cultural background.

While preparing the tools for this study, the authors had to discuss thoroughly both language and cultural issues. For instance, we discussed which objects could be referred to in the texts of the tasks so that they would be familiar to children of all three samples. We believe that our study can contribute to the body of literature about comparative studies; in particular, some of our observations point to the difficulty of translating tasks with fidelity from one language to another, especially for very young children. This is also an important limitation of our study: comparability of the results from the different samples is partial and highly dependent on the different linguistic, cultural, and social contexts in which the data have been collected.

The interpretation provided for the results suggest that Kindergarten teachers can work on different linguistic aspects to promote children’s familiarity with mathematical language, which will appear later in schooling (Downton & Maffia, 2023; Vanluydt et al., 2020). For instance, reading story books may help in presenting different words (both ‘two times’ and ‘double’) in contexts that make sense to children.

The analysis presented in this contribution has referred only to correct/incorrect answers to the task and qualitative data have only been used to provide a few examples. A further qualitative analysis may provide additional information about the influence of linguistic background on early representations of multiplicative comparison. In particular, we must recognize that there are cases where the child was able to produce a coherent representation (by drawing or using manipulatives) of the situation even if the provided answer was not correct. Furthermore, we did not distinguish between the answers provided by drawing or manipulatives; we believe that those cases deserve attention in future research.

[2]University of Gothenburg, Sweden

[3] School of Education, Macquarie University Sydney, Australia

This study applies variation theory of learning to explore the learning opportunities offered by a teacher during a mathematics teaching activity on repeating patterns, aiming to enhance six-year-olds´ understanding of units of repeat and their ability to generalize this structure. Analyzing a video from an intervention study, we identify three critical aspects: 1) the composition of units of repeat, 2) the repetition and variability in the size of the units of repeat, and 3) how identical units of repeat constitute a whole. These findings have implications for early mathematics education, highlighting the need for systematic pedagogical approaches to strengthen students' structural awareness, and emphasize the importance of strong pedagogical content knowledge among teachers.

Keywords: Repeating patterns, structural awareness, early childhood education, variation theory

Introduction

Over the past decade, young students' understanding of patterns and structures connecting fundamental mathematical concepts such as number, measurement, shape and space has gained increasing recognition (Clements & Sarama, 2009; Junker et al., 2025; Mulligan & Mitchelmore, 2009). A range of studies identify patterning as a predictor of mathematical competence (Rittle-Johnson et al., 2019; Verdine et al., 2013; Zippert et al., 2020), linking it to early algebraic, multiplicative (Mulligan et al., 2020; Papic et al., 2011), and spatial reasoning (Rittle-Johnson et al., 2019). Children's ability to abstract structures and represent repetitions and growing patterns enhance numeracy, as the predictable nature of numerical sequences is crucial for counting and calculation skills (Wijns et al., 2021).

The role of patterning in early childhood mathematics education has been the focus of an emerging research domain well researched (Gripton et al., 2023; Wijns et al., 2021; Papic et al., 2011) and linked to number knowledge, part-whole reasoning, and development of multiplicative concepts. However, many studies, including interventions, have been somewhat limited to pattern replicating tasks with few focused on deeper analysis of how to facilitate children's construction of a generalized composite structure and how to develop relationships with number knowledge (Mulligan et al., 2020). Building on this gap in the field and recent intervention studies showing that teachers' ownership of the foundational ideas of patterning and structural awareness is significant for success (Björklund & Elofsson, 2024; Tsamir et al., 2020), the present study aims to explore the learning opportunities offered by a teacher during a mathematics teaching activity with six-year-olds. The focus is explicitly on repeating patterns and students' learning to explain and articulate emergent generalizations. The

following research question will be addressed: In what ways do systematic variation contribute to six-year-olds' discernment of units of repeat and number structure?

The research question will be addressed through an analysis of a mathematics teaching activity that was video-recorded as part of a larger intervention study involving 11 Swedish preschool class teachers and their students. This initial analysis serves as the starting point for a more systematic examination of data (video recordings) from the project. The analysis, informed by variation theory of learning (Marton, 2015) and theories of mathematical structure (e.g., Venkat et al., 2019), directs attention to the critical aspects of repeating patterns that students need to discern in order to develop structural awareness.

Conceptual framework

Mathematical patterns in early education can be found in three categories: spatial structure patterns, repeating patterns, and growing patterns (Papic et al., 2011). This study focuses on repeating patterns, as they are fundamental for more advanced patterning and number knowledge. Repeating patterns (e.g., ABAB or ABCABC) consist of small subsets referred to as the units of repeat (e.g., ABC where the unit of repeat has the length of three), with a cyclic structure allowing prediction of unknown units (Papic et al., 2011). The complexity of a repeating pattern is related to the arrangement of the single units in the units of repeat. Patterns where the units of repeat have two single units, like AB, are seen as the simplest. As the number of single units increases (e.g., ABC or ABCD) or as individual single units are repeated (e.g., AAB or AABB), the pattern becomes more challenging (Lüken & Sauzet, 2021; Papic et al., 2011). Pattern structure requires generalizing relationships, as seen in repeating patterns like ABAB or growing patterns like 1, 4, 9, 16 (Mulligan et al., 2020).

Utilizing a structural approach in teaching aims to deepen students' understanding of both similarities and differences, as well as to enhance their ability to form units and simultaneously consider parts and wholes (Björklund & Pramling, 2014; Mulligan & Mitchelmore, 2009). Systematically arranging sets of items in examples, along with actions that highlight relationships and properties, helps learners perceive local relations, which is believed to foster numerical thinking (Venkat et al., 2019).

Research on patterning

Studies investigating children's patterning can be traced to the field of early numeracy and the focus on numerical competencies for success in the early years of school. A study by Rittle-Johnson et al. (2019) found that preschoolers' understanding of repeating patterns and spatial skills predicted both concurrent and future mathematics achievement (Zippert et al., 2020). With increasing evidence that patterning is a critical predictor of later mathematical performance, several studies have focused on repeating and growing patterns in preschool and early education. For example, research by Papic and colleagues (2011) found that preschoolers show an understanding of the unit of repeat and spatial structuring, retaining and expanding these skills to growing patterns one year later. Additionally, interventions for kindergarten and first-grade students showed impressive growth in patterning and spatial structuring skills including partitioning, similarity and congruence, unitizing and identifying properties of 2D and 3D shapes (Mulligan et al., 2020).

Björklund and Pramling (2014) investigated how six-year-olds discern patterns in concrete activities and their capacity to differentiate repeating units. In line with Papic et al. (2011), they highlight the need for children to be supported in the process of focusing on structural features to discern units of repeat, rather than just focusing on concrete features like color or size. In a related study Lüken and Kampmann (2018) found that patterning and structural abilities positively influenced arithmetic skills in grade 1. More recent studies show that preschoolers can understand and construct growing patterns (Wijns et al., 2021) and in a study with Norwegian first graders (six-year-olds), group differences were found in terms of decomposition and awareness of mathematical pattern and structure: only students with high number sense used relational strategies and those with low number sense used more variants of recursive patterning strategies (Junker et al., 2025).

These studies indicate that children's understanding of patterns often begins with recognizing simple, concrete properties of the objects forming a pattern, such as color or size. However, with guided support that emphasizes structural features, children become able to recognize the units of repeat and use pre-algebraic reasoning to describe patterns. This shift introduces learners to the structural underpinnings of mathematics, especially important for algebraic and multiplicative reasoning.

Method

The present study was conducted in Swedish preschool classes, where an intervention aimed at enhancing six-year-old students' understanding of number structure was implemented over a school year with 11 teachers and their students. The Awareness of Mathematical Pattern and Structure (AMPS) program developed by Mulligan et al. (2020) for the Australian school context, was adapted to fit the Swedish context and curriculum. Specifically, five pathways were selected based on their relevance to the Swedish educational context. The intervention was implemented as part of a larger research project, SATSA[1]. Teachers participating in the intervention were asked to video-record selected teaching activities during its implementation. In this paper, we analyze one mathematics teaching activity captured in a 17-minute-long video recording provided by one of the teachers. Twelve six-year-old students participated in this activity. The activity is from the first pathway in the intervention, conducted at the beginning of the intervention period. The teaching focuses on the concept of repeating patterns, exploring how patterns are composed by identical units of repeat, which can vary in structure across different patterns. This paper presents an initial analysis, serving as the starting point of a more systematic analysis of the video recordings collected from the participating teachers' classrooms.

Variation theory as a framework for analyzing mathematics teaching activities

In this study, we apply variation theory of learning (Marton, 2015) as a theoretical lens to analyze the learning opportunities offered in the mathematics teaching activity. Variation theory directs attention to how a phenomenon is experienced where different ways of experiencing one and same phenomenon is based on what aspects of that phenomenon are discerned. The surrounding world is assumed to be experienced primarily in a holistic sense and becomes more differentiated (detailed

[1] A research project funded by the Swedish Research Council (grant number 2020-03712)

and nuanced) with increasing experiences. Learning is then described as making distinctions that appear as changes in a person's way of experiencing, due to becoming aware of aspects not previously discerned.

Teaching, according to this framework (see Marton, 2015), should start from the aspects of a learning object (phenomenon) that the learner has not yet discerned. Drawing attention to aspects that were previously not discerned is possible through variation and generalization. Critical (new) aspects of the phenomenon are made possible to discern when contrasted against an invariant background. For example, a foundational aspect of repeating patterns is the units of repeat, identifiable by contrasting patterns with varying units of repeat, whereas the aspect "unit of repeat" will stand out and be discerned not as identical in color or number but in how repeated units constitute a similar kind of structure. Taking these principles as starting point, analyzing the video recording means that episodes where the teacher introduces an aspect through her interactions with artefacts are singled out. These episodes are further scrutinized regarding how the artefact is handled (e.g., whether cubes are combined or separated, how units of repeat are positioned, and which gestures are used to emphasize certain features). This process makes it possible to investigate both the necessary aspects for experiencing a phenomenon (like a pattern) in a certain way (as a structure constituting of units of repeat) and how these aspects can be made possible for young learners to discern.

Learning opportunities offered in a repeating pattern activity

The students and their teacher are seated together in a circle on the floor. The teacher introduces a 'train' made of six multilink cubes arranged in an ABC pattern (see Figure 1a). Building on their previous exploration of AB patterns, the teacher asks, "Does this train show a repeating pattern?". She places the train in front of her, repeats the question, and invites responses. The students offer mixed answers, and the teacher asks one student to respond.

Student1: Uh, almost because it needs to be orange-yellow-orange-yellow-orange-yellow.
Teacher: Yes, that's how it would be if it was an alternating pattern.

In this episode, the student expresses that a part of the pattern should be repeated, indicating that the student has discerned that repetition is a key characteristic of repeating patterns (a basic concept in patterning). However, by suggesting an AB pattern instead of identifying the ABC pattern, this also suggests that the student has not yet discerned that the size of the repeating unit can vary across different patterns, and that units of repeat do not always consist of two single units. The teacher then draws attention to their previous work with AB patterns, using this as a comparison to guide the student to discern another important concept: while the structure of repetition remains invariant, the length and complexity of the units of repeat can vary.

The teacher then asks another student for her thoughts.

Teacher: What do you think, Alice (Student2)? Is it a repeating pattern?

The student splits the train into two identical units of repeat and puts them on the floor (Figure 1b).

Student2: No. Yes look, it has two units.

The teacher rearranges the units of repeat and places them in two rows (Figure 1c).

When the teacher asks Alice (Student2) for her thoughts, she chooses to split the train into two identical units of repeat and places them on the floor. By doing so, she demonstrates an awareness that repeating patterns can be divided into smaller, identical units. This indicates that she has discerned the structure of the train as consisting of two units of repeat. When the teacher rearranges the units of repeat into two rows, it further enables the students to see that they are identical. The act of splitting and comparing the units of repeat in one consecutive row and in two separate rows reinforces the idea that the units of repeat are identical and constitute a larger whole.

Teacher: Look, they are exactly the same. See, the units are the same, and there are three cubes in each (simultaneously moves the units of repeat into one row again, as in Figure 1b). How many cubes are there in total?

When asking for the total number of cubes, the teacher shifts attention *from* the units of repeat *to* the whole. The students count, offering different answers. The teacher asks one student (Student3) to tell the total number of cubes. The student counts aloud, pointing to each cube from left to right.

Student3: One, two, three, four, five, six.
Teacher: Exactly. There are six cubes, just like this one, right? (brings out an AB train made of blue and green cubes that they had examined earlier)

Both the ABC train and the AB train are now in front of the students (Figure 1d).

Teacher: How many units of repeat are there in that one? (pointing at the ABC train).

A student (Student4) who raised her hand hesitates when given the opportunity to answer, and the teacher offers reassurance.

Teacher: In this one, there are three. (dis-assembles the AB train into three units of repeat).
Student4: Three, that one has two (pointing to the units in the ABC train).
Teacher: Yes, this one has only two.

In this episode, the whole is kept invariant (both trains consist of six cubes) and the teacher draws attention to how this whole can be seen as a structure of identical units of repeat. By contrasting trains with different units of repeat (two versus three single units, see Figure 1e), the teacher highlights an important concept, particularly for developing multiplicative reasoning. The simultaneous comparison of the two trains is crucial for making this concept discernable; the size of the repeating units directly affects the number of units of repeat in each train. Although both trains have an equal number of cubes, they differ in the number of repeating units. By asking “How many units of repeat are there in that one?” the teacher directs the students' attention to identify both similarities and differences between the two patterns. By splitting the AB train into three repeating units, the teacher makes the concept more tangible, helping the students to see the relation between the total number of cubes and the number of repeating units. This clarifies what is the same and what is different, helping the students to discern the structure of the patterns.

Another student (Student5) signals for attention, indicating that she wants to share something.

Student5: If you want it to be correct, if they are supposed to be the same, then you can do this. If they should be the same. You can rearrange everything so that it becomes like this (moves an AB unit on top of the ABC train) and the same (moves the other two AB unit and places it on top of the ABC train).
Teacher: Exactly. Three 2’s (pointing to the units of repeat in the AB train) are the same as two 3’s (moves the AB units and arranges the trains again in two separate rows).

Student5: Yes!

In this episode, the teacher guides the students to focus on the units of repeat and their role as parts of a larger whole, also using alignment and row and column structure (collinearity). The interaction begins with a student suggesting that the AB units can be rearranged to match the ABC train, which the teacher affirms. By pointing out that "three 2's are the same as two 3's", the teacher highlights the equivalence in the total number of cubes, even though the patterns differ in structure.

The students are next instructed to build their own identical ABC trains with two units of repeat, adding more units gradually as instructed. The teacher asks questions about the number of repeated units and the total number of cubes in the trains, eventually leading to four units and twelve cubes. The teacher arranges the units of repeat into four columns in front of the students (Figure 1f).

Teacher: You can count like this: 1, 2, **3**, 4, 5, **6**, 7, 8, **9**, 10, 11, **12** (counting all the cubes in the left column first: 1 (blue), 2 (yellow), 3 (red); then the next column, and so on). Or 3, 6, 9, 12 (pointing at the blue cube in each column).

The teacher's instruction to build ABC trains with gradually increasing numbers of units of repeat allow the students to explore the concept of repeating units and the relation to the whole.

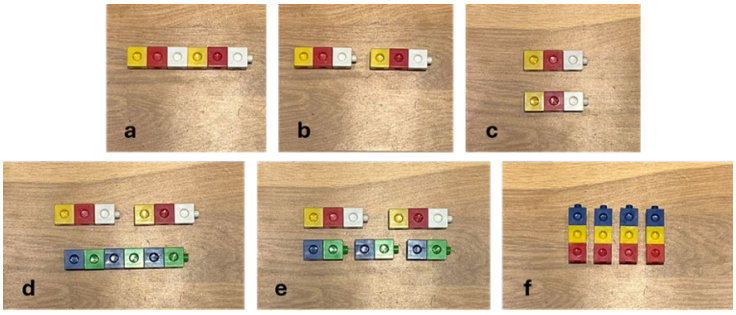

Figure 1 (a-f): Stepwise arrangement of multilink cubes used in the mathematics teaching activity

As the students complete this task, the teacher reinforces their understanding by arranging the repeating units into four columns, making it discernable that they are identical in both design and quantity. This spatial structure helps students see how each unit of repeat is part of a larger whole. During the counting exercise, the teacher first emphasizes the whole by counting all the cubes in sequence using rhythmic counting, and then highlights the units of repeat by skip-counting by 3's. This approach not only helps students recognize the repeating units but also illustrates how these units collectively form the whole and establish a multiplicative counting pattern.

Discussion

In this study, we aimed to explore aspects that students need to discern to enhance their understanding of repeating patterns as composed by units of repeat and to generalize number structure. Our analysis of a mathematics teaching activity in a Swedish preschool class revealed three critical aspects that need to be discerned. The first aspect, *recognizing the composition of units of repeat*, is essential for students to grasp the foundational concept of patterns. The analysis indicated that when the teacher emphasizes the composition of units of repeat (e.g., the cubes connected making up a train), and organizes them with alignment and spatial structure, it helps students understand how single units contribute to the formation of a pattern of composite units of repeat. This aligns with existing

literature highlighting the importance of identifying and distinguishing units within mathematical structures (Björklund & Pramling, 2014; Papic et al., 2011). The second aspect, *the repetition and variability in the size of the units of repeat*, was particularly crucial in this context. As illustrated in the student-teacher interactions, the teacher's guidance prompted students to consider not only the repetition of the units of repeat, but also the complexity of those repetitions. This complexity can significantly affect students' ability to recognize patterns and develop multiplicative reasoning skills, as noted by Rittle-Johnson et al. (2019) and Verdine et al. (2013). By contrasting different patterns, rather than teaching these in increasing order of difficulty and complexity (e.g., AB vs. ABC), the teacher made it possible for students to discern the structural differences in how patterns can be organized, thus enhancing their mathematical reasoning. The third aspect, *how identical units of repeat constitute a whole*, further reinforced students' comprehension of number structure. By asking students to compare the number of repeating units in two different patterns and quantify them, the teacher enabled them to discern the relationship between the units of repeat and the whole. This focus on comparing patterns in this way supports students structural awareness, supporting the development of a deeper understanding of number structure, an essential skill for early arithmetic.

The findings from this study highlight the importance of teachers' strong pedagogical content knowledge in teaching patterns and number, as this supports effective pedagogy and students' mathematical development. Teachers need both content knowledge and effective pedagogical strategies to help students explore these mathematical structures and also connect them to concepts like multiplication, division and fractions (Tsamir et al., 2020). The systematic use of concrete materials in structured ways and drawing attention to the units of repeat is essential in guiding students' development of generalization. This study demonstrates ways in which such systematic teaching can be conducted.

Becoming confident numeracy players through home play-based early learning activities

Mellony Graven[1],

[1]Rhodes University, Faculty of Education, South Africa, m.graven@ru.ac.za

This paper explores how participation in a Family Maths Storytime Programme (FMSP) provided opportunities for play-based home numeracy learning among South African, pre-Year1learners. Based on data from 20 (transcribed and coded) parent interviews, the paper focuses on comments about their children's confidence, which emerged as a theme in all interviews. Through focusing on a single purposefully selected parent interview the paper analyses multi-directional connections between the description of her child's emergent number knowledge, numeracy practices, and numeracy learning dispositions, stimulated by engagement in the FMSP. This analysis highlights how these connections generate confidence in the process of engaging in numeracy practices, and how this confidence simultaneously provides momentum for further numeracy engagement in the home.

Keywords: Family maths, early learning, play-based learning, transition to school.

Introduction and context

Educational inequality in South Africa is extreme. Spaull and Kotze (2015, p. 13) note that "only the top 16% of South African Grade 3 children are performing at an appropriate Grade 3 level" and the "learning gap between the poorest 60% of students and the wealthiest 20% of students is approximately three Grade-levels in Grade 3". Grade R (reception grade, ages 5 to 6 years) is a relatively recent introduction to the South African public formal schooling system (SA DBE, 2011) and is aimed at addressing performance gaps already evident in the early years of schooling. South Africa's participation in international comparative benchmark studies points to the differences in educational and linguistic resources available in learner homes as a key contributing factor to the extreme inequality in mathematical performance (Reddy et al., 2016).

The South African Numeracy Chair (SANC) began in 2011, with the mandate to research and intervene for change in primary mathematics education inequality. As the incumbent Chair, I worked with post-graduate researchers, teacher educators, schools, teachers, learners and communities to establish several projects that included, teacher professional development (PD), after school maths clubs, and family maths events. The Family Maths Storytime Programme (FMSP) was designed to provide home-based support for Grade R children in local communities that were historically marginalised by apartheid. The FMSP and linked research contributes to a gap in research and intervention work with early grade children in relation to use of story- and home-based resources that merge numeracy with early literacy practices.

A range of resources were developed and provided as a stimulus for numeracy (and linked literacy) learning. These included four number story books (with storyboard pages, finger puppets, flash cards of number words and numerals) and dice and cards. The storylines and pictures provided opportunities (first in the number range of 0-5 and then 0-10) for: counting, subitising, counting on, skip counting, establishing number facts, recognising and predicting patterns, number word

recognition and numeral recognition. Linked activities (e.g., using story-linked paper puppets to play number games and retell and enact stories) encouraged learner mathematical talk.

Three sessions were held (spaced at least a week apart) with parents of Grade R learners from two local schools. For succinctness, the term 'parent' includes caregivers who stood in for the role of parent. The language of instruction in both schools was English even though learners spoke mostly Afrikaans or isiXhosa at home. Resources were provided in English and the learners' home language. In each session, I demonstrated reading a number story with the children present, asking them questions along the way (for example, if two frogs jump over how many will be on each lily pad?). I then had a child pretend read and retell the story (using puppets and flashcards on a storyboard) and played number focused puppet, card and dice games—all the while asking a range of *learning focused* questions prompting learners to subitise, count, recognise numerals and number words, predict, follow a pattern, work out one/two more or less, and work out missing parts in part-part-whole games with puppets of story characters. For example, showing them 5 monkey puppets from one of the stories asking 'how many?' — then splitting the puppets between two hands and showing them the puppets in one open hand and asking 'how many are hiding in my closed hand?' (See Jorgensen & Graven, 2022 for an outline of the games).

Literature review and conceptual framing

The FMSP was informed by literature that highlights the role of families in children's mathematical and literacy learning trajectories (Huntsinger et al., 2016) and the importance of play based activities that integrate literacy and numeracy in early learning (De Holton et al., 2001; Purpuro & Napoli, 2015). It integrated numeracy and literacy learning through promoting play-based learning activities linked to number stories. A guiding assumption was that play, in the form of a) representational play (using numeral and word flashcards when retelling the story); b) manipulative play (e.g., using puppets to retell the story on a storyboard page) and; c) rule-bound play (e.g., playing puppet, dice and card games) would provide opportunities for number exploration and concept development and that age-appropriate story scenarios would motivate learning (De Holton et al., 2001).

The FMSP design was guided by socio-cultural theory, viewing learning as occurring within social contexts where language and more knowledgeable others (MKOs) play a critical role in mediating learning within a learner's zone of proximal development (ZPD) (Vygotsky, 1978). Drawing on earlier work (Abtahi et al., 2016) I see the ZPD as multidirectional whereby, within learning activities, the role of MKO can shift between children, adults and the artefacts used in activities. The FMSP prioritised encouraging mathematical talk through having learners pretend read, retell, and enact stories and encouraged parents to ask numeracy focused questions during activities to stimulate talk and mediate for progression. So, for example, when playing with two dice they might ask 'how many dots altogether?' and, if children persist with counting on by touching every dot, they can be encouraged to subitise the number on the dice with the most dots and count on from there.

Bourdieu's (1997) theory of cultural capital and his notion of habitus provided a way of understanding how the noted performance gaps emerge in the early years of schooling. For Bourdieu (1977, p.86), habitus is a "system of internalised structures, schemes of perception, conception, and action common to all members of the same group or class". An implicit sense of habitus begins for learners in the

context of the family. The home habitus becomes reconstituted when new practices emerge and are valued within the home system. The extent to which these new practices can operate as a form of capital outside the home depends on the field one operates in. The field in focus here is the reception year classroom. Cultural capital of wealthier families, with extensive educational resources in the home, translates more easily into capital within the schooling field while learners from families who have been historically marginalised from economic and educational opportunities may not have a feel for the game (Bourdieu, 1977) of schooling (Jorgensen, 2016). Entering the classroom, all children must learn the game of schooling to succeed, involving enacting certain numeracy and literacy practices (e.g., participating in the pedagogic ritual of 'Q&A'—asking and responding to *learning* focused questions.) Supporting learners to become fluent in play-based numeracy learning activities, along with the use of questioning to stimulate mathematical talk and reasoning, was thus considered a productive route to connecting home-based with school-based numeracy learning trajectories.

Methodology of the broader study

Following ethical approval for the study, post-programme interviews were conducted with all 20 participating parents, generating rich data about their experiences of the resources and activities and their observations of their children's learning. Data analysis of the transcribed interviews involved a grounded approach (Glaser & Strauss, 1967) using NVivo to generate coding for thematic narrative synthesis (Elliot-Mainwaring, 2021). I worked with a colleague (Robyn Jorgensen who had attended one of the FMSP sessions) to code the data, as she had some distance from it and was thus more able to generate codes and themes grounded in the transcribed utterances (see Graven & Jorgensen, 2024 for full data coding and general findings). Interviews began with an initial prompt asking parents to share their experience of the FMSP.

Data was coded at the level of whole response rather than at the level of a single idea. This allowed maintenance of the context of utterances and led to responses often having more than one code. Following Robyn's coding, I checked the data against the codes and through discussion a few additional codes were added to data chunks and some codes with highly similar data were merged. Acknowledging that the coding process can yield different results if coded by another coder or at a different time, the value of the coding is not in the specificity of coding (or frequencies for each code) but in the themes generated. The data pointed to ways in which the FMSP activities had influenced children's learning in relation to three main categories, namely, new knowledge, practices, and dispositions, with a fourth category of codes involving the nature of parent learning. The first three categories resonated with Bourdieu's (1977) constructs of capital, practice, and dispositions and these provided a conceptual lens for organising and analysing the full data set.

In this paper I focus on the only code that emerged across *all* twenty interviews, namely learner confidence (or self-confidence), which was placed in the category of new dispositions (see Graven & Jorgensen, 2024). Statements about children's self-assurance of their own knowledge or abilities in relation to engaging in mathematical activities (including reading number words, pretend reading or enacting number stories) were considered indicators of confidence. These indicators were interwoven in data chunks (or segments) across multiple codes and categories. In this paper I explore the question: *How did children's emerging confidence as expressed in parent interviews connect with the*

emergence of new numeracy knowledge, practices and dispositions? As it is beyond the scope of this paper to share coded excerpts from all twenty interviews, I have selected data from a single interview to illuminate and analyse the nature of the interconnectedness between confidence and new knowledge, practices, and dispositions. I have purposefully chosen an interview that has several anecdotes that similarly emerged across multiple interviews, including: playing 'teacher' when sharing activities with neighbours and friends; asking lots of numeracy learning questions; seeing (and engaging with) numbers in the world around them; initiating, leading and willingly engaging in numeracy games. Thus, while the utterances shared in this interview are specific to what Sadie (as parent) noted about Elsa's (her child's) engagement (both pseudonyms) with number ideas and FMSP resources in the home, each of the ideas discussed here recurred across multiple interviews.

Focusing on a single interview allows narrative flow and full data chunks to be shared to support the qualitative analysis of how Elsa's emerging confidence (as noted by Sadie) is interwoven and expressed in her emerging new forms of knowledge, practices and ways of engaging in learning activities. I began with the full interview, deleting non relevant parts. So, for example, I removed initial introductions. I then re-read the interview multiple times with the intention of finding quotes that specifically spoke to Elsa's increased confidence. I noticed, however, that while some quotes were more explicit than others in highlighting Elsa's confidence, the interview tended to shift seamlessly between Elsa's confident ways of *knowing*, *doing* and *engaging with others* around mathematical activities. I thus adopt a narrative style of sharing Sadie's story. What follows is my story of her story (after Sfard & Prusak, 2005). In telling the story, I weave together Sadie's anecdotes about Elsa with my analysis of the interplay between Elsa's self-confidence and her emerging ways of knowing, doing, and engaging with numeracy ideas. To the extent possible within space constraints, I include Sadie's full comments trimming only superfluous utterances. This allows the reader to judge whether my analysis resonates with their reading of the data.

Sadie's story of Elsa's numeracy engagement at home: Findings and discussion

Responding to the invitation to share what she had learned through participation in the FMSP, Sadie began by explaining how Elsa was engaging mathematically with the world around her and seeing the world increasingly through a mathematical lens:

> It kind of opened my brain. When I see my child, even on a Sunday when we go to church she counts the houses. She says, "There are two houses, there's No. 2, there's No. 18." She is getting it right when she sees numbers or words…. When she walks down the steps she jumps, and says, "Count with me, one, two, three. What comes after 20?" And I say "21". Then she counts up to 30. Now she knows 31, 32, …

Sadie noted Elsa's emerging number knowledge stating "she is getting it right" and "now she knows 31,32" while also pointing out that Elsa asks for assistance to extend her knowledge horizons beyond what she already knows (e.g., asking "what comes after 20?"). Sadie continues explaining how Elsa uses questioning to engage herself and others in mathematical activity and conversation.

> She asks lots of questions. She even asks my mother. She says, "Mummy please can you come and sit here, I want to ask you something. Tell me how many plates are in the cupboard, how many

> forks are there?" Then my mother (Elsa's grandmother) says, "Go and count my angel and then come and tell mommy." Then she takes everything out of the drawer, forks, knives and everything so that she can count them all. Then she splits them up. She puts the spoons, forks and the knives separately, then she counts, "10 plus 10 plus 10 Mummy. Give me the answer because I don't know."… Even with her father. "Daddy how many wheels on the car?"

In the second last sentence we see how Elsa asks questions beyond what she knows but are within her reach (or ZPD). Elsa is aware that she does not know how to add 10 and 10 and 10 but expresses an eagerness to learn it. Her questioning and interest thus extends beyond the number range that was in focus in the FMSP (0-10 in the stories and 0-12 for the games with two dice). Sadie then shares how Elsa similarly engages with her older and younger brothers. She shares Elsa's confident declarations about "knowing numbers" and that with this knowledge she can participate in her older brother's homework and help her younger brother to "also" become "clever" with maths.

> Now she wants to use the brother's books. He does his homework at the big table. Then she says "What are you doing? I know the numbers, I know."… She wants to do so much, and you can see she is enjoying it. She is experiencing more about numbers. She tells her [younger] brother she will help him with maths. She says, "Come and sit, you are also going to get clever."

In these anecdotes Sadie expresses how Elsa is confident about having the knowledge capital needed to engage with both brothers mathematically. When asked about the books and resources Sadie explained:

> [Before] she only read for about three minutes, then she was finished with the book. And now with these books you gave us, she knows exactly what is on the pages. She wants to talk about the books… The book my grandmother bought her as a present from the library, she would just look at. Then she would look through the pages, then put it down because she was tired, go and get her [FMSP] book and then say, "Come, mommy, come and sit here, I want to read to you."

Here, we see that Elsa is initiating reading and talking about the FMSP books that support her 'pretend reading'. Sadie contrasts Elsa's engagement with the FMSP books with a book from the library that had her only looking at the pages rather than engaging with the ideas and pretend reading. The pictures, numerals and words (including number words in large font) in the FMSP storybooks are designed to guide pretend reading and storytelling. Sadie continues sharing how Elsa enthusiastically engages with the FMSP dice and card games.

> Then we have to play 'Dingaan's Kraal' and she won't let me go. I have to stay and play with her… She used to throw one dice, but now she has seen me throw two dice, she also wants to play with two dice. And she says the numbers on the two dice… She knows the numbers. She knows that the five has got the two dots at the top, and two dots at the bottom, with one dot in the middle. I think she remembers… She knows the 6, then she counts, "7, 8, 9 and 10." When she gets to 10 she wants to count them on her fingers. And when it is more, I must add my fingers. Like the six and six. But now she wants to learn how to write the word twelve.

Again, we see how Elsa initiates playing mathematical games. Dingaan's Kraal is played as a matching numbers card game and as a 'bonds to 10' card game. Sadie once again explains how while

playing these games Elsa demonstrates and practices her number knowledge while simultaneously extending her learning horizon. Elsa's confidence in being able to subitise and count on, and recognise and write the number words 0-10, provides a basis for wanting to learn to recognise and write the number word twelve. (The FMSP flashcards of numerals and number words were designed to accompany the stories and so only went up to ten while the sum of two die extend to twelve).

Sadie then shares an anecdote about her and Elsa's storybook reading with imaginative role-play, using everyday objects to represent trees, umbrellas, and characters in the stories to enact unfolding number patterns. In the first two FMSP stories in the number range 0-5, five monkeys in a small tree and five children under a small umbrella move one by one to a bigger tree and umbrella respectively. In this imaginative and representational play, Elsa is seen to use comparative mathematical language to speak about what is happening while they are acting out the stories.

> I read to her then she mentions how she reads to me. "I am the mum, you are the child," then she reads to me. With the 'Monkey' book, she wants to sing it for me, "Five little monkeys." She says, "there were five monkeys in a big tree." Sometimes the spoons are the monkeys… And then we take the plastic cups, and they are the trees, and then she takes the spoons and says, "Five monkeys in this tree. And the monkey says, "Oh no this tree is too small," and she jumps the big tree with the spoon. And with the umbrella, she takes a baby blanket for an umbrella. Then I say to her, "Come let's play a game. We take two chairs and make a tent for the big umbrella, then I take the small blanket, and that is the small umbrella. And then we take all the spoons she played with, and they are the children. And I say I am going to pretend I am the child. Then she says, "The child must jump to the big umbrella," and I jump… Then I ask her, "How many more?" and she says, "There are four under this umbrella, and one under that umbrella. More under this one and less."

Elsa's confidence in knowing the unfolding patterns in the storylines enables enacting the stories without the book or the finger puppets. Sadie shares how Elsa has shifted from being relatively shy with children to being eager to read to her friends and teach them counting—again initiating the engagement by calling neighbours to come and play and leading ('teaching them') the activities:

> She did not want to play with the neighbours before, but now she wants to go out and play with the other children, but we don't want her to go because it is not safe in the street. So, when the children ask if she can play, we tell them they must play in the yard. She calls them to come and play…. But she wants to read the book about the monkeys to those children. They are all in Grade R. She says, "Come I am going to read to you. Don't you understand English? I can try and read in Afrikaans"… She never had friends calling, but now she is more interested in teaching them how to count… She was a shy girl but now she has more friends, talks and does stuff.

Here Elsa's confidence in her ability to read her FMSP storybooks and being able to engage in mathematical talk is said to have shifted her from having a shy disposition to one who is willing to lead others and initiate play and learning activities. This confidence is seemingly supported both by her awareness of her emerging numeracy and literacy knowledge, and her developing fluency in doing and talking mathematics. Elsa was given books and resources in both English (the language of instruction in the Grade R class) and Afrikaans (the language spoken at home) allowing her to offer to 'read' in Afrikaans. The excerpt points to the way in which Elsa's strengthened numeracy and

literacy capital, and her ability to engage in mathematical talk and play, generate confidence in her mathematical and reading skills to the point of being ready and willing to 'teach' others. It further highlights how her emergent confidence when enacting her knowledge in various practices simultaneously promotes increased engagement in play-based learning activities, which in turn likely leads to further confidence. This finding resonates with Murray and Harrison's (2011) finding that parents can identify their children's confidence and school readiness. They propose developing early years' home-based learning opportunities to develop resilience and confidence in children to strengthen school literacy and numeracy trajectories.

Conclusion

In the sharing and analysis of *Sadie's story* of Elsa's engagement with mathematical and reading practices at home, we hear of Elsa's emerging self-confidence. This confidence is visible to Sadie in Elsa's appreciation of her own numeracy knowledge (e.g., 'I know numbers') and capacity (and eagerness) to engage with others in mathematical activities and conversations (as evidenced by the many people that Elsa is said to initiate mathematical activities and conversations with.) Through analysis of Sadie's post-FMSP interview, we see multi-directional connections between Elsa's mathematical learning confidence, knowledge, practices and dispositions (ways of engaging).

The FMSP provided resources to develop learners' numeracy and literacy capital at home to strengthen their learning trajectories in their transition to schooling. A play-based approach, which integrated numeracy learning with reading and enacting simple number stories, and playing dice and card games, built a bridge between home play practices and school learning practices (e.g., engaging in Q&A—asking learning type questions to promote conversations that support and extend learning). Resonating with a socio-cultural perspective on learning, confidence emerges as part of the process of learning new knowledge, practices and dispositions and as a product of these processes. Beyond this, confidence, as simultaneously a product of learning and part of the learning process (see, Graven 2004 for a similar finding with in-service teacher learning), gives momentum to Elsa engaging in many more mathematical learning opportunities that transcend engagement with FMSP resources.

The paper highlights how provision of purpose designed numeracy resources and activities, in partnership with parents, can support home based numeracy learning opportunities that provide momentum for learning beyond the resources. As researchers and educators committed to equity in mathematics education, we must search for effective ways to challenge the findings captured in the title of Spaull and Kotze's (2015) article: *Starting behind and staying behind in South Africa: The case of insurmountable learning deficits in mathematics*. Interventions, such as the FMSP, can act for change, challenging the extreme performance gaps that indicate continued marginalisation of most South African learners from successful mathematics learning trajectories.

The development of mathematical understanding begins with the birth of a child throughout subsequent stages of learning. Children who experienced a mathematics learning disability at the end of preschool were more likely to continue experiencing this disability throughout primary and secondary school. The article describes and analyses theoretical materials and data about mathematics skills in preschool as an effective indicator of the potential development of mathematics learning difficulties. The research focus on the analysis of parents' and teachers' view of mathematics among 4-6 year old Latvian preschool children. Main findings reveal the relationship between parents' and teachers' evaluation of children' mathematics skills in preschool.

Keywords: Children, mathematics learning difficulties, parents, pre-school, teachers.

Introduction

The acquisition of mathematical knowledge is often challenging for individuals with intellectual disabilities (Chodura et al., 2015; Nuari et al., 2019; Scherer et al., 2017) and those with specific learning disabilities in mathematics (Dekker et al., 2016; Harvey & Miller, 2017; Martin et al., 2017). A specific disability in mathematics, which may be referred to as dyscalculia, is usually diagnosed in the later years of primary school. This approach fails to capitalise on an important period of early brain plasticity during which interventions would be most effective (Ashkenazi & Henik, 2010; Zamarian et al., 2009). The term 'mathematics difficulties' is used to describe both students with low mathematics achievement and students with a diagnosed mathematics disability. Specific learning disabilities are often diagnosed in the later primary grades (Geary et al., 2004; Berch & Mazzocco, 2007). Implementing early diagnosis and targeted remediation can significantly enhance a child's performance in mathematics, as well as prevent mathematics learning failure by targeting basic skills (Desoete et al., 2012; Nelson & Powell, 2018). It is of the utmost importance to identify the early indicators of potential mathematical difficulties to integrate them into appropriate intervention programmes. Consequently, the mathematical achievement of a child in preschool, as assessed by parents and teachers, could serve as an effective indicator of possible learning difficulties in mathematics for children with specific learning disabilities.

Mathematics learning difficulties

As learning disabilities in mathematics are associated with difficulties in understanding numbers and quantities, using number symbols and basic arithmetic operations, the symptoms of this disorder

appear in approximately 6% of children as early as the second year of primary education (Shalev, 2007; Jiménez-Fernández, 2016). In the early years of primary education, students with mathematics difficulties demonstrate lower achievement in counting tasks (Stock et al., 2010) as well as in the accuracy of calculations (Tolar et al., 2016). Furthermore, they experience difficulties in comparing quantities or representing them. Symbolically, they experience difficulties with text-based tasks (Driver & Powell, 2015; Nelson & Powell, 2018). Children with learning disabilities in mathematics typically exhibit greater difficulties in the following mathematical content areas: number sense, basic or fundamental arithmetic operations, and problem solving (Jiménez-Fernández, 2016).

Infants are instrumental in demonstrating an understanding of number that predicts their future mathematical performance in preschool (Starr et al., 2013). Furthermore, early developmental experiences with mathematics influence their preparedness for preschool and school (Nelson & Powell, 2018). Children who experience difficulties in mathematics tend to demonstrate inherent difficulties in a range of informal and formal mathematical abilities from an early age, even before they reach preschool. These difficulties encompass various aspects of numerical literacy, including reading and writing numbers, grasping fundamental counting principles, and learning basic arithmetic facts (Desoete et al., 2012; Geary et al., 2004; Mazzocco & Thompson, 2005). These difficulties in informal and formal mathematics learning place children at an initial disadvantage, as there is a strong correlation between early mathematical competence and the subsequent acquisition of mathematical skills and the rate of growth in mathematical achievement. Consequently, children with mathematics difficulties may experience a widening achievement gap between themselves and their peers, taking to the 'Matthew effects' observed in other domains (Namkung et al., 2019).

The aim of the study is to investigate parents' and teachers' view of mathematics achievement in two subgroups - above and below the 16th percentile level which was determined by the results of the BAASIK Mathematics performance subtest among 4-6 year old Latvian preschool children. The research questions were: RQ1: How do parents and teachers evaluate the mathematics skills of children with and without mathematical difficulties in pre-school (skills level was determined using the results of the e-BAASIK Mathematics performance subtest - above and below the 16th percentile)? RQ2: What is the relationship between parents' and teachers' evaluation of children' mathematics skills in preschool?

Methods

The study, part of the University of Latvia's project "Development of a Unified Set of Methodological Tools for Screening Children's Early Development" on early development screening, aimed to create the e-BAASIK toolkit for assessing developmental risks in children aged 1-6. It focused on 11 mental development domains according to the categories in the International Classification of Diseases, 11th edition (ICD-11). The e-BAASIK construct framework for the age group 3-6 years comprises 11 core scales: large and small motor skills, cognitive abilities, speech and language, adaptive behaviour, disruptive and dissociative behaviour, internalizing problems (anxiety, fear and depression), communication difficulties and autism, attention deficit hyperactivity disorder (ADHD), pre-reading skills, pre-writing skills and pre-primary mathematics skills (Raščevska et al., 2024a; Raščevska et al., 2024b). Data were collected between February 2022 and July 2023 from Latvian preschools in

all regions of Latvia, involving trained professionals and parental consent. The data employed in this study were derived from Math scales (initial mathematical skills) of the e-BAASIK Parent's Survey (PS), Preschool Teacher's Survey (TS) and Child's Ability and Skills test (CAST - a performance test) for the 4-6 age group, comprising the following skills: comprehension of the numerical values 1-5, 1-10; mathematically precise reasoning and fundamental arithmetic operations (see Table 1). Each item of PS and TS was evaluated with 1-4 points, and in the CAST with 0, 1, 2 points.

The sample consisted of children (50% girls, 50% boys) aged from 4 to 6, in age 4 and age 5 group n=280, in age 6 group n=253. For each child, the survey was completed by the parents (either mother or father) who had given their written consent to the study and survey was completed by concrete child's teacher who had participate in project. Descriptive statistics and Spearman's correlation coefficient (v.29, IBM SPSS Statistics) was used to analyse the relationship between the measurements of e-BAASIK Parent Survey basic scales and e-BAASIK Teacher Survey basic scales.

Results

The percentage of children aged 4-6 who achieved the highest rating in the mathematics skills subscale of the e-BAASIK Parent Survey and Teacher Survey is presented in the following table. The children have been grouped according to their risk status and performance on the e-BAASIK test (see Table 1).

A comparison of the maximum scores achieved by children on the mathematics skills items in the parent and teacher surveys, as presented in Table 1, reveals that children who are at risk of developing mathematical difficulties are significantly less likely to have fully mastered the relevant skill than children not at risk of developing mathematical difficulties. A comparison of the performance of children across all age groups (4, 5, and 6 years) in the two groups revealed that those in the NRG group consistently demonstrated superior mathematical abilities compared to their RG counterparts. As an illustration, in the recognition of printed numbers (question 3), 40.4% of the children in the NRG group achieved success, compared to only 17.9% in the RG group, as determined through parent evaluations. Similarly, in both the at-risk and non-at-risk groups, the majority of items were rated higher by parents than by teachers. Children in the at-risk group (aged 4-5 years) exhibited the greatest likelihood of scoring higher on question 1 (Can a child tell which is longer or shorter by comparing 2 pencils or other objects of different lengths?).

The data presented in Table 1 of the remaining articles demonstrate that children at risk exhibited the greatest difficulty in recognising printed digits, counting objects up to 10, understanding which number is larger and which is smaller, arranging a string of numbers in a logical numerical sequence, and finding a larger group of objects among numerically distinct groups of objects (questions 3-7). Conversely, six-year-olds at risk demonstrated the least proficiency in performing addition and subtraction of one and two digits, identifying the largest group of animals by number, and arranging numbers in ascending order (see Table 1). The discrepancy was particularly evident in tasks requiring numerical operations, such as addition (question 8) and subtraction (question 9).

Children in the NRG group demonstrated greater proficiency in complex mathematical tasks, particularly in addition and subtraction, at the age of six. In these operations, 74.8% of children in the

NRG group were able to achieve a correct answer, in contrast to only 40.0% of those in the RG group. This is despite these skills being explicitly outlined in the relevant curriculum. In the 4-year-old group, parents' ratings are generally higher than teachers' ratings on all mathematical skills items (see Table 1). In the sample of five- and six-year-olds, in both the at-risk and the norm groups, teachers were more likely than parents to give higher scores on some items, such as items 3, 6 and 8.

Table 1: Parent's and Teacher's view on children (age 4-6) math skills performance subtest results on e-BAASIK subscale

Questions	Group	Number of children in percentage who gave the highest rating					
		age 4		age 5		age 6	
		P***	T****	P	T	P	T
1. Can a child tell which is longer or shorter by comparing 2 pencils or other objects of different lengths?	RG*	55.4	52.8	75.0	62.7		
	NRG**	81.6	71.0	91.3	86.0		
2. Can the child count orally, calling the numbers in the correct order?	RG	50.0	28.3	85.4	72.5		
	NRG	81.6	61.9	95.2	91.9		
3. Does the child recognise the printed numbers 1 to 9?	RG	17.9	9.4	54.2	45.1		
	NRG	40.4	31.2	74.3	77.5		
4. Can a child determine the number of objects up to 10?	RG	33.9	13.2	73.5	56.9	74.5	75.5
	NRG	68.9	46.3	89.0	87.2	95.2	93.9
5. Does the child understand which number is bigger or smaller?	RG	10.7	1.9	32.7	25.5	59.6	57.1
	NRG	27.2	22.1	65.7	65.8	84.3	83.5
6. Can the child put 4-5 digits in the correct order if the digits are not given in order, e.g. 5, 7, 1, 4?	RG			22.9	20.0	34.0	44.9
	NRG			43.6	50.6	57.6	68.4
7. Can the child find the largest group of animals in the picture, e.g. with 3 cats, 5 dogs, 4 lions and 8 mice?	RG	22.6	13.2			53.3	47.8
	NRG	43.3	32.6			80.1	76.3
8. Can the child add 1 and 2 by performing an addition operation?	RG					40.0	43.5
	NRG					74.8	67.6
9. Does the child know how to subtract 1 and 2 when performing subtraction actions?	RG					33.3	30.4
	NRG					61.7	58.5
*RG - group with math difficulty risk (under 16th percentile according to BSPT results), in the sample of Parent's Survey age 4 and 5: n=56; age 6: n=46; in the sample of Teacher's Survey age 4 and 5: n=53; age 6: n=46; **NRG - group without risk (above 16th percentile according to BSPT results), in the sample of Parent's Survey age 4 and 5: n=224, age 6: n=207; in the sample of Teacher's Survey age 4 and 5: n=227, age 6: n=207; ***P- e-BAASIK Parent's Survey; **** T – e-BAASIK Teacher's Survey							

According to parents' ratings, children's mathematical skills improved with age in both the RG and NRG groups. For example, the skill to determine the number of objects up to 10 (question 4) increased

from 33.9% at age 4 to 74.5% at age 6 in the RG group and from 68.9% to 95.2% in the NRG group. The children's performance in mathematics, as assessed by teachers, also improved. For example, the skill to determine the number of objects up to 10 increased significantly from age 4 to 6, with NRG children improving from 46.3% to 93.9% and RG children improving from 13.2% to 75.5%. Despite the fact that teachers' and parents' initial assessments of children's mathematical skills at age 4 differ, teachers' and parents' assessments of 6-year-olds' mathematical skills are, in most cases, the same.

In the majority of tasks, the skills of the children were rated by teachers to be slightly lower than those rated by parents. To illustrate, in task to compare length of objects (question 1), 81.6% of four-year-old NRG children were rated positively by parents and 71.0% by teachers. Similarly, in oral counting task (question 2) 81.6% of four-year-old NRG children were rated positively by parents and 61.9% by teachers. This trend may be indicative of discrepancies in the observational environment, assessment criteria, or the interpretation of mathematical education content.

The tasks that required more complex thinking, such as putting numbers in order (question 6) or performing operations such as addition and subtraction (questions 8 and 9), were more challenging for RG children. There were significant differences between them and their NRG peers in their ability to complete these tasks. The ratings provided by both parents and teachers indicated that RG children exhibited marked difficulties in performing mathematical skills when compared to their NRG counterparts. For instance, the mean scores for skills requiring the ordering of four to five digits (question 6) were significantly lower for RG children, with parents scoring 22.9, while those for NRG children's parents were 43.6. Similarly, the mean scores for RG children's teachers were 20.0, while those for NRG children's teachers were 50.6.

A t-test of paired samples was conducted to ascertain whether there were statistically significant differences between parents' and teachers' mean scores for the scale items in the at-risk and non-at-risk groups. The results indicated that for 4- and 5-year-olds in the at-risk group, there were statistically significant differences between parents' and teachers' scores for scale item 4 only, while the scores for the other scale items were more or less the same. In contrast, the norm group of four-year-olds exhibited statistically significant discrepancies between parents' and teachers' ratings across the majority of scale, with the exception of scale item 5. In the samples of five- and six-year-olds, both in the at-risk and non-at-risk groups, there were minimal differences between teacher and parent ratings, with the exception of scale items 4 and 6.

A statistically significant difference was identified between the parent and teacher risk groups on the mathematics skills summary scale in the 4- and 5-year samples. In the 4-year sample, the mean score for parents was 16.44 (SD=4.4), while the mean score for teachers was 15.02 (SD=3.95, $t=2.40$, $p< .02$). In the 5-year sample, the mean score for parents was 20.00 (SD=3.87), while the mean score for teachers was 18.63 (SD=4.60, $t=2.32$, $p< .02$). The only statistically significant differences between parents' and teachers' scores in the norm group were observed in the 4-year-old samples (M=20.35, SD=3.31; M=19.15, SD=3.64, $t=5.26$, $p< .001$), and not in the samples of 5- and 6-year-olds. No statistically significant differences were identified between the parent- and teacher-rated summative scales of mathematics skills in the sample of six-year-olds, irrespective of whether the children were considered to be at risk or not. In conclusion, the analysis of both the Mathematics Skills Scales items

and the summative scales demonstrates that the differences between parent and teacher ratings are more pronounced at age 4 and in the non-risk groups but decrease or even disappear at ages 5 and 6 in both the risk and non-risk groups.

It is important to note that while the correlations between parents' and teachers' ratings of mathematics skills are statistically significant, they are also moderately close (4 years r= 0.55, 5 years r=0.43, 6 years 0.49, p< .001). This indicates that there are considerable individual variations in parents' and teachers' ratings.

Conclusion

A generalisation of the responses of parents and teachers to questions concerning children's mathematical abilities reveals a similarity in their assessments of performance in situations where no interpretations are necessary or possible. This is exemplified by tasks such as performing simple arithmetic operations, including adding and subtracting one or two digits. Such child performance is readily discernible and assessable for both parents and teachers, as it is mathematically correct, with no inherent interpretations or variations in solution.

In most cases, teachers' assessments diverge slightly from those of parents of children at risk. Teachers tend to rate the mathematical abilities of children at risk slightly lower than parents, whereas parents tend to award higher ratings to the mathematical abilities of children at risk. However, at the age of six, parents' ratings tend to align more closely with those of teachers in relation to children at risk and their mathematical skills. Nevertheless, it can be argued that both teachers and parents are able to assess children's performance accurately when they have a learning disability in mathematics and when they do not have a learning disability in mathematics. The similarities in the assessments are particularly evident in the case of six-year-olds, while the similarities and correspondences are somewhat less pronounced in the case of four-year-olds with and without a learning disability.

The stark contrast between at-risk and non-at-risk groups highlights the crucial significance of prompt recognition and prompt intervention, particularly with respect to fundamental capabilities such as numeracy and calculation. Although both parents and teachers are aware of typical developmental trajectories, teachers tend to be more cautious in identifying potential areas of concern. These findings reinforce the value of a collaborative approach involving teachers and families to support children's early mathematical development. However, discrepancies between parent and teacher ratings could be attributed to differences in observational conditions or interpretation of skills. These data underscore the divergent views of parents and teachers and the necessity for a standardised system to harmonise assessments, thereby promoting consistency and accuracy in identifying developmental needs.

How teaching actions with artefacts enable children's understanding of the part-whole relationships in an arithmetic task

Helen Lindgren[1], Camilla Björklund[1], and Clara Vidal Carulla[1]

[1]University of Gothenburg, Faculty of Education, Gothenburg, Sweden; helen.lindgren@gu.se

This paper originates from a study conducted by preschool teachers and researchers that jointly designed, implemented and assessed activities that focus on numbers and basic arithmetic skills with children 3-5 years old during one school year. The research question is "How can teaching actions and artefacts enable children to discern the part-whole relationship of numbers in a partitioning task?". The data analysed in this paper consist of 33 video recordings of an implemented teaching activity focusing on partitioning and how numbers constitute part-whole relationships. These have been analysed through variation theory of learning. The results support earlier findings that whether the artefact is used in a structured or unstructured way has an impact on the possibility to discern number relations, which can be enhanced by verbal communications, gestures and finger representations.

Keywords: Artefacts, teaching actions, numbers, preschool, variation theory.

Introduction

As part of formal education, preschools in Sweden should provide children with opportunities to develop "an ability to use mathematics to investigate, reflect on and try out different solutions to problems raised by themselves and others" (Swedish National Agency for Education, 2019, p. 15). However, some preschool teachers have been shown a lack of knowledge about mathematics and how to teach mathematics in preschool (Skolinspektionen, 2017). An example of a study addressing this issue is Palmér and Björklund (2023), who argue for the need of applied research in which preschool teachers and researchers work together in order to develop teaching content, activities and artefacts for teaching mathematics.

The study presented in this paper is part of a larger project, which aims to develop teaching about number and basic arithmetic in Swedish preschool for 3–5-year-olds. During one school year (September – May) six preschool teachers and three researchers worked in close collaboration to try out and develop teaching methods and artefacts that specifically enable children's discernment of number structure and the part-whole relationships within and between numbers. Artefacts were introduced and trialled to explore their potential to be used for the project's aims. In this paper, the specific aim is to gain in-depth knowledge of *what teaching practices provide opportunities for basic understanding of numbers and arithmetic skills in preschool*. To fulfil this aim, we seek to answer the research question: *How can teaching actions and artefacts enable children to discern the part-whole relationships of numbers in a partitioning task?*. To guide this exploration, empirically and analytically, we use Variation theory of learning (Marton, 2015).

Theoretical framework

The current project has its foundation in research that takes starting point in learning as change in ways of experiencing phenomena in the surrounding world, which means that numbers are by children experienced in qualitatively different ways that inform how a child handles numbers for example in

a problem-solving situation (see Neuman, 1987; Björklund et al., 2022). Cardinality, ordinality and numbers' part-whole relationships are considered essential aspects to discern, in order to interpret and make use of numbers. Numbers' meaning cannot, however, be "seen" due to their abstract nature (Duval, 2006). Representations are thereby also an essential aspect of numbers, because cardinality, ordinality and the part-whole relationships that are "invisible" features of numbers can be seen through the use of verbal and written symbols, real life situations and concrete materials such as pictures, or manipulatives (Lesh, 1981).

Symbols, materials or manipulatives are artefacts often used in mathematics education to represent some mathematical meaning and thereby aid children's learning. Artefacts can indeed be constructed in ways that more easily bring forth number structure, such as an abacus. Artefacts are however not self-instructive; they afford meaning through the child's use of the artefact and new meanings can be mediated through a teacher's way of using a specific artefact. Thus, it is significant to direct attention to *how* artefacts are used. In preschool settings, unstructured material is often used, such as pebbles or blocks, which can become structuring artefacts depending on how the artefacts are used (Venkat & Askew, 2018).

Variation theory of learning (Marton, 2015) offers a framework for describing and explaining the learning of new concepts in terms of discerned aspects. In line with this theoretical framework, the learner is assumed to have a holistic view of his or her surrounding world. However, this view constitutes of discerned aspects where some are foregrounded in the learner's awareness, and some are left in the background (Gibson & Gibson, 1955). To develop one's way of seeing the surrounding world (learning to see the world in a new more advanced way), such aspects that have not earlier been foregrounded need to be discerned. This is done through the contrasts appearing when an aspect is varied against an invariant background. This is a basic principle of learning in this framework, which is applicable in teaching when the teacher uses artefacts in a systematic way that brings fore necessary aspects through contrast and generalization. Central is also that these contrasts are made simultaneously, to allow the learner to discern significant similarities and differences (Marton, 2015).

Background in research

Children usually learn the counting rhyme in early years (see e.g., Mix 2002; Ahlberg, 1997). But learning to use numbers in arithmetic problem solving is a rather complex skill of making use of counting principles (Gelman & Gallistel, 1978), integrating seriation and classification (Piaget, 1965) and as empirical research has shown also in recent studies, recognizing the mathematical relationships between numbers reflected for example in basic number combinations (Venkat et al., 2019). This means that children experience 5 as a "structural phenomenon", constituting the parts 3 and 2 but also 4 and 1. When this structural aspect of number is not discerned by children, they may rely on single-unit-counting strategies, which are known to be error-prone and not developable strategies in a longer perspective (see Neuman, 1987; Ellemor-Collins & Wright, 2009).

Structural approaches to teaching and learning numbers have been used in mathematics education both with older school children (Schmittau, 2004; Venenciano et al., 2021; Polotskaia & Savard, 2018; Venkat et al., 2021) and younger preschool children (Björklund et al., 2021). These studies provide evidence of success in focusing on number in ways that emphasize part-whole relationships. Intervention studies with younger children have also shown that it is possible to teach numbers' part-

whole relations that support children's advancement of number knowledge and arithmetic skills (Cheng, 2012), even before formal mathematics education takes place (Palmér & Björklund, 2023; Kullberg et al., 2020) through systematically implemented activities. The challenge in teaching in the early years is however to find out and adapt the teaching acts (and artefacts) to the child's way of experiencing the mathematical phenomenon at hand (see Ekdahl, 2019), hence more research is needed regarding design and use of artefacts for number learning in preschool.

Method

The project is a collaboration between researchers and preschool teachers in one Swedish municipality. Teaching activities that have been tried successfully in previous projects are proposed to the participating preschool teachers, with whom the methods and goals are discussed, and the activities are carried out and video recorded for assessment and further development at recurring meetings. The research project thus involves development work in the preschools' practice with a focus on developing teaching. The purpose of the research project is to understand and explain what it is in teaching with a structural approach that contributes to knowledge development in children. The purpose of the development project is to develop and test teaching about numbers, based on an approach that favors children's sense of numbers and basic arithmetic skills in preschool. Ethical permission has been obtained to use video recordings involving children. The video recordings are used both for professional development and for research purposes.

During one school year from September to May, six preschool teachers from four different preschools and their teams participated in the project. Participating children were aged 3-5 years, 110 children in total, but the participation frequency varied during the year. The children were participating in the teaching activities conducted by their teacher. Video recordings of these teaching situations were collected by the teachers themselves.

The analysis for this paper is based on 33 video recordings (5 h and 47 min and 31 s) of teachers teaching one arithmetic task in one of the teaching activities with similar artefacts. The teachers enact the activity with single children or in pairs. These 33 video recordings have first been examined in terms of the teachers' actions with artefacts and how the teaching supports or does not support the child's ability to discern the part-whole relationship in the task. In this paper, three video recordings have been selected for a more thorough analysis of the teachers' use of artefacts to facilitate children's learning. In these recordings, the teachers enact the same activity that includes a partitioning task.

> Instructions for executing the task: Distributing dog biscuits
>
> Tell the children that you have a problem that you need help to solve. You are going to visit a family that has two puppies (show a picture or figures with two dogs). Then tell them that you have bought a package of dog biscuits to give to the puppies. There are 6 dog biscuits in the package (12 if the children find it too easy). Propose the following task: If you are going to distribute the 6 biscuits fairly between the puppies, how many biscuits will each puppy get?
>
> The children are expected to use different strategies to complete the task and distribute the biscuits between the two dogs. The important thing is to stop and examine how the children arrived at their solution and examine the partitioning, i.e. that it is fair (equal number of biscuits for each dog), that all biscuits have been distributed (none were left over), and if the biscuits are differently partitioned, they are still equally many altogether.

Each preschool teacher printed her own pictures of similar dogs and similar dog biscuits as artefacts to use in the teaching activity.

Three different ways of handling the artefact in the teaching were observed. Three video recordings were selected for more in-depth analysis, which are representative for the whole empirical data. These were then analyzed using variation theory principles that emphasize what aspects are foregrounded by the concepts of contrast and generalization.

In the analysis of the video recordings, the teachers' different ways of acting with the artefact bring for the parts and/or the whole to be discerned by the children. These are further interpreted as promoting or limiting children's opportunities to learn about numbers. Here, both how the artefact is structured in the situation and actions that direct attention to essential aspects are important keys to answering the research question. Since a particular interest is directed towards the potential of artefacts to facilitate learning, attention was directed towards how actions to structure the artefact affect what the child can experience and thus what learning opportunities are offered. Thus, in the analysis we look for how numbers' part-whole relationships are made possible to discern for the children through the ways in which the artefact is handled by the teacher. Three themes emerged from this analysis: *structuring with verbal communication*, *structuring with verbal communication and gestures* and *structuring with verbal communication, gestures and finger representations*.

Results

The presented episodes belong to a sequence in the activity of distributing dog biscuits when the preschool teachers introduce the activity to the children. Three different ways of using artefacts, supported by teaching actions that enable number structure to be discerned, emerge in the analysis (see Table 1).

In the introduction of the activity (see Table 1), the task is introduced in teaching activity A by counting the dog biscuits one by one and placing them in a pile. The artefact (dog biscuits) put in a pile then becomes an unstructured artefact. This way of handling the artefact does not make it possible to distinguish the number of biscuits to be distributed. A relationship between parts and whole is not possible to discern. In teaching activity B, the preschool teacher introduces the task by structuring the artefact (the dog biscuits) in two rows. This enables the children to discern that the number of biscuits can be grouped as parts of the larger whole. The preschool teacher further points out the two parts by keeping the groups separate and making a circling gesture over each row. Then, to emphasize that they are to be seen as one whole, they sweep their hand over both parts while simultaneously saying "twelve". In teaching activity C, the preschool teacher points out the two parts and at the same time accentuates the number of the parts by putting six fingers in front of each part with dog biscuits while saying how many there are.

Analysis of the teaching actions and use of artefacts

The artefact used in the analysed teaching activity is unstructured and not self-instructive; it is the actions of the preschool teacher with the artefact that determine whether the artefact becomes structured or unstructured. In the above-described introduction to the partitioning activity, the preschool teachers have used the artefact in three different ways: *structuring with verbal communication*, *structuring with verbal communication and gestures* and *structuring with verbal communication*, *gestures and finger representations*. In the following, these are described in more detail and the learning opportunities they entail are discussed.

Table 1: The preschool teachers' teaching actions when introducing the activity

¤ = dogs, I = biscuits, PT = preschool teacher

Teaching activity A Two dogs and 12 biscuits	**Teaching activity B** Two dogs and 12 biscuits	**Teaching activity C** Two dogs and 12 biscuits
PT puts two dogs on the table in front of the children without saying how many dogs there are. ¤ ¤ PT holds the twelve biscuits in her hand and places one at a time in a pile counting from one to twelve out loud. PT says "Here you get the packet (biscuit). Now you have to distribute them equally, so that they each get the same number of them". I ¤ ¤	PT puts two dogs next to each other on the table in front of the children and says "two". ¤ ¤ PT puts one biscuit at a time above the two dogs. First, six biscuits in one row, then six biscuits in a second row. I I I I I I I I I I I I ¤ ¤ PT asks the children to count the biscuits. The children count the first row and answer "six". PT points to the first biscuit on the first row and confirms that there are six of them. PT points to the first biscuit of the second row and asks the children how many there are. The children count the second row of biscuits. PT points to the first and second row and says, "there were six plus six, how much is that?" One of the children replies "twelve". PT confirms that there are twelve biscuits and swipes her hand above the two rows.	The biscuits are in one row split in two groups. I I I I I I I I I I I I ¤ ¤ PT shows the five fingers on her right hand and only the thumb on her left hand. PT shows the six fingers on the first dog and says, "this dog has six biscuits", then moves her six fingers to the other dog and says, "the other dog has six biscuits". PT swipes her hand above the two dogs with the biscuits and asks, "how many are there altogether?". One of the children replies "seven". PT asks the child to count again. The child counts twelve biscuits and says "twelve". PT repeats "twelve".

When *structuring with verbal communication*, the preschool teacher uses only verbal communication to direct attention to numerical features of the task. For example, by asking the children questions "how many" or by telling them how to handle the biscuits.

The preschool teacher's questions can make the children change the direction of their attention to essential features of the task, but there is limited support for discerning parts and whole or any relationship between them unless the child has already discerned it. By only talking about number of biscuits, the artefact is not structured to visualize such relationships either. Dog biscuits in a pile is an unstructured example and does not provide support for children to discern parts and the whole. This way of handling the artefact and the number relations only supported verbally is shown in teaching activity A.

When *structuring with verbal communication and gestures,* the preschool teacher uses the artefact in ways that point out the parts and the whole by using hands and fingers in interaction with the artefact

and at the same time verbalizes the part-whole relationship. Here, the children are partly supported in their discerning number relations because the artefact is structured in equal straight rows, which enables the children to discern the parts (number of biscuits in each group). The teacher's pointing and circling gestures also direct attention to the parts' relation to the whole. In teaching activity B, the preschool teacher makes visible that there are six in each part and twelve dog biscuits together (verbally communicated) to be distributed. The gestures add a significant component to the verbalized introduction, since it directs attention to what groups that are labeled with a counting word; the part(s) or the whole.

When *structuring with verbal communication, gestures and finger representations*, the preschool teacher, as exemplified in teaching activity C, interacts with the artefact by first arranging the biscuits in groups within a row and simultaneously pointing out and verbalising the parts and the whole, also using the fingers as representations. This addition of the finger pattern enables the children to discern the number structure of equally sized parts that (in combination with the verbal conclusion of the total number of biscuits) constitute the whole, that is, twelve dog biscuits together to be distributed as six in each part. Thus, the relationship between parts and whole is made visible.

Discussion

The activity observed in this study includes dogs and biscuits that are used as artefacts for teaching about number structure. In this paper, we set out to analyse in depth how different ways of handling the artefact offer preschool children opportunities to learn about numbers. To aid our analysis we used variation theory of learning (Marton, 2015). The analysis supports earlier findings (see e.g., Venkat & Askew, 2018) that whether the artefact is used in a structured or unstructured way has an impact on whether it is possible to discern number relations. However, it seems that even if structuring the artefact is significant for enabling children to pay attention to numbers in the task, this can be enhanced by verbal communication, gestures and finger representations. The results also show that an artefact that is unstructured from the beginning can become structured if the preschool teachers' actions together with the artefact are structured so that the mathematical content becomes visible to the child.

The preschool teacher uses representations such as gestures, finger patterns and verbal communication as a way to structure the artefact. If the preschool teacher structures the artefact into parts and at the same time points out the part and whole relationship both verbally and with gestures, several aspects are made visible at the same time and the child is given the opportunity to discern the part-whole relationship and additionally, how many there are in each part (see also Ekdahl, 2019). The finger pattern becomes a semi-abstract representation that clarifies the number for the child and supports the comparison between the number of different groups, that is, connecting the different modes of representation (Lesh, 1981).

Earlier research has shown that systematically implemented activities and teaching focusing on number in a way that emphasises part-whole relationships support children's advancement of number knowledge and arithmetic skills (Palmér & Björklund, 2023; Kullberg et al., 2021; Cheng, 2012). This paper is a first attempt to investigate in depth how this can be accomplished in a preschool activity and how artefacts and actions in teaching with preschool children can support or not support children's progress in numeracy and arithmetic skills.

Teachers' descriptions of mathematics education in preschool in relation to play-responsive teaching

Maria Lundvin[1], Hanna Palmér[2] and Camilla Björklund[3]

[1]Linnaeus University, Sweden; maria.lundvin@lnu.se

[2]Linnaeus University, Sweden

[3]University of Gothenburg, Sweden

This paper addresses the ongoing discussion about what mathematics teaching at preschool level means, and how it ought to be conducted, utilising the perspective of Swedish preschool teachers. The aim is to elaborate on how teachers talk about play, and mathematics teaching, and how this may be understood in the context of play-responsive teaching theory. An analysis of focus group interviews shows that the teachers view play as something self-evident and unquestioned, yet difficult to define. When the teachers talk about mathematics teaching, they distance themselves from how mathematics teaching is performed in school. They also emphasise that teaching requires play, and that learning mathematics often equates to children performing activities that, from the perspective of the teachers, involve mathematics. Thus, how teachers talk about play and teaching may therefore contain opportunities and challenges when seeking to implement play-responsive teaching.

Keywords: Preschool, teaching, mathematics, play-responsive teaching, teachers' descriptions.

Introduction

While researchers agree on the importance of children learning mathematics early, there are diverse views on how young children should learn mathematics, and what teaching mathematics in early education should involve. This issue becomes even more complex if the question of whether mathematics teaching is to be integrated with or separated from play is brought into consideration (Palmér & Björklund, 2016; Björklund et al., 2018). The Swedish National Agency for Education (2018) emphasises that play is fundamental in preschool and that mathematics teaching should be provided. How this teaching should be implemented is the subject of a frequent and ongoing debate (Jonsson et al., 2017; The Swedish Schools Inspectorate, 2016; Vallberg Roth, 2020). According to the Swedish Education Act (2010:800), teaching is processes guided by preschool teachers, aiming for children's development and learning. However, an inspection by the Swedish Schools Inspectorate (2016) showed that many preschools are failing to meet these objectives. These shortcomings are described as a direct result of teachers' uncertainty about what teaching entails and how it should be conducted. However, it has been shown that this can be countered if preschool teachers are made aware of their role in encounters with children (The Swedish Schools Inspectorate, 2016).

Play as a foundation for education means that playfulness should be preserved, while teachers at the same time direct children's attention to specific knowledge content. This is also emphasised as the purpose of play-responsive teaching (PRT) (Pramling et al., 2019). To date, PRT has been studied sparingly in mathematics education. To counteract this, the aim of this study is to elaborate on preschool teachers' talk about play and mathematics teaching: What characterises teachers' talk about

play and mathematics teaching in preschool? Further, we discuss how teachers talk about play and teaching related to PRT.

Mathematics education in preschool

The position of this study is at the intersection of mathematics education and early childhood education, with PRT as a central feature.

Play and mathematics teaching

Although there are different perspectives on how play is to be understood and used as a facilitator for learning, play is most often highly valued in early childhood practices. Sutton-Smith (1997) emphasises that there is a large variety of actions, objects, and forms that are characterised as play, while there are also differences in perspectives on the function of play. Whereas some emphasise that children develop cognitive skills through play, others emphasise play as being a product of children's own amusement, representing the exercising of free choice, power, and identity.

Regardless of view on play, play is a multifaceted phenomenon of which imagination and hypothetical thinking are significant features. These attributes are perhaps best characterised by "as if" and "what if" imagining, which is also recognised in mathematical exploration. For instance, Ginsburg (2006) argues that children commonly use intuitive mathematical knowledge embedded in play activities that provide a strong foundation for cognitive development. According to Vygotsky (2004), play is a creative process in which children may recreate their experiences only limited by their earlier experiences. Following this line of reasoning, it is necessary to provide children with a wider range of experiences as a means for their sense-making. Knowledge development can thus be seen as being guided (for example, in play) by others' experiences, in turn allowing children to "borrow" others' experiences to extend the richness of their own experiences. Play may thereby be seen as offering children relevance and meaning, within which mathematical objects can be integrated (van Oers, 2013a, 2013b). In addition, Brandt (2013) emphasises the importance of teachers as teachers' actions affect the educational potential in preschool activities regardless of the activities involving play or not.

In the last decade, the concept of teaching has been added to the Swedish preschool curriculum. The history of the concept of teaching is thus very brief in the Swedish preschool setting, as compared to other school levels (Swedish National Agency for Education, 2018). How the concept of teaching should be understood in relation to preschool is therefore not obvious (Björklund & Palmér, 2019). In a previous study of Swedish preschool teachers, it was shown that according to the participating teachers, mathematics teaching takes place in activities initiated by the children, rather than by the teachers. Teaching, starting from a specific mathematical concepts or principles was very rare. Furthermore, the material was considered to be an essential part, both as a starting point for teaching and for children's own initiatives. There was, however, an absence of intentional problematisation of the mathematical relationships offered by the teacher. The study also showed that mathematics teaching in the informal situations provided at preschools, confirms rather than challenges children's knowledge (Björklund & Barendregt, 2016). Other studies have shown resistance among Swedish preschool teachers to the use of the term teaching (Jonsson et al., 2017; Vallberg Roth, 2020). Teachers perceive teaching as something that requires more than, or differs from, ordinary preschool

activities. However, there is a wide variation in preschool teachers' opinions on teaching. While some express that teaching does not belong in preschool, others express that teaching is an obvious component. In general, both opinions are practice-based with weak theoretical connections (Vallberg Roth, 2020).

Play-responsive teaching

PRT (Pramling et al., 2019) is a theory and a proposal for teaching in preschool where play and teaching are united in a coherent process. In PRT, play is seen as an activity where children's initiatives, interests and actions are at the centre. Teaching is in PRT based on and adapted to children's play, contrary than using play solely as a tool to achieve predetermined teaching goals. Teachers' participation in play is therefore a prerequisite in PRT. The playfulness can be preserved while specific knowledge content is being attended to. PRT is based on double responsiveness which implies that teachers are sensitive to children's reactions and adapt their actions accordingly. The intention of the theory is not for teachers to consistently participate in children's play or to constantly teach. Rather, the intention is to encourage teachers to sometimes participate in children's play with the aim of teaching (Pramling & Wallerstedt, 2019). The theory characterizes play by the participants' shifting between fantasy and reality. The concept of "as if" refers to a fictional world, i.e. that in which play activity is pretend, and invented based on fantasy. "As is" by contrast, refers to the existing world, i.e. the elements active in play that are considered conventional knowledge, or how something actually is. Play is not considered to be in contradiction to the goal-oriented aspect of preschool; play can be both planned, and have goals (Pramling et al., 2019). Teaching is defined as an activity that is created jointly by the participants, one that assumes an exchange with responsiveness between the participants (Pramling et al., 2019). A prerequisite for teaching is that there is a direction in the interaction, with an aim of making someone aware of, or able to do something they did not know, or were not able to do before. This requires the participants to coordinate their actions, to establish a common shared attention, intersubjectivity (Pramling & Wallerstedt, 2019).

Method

This study is part of a larger research project aimed at implementing play-responsive mathematics teaching in preschools. The empirical material for this study was focus group interviews (Halkier, 2010) conducted with five groups of three to four participants (in total 17 participants). For the purpose of this study, the term *teacher* comprises both preschool teachers (11) and childminders (6). In Sweden, preschool teachers have at least a bachelor level university degree while childminders hold an upper secondary degree. Even though preschool teachers are responsible for the preschool education, it is jointly conducted (Swedish National Agency for Education, 2018) why both professions are included in this study. Each focus group included preschool teachers and childminders well-known to each other. One strength with focus group interviews is its possibility of capturing dynamics between participants, which can provide a deeper understanding of jointly constructed meanings and perceptions instead of individual opinions (Halkier, 2010). Therefore, the analyses focused on the conversations, not individual opinions. Ethical guidelines from the Swedish Research Council (2017) were followed which implies that all teachers were given information about the study and provided their written consent.

The interviews focused on play and mathematics teaching using a semi-structured approach, which implies that questions were predetermined but handled flexibly based on each interview situation. The teachers had no known experience or knowledge about the theory PRT. The interview questions were therefore based on core ideas in PRT, for example play, learning and teaching, but without specifically mentioning the theory. The interviews were audio recorded and were between 37 and 58 minutes in length.

Transcripts of the interviews were thematically analysed meaning that the characteristics of teachers' talk was systematically identified and organised, thereby offering insights into patterns of meaning, that is, themes, across the data set. By focusing on patterns of meaning, it is possible to see and make sense of collective or shared meanings. In line with Braun and Clarke (2012), the analysis was conducted through phases. In the first phase, a general repeated reading of the transcripts was performed to obtain an overall meaning. Content unrelated to play or mathematics teaching was removed. Next, a systematic analysis was conducted through coding implying labelling unique features of the data that were potentially relevant to the research question. A theme was generated when codes shared certain unifying features, thereby reflecting a coherent and meaningful pattern in the data. Here, it became clear how some themes related to play, while others referred to teaching. The themes were then processed, focusing on the uniqueness and essence of each theme. This analysis led to the identification of seven themes that constituted the essence of play and teaching for the participating teachers. Examples of the teachers' descriptions are provided in the results section.

Results

The thematic analysis yielded four themes on play and three themes on mathematics teaching. At first, the themes are presented individually with examples followed by an overall summary of the teachers' talk about play and, respectively, the teachers' talk about mathematics teaching. In the subsequent discussion, these themes are related to PRT.

The teachers' talk about play

In the interviews, the teachers were asked about play; what play is, what play is not, and what the role of play is in a preschool setting. In the teachers' talk about play, four themes became visible: non-questioned play, the joyfulness of play, play belonging to the children, and the hardness of definition.

Non-questioned play

When teachers talk about play, play stands out as being self-evident and unquestioned. For example, one teacher expressed that "play is the most important thing we have during the day". Without further prompting, play is described as having a fundamental role in preschool, according to the teachers.

The joyfulness of play

Teachers' talks also emphasised the joyfulness of play. For the teachers, play is something that is always happy and fun. One teacher expressed this concept by stating, "play must be fun, otherwise it is not play". According to the teachers, joyfulness is a key criterion for determining whether a situation constitutes play or not.

Play belongs to the children

The teachers discussed children as being the ones who rule the play. For example, one teacher stated, "play is controlled by the children, it is free and without demands". According to the teachers, play is inexplicit, without clear frames, and is something that belongs to the children. The teachers talk about play as being something voluntary and spontaneous based on children's initiative, as the above excerpt shows.

The hardness of definition

Although the three themes mentioned above could themselves be seen as the teachers' definition of play, the teachers had trouble trying to directly describe what play is and is not. The statements given are very brief and blunt, for example "play is play" and "That was a very difficult question". The teachers expressed a sense of frustration at not being able to describe what they emphasised as the most important thing in preschool. This was noticeable when they gave examples of non-play situations and changed their minds while talking. For instance, "Clothing is not play, but, when I think, it can actually turn into play".

Summary: The teachers' talk about play

The themes about play highlights some tensions. At the same time as play is seen as a self-evident and central part of preschool, there is an uncertainty about how play can be defined. Further, there is an uncertainty regarding the role of teachers in play, as freedom, joy, spontaneity and children's initiative are focused on in relation to play. A view of play as self-evident may reflect a resistance to ongoing changes in Swedish preschools that may be perceived as a threat to the emphasis on play in preschool. The difficulty in defining play indicates its complex and multifaceted nature and may reveal that play is largely experienced rather than verbally defined.

The teachers' talk about mathematics teaching

The interviews also dealt with questions about what teaching was and how it was conducted in preschool. In the teachers' talk, three themes became visible: play makes mathematics teaching fun, doing – with or without the teacher, and distancing from school.

Play makes mathematics teaching fun

In teachers' talks on mathematics teaching, play is a recurring element. According to the teachers, mathematics teaching in preschools requires play. The teachers talked about how play makes mathematics teaching exciting, fun, and interesting for the children, and makes the children want to engage in what teachers have planned. The teachers observed, "with play, you get the kids' attention much easier". For example, one teacher expressed "Play makes teaching mathematics fun and interesting, and then the children want to participate".

Doing – with or without the teacher

In the teachers' talk about mathematics teaching, the doing of the children was emphasised. The teachers' overall talk and the examples provided of teaching mathematics show that children should be allowed to actively participate in the mathematics teaching. Examples of children's doing, or active participation, in mathematics teaching include when children work with clay, climb, paint, use digital

tools, and build. One teacher explained: “Today a child made different balls of clay, then we started talking about bigger and smaller”. Another example of doing being expressed as central in mathematics teaching, also relating to size, was, “We have painted on large and small papers”. According to the teachers, it is important for children to be engaged in activities characterized as “doing”, with room for variation in whether and how the teachers interact, as shown in these examples above.

Distancing from school

When teachers talk about teaching, they often compare teaching in preschool to teaching in school by emphasising the differences. In their talk, they distance themselves from teaching in school, but without explicitly expressing how they perceive teaching in school as being performed. One teacher expressed “In school, there is compulsion in teaching, something every child has to do. At the preschool, we have more freedom and more fun”. Another teacher said, “The school divides play and teaching; in preschool, they go into one another”. As these examples show, according to the teachers interviewed, play, freedom, and fun are key factors that differentiate school and preschool mathematics teaching.

Summary: The teachers’ talk about mathematics teaching

The three themes about mathematics teaching highlight different aspects of preschool education. Play is expressed as important in making mathematics teaching fun, exciting and interesting, and thus helps to get children’s attention and engagement. The importance of children’s active participation, them doing things is emphasised. The teachers describe how the children's involvement in practical activities is central to their learning. This suggests an educational philosophy valuing learning through actions and exploration rather than passive reception of information. The teachers distance the preschool education from the formalized teaching methods in school. In preschool, according to the teachers, play and teaching are integrated in a way that creates a more flexible and joyful learning environment than in school. This distancing from the school can be seen as an effort to preserve the uniqueness of preschool education where play is an important component.

Discussion

The question elaborated upon above pertains to how the interviewed teachers talk about and view play and teaching. In this section, these observations will be discussed in relation to PRT. In PRT, teachers participate in children's play with the aim of teaching. PRT is possible in most situations in preschool, as all situations can become both play and a potential teaching situation (Pramling & Wallerstedt, 2019). Even though play-responsive theory does not provide a fixed definition of what play is, certain characteristics of play are emphasised, for example, *as if* and *as is*. Play is not defined in the teachers’ talks either, and the characteristics of play emphasised by the teachers are not the same as in PRT. For the teachers, the joyfulness of play stands out as a key observation, together with the fact of play belonging to the children. A similar discrepancy was found in connection to teaching. In PRT, teaching is defined as an activity that is jointly created by the participants, assuming an exchange with responsiveness between the parties involved. A prerequisite for teaching is that there is a direction to the interaction with the aim of making someone aware of, or able to do something they did not know, or were not able to do before (Pramling et al., 2019). The teachers interviewed did

not define preschool teaching, but instead talked about what teaching is not, that is, teaching in school. The teachers also talked about how play makes mathematics teaching exciting, fun, and interesting for the children. The role of play is thus very different in PRT compared to how the teachers talk about play and teaching. At the same time, teachers talk about play and teaching going into one another, which corresponds well with PRT. In the teachers' view, teaching does not seem to have the same value as play. Summarising the results shows that if PRT is to be implemented with these teachers in their mathematics teaching practice, an important starting point is to discuss definitions and relations between play and teaching.

Abstract

In recent years, numerous scientific studies have highlighted the educational benefits of programable toys suitable for kindergarten children. To evaluate the effects of a robotics program on routes and map-reading skills, this study conducted a comparative study involving an experimental group and a control group. A pre- and a posttest were applied to assess those skills, and statistical analysis, including Mann-Whitney U and Wilcoxon signed-rank tests, compared the performances of the two groups. The results indicate a positive effect of the robotics program, leading to the conclusion that robot programming activities can be used in early childhood to develop children's routes and map-reading skills through highly motivating activities and stimulating cognitive and social skills.

Keywords: Robotics, programming, routes, map-reading, early childhood education.

Introduction

The curriculum guidelines for early childhood education in Portugal highlight spatial thinking skills as key competencies for this stage (Silva et al., 2016). However, existing curricula often do not prioritize spatial skills as a curriculum objective, and there is a deficiency in learning activities that foster those abilities for young children (Bruce et al., 2015), especially regarding routes and maps.

Route knowledge refers to recognising your location, navigating through a town, or following a path from one point to another, which implies recognizing landmarks along a route, understanding the sequence of landmarks and turns, and forming a mental map that captures spatial relations between routes and landmarks (Farran, 2012). Routes involve both static and dynamic information, including the order of landmarks, decision points, and associations between landmarks and directional changes (Nys et al., 2015). Alsina (2022) argues that this content is complex as it requires identifying basic spatial notions and relations and developing a mental schema of space and geometric transformations inherent to position changes, such as rotations, reflections, or translations.

Spelke et al. (2011) define maps as two-dimensional and movable pictures representing a three-dimensional and stable environment surrounding the navigator. They argue that an effective use of a map requires either aligning its orientation with the environment or comparing its geometric properties, ignoring differences in scale and orientation. At early stages, map reading poses a challenge as children often struggle with orienting themselves in real space and understanding maps' symbolic and simplified language (Gonzato et al., 2011).

Research shows that robot programming for young children (as young as three years old) offers educational benefits, such as increased motivation, active learning, and early coding skills, as well as

tangible, hands-on experiences that foster cognitive and social skills and promote logical and mathematical thinking (Nogueira et al., 2021). Regarding spatial skills, studies show that robot programming has the potential to enhance the acquisition of basic spatial concepts (Bizarro et al., 2018), to develop spatial awareness and perspective-taking (Shumway et al., 2021), as well as spatial perception, mental rotation, and visual memory (Brainin et al., 2022). In the study of Palmér (2017), kindergarten children showed spatial thinking skills development after a four-month robotics program by mentally comparing paper and grid maps, interpreting symbols, envisioning actions, and conceptualizing relationships between maps and symbols.

Overall, there is a lack of studies focusing on the impact of robotics activities on routes and map-reading skills. Robot programming requires children to mentally anticipate and plan robot movements, which involves understanding spatial relations and navigating environments – skills shared with route planning and map reading. Additionally, it involves cognitive processes such as algorithm design, decomposition, generalization, abstraction, and evaluation (Csizmadia et al., 2015) as well as debugging processes which can enhance cognitive functions like planning, cognitive inhibition, and working memory (Di Lieto et al., 2017), essential for planning and describing routes.

This study's main hypothesis is that robot programming has the potential to enhance the development of routes and map-reading skills. Two main research questions were defined to verify that hypothesis: (1) Does participation in a robotics program influence children's ability to plan and describe a route? (2) What's the impact of a robotics program on children's map-reading skills?

Methods

A quasi-experimental study was carried out to achieve the defined objective, with a standard pretest-intervention-posttest assessment for the experimental group (EG) and the control group (CG). The intervention consisted of a robotics program developed over twelve weekly sessions lasting 45 to 60 minutes, conducted during kindergarten hours. During this period, the children in the CG carried out the activities planned by the responsible educators without any intervention from the research team. They had no interaction with robots in the school context. The pre- and posttest aimed to analyse children's route-planning and map-reading skills and were administered approximately 14 weeks apart. A total of 58 four- to six-year-old kindergarten children from five class groups of three different schools from the same public school cluster in northern Portugal participated in the study. The EG comprised 36 children (15 girls, 42%; 21 boys, 58%) from three class groups. The CG included 22 children (12 girls, 55%; 10 boys, 45%) from two class groups.

The robotics program was implemented over 12 weeks, consisting of a weekly session lasting 45 to 60 minutes during school hours. The sessions incorporated moments of large group, paired, and individual activities, combining structured guidance with opportunities for free exploration. Additionally, children were invited to create a graphical record of each session. The program was designed with a spiral structure and a gradually increasing complexity to adapt to diverse learning rates. It began with simple problem-solving tasks using a Bee-Bot robot, such as navigating paths with minimal direction changes on a grid mat. Then, additional direction changes, unmarked paths, obstacles, and maps were introduced. Using command cards representing a symbolic programming language enriched the children's problem-solving experiences. Some sessions included unplugged

programming activities, in which the children took on the role of the robot and were programmed by each other. In the program's final activity, each group of children told a story using robots.

For the purpose of this study, the following data collection instruments were used: an assessment tool specifically designed for this investigation, serving as both a pretest and posttest and including tasks related to routes and maps (cf. Figure 1), field notes, photographs and video recordings to document children's performance on the tasks. In Task 1, children were asked to conceive, describe, and represent a route to the cheese, avoiding the lava. They should 1A) explain the path they would follow and walk, 1B) represent that path graphically, and 1C) explain the drawn path. In Task 2, the children were given a map of the classroom, which they had to read to locate themselves and find a hidden treasure. Some aids were defined to help children complete the tasks, if necessary. For example, in Task 2, the researcher may need to help the child locate some objects in the room on the map and orient it correctly before asking the child to find their location on the map and locate the treasure.

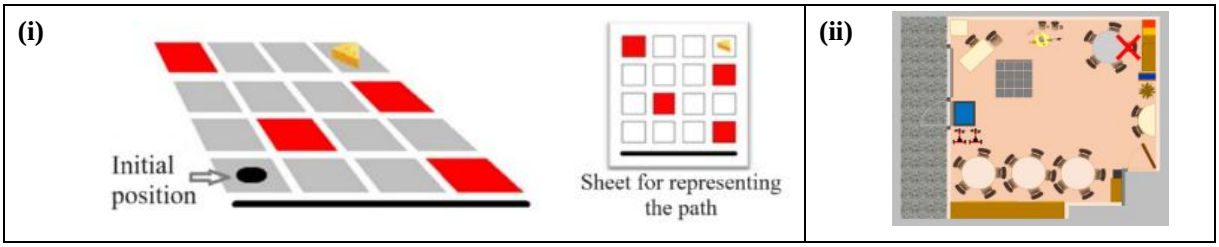

Figure 1: (i) Scheme of the Task 1; (ii) Scheme of the Task 2 of the pre- and posttest

These tasks are part of a broader instrument consisting of seven tasks designed to analyse various aspects of spatial thinking, validated by a panel of experts (Nogueira et al., 2023) and through an application in a pilot sample (Nogueira et al., 2024)[1]. Children's performance on each task was assessed using a Likert scale from 0 to 5. A single researcher conducted all stages of the assessment, took notes during the tasks, photographed key moments of the children's performance, and later analysed the videos along with the other records to assign a score to children's performance in each task. Statistical Package for Social Sciences, version 28.0, was used for statistical analysis. As all the variables displayed non-normal distributions, and given the small size of the sample, non-parametric tests were used: Mann-Whitney U test was applied to both the pretest and posttest scores to determine if there were statistically significant differences between the EG and the CG in each phase. Additionally, the Wilcoxon signed-rank test was used to compare each group's pretest and posttest scores to assess improvements over time. For each analysis, the significance level was set at $p < 0.05$. To assess the effect size for each one of the mentioned tests, we employed $r = Z/\sqrt{N}$, where Z represents the Z-score obtained from Mann-Whitney U and Wilcoxon signed-rank tests, and N represents the total number of observations (N=36+22=58 for Mann-Whitney U tests; N=2x36=72 or N=2x22=44 for Wilcoxon signed-rank tests) (Cohen, 1988; Pallant, 2007).

Results

In this section, we describe the results obtained for each of the EG and CG tasks in the pre- and posttest. The three tasks about routes (1A, 1B, and 1C) were analysed separately.

[1] Article submitted for the publication AIEM – Avances en Investigación en Educación Matemática, in July/2023 and accepted in July/2024. Not yet published.

As illustrated in Figure 2, for Task 1A, the means obtained by the EG in the pretest and posttest were 1.6 and 2.7, respectively. For the CG, the means were 1.1 in the pretest and 1.3 in the posttest, which seems to indicate a bigger improvement in the EG.

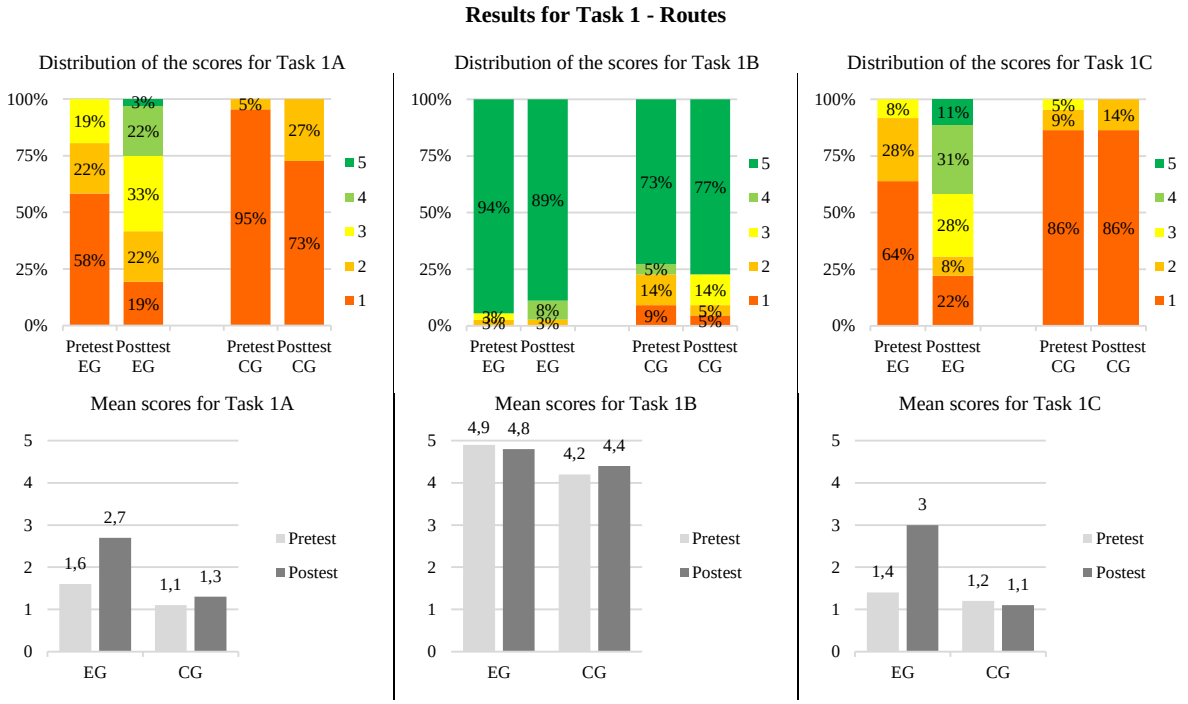

Figure 2: Results for the routes Task (1A, 1B, 1C) from the EG and CG in the pretest and posttest

In the pretest comparison between EG and CG, the results indicate a significant difference between the groups, with a medium effect size (cf. Table 3). In the posttest comparison, the difference was even more pronounced, suggesting the existence of a significant difference between the groups with a large effect size. Comparing the pretest and posttest scores within each group, the EG showed a significant improvement with a large effect size. The CG also showed a significant improvement with a medium effect size. These results demonstrate that both groups significantly improved from pretest to posttest, with the EG showing a larger effect size than the CG.

For Task 1B, both groups showed high scores in both tests (cf. Figure 2). As presented in Table 3, for the pretest comparison between EG and CG, the results indicate a significant difference between the groups, with a medium effect size. In the posttest comparison, the results showed no significant difference between the EG and CG. Comparing the pretest and posttest scores within each group, the EG obtained lower scores in the posttest, although the results indicate no significant change. The CG showed some improvement but no significant change. These findings suggest a significant difference between EG and CG in the pretest but not in the posttest. Furthermore, neither group showed significant improvement from the pretest to the posttest.

For Task 1C, the mean scores obtained by the EG in the pretest and posttest were 1.4 and 3.0, respectively. For the CG, the means were 1.2 in the pretest and 1.1 in the posttest (cf. Figure 2). As shown in Table 3, in the pretest comparison between EG and CG, the results indicate no significant

difference between the groups. In the posttest comparison, the results were extraordinarily different, showing a significant difference between EG and CG with a very large effect size. Comparing the pretest and posttest scores within each group, the EG showed a significant improvement with a large effect size. In contrast, the CG's results indicate no significant change.

Table 1: Statistical tests applied to the results for Task 1 - Routes (1A, 1B and 1C)

			Mann-Whitney U test									Wilcoxon signed-rank tests for each group		
			Pretest					Posttest						
Variable		Group N	Mean	SD	Z	p-value	r	Mean	SD	Z	p-value	r	Z	p-value	r
Task 1 - Routes	A	EG 36	1.6	0.80	-3.075	0.002*	-0.404	2.7	1.12	-4.597	0.000*	-0.604	4.370	0.000*	0.515
		CG 22	1.1	0.21				1.3	0.46				2.236	0.025*	0.337
	B	EG 36	4.9	0.59	-2.367	0.018*	-0.311	4.8	0.56	-1.336	0.182	-0.175	-0.213	0.832	-0.025
		CG 22	4.2	1.47				4.4	1.18				0.779	0.436	0.117
	C	EG 36	1.4	0.65	-1.783	0.075	-0.234	3.0	1.33	-4.963	0.000*	-0.652	4.615	0.000*	0.544
		CG 22	1.2	0.50				1.1	0.35				-0.333	0.739	-0.05

* $p \leq 0.05$

Concerning Task 2 related to map-reading skills, as indicated in Figure 3, the mean scores obtained by the EG in the pretest and posttest were 2.7 and 3.6, respectively. For the CG, the mean was 3.1 in the pretest and 3.5 in the posttest.

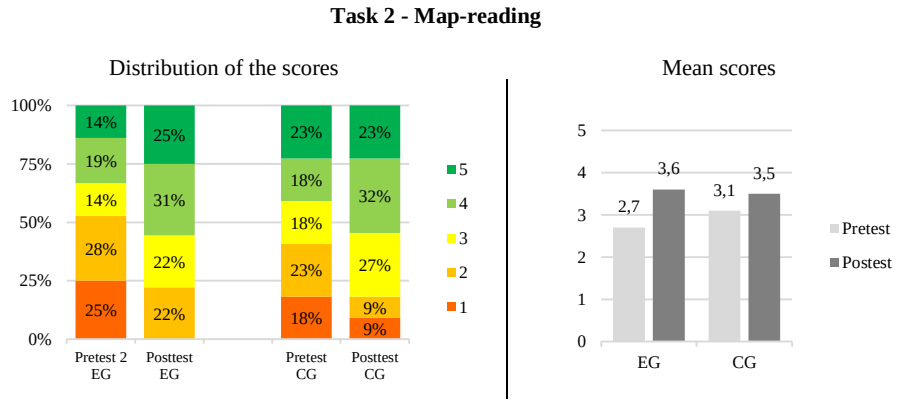

Figure 3: Results for the map-reading task from the EG and CG in the pretest and posttest

Both groups improved their results, but the improvement seems to have been more pronounced in the EG. The results of the statistical tests shown in Table 4 suggest no significant difference between the EG and the CG in the pretest and posttest comparisons. However, comparing the pretest and posttest scores within each group, the EG and the CG showed some improvement. For the EG, results indicate

a medium to large effect size, demonstrating significant improvement from pretest to posttest. As for the CG, results indicated no significant improvement from pretest to posttest.

Table 2: Statistical tests applied to the results for Task 2 - Map-reading

			Mann-Whitney U test									Wilcoxon signed-rank tests for each group		
			Pretest					Posttest						
Variable	Group	N	Mean	SD	Z	p-value	r	Mean	SD	Z	p-value	r	Z	p-value	r

	CG	22	3.1	1.46				3.5	1.22				1.589	0.112	0.240

* $p \leq 0.05$

Discussion and Conclusions

Regarding the first research question – Does participation in a robotics program influence children's ability to plan and describe a route? – each of the three tasks was analysed separately. The oral description of a mentally visualized route (Task 1A) or one represented graphically (Task 1C) is a skill shown to be the most challenging for children, and it is also the one where the robotics program seems to have had the most significant impact. In the pretest, no child from either group scored higher than three points, and all children required assistance to complete the tasks. They struggled to verbally and sequentially elaborate on and explain the planned route. This difficulty is understandable, as Alsina (2022) argues that such tasks require mastery of various spatial thinking elements, particularly geometric transformations, and a higher degree of linguistic competence. Additionally, they involve decomposition and sequencing processes inherent to CT (Csizmadia et al., 2015), which are central in robot programming. Also, as argued by Di Lieto et al. (2017), programming robot actions involves mentally anticipating each step, choosing the right command, and continuously updating the program to achieve the goal, which is a process that enhances planning, inhibition, and working memory. This could explain the significant improvement with a large effect size observed in the EG posttest, while the CG generally maintained pretest performance levels. As for the graphic representation of the route observed in Task 1B, results suggest that it was not very challenging for children, with a high percentage completing it without difficulty (cf. Figure 2). Thus, the high pretest performance by both groups (98% of the EG and 73% of the CG scored five points) may have limited the margin for improvement in the posttest.

Considering the second research question – What's the impact of a robotics program on children's map-reading skills? – the results for Task 2 indicate no significant differences between the EG and CG in either the pretest or posttest and an improvement in both groups' performance in the posttest. However, the tests show that the improvement observed in the EG was considerably more substantial than in the CG, suggesting a positive impact of the robotic activities on the development of map-reading skills. Although the robotics program may have positively affected children's map-reading skills, it seems reasonable to conclude that this effect was not very pronounced. Reading and

interpreting a map of a real space is a complex task that requires mastering specific aspects, such as understanding that a map is a top-down view of the space (different from the perspective of someone moving within it), the need to orient the map, and also recognizing reference points. Consequently, as Gonzato et al. (2011) argue, map-reading is a complex challenge for children, who often struggle with spatial orientation and maps' simplified, symbolic language. Therefore, we believe that developing this skill requires activities more suited to its specific nature.

One limitation of this study is the absence of a follow-up to assess the longer-term effects of the robotics program. Implementing such was not viable, as the posttest was conducted at the end of the academic year. Also, being a study developed within the scope of a doctoral thesis, it faced some human resources constraints. The entire development of the robotics program, as well as the administration of the pretests and posttests, was carried out by a single researcher. While this ensured consistency and uniformity in the procedures, it also posed obstacles to data collection. Specifically, it led to the use of a small convenience sample (n=58), which limits the generalizability of the findings and prevented the examination of gender and age-level differences, for example.

Robots stand out as a particularly interesting option among the various technological resources that can be used for educational purposes in early childhood education. In addition to strongly motivating and engaging children, robots promote active and hands-on learning based on problem-solving, which can be leveraged to develop a wide range of skills, from cognitive to social and psychological. This study advances our understanding of the possibilities for exploring robotics to enhance logical-mathematical reasoning, demonstrating that these activities can substantially enhance specific spatial thinking skills, such as routes and map-reading. Programming activities, which require children to anticipate and plan robot movements mentally, have shown to be particularly relevant in developing the ability to plan and describe routes. Thus, this study's results indicate that robotics is a promising option for creating learning environments that engage children and provide rich, problem-solving experiences that support the development of essential daily skills.

Mathematical argumentation in preschool – an exploratory study

Mona Nosrati[1], Beate Nergård[1] and Kjersti Wæge[1]

[1]Norwegian Centre for Mathematics Education, NTNU, Trondheim, Norway; monanosr@ntnu.no

This paper presents results from the first stage of a study on mathematical argumentation among Norwegian preschool children aged 2-5. The aim of the study was to gain insight into situations in which mathematical argumentation might naturally occur among young children, and to better understand what factors may aid or hinder the development of an argument. In observing the youngest children, the question of "which situations can really be classified as mathematical argumentation?" was recurrent. Here two episodes from children's free play are presented, and a discussion of methodological challenges in the process of analysis - with a particular focus on identifying whether 'claims', 'data' and 'warrants' are consistently mathematically anchored.

Keywords: Mathematical argumentation, preschool, free play

Mathematical argumentation

There is a growing body of research on preschool children's mathematical reasoning, justification and argumentation (e.g. Nergård, 2023; Perry & Docket, 2008; Sumpter & Hedefalk, 2015), and researchers have recently turned their attention to preschool as an environment where children develop argumentative skills (e.g. Johansson et al., 2014; Sumpter & Hedefalk, 2018). Some studies have focused on the conversational moves that teachers use to support children`s mathematical argumentation (Björklund et al., 2018), others have explored the preschool children`s use of concrete objects, gestures and verbal language in mathematical explanations (e.g. Johansson et al., 2014; Nergård, 2023; Sumpter & Hedefalk, 2015). Sumpter & Hedefalk (2015) explored children`s use of mathematics in their arguments, and in the context of their finding, they indicate that more research is needed on how we facilitate children`s mathematical argumentation and reasoning. However, in order to facilitate and contribute to mathematical argumentation, mathematical arguments need to be identified.

Identifying mathematical argumentation among younger children can be challenging for several reasons. Young children often lack the formal language and terminology typically associated with mathematical reasoning, and their ideas may be expressed in informal, intuitive ways, making it difficult to discern whether they are engaging in genuine mathematical thinking. The playful, imaginative and frequently shifting nature of early learning environments further complicates the task. The challenge lies in recognizing the underlying mathematical thinking within the informal and sometimes fragmented ways in which young children express their ideas in multimodal ways.

In defining what constitutes a mathematical argument, the literature presents various perspectives that are often superimposed on Toulmin's model for analysing general argumentation (1958). According to Mueller et al. (2012), a mathematical argument is characterized by the intent to convince others of the truth of mathematical ideas. Lithner (2008) offers a more structured framework, introducing the concept of *anchoring* arguments in the relevant mathematical properties of the objects, transformations, and concepts involved. Lithner defines *objects* as fundamental entities, or the

"things" involved in the process, *transformations* as the operations applied to these objects, and *concepts* as the key mathematical ideas emerging from their interaction. Building on Lithner's framework, Sumpter (2016) argues that the presence of these objects, transformations, and concepts allows for the analysis of the *warrant* and *backing* of an argument from the perspective of its mathematical content.

Similarly, Nordin and Boistrup (2018) emphasize the importance of anchoring arguments in these mathematical components when determining whether they are mathematical in nature. Based on the work of Toulmin (1958) and Lithner (2008), they developed a framework for the analysis of mathematical argumentation among school children. In one of very few papers analysing mathematical argumentation among preschool children, Nergård (2023), applied the same framework, consisting of the following four steps: **1)** Identify **claims** in the video recordings of children in play, **2)** Search for **data** which supports the claim, **3)** Search for **warrants** which motivate how the data support the claim, and **4)** Make sure that the argument is **anchored mathematically**. A further two steps were included where applicable, where the author **5)** searched for possible warrants which motivated the warrant (**backing**), and **6)** interpreted the identified elements, taking the particular **context** into account. In these steps Nergård uses a multimodal approach, identifying arguments through a broad range of modes, such as speech, gestures (pointing) and moving artefacts.

It is this framework for analysis that we have applied to the data discussed in this paper. In particular, the first five steps described above were identifiable and applicable.

Methods

Data collection

Video recorded observations of everyday indoor activities including free play, organised activities (such as baking) and daily activities (such as getting dressed or setting tables) were collected over a period of three months in two preschools located in Norway. In each preschool we followed a group of children aged 2 – 5, with 24 and 28 children respectively. Two researchers were present and filmed the children's activities on 12 occasions, for 2-3 hours each time. Where the children directly addressed the researchers with their thoughts, simple follow-up questions were asked, but the researchers would not initiate talk about new or different topics.

This process resulted in a total of 91 clips, where each clip was a self-contained 'scene' in which one or more children were engaged in an activity. The clips varied in length from 30 seconds to 21 minutes. They were named according to the activity taking place and coded as free play (FP), daily routine (DR) or organised activity (OA).

Data analysis

Each of the three authors viewed all clips individually, wrote a small description of what was observed in the form of memos, and coded each clip as red (no mathematical argumentation), yellow (potential mathematical argumentation) or green (clearly containing mathematical argumentation). The framework for identifying mathematical argumentation (Nordin & Boistrup, 2018) outlined in the introduction was used in this process. The clips were also coded according to whether or not there was any mathematical content, how many children were involved, whether they were playing in

parallel, with some interaction, or fully collaboratively, and the available concretes were noted. After having looked through all clips individually, the authors compared the colour codes given. Where there was disagreement or agreement on a yellow code (a total of 9 clips), indicating general uncertainty, arguments for each choice were given, and the criteria for mathematical argumentation revisited, until a consensus of either red or green was reached.

An overview of the categorisations resulting from the above process can be seen in table 1. Of the 6 clips identified as mathematical argumentation, 3 featured an individual child addressing their surroundings, and three featured 2 or more children in joint activity.

Table 1: Overview of clip categorisation

	Number	**Situation**
All clips	91	Free play (36), Daily activity (14), Organised activity (41)
Mathematical content	21	Free play (12), Daily activity (6), Organised activity (3)
Mathematical argumentation	6	Free play (6)

It was relatively easy to identify whether or not a clip contained mathematical content. Examples include the use of shapes, numbers or spatial descriptions. Of the 91 clips, 21 touched on these topics in some way or other. The remaining 70 clips did not contain any clearly identifiable mathematical content, an example being a session where children and adults talked about emotions. However, deciding whether clips containing mathematical content should be categorised as mathematical argumentation or not, was more challenging. In particular we were repeatedly faced with the question of how much we could allow ourselves to infer from the child's actions. That is, how much should suspected intent be given weight in the process of analysis?

Findings

Below we present two examples with two of the youngest children in the dataset. The first illustrates a relatively easy identification of mathematical argumentation (coded green by all authors), while the second highlights potential difficulties in confidently identifying mathematical argumentation (initially coded red by two and green by one author) with children so young.

Example 1: Boy (2 years old) playing with «clip-on»-tiles

In this clip a three-year-old boy plays with clip-on tiles. He bends them around, seemingly with the

aim of completing the circle in order to drive a little toy car around it (See figure 1). The inserted photos are screenshots from relevant time-points in the transcript.

Figure 1

Boy: I don't have a round «runding» in Norwegian, often used by children to denote a circle)
Researcher: You don't have a round? How can you have a round?
Boy: Then I need so many… one, two, three, four, five, six (counting imaginary missing pieces and pointing with his finger to where they would be, see figure 2)

Figure 2

Researcher: Can you see if you can manage?

The boy goes off to find more pieces and attaches them to what he has.

Boy: That was very small (with a tone indicating that what he has done is insufficient)
Researcher: Was it not enough?
Boy: No
Researcher: Why not?
Boy: Can try… no, it doesn't work (he demonstrates how the ends won't meet, see figure 3)

Figure 3

Boy:	It is not a round!
Researcher:	How can you manage?
Boy:	Then I need more of these, all around here (indicating with his hand)
Researcher:	Can you find some?
Boy:	No (he has used all those around him)
Researcher	Are there no more?
Boy:	They are in the little room

They go together to the room next door where the child takes several pieces and brings them back.

Researcher:	Do you think that is enough?
Boy:	Yes, think it is enough… (tries) think we need more… don't think it works… Oh yes! It worked! (clicks the ends of the circle together)

He then picks up the toy car and drives it around what he has built, clearly pleased (see figure 4)

Figure 4

This clip was marked as green by all authors, in accordance with the chosen framework for analysis:

The **mathematical anchoring** is clear from the outset, the boy wishes to close a circle to make a «round», for his little car to drive around (geometrical shape). The boy makes a mathematical **claim**: "I don't have a round". He supports this claim by pulling on the two ends of the track to show that they do not meet to make a full circle (**data**). He indicates why by counting the imaginary missing pieces and pointing to their positions in the unclosed circle (**warrant**). In the final sequence he

concludes and makes another claim: “think it is enough”. He supports this claim by placing more of the pieces he collected into the circle (**data**). He says, “it worked” and illustrates this by clicking the ends of the circle together (**warrant**). He subsequently drives the toy car around the closed track, and this may be interpreted as a statement in support of the warrant (**backing**).

Example 2: Girl builds with wooden blocks

A four-year-old girl is playing with wooden blocks of different colours and sizes. She is building something that appears symmetrical (figure 5a). She then places a small green block on one side (figure 5b) and proceeds to reach for and pick up another green block (figure 6a) before she glances at her creation and puts it back down (figure 6b) while saying: «A small green. A small green». Then she reaches for another green block and places it on her building, seemingly pleased (figure 7 a, b and c).

Figure 5 (a and b)

Figure 6 (a and b)

Figure 7 (a, b and c)

This clip was marked as red by two of the authors, on the basis that the two green blocks look the same and that her rationale for choosing one over the other was not clear. Consequently, there seemed to be an uncertainty about whether or not her building of the tower was mathematically anchored

(through creating a symmetrical pattern), or not. The third author however, noticed a slight difference in size and perhaps shade of green, and argued that the girl makes her **claim** of «small green (needed)» on the basis that her creation was based on symmetry (**mathematical anchoring**), and that the green she had initially picked up would break that symmetry (**data**, towards which she glances), and finally she connects the claim and data with completing symmetry with her new choice (**warrant**).

What made the classification of this clip more complicated, besides the fact that the shades and sizes of the green blocks were only very subtly different, was that the girl, in the second half of the clip, after the sequence described above, continued to build *without* symmetry. This again brought the mathematical anchoring, which is an essential element in the identification of mathematical argumentation (Nordin & Boistrup, 2018) into question.

In this case, based on the observation that the creation remained symmetrical for a good while, and the girl's clear rejection of an item that broke with this symmetry, it was agreed by all authors that the first four steps of the framework were met. The decision also rested on the fact that a child's focus or intention may change rapidly in play, perhaps more so the younger the child, and that it would not be unnatural for her to aim for symmetry initially and then play on without this restriction in place.

Discussion

The examples presented here illustrate the use of Nordin & Boistrup's (2018) framework for identifying mathematical argumentation among preschool children and highlight some of the methodological challenges when studying the youngest children.

Even though a multimodal approach certainly helps (Nergård, 2023), it can still be challenging to identify whether there is a mathematical anchoring in their claims. A certain amount of inference is inevitably left to the researcher, as was found in Sumpter's various studies (Sumpter, 2016; Sumpter & Hedefalk, 2015). However, our view is that this problem is somewhat remediated by analysing such data in teams rather than individually. While existing frameworks for analysing mathematical argumentation among children work relatively well in the more explicit cases, future research may require more detailed guidelines for the interpretation of the different steps of an argument among the youngest children, particularly during free play, where various modalities may look different from that of older children (Johansson et al., 2014).

Also, as a purely qualitative observation it may be worth noting that of the six scenarios which were coded as mathematical argumentation, three were in play with magnetic or 'click-together' shapes, one was with Lego, one was with wooden blocks, and one was in a game of tic-tac-toe.

The fact that mathematical argumentation occurred in free play with shapes of some kind is perhaps not surprising. However, in analysing the data, we found it much easier, and felt it more valid, to infer a child's intentions (e.g. that a missing piece is required to complete a pattern) where the manipulatives showed this clearly, such as with magnetic tiles or the click-in tiles presented in example 1. The more 'degrees of freedom' the manipulatives allowed in their placements, going from the relatively strict possibilities of magnets, through the slightly wider possibilities of Lego, to the even less restricted wooden blocks - with which constructions could be rendered intentionally or unintentionally asymmetrical or irregular more easily - the harder it was to draw conclusions about a

child's intentions. Whether this was because the more restricted manipulatives *invited and resulted in* more mathematical thinking, claims and argumentation from the children, by virtue of leaving very clear visual clues where patterns were not completed, or whether the thinking and argumentation was just *easier to spot* for us as researchers in these cases, is an open question which may be the topic for future discussion and research.

Subjective perception of the readiness of novice kindergarten teachers to develop children´s early years mathematics

Eva Nováková

Masaryk University, Faculty of Education, Brno, Czech Republic; novakova@ped.muni.cz

Abstract

The study reports on research, the aim of which was to find out how novice kindergarten teachers evaluate their own level of professional readiness for the development of children´s mathematical preliteracy at the beginning of their career. The research method of data collection was writing thematic text. The basic method that made it possible to find answers to research questions and formulate findings was the thematic analysis of respondents´ narratives. The results show the respondents´ subjective perception of their own disciplinary mathematical professional competences: in which areas of early mathematics do the respondents consider themselves the most and least competent for the cognitive development of a child in kindergarten.

Keywords: *Kindergarten teachers, professional development, preschool education, early years mathematics.*

Introduction and theoretical framework

Our research focuses on novice preschool teachers. We define them as those at the beginning of their professional careers, typically with up to 3 years of experience. They have relevant higher education qualifications (in our research, a Pre-school Teacher Training bachelor's degree in early childhood education) and pedagogical competence, but they lack practical teaching experience.

Novice teachers are a promising yet vulnerable professional group. They are often associated with (unreasonable?) expectations. It is assumed that they will bring modern approaches and innovations to schools; however, upon entering the profession, they face a range of challenging problems that are difficult to solve. They often grapple with ambivalent emotions; on one hand, looking forward to entering the profession, and on the other hand, experiencing insufficient self-confidence and fears (Darling-Hammond, 2017; Tammets et al., 2019; Stewart & Jansky, 2022). They perceive the start of their teaching careers as a very demanding phase, sometimes referred to as the "practice shock" (Veenman, 1984; Liston et al., 2006).

A teacher's belief in whether and to what extent they can influence a student's performance (Guskey & Passaro, 1994) is based on the psychological construct of self-efficacy developed by Albert Bandura (1997). Beliefs about an individual's ability to organize and carry out a particular activity through which a stated goal is achieved is a determinant of academic success in an educational setting; it is an important motivator. It plays a key role in many aspects of teaching and has a great influence on the learning performance of students and the teaching methods chosen by the teacher (Pajares, 1992).

A teacher's beliefs can be influenced by a variety of factors. Kalaja and Barcelos (2003) state that they depend on the context and experiences of the individual, are dynamic and can be contradictory. Teachers with higher self-efficacy in mathematics pay more attention and focus longer on problem solving, are more patient and exert more effort in solving, and can estimate their own performance more accurately and clearly than others (Klassen & Chiu, 2010; Yavuz et al., 2013). Pendergast et al. (2011) found that after finishing their teaching practice at the end

of their studies, the self-efficacy of student teachers (also kindergarten teachers) decreased. The authors interpreted this decrease as a result of the reality shock that students experienced after the practical experience.

In our study, we note teachers' beliefs in the importance of subjective perceptions of their own preparation of prospective kindergarten teachers in college, and the suitability and appropriateness of various activities for early mathematics learning.

A significant professional competence for (not only novice) teachers is subject-specific competence. Higher education training for teachers significantly develops their knowledge base for teaching, which Shulman (1987) considers a key aspect of the journey toward teaching professionalism (Korthagen et al., 2011). Knowing the necessary amount of basic mathematical knowledge can be useful to them in their profession in developing children's mathematical pre-literacy. By mathematical pre-literacy, we mean a set of gradually developing prerequisites for mathematics in children before they enter school; a complex of abilities, skills, attitudes and values needed for the initiation and successful development of mathematical literacy and its use in different individual and social contexts (Nováková & Novák, 2019). While it is important to respect the unique nature of the professional activities of preschool teachers, given the specifics of the age of the children they work with: the ability to create a multidisciplinary learning environment (Pramling & Pramling Samuelsson, 2011), the ability to integrate play and learning (Pramling Samuelsson & Carlsson, 2008), and to lead a collaborative and supportive interaction with children (Howes et al., 2003).

In preschool teacher education in the Czech Republic, mathematics-related subjects have only a marginal role in the curriculum. In our previous research (Nováková & Novák, 2019), we found that novice teachers generally do not consider further deepening of their mathematical knowledge necessary for their professional development. They believe that they have already acquired the basic mathematical knowledge needed for early mathematical preparation of children in preschool during their primary education. These insights often take the form of implicit, "tacit" knowledge (Švec, 2012). As Žilková et al. (2013) point out, they enter their pre-service higher education and teaching practice with many mathematical misconceptions. These facts led us to attempt to take a more objective look at preservice teachers' beliefs about their professional assumptions based on their knowledge of basic mathematics.

The main aim of the research was to determine how novice, university-educated teachers assess their level of acquired mathematical knowledge as part of professional preparedness for developing children's mathematical pre-literacy. We based our assumption on the fact that this subjective perception is grounded in the individual's reflection on their own situation, influenced by their opinions, knowledge, and experiences.

In line with the research objective, the research question was formulated as follows:

> RQ: Which aspects/areas of children's mathematical pre-literacy do novice teachers consider themselves to be the most prepared for, and which do they consider themselves the least prepared for?

Methods

As a research method for data collection, we used thematic writing focused on the self-reflection of novice teachers. The text they produced is a construction of their own subjectivity. The advantage of free written production is that the mediating effect of the researcher is smaller compared to an interview, and the participant works at their own pace (Elizabeth, 2007).

The research sample consisted of 129 graduates of the Pre-school Teacher Training program at the Faculty of Education, Masaryk University in Brno. The theme of the written self-reflection

was introduced through a prompt corresponding to the research question. The extent was given by one page of text. The writing was free and uncontrolled by the researcher—the flow of writing was not restricted in any way.

The primary method used to formulate findings was thematic analysis of the text (Braun & Clarke, 2006). According to Vaismoradi et al. (2016), thematic analysis is a systematic process that begins with coding and exploring meanings that describe and interpret participants' perspectives. The individual statements were analyzed to find answers to the research question.

The first step in data processing was the creation of codes for individual research areas. We opted for an open coding approach (Švaříček & Šeďová, 2007). For the coding process, we utilized the QDA Miner software (Provalis Research). This software enabled us to determine the frequency of each code's occurrence in the respondents' statements. A total of 18 codes were identified by the researcher across two categories: pre-numerical ideas and pre-geometric ideas. The codes extracted by the researcher from the written statements reflected the participants' subjectively perceived positive (16) or negative (11) aspects of early years mathematics.

Research results

The respondents' statements are highly varied and, in some cases, even contradictory, as is evident from the authentic examples. They reflect the level of theoretically acquired knowledge from previous education as well as the respondents' existing experiences from their own practice. We expressed these frequencies in percentages and illustrated them graphically (Figures 1 and 2). To further illustrate the teachers' opinions, we present examples of their authentic statements, highlighting the corresponding extracted codes.

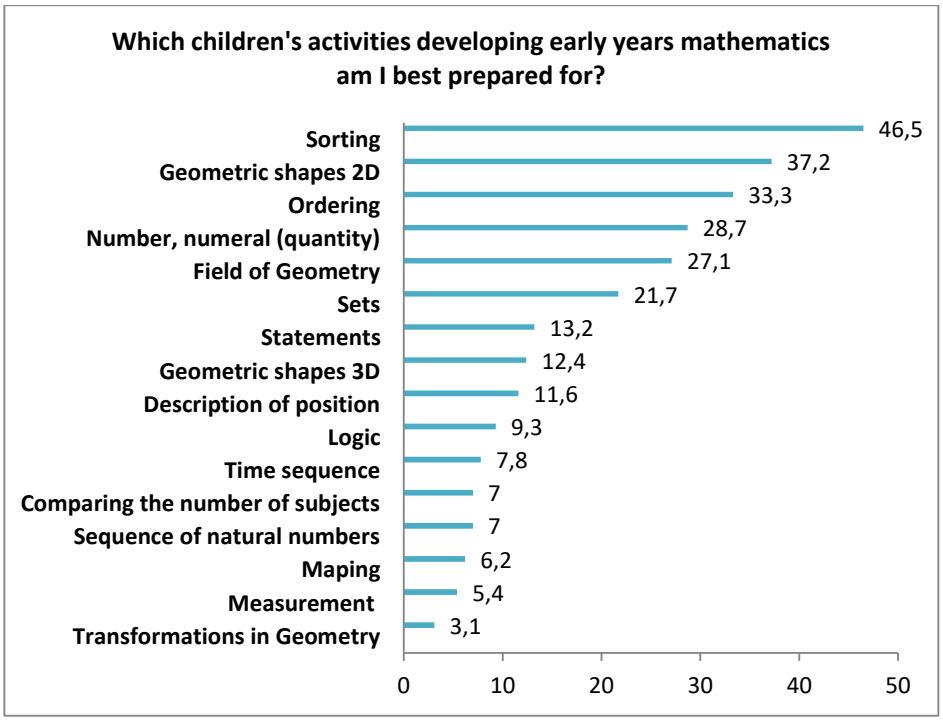

Figure 1

Early years mathematics topics in which respondents consider themselves **best prepared**

The highest frequency is observed for the code *Sorting* (46.5 % of teachers report as an activity for which they feel best prepared to work with children). This code does not appear at all among the activities for which respondents feel least prepared. The interpretation of this finding is clear: sorting objects or toys by visible, sensory attributes is often a deliberately introduced or spontaneous activity not only in preschool classrooms but also with younger children.

> "In my practice, I have had the opportunity to see and apply sorting and ordering and I believe I am well-prepared in this area. I never really realized that the activities I do with children include so many opportunities for developing mathematical pre-literacy."

The high frequency of the code *Ordering* (33.3 %), for which respondents feel well-prepared, is also not surprising. Arranging objects or figures by a given attribute in ascending or descending order is familiar to children – it has its natural reflection in reality (a line of children by size, waiting in a queue, cars stopped at a red traffic light) as well as in many fairy tales (e.g., "The Enormous Turnip," "Snow White and the Seven Dwarfs").

The code *Time sequence* (with a frequency of 7.8 %) also reflects the nature of ordering and relates to mastering orientation in time and distinguishing basic time concepts (day, night; yesterday, tomorrow; before, after). It is also common to sequence events, activities, or happenings throughout a child's day or time spent in preschool, as well as recognizing the sequence of life stages.

> "I discovered that understanding the days of the week, months, seasons, and other temporal sequences, and how things follow one another, also belongs to mathematical pre-literacy."

More than a quarter of the respondents (28.7 %) indicate that they are best prepared for activities represented by the code *Quantity (number, numerals*). They reflect their practical experience, where they use various number models for determining quantity (count of objects) during everyday situations and games. The fact that the Quantity code also appeared among the activities where some students feel least prepared (10.1 %) can be explained by their concerns about the abstract nature of numbers and their symbolic representation by numerals as specific symbols. This is also reflected in an authentic statement from one of them.

> "I feel least prepared in the area of numbers and symbolism. The problem is numerals—I don't know how to better present these symbols to children, other than always using dots or other representations of quantity."

It is not surprising that the highest frequency of strengths within the category of geometric ideas was found in the code *2D Geometric Shapes* (37.2 %). Recognizing and distinguishing basic plane geometric figures—such as circles, squares, rectangles, and triangles—and assigning the correct name to each shape are traditionally among the most common activities in kindergarten settings. However, these activities can sometimes lead to misconceptions (Levenson et al., 2011; Žilková, 2013). For instance, the boundary of a circle (circumference) is often incorrectly referred to as the circle itself, rather than the plane area it encloses. Teachers' statements suggest that they perceive activities involving geometric shapes in a broader context and are capable of incorporating them effectively into their own teaching portfolios.

> "I feel most confident working with geometric shapes, their recognition, differentiation, and sorting. It is easily visualizable, and children find it more relatable than other topics. I already have many activities prepared on this topic."

Similarly, the codes *Field of Geometry*–unspecified (27.1 %), *3D Geometric Shapes* (12.4 %), and *Description of position* (11.6 %) are identified as areas where students feel most prepared.

However, the situation is not entirely clear-cut. These codes also appear among those where students feel least prepared: the codes Description of position (8.5 %), and 3D Geometric Shapes (7.8 %). Perceiving and organizing space, orienting oneself in real space (classroom, playground) in natural situations such as nature walks, sports, dining, etc., and in deliberately created situations, are among the most significant skills developed in early childhood. Therefore, this activity is considered one of the most natural ways to develop spatial imagination, manipulative skills, and creativity.

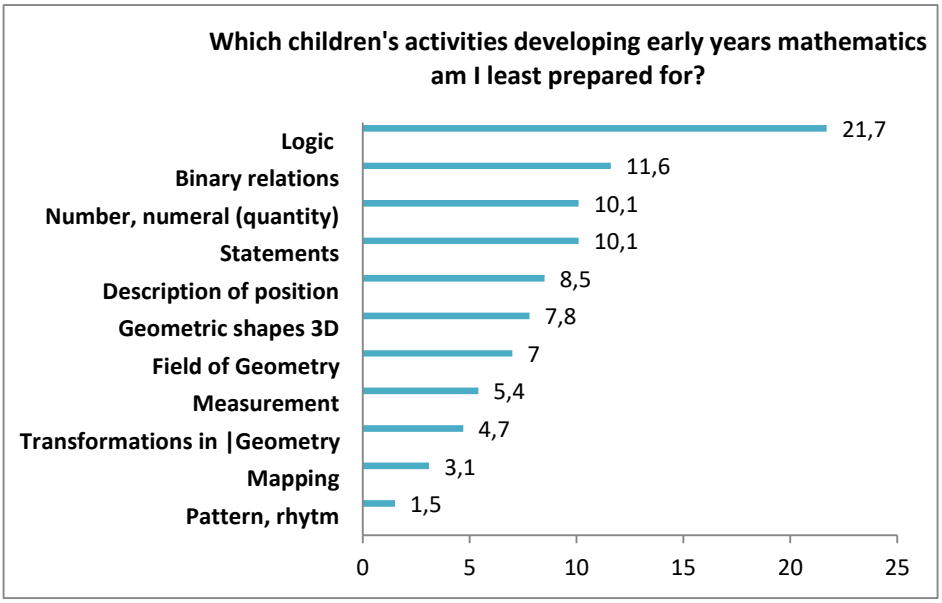

Figure2

Early years mathematics topics in which respondents consider themselves **least prepared**

In the overview of codes where respondents feel the least prepared, the code *Relation* appears frequently (14.3 %). A detailed analysis of the statements reveals that they are referring to the relation of mapping (while relations such as sorting and sequencing are considered their strengths). This reflects some students' limited experience with activities involving mutually exclusive assignments like "how many – so many": how many fingers, so many beads; how many cups, so many spoons.

> "I feel confident with activities where children match objects or connect pictures with lines on worksheets. For example, matching mugs and plates, or pictures of flowers and butterflies."

The perception of logical statements, represented by the codes *Statements*, *Logic*, is ambiguous. While some teachers consider themselves well-prepared to use them (13.2 % and 9.3 %, respectively), 21.7 % of respondents feel least prepared in this area. Concerns about using statements that are understandable to children but logically accurate and precise in everyday preschool activities seem to be related to teachers' lack of confidence in their own communication skills.

> "I feel less prepared in propositional logic. I am not sure if I can translate this into activities suitable for preschool children."

Transformations in Geometry (4.7 %) and *Measurement* (5.4 %) have a significantly lower representation among the codes where students consider themselves to be most well-prepared. At the same time, both codes are listed among those that students subjectively perceive as their weak areas. The students' statements provide some explanation for this observed fact.

> "I feel least confident in the area of measuring geometric shapes because I am not aware of having observed measurement in preschool.
>
> "I struggle with congruence and symmetry. I have not yet been able to fully connect this topic with practice, so I find it difficult to come up with activities for children related to this topic."

Conclusions

In summary, based on the respondents' statements, we can attempt to answer the research question. By comparing the number of positive and negative self-reflections on their own abilities to develop early years mathematics, we infer that novice teachers consider themselves sufficiently competent to effectively contribute to this aspect of children's personal development. Their opinions are highly diverse, as evidenced by the range of topics in which they feel most and least prepared.

The narratives reflect both the knowledge acquired during previous education, particularly from studying mathematical subjects at university, and the initial experiences from their teaching practice in kindergarten. From the individual statements and the identified codes, it is evident that the respondents perceive early math education through a broad range of topics. We consider this to be a good starting point for potentially creating a suitable, comprehensive, and diverse set of activities to develop children's mathematical literacy in their future professional work. Awareness of their weaker areas in their subject-specific (mathematical) preparedness can also serve as a good starting point for focusing on further professional growth.

Regarding the specific areas of early years mathematics, respondents regard pre-numerical concepts (especially sorting and ordering) and geometric concepts (2D and 3D shapes, spatial awareness, and orientation in plane and space) as the most significant and practically necessary. The development of geometric concepts is also commonly featured in didactically targeted activities in preschool education.

Respondents identified logic as a weak point in their preparedness, expressing this concern in various ways. We categorized these under the codes 'logic' and 'statements.' The development of (pre)logical thinking is a crucial component of preparing preschool children for entry into formal education. For beginning teachers, this topic is new, and they find its transformation into specific activities in kindergarten to be challenging.

The Czech Republic, unlike many other European countries, still requires preschool teachers to have qualifications at the level of secondary vocational education (ISCED 2011: level 3), although the proportion of teachers with higher education is currently increasing. The ratio of secondary school-educated to university-educated kindergarten teachers in the Czech Republic was 75.9 % to 22.6 % in 2011, and by 2017, it had changed to 60.5 % to 37.4 % (Loudová-Stralczynská et al., 2022).

International research provides evidence that higher qualifications of teachers lead to better professional knowledge compared to those with lower qualifications; this positively affects the quality of preschool education and children's outcomes (Kelley & Camilli, 2007; Oberhuemer et al., 2010; Saracho & Spodek, 2007). Barnett (2004) analyzed several studies focusing on teacher education and the quality of child care. His analysis shows that the higher the teachers' education, the more responsive they are to children's individuality and the more competent they are in enriching cognitive experiences.

We are aware of the limitations of our research, and its conclusions cannot be generalized for preschool education practice. The respondents in our research are graduates of only one university, and their statements largely reflect the outcomes of their previous education. They

view various areas of early years mathematics from a student's perspective – they have yet to confront their ideas and expectations in their professional practice.

Dealing with multiplicative problems in pre-primary education: Analyzing children's performance and strategies

Georgia Pitta and Xenia Vamvakoussi

University of Ioannina, Department of Early Childhood Education, Ioannina, Greece;
g.pitta@uoi.gr

We present findings of the 3rd cycle of an ongoing design research study aimed at developing an instructional program to support pre-primary children's multiplicative reasoning. The 3rd enactment of the program was conducted with a class of 22 Year 1 and Year 2 kindergarten children (mean age 5 years and 7 months) who were pre- and post-tested individually. We focus on two tasks, common at both test moments, which were not addressed during the intervention. The results show that all Year 2, but very few Year 1 children were able to transfer what they had learned during the intervention to novel problem situations. Further, we found emerging inter-individual differences with respect to children's ability to represent mentally the quantities and operations involved in the given problems.

Keywords: multiplicative reasoning, kindergarten, multiplicative problems, performance, strategies.

Introduction

Research evidence indicates that young children have multiplicative reasoning competencies with respect to continuous as well as discrete quantities (Mix et al., 2002). These (limited) competencies can be enhanced when children are exposed to formal and informal multiplicative experiences (Hunting & Davis, 1991; Van den Heuvel-Panhuizen & Elia, 2020). However, early childhood education over-emphasizes counting and additive relations in the context of discrete quantities and pays less attention to multiplicative situations (Hunting & Davis, 1999; Sophian, 2004; Vamvakoussi & Kaldrimidou, 2018). This asymmetry has consequences for children's mathematical development. Indeed, children's performance in simple multiplicative tasks decreases when they are able to represent discrete quantities via counting (Ni & Zhou, 2005). Further, children miss the opportunity to build the conceptual background necessary for understanding important mathematical concepts, notably fractions (Sophian, 2004).

In this paper, we present results from the third cycle of a topic-specific design research study (Gravemeijer & Prediger, 2019) aimed at developing an instructional program to foster kindergarten children's multiplicative reasoning with respect to discerning and expressing multiplicative relations and solve multiplicative problems.

Theoretical background and design of the program

We based our design on three key principles: First, treating discrete and continuous quantities similarly and simultaneously, a choice grounded on different, albeit complementary, reasons: It has been argued that both types of quantity are constructed based on the same mental operation, namely unitizing (Steffe, 2013); that counting and measurement are more similar than typically assumed (Sophian, 2004); and that three fundamental multiplicative operations (namely, equi-partitioning, iteration of a quantity and counting/measuring with different units) are the same in both contexts

(Vamvakoussi & Kaldrimidou, 2018). Second, providing linguistic tools for expressing multiplicative relations, because such tools enable young children to recognize similar relations in different contexts and organize their formal and informal experiences with multiplicative situations (Hunting & Davis, 1991). This claim is supported by recent evidence indicating that simple vocabulary pertaining to multiplicative relations (e.g., "double") at Grade 1 is associated with higher proportional reasoning abilities at Grade 2 (Vanluydt et al., 2021). Third, highlighting the inverse relationship between the operation pertaining to multiplication (iterating a quantity) and those pertaining to division, particularly equipartitioning. This relationship is of great importance for multiplicative reasoning (Greer, 2012). Consistently with this idea, the relationships "A is a multiple of B" and "B is a submultiple of A" were treated as the same relationship seen from two perspectives.

These key principles were implemented in the design of the instructional program which consisted of three story-based activities (A1, A2, and A3) featuring a scenario with a sports team of 10 imaginary creatures. The characters were represented by wooden cylinders of the same base diameter and height ranging from 1 to 10 units in length. Multiple copies of the unit were available to students.

In the first activity (A1), terms for multiples and submultiples were introduced to describe the relationship between the "players" and the "team leader" (whose height was equal to the unit length). The relationship was established through measurement and expressed from two perspectives (e.g., A is triple B/ B is one third of A). The introduction of the terms capitalized on the salient regularity in their production in Greek (Pitta & Vamvakoussi, 2022) which is based on number words and was assumed to allow children to employ aspects of their knowledge of natural numbers productively (Steffe, 2013) to acquire vocabulary necessary to express multiplicative relations. The second activity (A2) targeted proportional problems: A discrete or continuous quantity was assigned to the "team leader" (i.e., the unit) and the quantity corresponding to a "player" was requested based on her height and vice versa. Finally, the third activity (A3) focused on multiplicative change using "fraction machines" (Hunting & Davis, 1991) which, unlike the typical ones, operated in two directions: on one side, the incoming quantity was multiplied by a natural number n, while on the other, by its reciprocal 1/n. This modification allowed for bringing to the children's attention the inversibility of the processes.

In all three activities, manipulatives made of cardboard were used to represent the quantities (disks for discrete, and bars for continuous quantities). Additionally, in A2 and A3 we used a manipulative representation of the ratio between the known and the unknown quantity. Figure 1 illustrates the process of finding a submultiple of a given continuous quantity (one third in the example) using this tool: Children are given options for the unknown quantity and are asked a) to estimate which is the appropriate one (1a), b) to check if the given quantity can be composed by iterating the selected bar 3 times (1b). The tool is then used to illustrate the partitioning of the initial bar (1c), as well as the quotient (1d). In the discrete condition, the available options were presented as linear arrangements of discs glued on paper strips. To find a multiple of a given quantity, the same tool was used in reverse. The use of the tool structures the intended processes similarly for continuous and discrete quantities, highlights the inverse relationship between multiplication and division, and was also assumed to help children keep track of important elements of the problem situation.

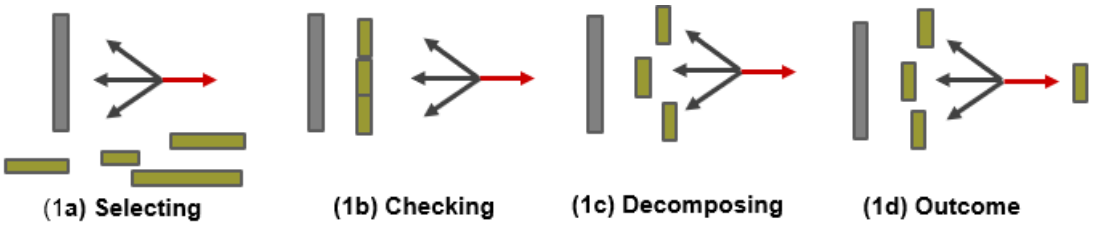

Figure 1: Finding one third of a continuous quantity with a manipulative representation of ratio

The program activities and materials have been designed, evaluated, and redesigned after two enactments with small groups of Year 2 kindergarten children (of a maximum of 4 members in each group) (Pitta, et al., 2021; Pitta & Vamvakoussi, 2022). It should be noted that Greek kindergarten classes typically comprise Year 1 (hereafter, Y1) children who enroll at 4 years of age; and Year 2 (hereafter, Y2) children who enroll at 5 years of age. Findings from the two enactments of the program showed that it was within the range of abilities of Y2 children and substantially enhanced their multiplicative reasoning competencies. In the 3rd cycle of the study, we enacted the program in a more ecologically valid setting: An entire mixed-age class (Y1 and Y2 children), participated in the intervention. We were interested in whether a) the program would have a positive effect on children's multiplicative reasoning competencies in the larger group/mixed age setting; b) the potential learning gains would be transferable to unfamiliar multiplicative situations; c) there would be inter-individual differences regarding potential learning gains. In this paper we focus on one type of difference, namely the extent of children's reliance on manipulative representations during problem-solving. This is because dependence on perceptual input can differentiate between children who solve a problem correctly, with less dependence indicating a higher level of mathematical thinking (Baroody, 2017).

Method

Participants

The participants were a class of 9 Y1 and 13 Y2 kindergarten children from an urban private school in Western Greece (mean age 5 years 7 months, ranging from 4 years 10 months to 6 years 4 months). Nine of the participants were girls (4 Y1). All children were native Greek speakers. They participated voluntarily with their parents' informed consent.

Procedure and research tools

The 3rd enactment started in January and was completed in May of the school year 2022-23. The students participated in the intervention in two groups of 11 mixed-age children; each group participated in nine sessions (approximately 45 minutes each) that took place in their classroom. During the intervention, each problem stemming from the activities was elaborated first for continuous, and immediately after for discrete quantities, to highlight the similarities. For any new problem, the teacher-researcher gave children the opportunity to solve it first on their own; she modelled the intended operations when necessary; she introduced the new terms, used them systematically, and prompted children to use them as well.

The children were pre- and post-tested via individual interviews. The interviews were conducted in two parts and were video recorded.

There were two categories of tasks used for pre- and post-testing. The first comprised problems similar to the instructional tasks, whereas the second comprised two tasks that had not been part of the intervention and tested for transfer of competencies to a new context. In the following, we will focus on these "transfer tasks". The first transfer task targeted "equal groups" and "equal measures" situations, in the discrete and continuous condition, respectively. A total of 18 problems was produced varying the number of equal groups or equal measures (n=2, 3, 4), as well as the type of problems that can be posed based on the same multiplicative situation. Figure 2, presents a model for this task in the discrete condition for n=3.The problems were formulated as follows:

Equi-partitioning (partitive division problem): Three friends (2a) will fair-share these candies (2b). Can you show me how many candies each child will get? How do you know?

Iteration of a quantity (multiplication problem): Three friends (2a) fair-shared a pack of candies. Helen took those two (2c). Can you tell me how many candies were in the pack? How do you know?

Measuring (quotitive division problem): A party of friends fair-shared these candies (2d). I don't know how many children there were (multiple copies of possible recipients available, 2e), but I know that Helen took those two (2c). Can you tell me how many children there were?

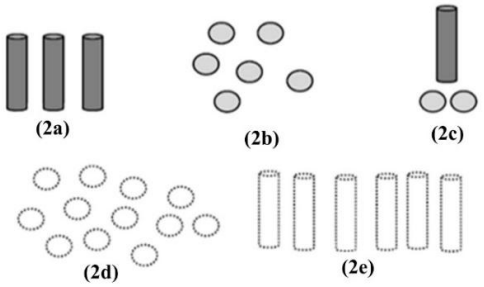

Figure 2: A model for the "equal groups" situation (n=3)

For the second task, the children were given discrete and continuous quantities and were explicitly asked to find a multiple and the corresponding submultiple of this quantity, for n=2,3,4. For example: "I have this chocolate (*paper strip bar*). I will give George one-third of the chocolate. Which of these pieces (*4 options*) do you think George will get? How do you know?" In this task (a total of 12 problems), recognizing and interpreting the terms was a prerequisite for solving the problems.

In all problems, the children were asked to explain their answers to ensure that their choices were not random. The ratio representation tool was available to the children.

Results

Performance

Children's response to each problem was evaluated and scored as 1 (correct) and 0 (incorrect), respectively. Each child's overall performance was calculated as the sum of their correct answers across all problems (a total of 30). Interestingly, among all possible total scores, only few were present in our data. Table 1 presents the frequency of each total score at pre- and post-test. At pre-test, only four children (including one Y1 child) solved two or three problems correctly. All correct answers

were given in the discrete condition, specifically a) in a fair sharing problem with two recipients and, in one case, three recipients, b) recognition of the term "half," and c) recognition of the term "double".

Table 1: Frequency of total scores in the Pre- and Post-test

Pre-test			
Total score	Y2	Y1	Total
3	1	0	1
2	2	1	3
0	10	8	18
Total	13	9	22
Post-test			
Total score	Y2	Y1	Total
30	7	1	8
29	3	0	3
21	2	0	2
20	1	1	2
0	0	7	7
Total	13	9	22

At post-test, 7 out of 9 Y1 children had a total score of zero. Two of them refused to engage with the tasks from the beginning, while the others quitted midway without answering correctly even the simplest of tasks (i.e., when the relation in question was 1:2 / 2:1).

The remaining children (after the intervention) can be broadly divided into two groups: In the first (Group A), 11 children (including one Y1 child) solved at least 29 out of the 30 problems, while in the second (Group B), 4 children (including one Y1 child) solved 20-21 problems. It is worth noting that the incorrect responses were mainly observed in problems with n>2, primarily (but not exclusively) in the discrete condition, and mostly for submultiples.

Strategies

The children's strategies at the post-test were examined based on the extent to which they needed to use the manipulatives given and/or the ratio representation tool during the problem-solving process to represent the involved quantities or relationships. Three categories emerged:

The first category (S1, manipulatives-based strategy) included the cases in which a child used the given manipulatives, including the ratio representation tool, to represent all involved quantities. For example, in a partitive division problem (6 candies for 2 children), Child 1 used the materials representing the candies as well as the dolls representing the recipients; she initially matched each recipient with a pair of candies and then distributed the remaining candies one by one.

The second category (S2, partially mental strategy) included the cases in which a child used the materials, but not for all the involved quantities. For example, in the above problem, Child 2 used the material representing the candies, but not those representing the recipients. More specifically, she placed the 6 candies in a line, stated that she needed to create two groups of candies and pointed to the middle of the line saying, “There are two groups of three on the table, and Helen will take one group, and her sister will take the other one”.

The third category (S3, fully mental strategy) included cases in which a child solved the problem mentally, using the materials only to justify their answer. Such strategies indicate that the child performed mentally the necessary operations. In the following example, Child 3 employs an S3 strategy while solving a multiplication problem (3 candies per child x 3 children):

Child 3: [Looks at the available candies for a while] It's 9 candies [Arranges 9 candies in a line].

Interviewer: How do you know?

Child 3: [Points to a group of three with his fingers] Three, three, three makes nine. It's triple. Three times. Nine.

S3 strategies were also observed in the case of continuous quantities. In the following excerpt, Child 4 estimates in advance which of the options corresponds to half of the given quantity:

Child 4: [Looks at the options for a while and chooses the correct one] This is the one half.

Interviewer: How do you know?

Child 4: If you place it here [points at the bar], it is one of the two pieces. Look. [Opens thumb and index finger to the length of the piece] One, two [measures the chocolate].

An additional category (S0) included cases corresponding to incorrect or unjustified answers. Table 2 presents the frequency of these categories across all problems, for all 15 children at post-test. The dominant strategy was, by far, the S1 strategy; about 15% of the strategies were S2 or S3.

Table 2: Frequency and percent of different strategy categories, in the total of responses

Strategy Category	N (%)
S0 (No /Erroneous Strategy)	41 (9.1)
S1 (Manipulatives-based strategy)	342 (76)
S2 (Partially mental strategy)	37 (8.2)
S3 (Fully Mental strategy)	30 (6.7)
Total	450 (100)

We calculated the number of S2 and S3 strategies per child across all problems and we categorized the children accordingly, as presented in Table 3. Eleven out of 15 children demonstrated at least one S2 or S3 strategy. Four children (including one Y1 child) employed no such strategy; they all belonged to Group B. The remaining Group B children used at most 3 S2 or S3 strategies.

Table 3: Frequency of children groups based on the sum of partially (S2) and fully (S3) mental strategies across all problems at post-test

Sum of S2 and S3 strategies	0	1-3	4-6	7-9	10	14
Frequency	4	5	2	2	1	1

Finally, the sum of S2 and S3 strategies coming from Group A children ranged from 1 to 14. It is also worth noting that most of these strategies appeared in problems pertaining to the relations 1:2/ 2:1. However, 9 children demonstrated at least one such strategy for relations other than 1:2/2:1.

Conclusions and discussion

We presented findings from the third cycle of a topic-specific design research study (Gravemeijer, & Prediger, 2019) aimed at developing an instructional program to foster kindergarten children's multiplicative reasoning. In the previous two cycles, the program was enacted with small groups. In this cycle, an entire, mixed-aged, kindergarten class participated in the program in groups of eleven, which is a more ecologically valid setting in the Greek educational context. We presented findings for two tasks to which the children had not been exposed during the intervention and, thus, constituted a novel context for them. This claim was corroborated by findings indicating that at pre-test very few children were able to tackle a very limited number of the given problems.

Our results showed that, first, all Y2 children and two Y1 children had substantial learning gains: Not only did they recognize the terms for multiples (n=1, 2, 3, 4) and corresponding submultiples, but were also able to construct multiples and submultiples of given discrete as well as continuous quantities. Further, they were able to transfer what they had learned in the context of the intervention to the context of "equal groups" and "equal measures" situations, across all types of related problems (i.e., multiplication, partitive division, and quotitive division problems). The majority showed a remarkably consistent performance across problems; a smaller group of children had not yet stabilized their performance on problems involving relations other than 1:2/2:1 that are known to be the most accessible to children of this age (Hunting & Davis, 1991).

Second, it is evident that these research tasks were too demanding for most Y1 children. The two notable exceptions indicate that this is not merely due to age, highlighting the possibility of substantial inter-individual differences among Y1 children, beyond those between Y1 and Y2 students. We note that, based on our experience of Y1 children's participation in the intervention, we expected more of them to be able to tackle problems at the post-test moment, at least for the second task. Analysis of the intervention data will shed light on Y1 children's ways of engagement with the activities and inform our decision on mixed-age grouping in future enactments.

Third, there are indications of emergent inter-individual differences with respect to the extent manipulatives were necessary for children during the solution process. Mental representation of the problem situation differentiates children who solve correctly a given problem (Baroody, 2017), as is evidenced by the examples we presented. This feature will be further explored in combination with children's problem-solving methods (currently under analysis), with a view to outline a learning trajectory (Clements & Sarama, 2021) pertaining to early multiplicative reasoning.

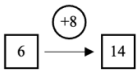
Although the influence of language and numerical abilities on early arithmetic word problem solving has been explored, spatial ability has received limited attention despite evidence suggesting a causal spatial-mathematical link. Using confirmatory factor analysis and structural equation modelling, we investigate the extent to which spatial visualization and visuospatial working memory predict the problem-solving success of 137 six- to seven-year-olds in England. Integrating Thompson's (1993) distinction between quantity and quantitative relations, Davydov's (1982) discrete versus continuous quantities, and Vergnaud's (1982) dynamic versus static relations, we propose a novel framework for categorizing one-step additive word problems. Preliminary analysis indicates that spatial visualization is relevant for solving Dynamic Relation-Relation Unknown problems, aligning with literature suggesting its importance in solving novel and challenging problems.

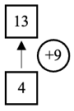
Keywords: Additive word problems, quantity, quantitative relation, spatial visualization, visuospatial working memory.

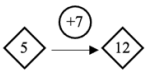
Introduction

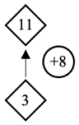
Early arithmetic word problem solving skills are important, partly because they predict later academic and future career success (Murnane et al., 2001). The influence of language and numerical factors in arithmetic word problem solving has received considerable attention in the fields of educational psychology and mathematics education (Verschaffel et al., 2020). However, one understudied yet promising lens for understanding young children's arithmetic word problem-solving capability is their spatial ability as there is evidence of a causal spatial-mathematical link (Hawes & Ansari, 2020).

While research with older school children suggests that spatial ability may be important for solving certain types of word problems (Gilligan-Lee et al., 2022), there have been few investigations focused on the relationship between spatial ability and arithmetic word problem solving in young children. The present study aims to address this gap in the literature by investigating the extent to which spatial visualization and visuospatial working memory predict one-step additive word problem-solving performance of different problem types in young children. Toward this aim, this paper proposes a novel framework for categorizing one-step additive word problems.









Word Problems

This study focuses on one-step additive word problems. Central to this study's conceptualization of arithmetic word problems is the distinction between a quantity and a quantitative relation (Thompson, 1993). A quantity is an intrinsic attribute of an object that does not depend on anything other than the object itself, such as the set size. A quantitative relation, in contrast, describes the connection between quantities. While both can be represented with a numerical value, when measured, quantitative relation is best represented by integers (Vergnaud, 1982).

Adapting Davydov's (1982) conceptualization, we propose a further subdivision of quantity into two types: *discrete quantity* and *continuous quantity*. Discrete quantities are measured through one-to-one counting, whereas continuous quantities are measured using an imposed unit. For example, the statement, 'Ann has 8 books' presents a discrete quantity given that the number of books Ann has is a specific, fixed quantity, measured through counting. On the other hand, the statement, 'Ann is 8 steps from the wall', presents a continuous quantity given that Ann's position is determined via an imposed measurement unit (i.e., steps).

Adapting Vergnaud's (1982) conceptualization, the quantitative relation can also be further subdivided into two types: *dynamic relation* and *static relation*. A dynamic relation describes the transformation in the state of nature over time (i.e., initial and final quantity). A static relation, in contrast, describes the comparison of disjoint quantities (i.e., referent and compared quantity).

As shown in Figure 1, the two types of quantities—discrete and continuous quantity—and the two types of quantitative relations—dynamic and static relation—form four quadrants. When each quadrant is phrased as a one-step additive word problem, two of the three facts are presented and the problem solver's task is to determine the missing third fact, or the unknown (Verschaffel et al., 2020). Therefore, along with the two types of quantities and quantitative relations, the two types of unknowns (quantity or quantitative relation) form this study's two-by-two-by-two framework for categorizing one-step additive word problems (2 [Quantity] x 2 [Quantitative Relation] x 2 [Unknown]). Word problems can be categorized in different ways, depending on whether one, two, or all three dimensions are used.

Quantity	Unknown	Quantitative Relation			
		Dynamic Relation		Static Relation	
Discrete Quantity	Quantity Unknown	Initial[a] or Final[c] Discrete Quantity Unknown Problems	Ann had 6 marbles.[a] Ann won 8 more marbles.[b] Ann now has 14 marbles.[c] 	Referent[a] or Compared[c] Discrete Quantity Unknown Problems	Ann has 4 marbles.[a] Bob has 9 more marbles than Ann.[b] Bob has 13 marbles.[c] 
	Quantitative Relation Unknown	Dynamic Relation[b] (between Discrete Quantities) Unknown Problems		Static Relation[b] (between Discrete Quantities) Unknown Problems	
Continuous Quantity	Quantity Unknown	Initial[a] or Final[c] Continuous Quantity Unknown Problems	Ann was 5 steps from the wall.[a] Ann walked 7 more steps away from the wall.[b] Ann is now 12 steps from the wall.[c] 	Referent[a] or Compared[c] Continuous Quantity Unknown Problems	Ann is 3 steps from the wall.[a] Bob is 8 steps farther from the wall than Ann.[b] Bob is 11 steps from the wall.[c] 
	Quantitative Relation Unknown	Dynamic Relation[b] (between Continuous Quantities) Unknown Problems		Static Relation[b] (between Continuous Quantities) Unknown Problems	

Note. The dimensions of quantity, quantitative relation and unknown form a two-by-two-by-two framework for one-step additive word problems. The categorization of word problems differs based on whether one, two, or all three dimensions are involved. When each quadrant (Discrete Quantity–Dynamic Relation, Discrete Quantity–Static Relation, Continuous Quantity–Dynamic Relation, and Continuous Quantity–Static Relation) is framed as a one-step additive word problem, two of the three facts are provided, and the missing third fact becomes the unknown to be solved. The unknown is either a quantity[a and c] or a quantitative relation[b].

Figure 1: The two-by-two-by-two framework for one-step additive word problems

Spatial Ability

We define spatial ability as the ability to "generate, manipulate, and reason about spatial relations between and within objects" (Hawes et al., 2022, p. 112). This study concentrates on two spatial skills

that have been most consistently identified in the literature as having a strong association with mathematical thinking: spatial visualization and visuospatial working memory (VSWM). Spatial visualization is the ability to manipulate and transform visual-spatial images (Hawes & Ansari, 2020). Typical measures of spatial visualization include 2-dimensional mental rotation tasks, 3-dimensional mental rotation tasks, mental composition tasks, and mental paper-folding tasks. An extensive body of literature suggests that the relation between spatial visualization and mathematical performance is correlational, possibly causational and even bi-directional (Newcombe et al., 2019).

VSWM is the ability to temporarily store and manipulate visuospatial information (Hawes et al., 2022). There are two types of VSWM: simultaneous and sequential (Allen et al., 2019). In simultaneous VSWM tasks, all information is presented at the same time. In sequential VSWM tasks, the presentation of stimuli is in a sequence. A systematic review on the relationship between VSWM and mathematical performance indicates that sequential VSWM may be particularly promising in studying the spatial-mathematical link (Allen et al., 2019). Yet, studies have only investigated the influence of sequential VSWM on numerical operation (i.e., computation problems) but not on mathematical reasoning (i.e., word problems), which highlights "an evident lack in the literature of such focused work" (Allen et al., 2019, p. 526). Therefore, this study will focus on sequential VSWM and how it relates to one-step arithmetic word problem solving.

Methods

We used data from 137 Year 2 students in England (50.4% female, 49.6% male; age range: 6.52-7.74yrs; mean age: 7.10yrs). A non-probabilistic convenience sampling method was used to recruit participants. A two-step recruitment procedure was used whereby four schools in South East England were recruited first, followed by the pupils. Two schools used the opt-out parental consent approach, and the other two schools used the opt-in parental consent approach. Students were administered a battery of tests one-to-one by the first author, over a span of two testing sessions lasting approximately 30 minutes each, spaced at least an hour apart (but no less than 30 minutes).

Each student was given a total of five tasks. The two spatial tasks were the Wechsler Abbreviated Scale of Intelligence-Second Edition (WASI-II) Block Design subtest, and PathSpan. The Block Design subtest, which requires the participant to use red-and-white cubes to recreate the design shown on the Stimulus Book, within a specified time limit, was used as a measure of spatial visualization (Atit et al., 2022). PathSpan, which is a digitalized version of Corsi Block-Tapping task on iPad, was used as a measure of VSWM (Hawes et al., 2019). Participants are presented with a sequence of dots that light up one at a time in a random pattern, which they must then replicate by touching the dots in the same order they were lit. The Wechsler Individual Achievement Test – Second UK Edition (WIAT-II^{UK}) Listening Comprehension subtest, which involves selecting a picture that matches a word or sentence and generating a word that matches a picture or oral description, was used as a measure of language ability. In this study, listening comprehension was deemed a more relevant measure of language ability than reading comprehension because the one-step additive word problems are read aloud to the participants (Diakidoy et al., 2005). The two mathematical tasks were the word problems task and WIAT-II^{UK} Numerical Operations subtest, which involves identifying and writing numbers, counting, and solving arithmetic computation problems.

The one-step additive word problems were developed through an iterative process for the purposes of this study. The discrete quantity problems were adapted from the literature (Carpenter et al., 1999); the continuous quantity problems were developed based on prior research. All problems have passed three rounds of review and revision, including two rounds of pilot studies, and one round of expert validation with a psychologist who specializes in children's mathematical development and a lecturer in mathematics education. There were 24 problems in total, with three problems in each of the eight categories of one-step additive word problems. Twenty-four unique number facts between 11 and 20 were used in the word problems, selected based on the National Curriculum and consultations with multiple primary school teachers. The number facts were randomized to create four final alternative versions (Forms A-D) of the word problems. Form A was given to 35 participants, while the other Forms were each given to 34 participants. The answers were scored as either correct or incorrect.

Using R and RStudio, confirmatory factor analysis (CFA) was performed on 24 dichotomous word problem items to identify the combination of dimensions with optimal model fit so that the problems can be categorized accordingly. The Weighted Least Squares Mean and Variance adjusted (WLSMV) estimator was employed. Then structural equation models (SEM) were used to answer the substantive question by investigating the relationship between word problem solving performance and spatial visualization and VSWM. Age, gender, language and numerical abilities were included as covariates as they affect word problem-solving success (Daroczy et al., 2015). This paper presents findings from the preliminary analysis of an ongoing study.

Findings

Reliability of Word Problems: CFA

The four versions of the one-step additive word problems were examined for equivalence using Generalized Mantel-Haenszel differential item functioning (DIF) analysis, with test scores as the matching variable. No DIF items were identified with Form D as the reference with a χ^2 value of 3.84 ($p < .05$) as the detection threshold. Therefore, the four test versions were treated as equivalent for subsequent analyses.

The 24 items were tested for internal consistency. The Kuder-Richardson 20 coefficient was 0.93 (95% CI [0.91, 0.95]), indicating strong internal consistency. Most items showed statistically significant tetrachoric correlations, ranging from $r = .14$ to .84. The items were tested for fit. All items had Loevinger's H values greater than .20 (ranging from .27 to .70). However, item 22 did not meet the unidimensionality criterion and was excluded from further analyses.

CFAs were conducted to test the categorization framework of one-step additive word problems (see Figure 1). Eight models, derived from the framework's dimensions—a 1-factor model, three 2-factor models, three 4-factor models, and an 8-factor model—were compared to identify the best-fitting model for investigating the substantive research question. The four-factor model of word problems, wherein quantitative relation and unknown dimensions were used, demonstrated the best fit, as indicated by the model fit indices ($\chi^2/df = 1.14$, $CFI = 0.99$, $TLI = 0.99$, $RMSEA = 0.032$). Therefore, the framework was revised accordingly (i.e., 2 [Quantitative Relation] x 2 [Unknown]) and the four categories of word problems (i.e., Dynamic Relation–Quantity Unknown, Dynamic Relation–

Relation Unknown, Static Relation–Quantity Unknown, and Static Relation–Relation Unknown) were used in subsequent analyses. All factor loadings were significant ($p < .001$), ranging from .70 to .99, indicating that the items reliably measured their respective factors.

Relationship between Word Problem Solving and Spatial Ability: SEM

Table 1 presents the descriptive statistics and correlations among variables. All five variables were significantly associated with each other, except for VSWM and listening comprehension. Performance on word problems had the strongest correlation with numerical operations ($r = .69$), followed by listening comprehension ($r = .46$), spatial visualization ($r = .38$) and VSWM ($r = .36$).

Table 1: Descriptive statistics and correlations among observed variables

	Listening Comprehension	Numerical Operations	Spatial Visualization	Visuospatial Working Memory	Word Problem Solving
Numerical Operations	.36**				
Spatial Visualization	.21*	.47**			
Visuospatial Working Memory	.16	.40**	.46**		
Word Problem Solving	.46**	.69**	.38**	.36**	
Mean (SD)	17.78 (3.89)	12.71 (3.26)	11.65 (6.83)	5.39 (1.22)	9.38 (6.96)

Note. $n = 137$; $^{**}p < .01$, $^{*}p < .05$; The score on Word Problem Solving is the total number of correct responses on items 1 to 24, excluding item 22.

Using the revised four-factor model of word problems (2 [Quantitative Relation] x 2 [Unknown]), SEM was conducted to investigate this study's substantive research question. The two predictors (spatial visualization and VSWM) and the four covariates (age, gender, numerical operations, and listening comprehension) were added to the latent factors using a step-by-step approach to test whether the predictors made unique contributions to word problem-solving performance.

As shown in Table 2, in Model 1, when only gender and age were included as controls, both spatial skills significantly predicted three of the four factors. However, the specific factors predicted by each spatial skill varied. VSWM was positively related to Factor 1, Dynamic Relation–Quantity Unknown problems ($\beta = 0.23$, $p < .05$); Factor 3, Static Relation–Quantity Unknown problems ($\beta = 0.21$, $p < .05$); and Factor 4, Static Relation–Relation Unknown problems ($\beta = 0.27$, $p < .05$); but not Factor 2, Dynamic Relation–Relation Unknown problems ($\beta = 0.19$, $p = .06$). Spatial visualization was positively related to Factor 1, ($\beta = 0.28$, $p < .01$), Factor 2 ($\beta = 0.44$, $p < .001$), and Factor 3 ($\beta = 0.24$, $p < .01$). However, it did not significantly predict Factor 4 ($\beta = 0.13$, $p = .22$).

In Model 2, when numerical operations was also included in the model as a covariate, only spatial visualization significantly predicted Factor 2 ($\beta = 0.25$, $p < .05$). In Model 3, when listening

comprehension was further added to the model as a covariate, spatial visualization no longer significantly predicted Factor 2 ($\beta = 0.22, p = .07$). Numerical operations and listening comprehension significantly predicted all factors.

Table 2: Standardized estimates and model fit statistics for the SEM models

	Model 1				Model 2				Model 3			
	Standardized Estimates (β)											
	Factor 1	Factor 2	Factor 3	Factor 4	Factor 1	Factor 2	Factor 3	Factor 4	Factor 1	Factor 2	Factor 3	Factor 4

Note. ***$p < .001$, **$p < .01$, *$p < .05$; Factor 1: Dynamic Relation–Quantity Unknown; Factor 2: Dynamic Relation–Relation Unknown; Factor 3: Static Relation–Quantity Unknown; Factor 4: Static Relation–Relation Unknown; Acceptable model fit: $\chi^2/df < 2$, $CFI > 0.95$, $TLI > 0.95$, $RMSEA < 0.05$.

Discussion

The role of spatial ability on early years arithmetic word problem solving has received limited attention despite the strong evidence of a causal spatial-mathematical link (Hawes & Ansari, 2020). Adapting Thompson's (1993) distinction on quantity and quantitative relation, as well as Davydov's (1982) conceptualization of discrete versus continuous quantity, and Vergnaud's (1982) conceptualization of dynamic versus static relation, this study proposed a novel framework for

categorizing one-step additive word problems. Using data from Year 2 students in England (6- to 7-year-olds), the framework was tested through CFAs and found a best fit four-factor model (2 [Quantitative Relation] x 2 [Unknown]), suggesting categorization of problems into four types: Dynamic Relation–Quantity Unknown, Dynamic Relation–Relation Unknown, Static Relation–Quantity Unknown, and Static Relation–Relation Unknown problems.

Preliminary analysis found that while spatial ability predicted performance on all four problem types, only spatial visualization continued to predict performance on Dynamic Relation–Relation Unknown problems when numerical ability was included in the model—but not when language ability was also included. This finding supports emerging evidence that spatial visualization is more important for solving novel, difficult problems, while VSWM is more relevant for familiar, procedural ones (Mix, 2019). The finding that young children's spatial ability may be more strongly associated with mathematical reasoning about the relations between quantities rather than the quantities themselves is not surprising given that spatial thinking is fundamentally relational (Hawes & Ansari, 2020). More interestingly, spatial ability may be relevant for mathematical reasoning about the transformation of not only quantities that are naturally measured relative to a reference point, such as position, but also quantities that are measured independent of a reference point, such as set size. This finding confirms studies that indicate that spatial ability is not only related to mathematical domains that are inherently spatial, such as geometry and measurement, but also mathematical domains that do not appear to be inherently spatial, such as numeration and algebra (Casey et al., 2015). Future research should explore the types of visual representations young children produce in solving one-step additive word problems and whether they have a mediation effect between spatial ability and word problem-solving performance, as has been done with older school children (Hegarty & Kozhevnikov, 1999).

Perceiving and describing structures of kindergarten children

Priska Sprenger[1], Barbara Ott[2] and Ángela Uribe[2]

[1] University of Education Freiburg, Germany; priska.sprenger@ph-freiburg.de

[2] St.Gallen University of Teacher Education, Switzerland

Successful structuring processes are an important basis for arithmetical learning. This includes describing (individually) perceived structures of a set. Therefore, a learning situation with two groups of children in the last year of kindergarten (age 5) in Switzerland was analysed. In this paper we investigate which structures the kindergarten children perceived and described and whether they oriented themselves towards other participants in their descriptions. The results of the study show that children use four main strategies in their descriptions and that they adopt descriptions from other children as well as from the kindergarten teacher. These takeovers can be seen both positively (children learn how to describe structures) and critically, as they may inhibit their own individual perceptions.

Keywords: Perceiving structures, describing sets, early mathematics education, interaction.

Introduction

There is a broad discussion about teaching and learning in early childhood (Björklund et al., 2020). Numerous studies focus on which materials and structures can support children in their structuring processes, especially regarding patterns and structures. Finger patterns used to support a part-whole understanding (e.g., Kullberg et al., 2020) play just as much a role as well as, for example, dealing with repeating, growing or spatial patterns, e.g. by structuring a set with counters so that you can quickly see how many there are (e.g., Lüken & Kampmann, 2018). This paper analyses a learning situation where kindergarten children in their final year (age 5) are asked to arrange a set in a ten-frame structure (egg cartons) to quickly recognize the number. The analysis focuses on the described structures and participant interactions, discussing their significance for individual learning processes.

Theoretical and empirical background

Structuring processes

Numerous studies indicate a correlation between a structuring perception of sets and both arithmetical and general mathematical learning (e.g., Dornheim, 2008; Kullberg et al., 2020; Lüken & Kampmann, 2018). There is also a correlation between the development of mathematical number concepts and the use of different structuring approaches, which serves as a foundation for arithmetical learning (van Nes, 2009). Additionally, quickly recognizing structured quantities is correlated with later success in arithmetic lessons (Dornheim, 2008). Perceiving sets in structures is also a prerequisite for determining cardinality through structural use: only by perceiving a set in (sub-)structures it is possible to use these structures to determine the cardinality of the set (Sprenger & Benz, 2020a, b). When determining the cardinality of a set, two processes can be distinguished (Steffe & Cobb, 1988; Benz, 2014): the process of perceiving the set and the process of determining cardinality. Benz (2014) developed a theoretical model illustrating the connections between these processes. Initially created through an inductive approach, the model has been empirically evaluated (e.g., Benz, 2014; Sprenger

& Benz, 2020a, b). This model distinguishes three ways of perceiving a set: as individual elements, as a whole, or in (sub-)structures. Each way of perception offers different possibilities for determining cardinality (e.g., Benz, 2014; Sprenger & Benz, 2020a, b). Since perception is an invisible process, it is challenging to analyse and understand. Several research approaches exist to investigate the process of perceiving a set in (sub-)structures (see Sprenger & Benz, 2020b). One way is analysing eye-tracking data to gain insights into the invisible process of perception (Sprenger & Benz, 2020a, b). These analyses have led to the insight that children do not always say what they think. For instance, when children state they have counted the elements of a set, it does not necessarily mean they do not perceive structures (Sprenger & Benz, 2020a). Two other ways for inferring perceptual processes include asking for verbal explanations of perceptions or having children create their own set representations (e.g., Benz, 2014; Gervasoni, 2015; Lüken & Kampmann, 2018). For all three possibilities, interpretations must be cautious to make accurate statements about children's perception of (sub-)structures.

Learning in interaction processes

Mathematical learning in kindergarten is embedded into kindergarten socialization. Interactions between the learners can be seen as a constitutive element for learning (Krummheuer & Brandt, 2001). Such a collaborative learning (Langer-Osuna, 2018) in mathematics education works through interaction between children, where identity (this refers to the way in which children position themselves and others in social interactions), learning and participation are closely linked. Various forms of participation can be distinguished (Krummheuer & Brandt, 2001): A person can adopt another person's wording and apply it to a new content, or they can adopt the idea behind the content and reformulate it. Complete imitation (content and wording) is also possible.

Research interest

Perceiving and describing structures is an important prerequisite for arithmetical learning and it is therefore crucial for children, to learn reliable structures they can use for their calculation strategies (Kullberg et al., 2020). As the ten-frame is also a useful didactical presentation for representing such reliable structures in primary school, this structuring is ideal for investigating how children in kindergarten age perceive and describe structures. This leads to the first research question:

1. How do children in the last year of kindergarten describe sets within a ten-frame-structure?

Talking about structures can be challenging for children, especially those of kindergarten age (Sprenger & Benz, 2020b). This raises the question of whether interaction with others can have an influence on their own descriptions, which leads to the second research question:

2. How do children adopt descriptions of others during a learning situation?

Method

The data presented in this paper are part of the project “MATHEsprechen in kindergarten: Using language repertoires in mathematics productively right from the start”, which investigates the overarching question of the extent to which the use of multilingual resources is stimulated in kindergarten children through mathematical activities with materials in a learning environment. The

mathematical content of the learning environment is about perceiving and using structures in sets. The whole learning environment consists of five parts (three kindergarten parts, two family parts) and was tested in a design experiment in September 2023 in two Swiss kindergarten groups: the first with 10 children (average age: 5 years, 7 months), the second with six children (average age: 5 years, 3 months) in the last year of kindergarten. For the analysis presented in this paper, we examine the learning situation from part 1, conducted in German with both groups. The same teachers (KG1 and KG2) led both situations. KG1 is a person of the research team. Both kindergarten groups had the same learning situation in which they should find a possibility to put a number of eggs in the carton so that one can quickly see, how many eggs there are. The egg cartons for 10 eggs are familiar to the children from their everyday life and resemble a ten-frame, a key visual tool in primary school, whose basic structure (bundle of tens, structure of fives, etc.) can be extended to a field of twenty and hundred. The two learning situations were videotaped with parental consent, transcribed, and coded using MAXQDA, a qualitative data analysis software that helps researchers organize, code, and analyse qualitative data. In a circular, inductive process, four main categories were identified, and participant interactions were coded and analysed.

Results

Strategies for describing structures

Four main strategies were identified when the children placed and described the quantities four, five and six, which are presented below. The adoption of the descriptions of the different participants is described for each group. These relationships are indicated by arrows in the following figures.

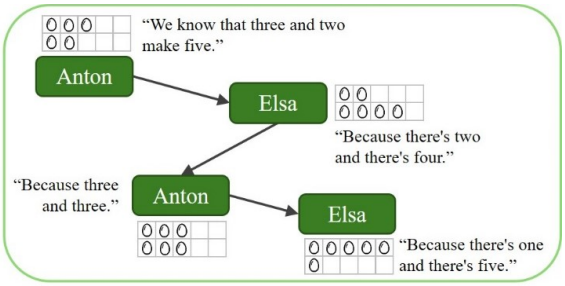

Figure 1: Adoption of the description for strategy "Describing subsets in rows" – (group 1)

In group 1 (green), Anton and Elsa each describe the quantities in two subsets. They name the number of eggs in each row, such as "We know that three and two make five" (Anton) or "Because three and three" (Anton) (see Figure 1). Elsa takes up this approach later and describes two more egg cartons using this strategy by describing the subsets of the two rows. This strategy was also observed in the second group (orange). Ester describes the egg carton with five eggs: "Because here are two and here are three" (see Figure 2). She first names the row with the smaller number of eggs and then the row with the larger number. Lilly adopts this approach immediately afterwards and also names the row with the smaller number first. Ester also keeps her strategy for other arrangements of the five eggs. She always names the smaller number of eggs first, regardless of whether this row is the top or the bottom row (see Figure 2). In an egg carton with one egg in the top row in the middle and three eggs in the bottom row (see Figure 2, right), Lami first describes the arrangement by counting the eggs

one by one. Anna describes the set in two subsets: “Because here are three and there one” and Lami adopts this description and says: “There three and here one.”

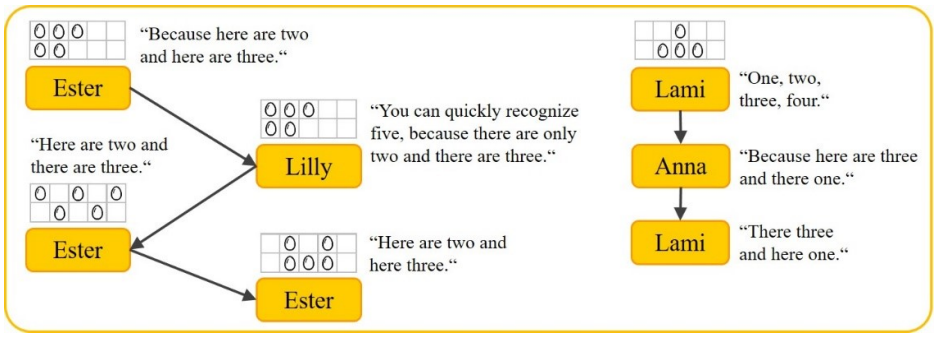

Figure 2: Adoption of the description for strategy “Describing subsets in rows” – (group 2)

Another strategy that children in both groups used to describe the quantities is to name subsets that do not correspond to the rows. In group 1 (see Figure 3) KG1 describes the set with five eggs: “I see four there and one more.” She points to the eggs on the left, which are arranged like a dice-four, then to the third individual egg in the top row. Naomi adopts exactly this description later (see Figure 3).

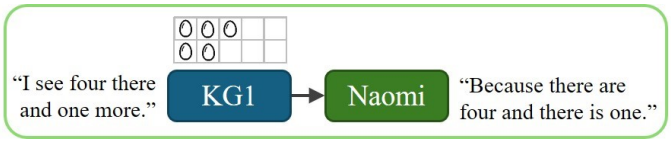

Figure 3: Adoption of the description for strategy “Describing subsets not in rows” – (group 1)

In the second group, Anna also describes this almost identical arrangement: “Because here are four and one” (see Figure 4). Lami takes up such a description in subsets and describes his arrangement: “Here is four and there is two.” He points with his hand to the four eggs on the left and the two eggs on the right (see Figure 4).

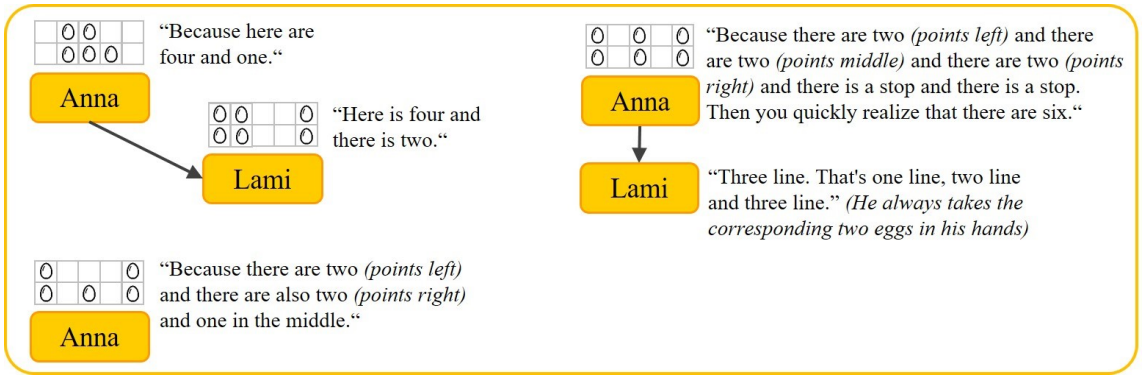

Figure 4: Adoption of the description for strategy “Describing subsets not in rows” – (group 2)

Anna arranges her eggs in three rows of two with the quantity of six eggs (see Figure 4). She points to a pair of two from left to right and explains: “...there are two and there are two and there are two...” Lami has initially sorted his eggs differently in his egg carton. He sees Anna’s arrangement and rearranges his eggs so that they resemble Anna’s arrangement. He also follows her example in the description and talks about three lines. He takes each of the two eggs in his hands and says “... That’s

one line, two line and three line [*sic*].” The arrangement of the five eggs in the egg carton in Figure 3 above was placed by KG2. Anna names three subsets of why she can quickly see that there are five eggs: “Because there are two and there are also two and one in the middle” (see Figure 4, above).

A third strategy, particularly noticeable in group 1, is referring to empty places (see Figure 5 and 6). Right at the beginning of the learning situation, Elsa argues that there is an empty place in the egg carton with three eggs in the top row and two in the bottom row (see Figure 5). She says: “Only one is missing, then it would be six.” She is referring to the empty place under the third egg in the top row, which would create the picture of a dice-six.

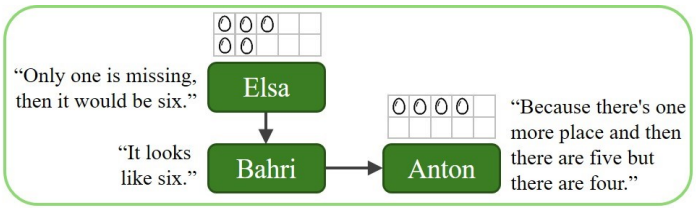

Figure 5: Adoption of the description for strategy “Referring to empty places” – (group 1)

Neither she nor Bahri, who takes up her idea and also says that it looks like a six in the same arrangement, explicitly names the dice pattern. At a later stage, Anton also explains that when four eggs are arranged in a row, it is easy to see that there are four because there is still a free place in the row (see Figure 5).

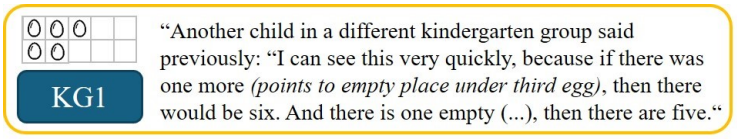

Figure 6: Adoption of the description for strategy “Referring to empty places” – (group 2)

In the other group, KG1 introduced this idea of referring to empty places in the conversation with the children. Throughout the learning situation, no child used this strategy. The fourth strategy observed was the explicit reference to dice patterns (see Figure 7 and 8).

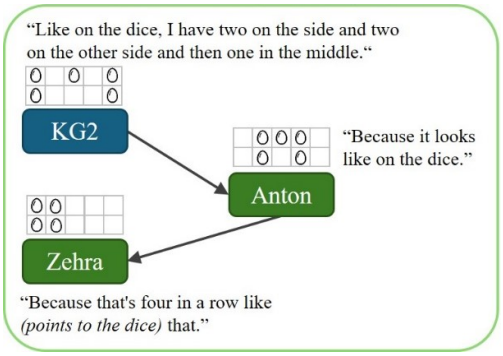

Figure 7: Adoption of the description for strategy “Referring to dice patterns (explicit)” – (group 1)

In the first group of children, KG2 has arranged the quantity of five eggs, which should correspond to the dice pattern of five. She describes: “Like on the dice, I have two on the side and two on the other side and then one in the middle.” Anton also describes a similar arrangement with a reference

to the dice-five (see Figure 7). In the arrangement of the four eggs, Zehra refers to the dice-four as a reason why it is so easy to see that there are four eggs. KG2 adds both to Ester's and to Anna's description of the five eggs (see Figure 8) that it looks like a dice pattern.

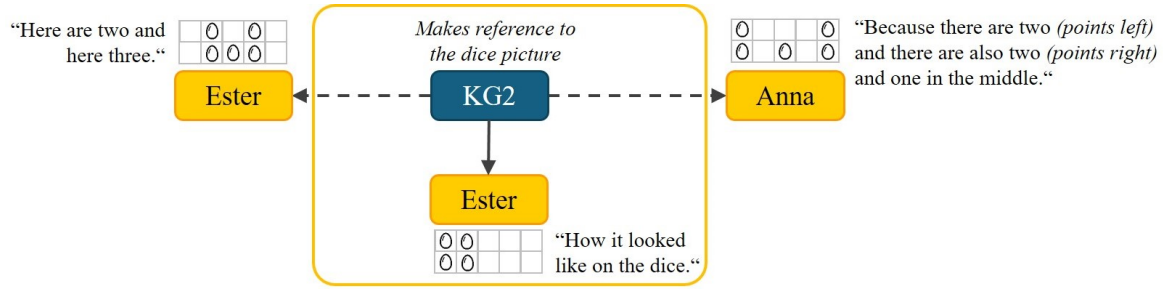

Figure 8: Adoption of the description for strategy "Referring to dice patterns (explicit)" – (group 2)

Only towards the end of the learning situation does Ester describe on her own initiative that the arrangement of the four eggs in the egg carton looks like on the dice. This situation is particularly interesting because a four was rolled with a large foam dice shortly beforehand and the dice pattern of four is still visible to her.

Adopting descriptions in interaction processes

As can already be seen in the previous results, the children refer to each other's descriptions in their descriptions. In the situation shown in Figure 3 there can be seen a complete imitation. Often the children adopt an idea of structuring (e.g. Describing subsets in rows), transfer this to a different arrangement of eggs, slightly (e.g. Figure 1) varying the wording. In Figure 5 Anton's reformulation of the idea to use the empty places differs greatly from Elsa's.

Lami, whose family language is Spanish and who is learning German in kindergarten, shows all forms of participation. In the situation shown in Figure 2, he first describes the arrangement of the eggs in the egg carton by tapping each one individually with his finger and counting them. Anna then explains that she recognises three (bottom row) and one (top row). Lami picks up on this explanation and names the same two subsets, pointing to the corresponding row at the same time (imitation). When laying the number of six eggs (see Figure 4, figures on the right), Lami shows another form of participation: He has initially arranged the eggs differently in his carton and then rearranges them to match Anna's arrangement (three groups of two). He then adopts the idea of Anna's description ("two and two and two") and reformulates it as "Three line [*sic*]. That's one line, two line and three line [*sic*]." He emphasises his explanation by raising each of the two eggs with his hands.

Different observations are made with respect of the role of the two KG in the participation. In group 1, the reference to the dice patterns was made by KG2 and this idea is taken up by Anton and Zehra (see Figure 7). Anton refers to almost the same representation as KG2 (dice-pattern of five), Zehra refers to the dice-pattern of four (see Figure 7) and reformulates the description of KG2. A naming of subsets that do not refer to the rows is initiated by KG1 in group 1 and is adopted by Naomi with the same wording (see Figure 3). In group 2, KG1 introduces a reference to empty places. However, this strategy is not taken up by any of the children (see Figure 6).

Discussion

The children in both kindergarten groups show a variety of strategies for describing quantities. Four main strategies can be identified: (1) Describing subsets in rows (see Figure 1 and 2), (2) Describing subsets not in rows (see Figure 3 and 4), (3) Referring to empty places (see Figure 5 and 6), (4) Referring to dice patterns (explicit) (see Figure 7 and 8). These descriptions allow assumptions to be made about the structuring perception of sets by different children. For example, in the case of Lami, it could be deduced that he does not perceive the set as subsets, but as individual elements (Sprenger & Benz, 2020a, b), since he is counting the eggs (Figure 2). This analysis changes, however, if we consider that Lami has taken over the arrangement of the eggs from Anna and that he initially arranged the four eggs differently in his egg carton. He does not succeed in interpreting a structure in this "foreign" arrangement and possibly uses counting as a familiar strategy (Sprenger & Benz, 2020a) to show that the eggs are the same in both cartons. This gives him the opportunity to "see" her individual perception of a structure and possibly adapt. This can also be seen in the exchange between Ester and Lilly (see Figure 2). After adopting Ester's description of subsets, Lilly ads: "Yes, or you count." As in the scene with Lami, it remains unclear whether we can say anything about Lilly's individual perception at this point, or whether she is merely repeating Ester's description, but counting would actually have been an equivalent or closer strategy for her (Sprenger & Benz, 2020a).

The results show that the children orientate themselves towards each other and adopt both, the idea or the wording of descriptions of structures (Krummheuer & Brandt, 2001). In this setting, children often take one strategy for describing quantities and apply it to different arrangements of eggs, typically adhering closely to the wording of their peers with slight modifications. This demonstrates how children possibly learn through social interaction and how they describe arrangements of quantities. This result must be interpreted with caution, as the children's prior knowledge was not measured in the study. Consequently, no assertion can be made regarding the children's extant structuring skills prior to the study, nor the influence these exerted on the observed interactions. However, the response to impulses from the KG varied between the two groups, indicating that a teacher's introduction of an impulse does not automatically lead to children adopting that description.

Learning from each other by adopting the wording and the strategy of describing quantities seems to play an important role in learning flexible structural descriptions of a set. This adaptation can certainly be viewed critically: It is positive that children learn how structures can be described. On the other hand, it is difficult to evaluate whether the child really perceives the set in this way, or whether individual perception is left "by the wayside". It is therefore important how the conversation is conducted in such a learning situation, what language is used, what questions are asked or what materials are offered. Such variety gives the child the opportunity to show what structures he or she perceives in the set. Careful planning is an important prerequisite, especially as children do not always say what they think (Sprenger & Benz, 2020a). Learning situations in groups seem to be very fruitful here, as children can learn from each other.

Acknowledgment

The study is conducted within the project MATHEsprechen. We thank the foundation Movetia for their financial support and the teachers and families for their participation.

Norwegian preservice teachers' views on the use of digital technology in early childhood institutions

Mona Karbaschi Vee[1], Dorota Lembrér[2] and Tamsin Meaney[1]

[1]Western Norway University of Applied Sciences, Norway; Mona.Karbaschi.Vee@hvl.no

[2]Malmö University, Sweden

With the inclusion of digital technologies in the Norwegian curriculum as a way that teachers can engage young children, including with mathematics, there is a need for teacher educators to understand how to educate preservice teachers to do this. A survey of 100 Norwegian preservice teachers provided insights into whether seeing digital tools being used on practicum affected their views about using digital technologies to engage children with mathematics. The results show few differences in responses between the groups. If anything, seeing digital technologies being used on practicum seemed to make the preservice teachers more uncertain about their inclusion. This suggests that teacher education courses need to include more input into how digital technologies could be used creatively and in play to engage young children with mathematical ideas.

Keywords: Preservice teachers, early childhood education, digital technologies.

Introduction

In early childhood education and care (ECEC), technology has been employed to enhance teacher-child interactions and is recognised as a valuable tool in teaching and learning (Granone & Reikerås, 2023). In the Norwegian curriculum, known as the Framework Plan (Ministry of Education and Research, 2017), there is an expectation that teachers choose digital technologies to best support children to play, be creative, and engage them with mathematical ideas. Learning is, thus, expected to occur through play, with children's interests being important for play. However, the integration of digital technologies is affected by a number of factors, such as a lack of pedagogical understanding, which is reflected in ECEC teachers' uncertainty about how to utilise digital apps, games, and programs (Pesonen & Valkonen, 2023). The may be part of the reason why this integration has only been partially achieved (Zilka, 2021). Earlier research (Vee, 2023; Vee & Meaney, forthcoming) shows that preservice teachers often only focus on the potential for learning of mathematics when they are considering how to use digital technologies in ECEC and do not seem to consider how it could be done through play. Adding to the complexity of integrating digital technologies, a 'moral panic' to do with screen time presents them as a threat to ECEC practice, which could inhibit their use by teachers (Demeshkant et al., 2023).

Therefore, it is important to identify the factors that support educators to use digital technologies in active and creative ways, based on age-appropriateness, which situates children as active participants in their knowledge development (Undheim et al., 2024). In relation to mathematics education, digital technologies or artefacts have been noted as affecting the interaction process (Granone & Reikerås, 2023), thus, requiring special attention in ECEC courses. Yet, in a literature review by Papavlasopoulou et al. (2024), little research has investigated how ECEC teacher education courses support preservice teachers to integrate digital technologies into their practices, including to support

young children's mathematics education, problem-solving or critical thinking skills. Of the research which has been done, little was undertaken in countries with a play-based curriculum, such Norway (Ministry of Education and Research, 2017).

To contribute to research in this area, there is a need to better understand ECEC preservice teachers' knowledge and attitudes, including to do with digital pedagogical practices (Zilka, 2021). In particular, there is a need to understand whether seeing digital technologies on practicum placements in ECEC affects preservice teachers' beliefs about using digital technologies for engaging children playfully and creatively with mathematical ideas. Although it is commonly considered that practicum experiences can affect preservice teachers' views and attitudes, Österling and Christiansen (2022) found that "research on practicum-as-usual shows minor development of self-efficacy and conceptualizations of mathematics, and sometimes even a negative development of conceptions of reform-oriented mathematics teaching" (p. 9). The studies they reviewed suggested that the differences between preservice teachers were considerably, restricting possibilities that practicum alone might be sufficient to change attitudes or practices.

To determine if seeing digital technologies being used on practicum as part of the teacher education courses affected preservice teachers' views about how they could develop children's mathematical understanding, our research question is: Do preservice teachers who have seen digital tools being used in ECEC have different views on using digital technologies with young children?

Methods

The data were collected through an anonymous online survey from Norwegian ECEC preservice teachers (PTs) in the first two months of 2024. An online survey was chosen because it provided the opportunity to gather data from a range of people in different geographical places, within a limited period of time (Braun et al., 2021). A hundred and twenty-five preservice teachers, from the three campuses of the Western Norway University of Applied Sciences, who participated in a compulsory course on mathematics and language and had undertaken at least one practicum in ECEC completed the survey. Of these 125, 100 provided responses to the questions of interest in this study.

The survey consisted of 22 questions. These were mostly multiple-choice questions and statements requiring Likert scale responses. The PTs could choose between "disagree fully", "disagree partly", "undecided", "agree partly", and "agree fully" and "don't know". This paper focuses on the questions about using digital technologies creatively and in play to engage young children with mathematical ideas. We amalgamated the responses of the first five questions to form two groups of preservice teachers: those who had; and those who had not seen digital technologies on practicum. The questions asked about whether the preservice teachers had seen tablets, computers, mobile phones, digital play, or other digital technologies during practicum. The preservice teachers who gave responses to the survey questions, "I saw the equipment but didn't see it in use", "don't remember", "no, never" were considered to have not seen digital technologies (21 responses). The preservice teachers who stated that they had seen one or more digital technology being used "every day", "once a week", "once a month", or "only once during the practicum" formed the group, who were considered to have seen digital technologies being used (79 responses).

We compared the responses of these two groups of preservice teachers to the questions about the usefulness of apps/robots to provide mathematical learning and play opportunities, about whether digital technologies could increase children's problem-solving competence, and whether it was too early for children to use digital technologies for learning mathematics in ECEC. The last question was about whether digital technologies should be used in ECEC.

The results are presented as graphs that compare the responses between the two groups. The title of each graph includes the survey question. When there were differences in the means in the Likert scale results, we used Fisher's exact test to determine if the differences were significant.

Results

There were very few significant differences between the responses from the two groups for both the general questions about using digital technologies for mathematics and specific questions about the connections between the use of digital technologies creatively and in play to engage young children with mathematical ideas. This suggests that seeing the digital technologies being used on practicum may have little effect on preservice teachers' views.

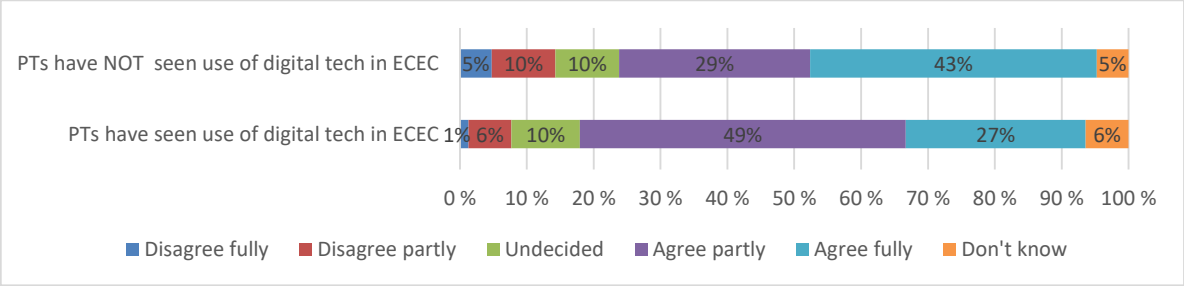

Figure 1: Responses to the statement about the usefulness of apps for providing mathematical learning opportunities

Figure 1 shows the preservice teachers' responses about the use of apps for providing opportunities to engage young children with mathematics. In both groups, the vast majority of preservice teachers were positive about using apps, with 15% of preservice teachers who had not seen digital and seven percent who has seen them being used partly or fully disagreeing about their use for engaging children in mathematics. Fisher's exact test showed no significant difference between the groups for any of the categories or when partly and fully disagree and agree were combined. There were similar percentages of both groups who were "undecided" or who "didn't know" if apps could provide mathematical learning opportunities. This question had the smallest percentages of "undecided" or "didn't know" responses suggesting that more preservice teachers were certain about their responses than they were about the other questions.

In Figure 2, of the group of preservice teachers who had seen digital technologies being used on practicum, almost twice as many were undecided about whether apps could be used to provide learning opportunities through play. Of those who had an opinion, there were no significant differences between the groups about the usefulness of apps for providing opportunities to learn through play. In both groups, there were higher percentages of preservice teachers who did not agree with the statement. This suggests that rather than providing preservice teachers with experiences of

how apps could contribute to children playfully learning through them, practicum experiences may have made them less certain.

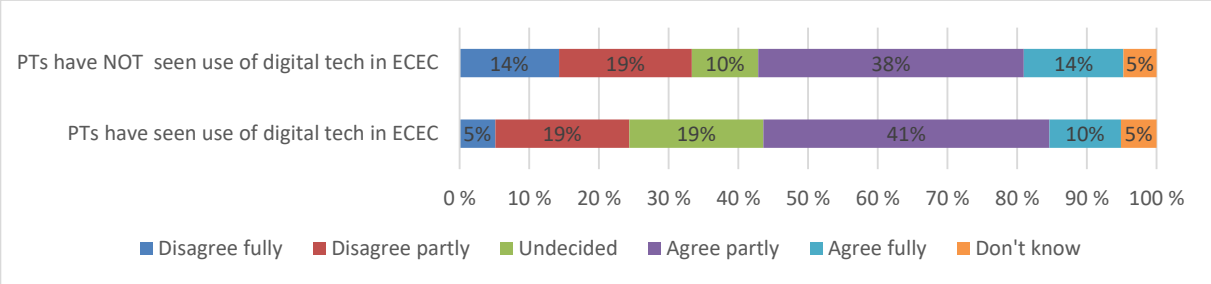

Figure 2: Responses to the statement about the usefulness of apps for providing learning opportunities in play

In regard to the questions about whether robots could provide opportunities for mathematical learning (Figure 3) and learning through play (Figure 4), there were much higher percentages of preservice teachers in both groups who did not know. This suggests that teacher education needs to provide preservice teachers with experiences of how robots could be used in ECEC.

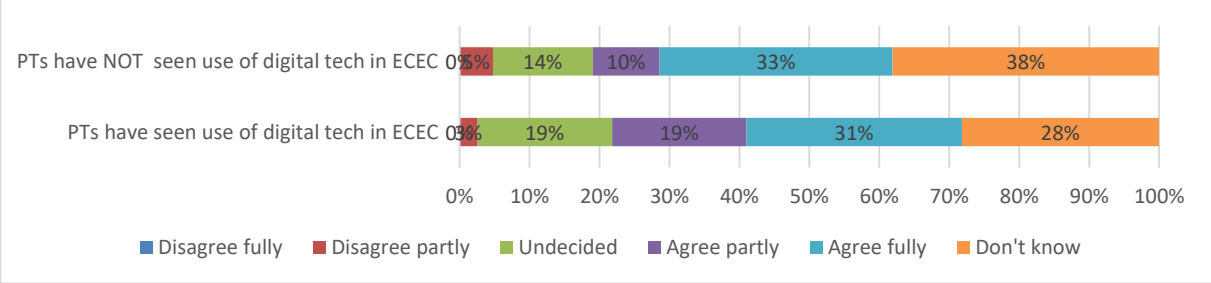

Figure 3: Responses to the statement about the usefulness of robots for providing mathematical learning opportunities

The results in Figure 3 suggest that of those who had an opinion, a much higher proportion of both groups partly or fully agreed with the statement about using robots for supporting children's engagement with mathematics than disagreeing partly or fully. There was no significant difference between the preservice teachers who had seen the use of digital technologies in ECEC and those who had not.

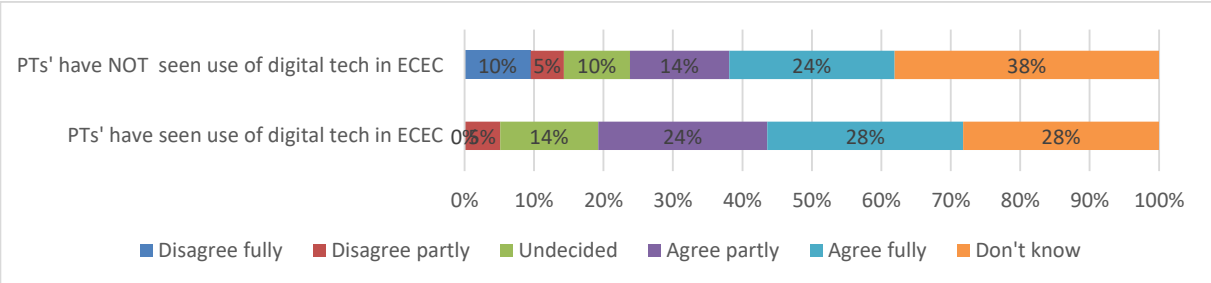

Figure 4: Responses to the statement about the usefulness of robots for providing learning opportunities in play

Both groups of preservice teachers were also generally positive about robots being useful for providing learning opportunities through play (Figure 4), although not to the same degree as they had been with apps. However, those who had not seen digital technologies being used in ECEC were less positive than those who had seen digital tools being used, although the difference was not significant.

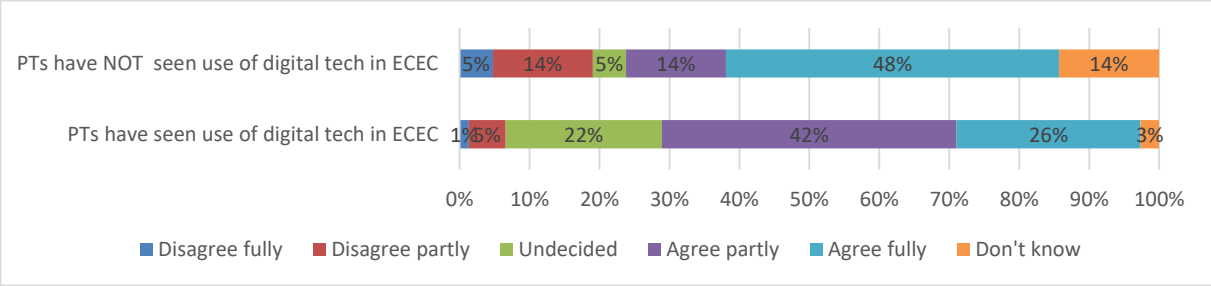

Figure 5: Responses to the statement about the usefulness of digital technology for problem-solving

The preservice teachers in both groups responded positively to the statement that digital technologies could support problem-solving competence (Figure 5). The Fisher's exact test shows a significant difference (P=0.015) in responses to "agree partly" between the preservice teachers who have seen the use of digital technologies and those who have not seen it in use. However, when the respondents for partly agree were combined with fully agreed, there was no significant difference between the groups. This suggests that although positive about the usefulness of digital technologies for developing children's problem-solving competencies, those who had seen digital technologies being used were less certain. This is reinforced by 22% of this group being undecided about this statement, compared to five percent of those who had not seen digital technologies being used.

Figures 6 and 7 show the preservice teachers' responses to general statements about digital technologies being used in ECEC. Although one statement was generally negative about using digital technologies "children were too young to use digital technologies for learning mathematics" and the other more positively worded, "digital tools should be used in ECEC", the responses showed similar results, with no clear trend.

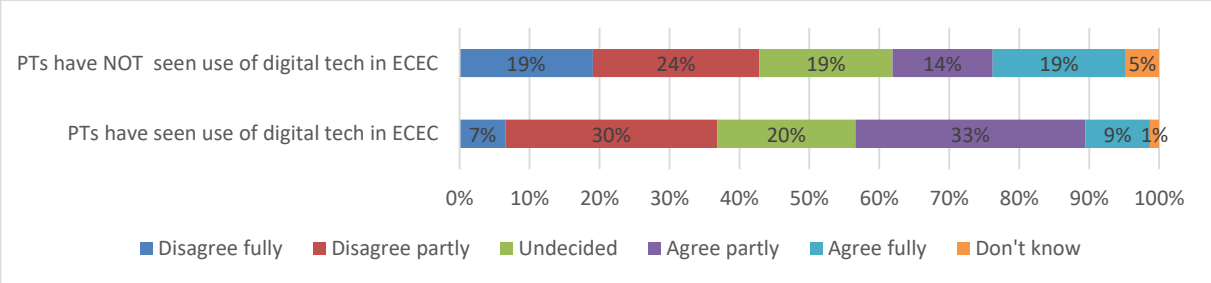

Figure 6: Responses to statement "children were too young to use digital technologies for learning mathematics"

The preservice teachers in both groups did not show a clear indication of agreement or disagreement with the statement about using digital technologies for learning mathematics (Figure 6). Although the preservice teachers in the group who had seen digital technologies were slightly more in agreement with the statement, there were no significant differences in the responses. These responses contrast

with the much more positive responses to the statements about the use of apps and robots for learning mathematics. This suggests that teacher educators may find that in different circumstances, the preservice teachers have different opinions.

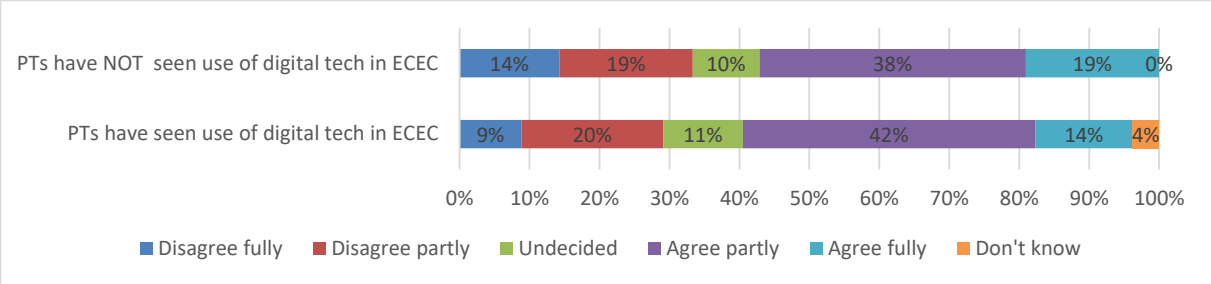

Figure 7: Responses to the statement about the usefulness of digital technologies in ECEC

Although the majority of the preservice teachers in both groups responded positively to the question of whether digital technologies should be used in ECEC (Figure 7), there was still a large number who were negative or undecided about this statement. When the responses "disagree fully" and "disagree partly, "undecided" and "don't know", and "agree partly" and "agree fully" were combined, there were no significant differences between both groups. Given that the Framework Plan (Ministry of Education and Research, 2017) requires the use of digital technology, it may be more difficult for the preservice teachers to disagree with this statement than one about the specific case of young children learning mathematics.

Discussion and conclusion

In this paper, our aim was to determine whether the preservice teachers' views were different if they had completed a practicum in which they saw digital technologies being used in regard to their potential contributions to children's mathematical understanding, problem-solving and play. Similar to the results identified by Österling and Christiansen (2022), it seemed that practicum experience had only a minor effect. In the responses to most of the statements, there were no significant differences in the number of preservice teachers who responded in one way or another. Although there was a difference between those who answered "partly agree" in regard to the statement about digital technologies supporting children's problem solving, this difference disappeared when the preservice teachers who had answered partly agreed were combined with those who fully agreed.

Although we distinguished between those who had seen digital tools being used in ECEC and those who had not, the responses to the survey did not provide sufficient details to know exactly what experiences the preservice teachers had. Future research is needed to know whether the kind of experiences with digital technologies could influence the results. As over 20% of the preservice teachers had not seen any digital technologies being used, there seems to be a need for professional development of current ECEC teachers to ensure that the requirements of the Framework Plan (Ministry of Education and Research, 2017) are met in ways that contribute to children learning through play.

We presume that the preservice teachers who had not seen digital technologies being used in ECEC would have similar views to those held by preservice teachers before they completed practicum. If

this is the case, then it seems that preservice teachers became slightly more uncertain about the use of digital technologies as a result of seeing them being used. Therefore, there also seems to be a need for improved teacher education so that preservice teachers gain more experiences with digital technologies being used creatively and in play to engage young children with mathematical ideas. For example, although an earlier study showed that digital technologies can be an important stimulus for developing problem-solving skills (Granone & Reikerås, 2023), a quarter of the preservice teachers who had seen digital technologies were either undecided or did not know whether they could be used to develop children's problem solving. In the study of Undheim et al. (2024) the preservice teachers identified a lack of personal interest and engagement with the use of digital technologies. However, the results from our study suggest that the preservice teachers held opinions about using digital tools. For example, apps were considered valuable for children's engagement with mathematical ideas. These opinions, aligning as they do with the requirements in the Framework Plan (Ministry of Education and Research, 2017), can be a basis for improved teacher education.

Preservice teachers' responses to statements about digital technologies being used in ECEC highlighted specific areas about which they may need more support. In particular, preservice teachers were less certain about digital technologies contributing to children learning through play and seemed to have little knowledge about how robots could be used in ECEC. Therefore, teacher education courses need to provide more input about the use of digital technologies for preservice teachers that can support learning through play, problem solving and utilising young children's creativity to engage with mathematical ideas. However, as noted by Papavlasopoulou et al. (2024), little research has been done on how to develop and implement courses on using digital technologies in ECEC. Given the uncertainty in preservice teachers' responses, further research is needed.

Acknowledgement

Funding for this part of the project was provided by Western Norway University of Applied Science ECEC teacher education program with the aim of improving the teacher education. This project is also connected to KindKNOW (273404) and DiCoTE (326667).

Opportunities for learning in parent-child discussions about written numbers in everyday life

Chronoula Voutsina[1], Lois George[2] and Stephanie Flack[1]

[1]University of Southampton, Southampton Education School, Southampton, UK; cv@soton.ac.uk

[2] The University of The West Indies, Mona Campus, School of Education, Kingston, Jamaica

This paper presents findings from the 'Written Numbers in Everyday Life' project, that has been implemented with families of 3–5-year-old children in the UK and Jamaica. The project aims at empowering families to utilise opportunities for talk about written numbers on everyday objects in their environment. We conducted a qualitative thematic analysis of 72 posts (39 from the UK, 33 from Jamaica) that participating families uploaded to an online platform. Three themes emerged in discussions that parents reported that they had with their child: comments with a conceptual focus, comments with a conceptual and mathematical/numerical focus, comments with a conceptual and social purpose focus. The findings provide insights into the wide-ranging opportunities for learning that arise when parents are prompted and supported to recognise and use numerals in the everyday environment, as a learning resource.

Keywords: Written numbers, preschool, home environment, family engagement with learning.

Introduction

Family engagement is an early influencing factor on children's knowledge and dispositions towards mathematics, which, in turn, are linked with early and persistent attainment gaps (James-Brabham et al., 2023). The frequency of intentional parental engagement (Napoli & Purpura, 2018) and parental talk about number (Levine et al., 2010), have been highlighted as important for early mathematics development. Furthermore, positive dispositions, such as curiosity and interest in mathematics ideas are key factors in children's mathematics learning (Ginsburg et al., 2008), and these too are influenced by home experiences (Gervasoni & Perry, 2017). However, research has shown that some parents may be reluctant to engage with mathematics (Gervasoni & Perry, 2017) and parental engagement may be best achieved by incorporating early maths "within parents' overall, existing roles and responsibilities" (Mazzocco & Claessens, 2020, p. 3).

This paper presents findings from the 'Written Numbers in Everyday Life' project, that has been implemented with families of 3–5-year-old children in the UK and Jamaica. The project aims at empowering families to recognise and utilise everyday opportunities for talk about written numbers and their multiple meanings. The study that is reported here is part of the wider project. It is underpinned by the idea that the everyday knowledge and skills that are developed by diverse families' everyday experiences need to be recognised as 'funds of knowledge' (Moll et al., 1992), that can be built upon and used as resources for supporting learning. Thus, we explore the opportunities for learning that can emerge within family-based activities that prompt and support intentional adult-child talk about numerals in everyday environments, within two different cultural contexts. Eason et al. (2022) highlight the need to understand how diverse family contexts and activities can enhance early engagement with mathematics. This study addresses this critical gap in

early mathematics learning by seeking to answer the following research question: What themes emerge in adult-child conversations about the meanings of written numbers in everyday life, as reported by parents in the UK and Jamaica?

Fostering intentional parental talk about numerals in the environment

Written numbers, that is, Hindu-Arabic numerals in digit form (e.g., 8, 63) are cultural artefacts that represent quantitative and non-quantitative ideas (Brizuela, 2004). Research exploring young children's experiences with number in the family context has focused mainly on the impact of mathematically focused family activities on competencies such as counting and computational skills (e.g., Levine, et al., 2010). However, children see "very few examples of the computational use of written numbers before they come to school" as "written numbers, in our society, represent a large variety of numeral and/or quantitative concepts, as well as being exploited for other purposes." (Sinclair & Sinclair, 1984, p. 174). In everyday life, preschool children encounter numerals on everyday objects, such as, food/games packaging, books, the TV, and various kinds of signs that may have quantitative meanings (e,g., representing cardinality) and also numerals that have "social uses" and "nonquantitative purposes" (Tolchinsky, 2003, p. 110), such as, numbers on buses, phone numbers and barcode numbers, which are underpinned by social knowledge and communicate meanings that help us organise our lives. The role of adults (carers, teachers) in supporting children to make connections between their knowledge about numerals at preschool/school and the social knowledge about the use of numerals outside school, is important, for minimizing the risk of school mathematics becoming an alienating experience (Munn & Kleinberg, 2003).

As part of a previous study that adopted a phenomenographic approach (Voutsina & Stott, 2023), we found that, to make sense of the messages/meanings that numerals communicate in their everyday environment, preschool children combine knowledge of the following: Recognition of *a numeral* as a number (and not as a letter, for example), recognition of *the object* on which a numeral appears, recognition of *the context/location/situation* within which they encounter a numeral, and recognition *of other symbols* that may accompany a numeral, denoting its meaning (e.g., £, Kg, ml). Based on this evidence, we designed the "Written Numbers in Everyday Life' programme that aims to foster children's curiosity and awareness about the multiple meanings of written numbers outside the classroom, and support family talk about written numbers in everyday life. The programme involves a sequence of family-based Number Spotting challenges that prompt families to look for, at home or outside, either a specific numeral on different objects and in different contexts/locations that represents different concepts and communicates different meanings (e.g., the written number 4 on different objects representing, age, size, price etc.), or look for different written numbers that represent the same, specific concept (e.g., look for different written numbers that all show size on items of clothing/shoes, or different numbers that show age, or numbers that show quantity etc). In designing the challenges that aim at making children aware of the multiple meanings that numerals have in life outside the classroom, we drew from elements of Variation Theory (Björklund, 2016). We used variation and invariance to contrast examples of numerals, objects, contexts, other symbols and the multiple concepts/meanings that numerals represent, in order to support discernment of each of the aforementioned elements separately, as well as simultaneous discernment of more than one of the above elements and their relationship. All challenges are included in a set of printed family

activity postcards. Each postcard includes the same three prompts that adults are encouraged to use in conversations with their child about the spotted number: *What* does the number tell us? *Who* needs to know this? *Why*?

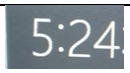
Implementation and method of data collection

Teachers in participating preschools send two activity postcards to each family every week, for 6-7 weeks. For each classroom, the researchers create a unique link to a Padlet board (Padlet is a software that provides access to shared digital boards where individuals or groups can upload and share visual/textual material). The instructions given to parents are to upload a photograph of the numeral that their child spotted as part of each challenge, showing the object and the location where it was spotted, together with a short comment on what they discussed about the number with their child. The Padlet enables us to collect data that provide insights on how different families engage with the programme, including the contexts, locations, activities and interactions that parents report.

We have introduced the programme to families of 3–5-year-old children in the UK, as well as in Jamaica, as we were interested in examining its transferability to a different cultural context. Jamaica was selected because English is the official language of teaching and the curriculum is still broadly aligned with the English curriculum. For this paper, we focus on the Padlet data that we collected from: three preschools (3–4-year-old children) and one Reception class (4–5-year-old children) in the UK, and two preschools (3–5-year-old children) in Jamaica, during the first year of piloting the use of the Padlet. Ethics permission was granted by the Ethics Committee of the University of Southampton (ERGO 80253) and the University of The West Indies, Mona campus (CREC-MN.099, 2023/2024).

Data analysis

Family engagement with the Padlet was voluntary and varied. Some families who participated in the programme did not post on the Padlet at all or did not post regularly. Parents' comments in posts varied in detail, focus and length. We received a total of 127 Padlet posts from UK families and 105 posts from parents in Jamaica over the course of seven weeks. To address the research question, we focused our analysis on a selected sample of 72 posts (39 from the UK and 33 from Jamaica). These were posts with comments that provided information on the discussion that parents reported that they had with their child about the meaning of the spotted number. Posts with comments related to numeral recognition/identification (e.g., "AC noticed there was a 2 and a 5 on our door!") or other brief comments with no reference to the parent-child discussion, were not included. All posts were anonymous. Therefore, we do not have data on how many different families provided the analysed comments. To analyse the comments, we applied inductive thematic analysis (Braun & Clarke, 2006). Through a "compare-and-contrast" approach (Boyatzis, 1998), we grouped comments under categories based on the aspects of the meaning of numerals that parents focused on in their reported discussions with children.

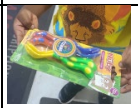


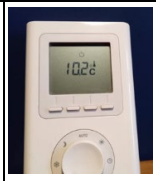
Findings

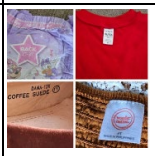
Three themes emerged: comments with a conceptual focus, comments with a conceptual and mathematical/numerical focus, and comments with a conceptual and social use/purpose focus.

Comments with a conceptual focus

With comments grouped under the conceptual focus category (examples shown in Table 1), parents reported having a discussion with their child about the concept that the spotted numeral represented, such as, the cost of items in the supermarket (e.g., post 1, Table 1), the age or size communicated by numerals on clothing labels (post 2, Table 1), without any further detail about the discussion.







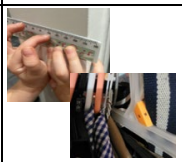


Table 1. Comments focusing on the concept that the numeral represents

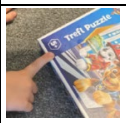
1		Whilst out shopping, we discussed the numbers on the shelves and the symbols next to them that show it means the price of the item. Theo was able to identify single numbers, such as 7, 6 etc. (UK)
2		CM saw that there was a number on her sandal. She did not know what the number meant. We had a discussion about shoe sizes. (JM)
3		We found the number 10 at the park and we spoke about how it is used as a date every month! (UK)
4		He visited my work and whilst on the laptop he says mommy I see the number 5. I said, yes, it's the time. (JM)

Comments with a conceptual and mathematical/numerical focus

Some comments indicated parent-child discussions that extended to mathematical/numerical-related notions and skills, such as counting, and/or references to specific attributes of the spotted numerals (e.g., naming of 2- or 3-digit numbers, discussing digital numbers). For example, parents reported prompting their child to count items in a box with the numeral 5 on, or practice verbal counting up to the spotted number (post 1, Table 2), or supporting their child's reading of 2-digit numbers (post 2, Table 2). The third post in Table 2 includes reference to multiplicative ideas ("two of each"), while post 4 reports the parent's use of the opportunity arising from spotting numeral 3 on a digital clock, to explain about analogue and digital representations of time and notions such am/pm, day and night. After a child's query whether 10.2 that they spotted on a thermostat is a 10 or not (post 5, Table 2), the parent uses this as an opportunity to discuss decimal numbers and the symbol for degrees Celsius, making a link with how the temperature that is represented by the numeral is experienced by them at home. Posts 6 and 7 (Table 2) are indicative of discussions extending to notions such as shorter/longer width in the context of spotting numeral 3 on a ruler, and references to comparing higher/lower values and to the notion of weight, based on numerals spotted on children's clothes.



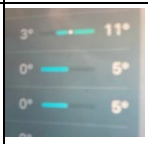


Table 2. Comments that include conceptual and mathematical/numerical focus

1		We found a bath toy in the pharmacy. I asked him to count the items in the package and he did so correctly. I then asked him how many toys are in the package and he said 5. I then asked him to show me the number 5 on the package and he did. We talked about the fact that the number says how many things are in the package. (JM)
2		Caria spotted this number on the column of my coworkers house all on her own and showed it to me. She said "mommy, it's a 4 and 0" I told her the number is 40 and we had a discussion about addresses/street numbers. (JM)
3		We talked about the fact the number 2 appearing twice is because it is saying that two of each item is in the package. (JM)
4		We talked about the time during the day and at night (am and pm), we tell you why sometimes the clock shows the number 15 instead of 3. (UK)
5		“Is that number 10 or not?” We found lots of 10s. This is the only one Jacob questioned if he had found one or not. We had a conversation about decimal place and the symbol of °c relating to temperature. He thought 10.2°C felt cold, which it certainly did. (UK)
6		She looked around the house and selected numbers found on clothing and shoes. She took a few pictures and we talked about the difference in numbers (higher value vs lower value). (UK)
7		“Put it up here and it’s longer, put it down here and it’s shorter.” Margot learning to measure the wall after spotting the number 10. (UK) Akeem and I spoke about the different clothes size, that each represents measurement and that the smaller number is for someone who weighs less. (JM)

Comments with a conceptual and social use/purpose focus

The examples of posts included in Table 3 are indicative of opportunities recognised and used by parents to further extend their discussions of the meaning of numbers to the social use of the spotted numerals, that is, the socially shared rules and conventions that numerals communicate in everyday situations, which inform and shape everyday behaviours, such as, driving behaviour (post 1), identifying locations (post 2, Table 3), protecting information (posts 3 and 5) and deciding what to wear (post 6, Table 3).

Table 3. Comments that include conceptual and social use/purpose focus

1		We talked about how here the speed limit of the road is 50mph but on the bend part of the road there is a lower maximum speed as you need to drive slower on the bend to safely keep control of the car. (UK)
2		We visited a pharmacy. She noticed the numbers hanging above each aisle and started counting. She was able to identify all the numbers. When she finished counting, I led her back to aisle #3 where I explained to her that in a store, things that are similar are placed together so that we can find them easily. "Like the toy aisle; all the toys are in aisle #2 over there". (JM)
3		We found the number "3" on one of my daughter's toys. We realized that numbers are like keys. They help unlock secrets, like combinations to locks. We decided to remember the number “3” and maybe use it as a passcode to open a drawer (3.3.3). (UK)
4		Number 5+ on this picture tells us that these puzzles are for children from 5 year and over otherwise it could be dangerous. Children under that age should not be playing with it. (UK)
5		We went to the ATM to get some cash. I showed him how to enter the PIN, I told him the numbers. He correctly entered the PIN! I told him these numbers stop the bandits from stealing our money. (JM)
6		Harper helped to check the weather on Mam’s iPad. He found the temperature was 5 Degrees C on two days. We talked about checking the weather before we do outside activities so we know what to wear. (UK)

The examples of posts included in Table 3 are indicative of opportunities recognised and used by parents to further extend their discussions of the meaning of numbers to the socially shared rules and conventions that numerals communicate in everyday situations, which inform and shape everyday behaviours, such as, driving behaviour (post 1, Table 3), identifying locations (post 2), protecting information (posts 3 and 5) and deciding what to wear (post 6).

Comments that included two or all three of the identified foci of discussion were categorised under more than one theme. Numerical analysis of the occurrences of the three themes in parental comments (Table 4) shows that overall, a focus on the social use of numerals was the most frequently included aspect of meaning within the analysed sample of posts, as it was identified in 44% of all analysed comments. A focus on the represented concept only, was reported in 28% of comments from the UK and 39% of comments from Jamaica. Discussions extending to a numerical/mathematical focus when talking about the meaning of a numeral were reported slightly more frequently in the UK sample (33%) than the sample of comments from Jamaica (27%).

Table 4: Number of parent comments under each theme of meaning related to spotted numerals

Theme	UK (39 posts)	Jamaica (33 posts)	Total (72 posts)
Conceptual focus only	11 (28%)	13 (39%)	24 (33.3%)
Numerical/Mathematical focus included	13 (33%)	9 (27%)	22 (30.5%)
Social use/purpose focus included	19 (48%)	13 (39%)	32 (44.4%)

Conclusion

Parents' self-reporting posts may have been affected by factors, such as, time commitment and what parents recall or choose to report. Acknowledging the limitation that parental posts do not constitute a direct record of discussions that may or may not have occurred, our aim is not to draw generalised conclusions about parental discussions. Rather, the contribution of this study is in unearthing and delineating the qualitative nature of opportunities for learning that can arise, and parents recognised and reported, within the two cultural contexts of our project. The study, thus, addresses the need for understanding the potential that diverse everyday contexts have for family engagement with number-related ideas (Eason et al., 2022). Our analysis revealed examples of reported parent-child discussions that addressed conceptual, mathematical as well as social aspects of written number meanings, across both cultural contexts. This provides important insights into the multifaceted and wide-ranging opportunities for learning that can emerge in the home environment when parents are prompted and supported to use written numerals that appear on everyday objects, as a learning resource, for drawing children's attention on numbers as attributes of their environment and triggering early discussions about different aspects of their meaning. A focus on the socio-cultural meanings and uses of written numerals in everyday situations provides a fruitful and powerful channel for empowering an inclusive approach to family engagement with various aspects of number. This is because knowledge of the messages that environmental numerals communicate and their social purposes in organising everyday life is knowledge that is socially developed (Moll et al., 1992) and most families have, within their own cultural contexts and environments. We thus concur with Eason et al., (2022) who note that embedding activities within the families' everyday life and diverse contexts can provide the potential for context-based and socio-culturally relevant intervention for all children and families.

Acknowledgment

The 'Written Numbers in Everyday Life' programme has been developed by Chronoula Voutsina and Debbie Stott, University of Southampton, UK, with funding from Research England: Participatory Research Fund 2023. We are grateful to all participating families.

Guardians' views on digital tools in preschool

Maria Walla[1], Hanna Palmér[2] and Jorryt van Bommel[1]

[1]Dalarna University, School of Teacher Education, Falun, Sweden; wmr@du.se

[2]Linnaeus University, Sweden

This paper presents a discourse analysis of responses to a survey conducted with guardians of children from three Swedish preschools. Two questions are elaborated on: (1) What Discourses occur in guardians' communication about digital tools in preschool? and (2) What are the implications of these Discourses for mathematics education in preschool? Four construed Discourses show diverse views on digital tools, with most guardians taking a positive view as long as these tools are used in such a way that children become producers of content, not consumers. This is in line with research highlighting the importance of focusing on how digital tools are used rather than on for how long. The study shows the importance of preschools clearly communicating when, how, and why digital tools are used in preschool.

Keywords: Digital tools, early childhood education, guardians, questionnaire, discourse analysis.

Introduction

In Sweden, preschool is offered to all children aged 1-5. The national preschool curriculum states that every child should use digital tools in a way that stimulates development and learning. To accomplish this, preschool should give children the opportunity to develop adequate digital skills and an understanding of the digitalization they encounter in everyday life. Further, children should be offered the opportunity to use mathematics to investigate and describe their environment and solve everyday problems (National Agency for Education, 2018).

Digital tools can support mathematics education in preschool. For example, digital tools that require creative solutions and/or reasoning, and that offer children guided discoveries and experiments, promote interaction and communication about shared mathematical ideas (Palmér, 2015; Trigueros et al., 2014). Further, digital tools can combine visual presentations, animations, and sound, thus providing a multimodal environment in which children can see, hear, and act simultaneously. They can also offer multilingual options, which can promote mathematics learning in multicultural preschools, where digital representations have proven to be easier for young children to manipulate and understand than comparable physical materials (Trigueros et al., 2014). Nikolopoulou (2020) has shown that digital mathematics teaching activities may include several mathematical topics such as serialization and sorting of objects, time and space concepts, numbers, classification, and matching. In a teaching intervention by Palmér (2017), programming was used to facilitate preschoolers' learning of mathematics. The children developed their ability to mentally compare and connect (real) movements with maps and symbols. Further, the children demonstrated an ability to mentally envision, hold in mind, and conceptualize actions and relationships between paper maps, gridded maps, and symbols. Thus, several studies indicate the broad potential in using digital tools when teaching mathematics in preschool.

In autumn 2023 the Swedish government changed direction radically when they decided that the preschool should essentially be screen free for the children. Since then, notions about "screen free" and "screen time" have been frequently debated, including among researchers from different disciplines (see for example Government Offices of Sweden, 2023). Some adhere to the World Health Organization's (WHO) recommendation that children under the age of 5 should have as little screen time as possible (The Public Health Agency of Sweden, 2024). Others challenge these notions by referring to educational research, emphasizing that digital tools are used differently at home compared to in educational settings, and arguing that digital tool use at school should not be equated with screen time. The debate about screen time focuses on *how long* children spend sitting passively in front of a screen (see for example Nilsen & Kjällander, 2023). However, the argument for limiting passive screen time is often misconstrued as a need to limit the use of digital tools in general, regardless of *how* children are using them. These debates, alongside the ongoing revision of the curriculum, have led to uncertainty in Swedish preschools. Are they to use digital tools, and if so, how and when? To meet this uncertainty, a combined development and research study was initiated in collaboration between researchers and three preschools aiming to develop a scientifically based strategy for a screen-wise preschool. Quite early in the study, the preschool teachers expressed uncertainty about how to respond to guardians, i.e. the person legally responsible for a child's care and well-being, who sometimes questioned and probed the preschools' use of screens based on the debate described above. It was decided to conduct a survey to find out more about the guardians' views on the use of digital tools in preschool, the extent to which they knew what digital tools are used for in preschool, and the extent to which, and how, their children use digital tools at home. This paper reports these results with a special focus on whether and how the guardians' views may influence the use of digital tools in preschool mathematics education. The following two questions will be focused on: (1) What Discourses occur in guardians' communication about digital tools in preschool? and (2) What are the implications of these Discourses for mathematics education in preschool?

Previous research

Today's preschoolers have never lived in a wholly analogue world, and they are using various digital tools at increasingly younger ages. As digital tools have become part of our everyday lives, the concept of screen time has become important for many guardians (Byrd-Bredbenner et al., 2017). Most guardians consider it important to regulate their children's screen time (Livingstone et al., 2015), in line with WHO's recommendations. However, as digital tools are so central to modern family life, it can be difficult to live up to WHO's recommended limitation, and guardians of young children may feel stressed and stigmatized as a result (Sandberg et al., 2024). Furthermore, there is a risk that the recommendations might lead to a focus solely on screen time instead of on how and why digital tools are used. Guidelines could support guardians in exploring digital tools with their children (Sandberg et al., 2024) as the use of these tools at home differs from their use in preschool (Nilsen & Kjällander, 2023). At home, digital tools are often oriented towards consumption, whereas in preschool, guided by trained teachers, children can explore the tools and use them to become producers of content. According to Craft (2012), the shift from being a consumer of digital content to becoming a producer can give children a sense of ownership and control over digital tools, helping them become more critical and reflective about how they use such tools in the future.

The debate about screen time is often dominated by a black-and-white view in which children's use of digital tools is seen as either a threat or an opportunity (Stephen & Edwards, 2018). However, Nilsen and Kjällander (2023) state that it is more important to focus on what digital tools in preschool can contribute instead of arguing that they are superior to analogue tools. Further, these authors emphasize the importance of quality in digital interaction and its educational purpose rather than the amount of screen time. This is in line with international research highlighting that the question should be about how screens are used rather than for how long. It is not the digital tool itself that determines whether its use will have a positive or negative effect; rather, it is how it is used that is important. The use of digital tools in mathematics teaching can have a positive, negative, or neutral effect, depending on the specific digital tool or software, how it is used, and for what purposes (Baki et al., 2011). Guardians in Sweden have expressed a desire to participate in their children's preschool learning (Öhman et al., 2024). To promote their participation, preschool teachers need to communicate with the guardians about what their role might be in this context (Öhman et al., 2024).

Theoretical framework

In this study, discourse analysis in line with Gee (2014a; 2014b) forms both the theoretical framework and the analytical tool (see Method). According to Gee (2014b), language creates meaning in social practices while also deriving its meaning from social practices. Language reflects and creates the existing reality, where discourses can be seen as part of the ongoing processes that continuously create and reshape meaning in and of social practices (Gee, 2014b). Small <u>d</u>iscourses and big <u>D</u>iscourses are distinguished from each other: in <u>d</u>iscourses, the relationship between words and sentences is described, while <u>D</u>iscourses can be seen as ways of using language, influenced by social positions and power relations (Gee, 2014b). In the present analysis, the construed <u>D</u>iscourses are seen as part of the social practices that create and reshape meanings of using digital tools in preschool.

Method

The empirical material in this paper is from a combined development and research study conducted in collaboration between researchers and three preschools, initiated by the principal for these three preschools. A survey was sent by e-mail to all guardians (n=288) in June 2024 by the principal. After two reminders were sent, 104 guardians had answered the survey, resulting in a dropout rate of 64%. The survey included open and closed questions and allows for a quantitative and qualitative analysis.

The analysis for this paper first focused on guardians' answers to the scaled questions: *What is your opinion of digital tools in preschool?* and *Are digital tools an important part of preschool education?* After that, the free text answers to the questions: *What do you think when you read/hear "digital tools in preschool"?* and *Are digital tools an important part of preschool education? were analysed.* Data consisting of written communication and the specifics in our two research questions led to eight of Gee's 28 tools for discourse analysis (Gee, 2014a). In line with Gee, the discourse analysis initially considered the larger context (#26, #23), and after that, how the guardians used communication to build meaning in a specific context (#17, #14). Finally, the analysis focused on the guardians' explicit expressions (#9, #7) and how the language was used related to this context (#2, #1). The following questions were posed in relation to each tool:

- Deixis Tool (#1): What is talked about as given, based on the context?
- Fill-In Tool (#2): What is not said? What knowledge and what assumptions are required for the communication to be clear?
- Doing and Not Just Saying Tool (#7): What are the guardians trying to do (keeping in mind that they may be trying to do more than one thing)?
- Why This Way and Not That Way Tool (#9): Whose voice is heard? What are the guardians' intentions when they talk the way they do?
- Significance Building Tool (#14): What words are used to build or keep the significance of some things and not others in the guardians' communication about digital tools?
- Relationship Building Tool (#17): How are words being used to build, sustain, and change relationships of various sorts among the guardians, other people, and/or institutions?
- Situated Meaning Tool (#23): What situated meanings, related to the context, do words and phrases in the guardians' communication have?
- Figured World Tool (#26): What typical stories or figured worlds are assumed in the guardians' communication?

Above, Gee's tools are presented as a bulleted list. However, the process of discourse analysis is iterative, meaning that the analysis moved back and forth from large to small perspectives. Through this discourse analysis, four Discourses were construed.

Results

According to the survey responses, 21.2% of guardians find that digital tools are used too much in preschool. At the same time, only 13.5% stated that they were aware of which digital tools are used in preschool, which indicates that some of the guardians stating that digital tools are used too much are not sure about which digital tools are being used. On the question of whether digital tools are an important part of preschool, 28.8% of guardians answered "yes", 49.0% answered "partially", and only 15.4% answered "no".

In the following, the four Discourses are presented, each starting with a translated quotation from the data. The Discourses should be understood in light of the results above, showing that there are more positive or partially positive voices than negative ones regarding the use of digital tools in preschool.

Digital tools need to be introduced early

Our children are growing up in a digitalized world and need to be equipped for the future.

In their communication about digital tools in preschool, the guardians describe how these tools should be introduced early so that "children can keep up with the technological development in society" and understand the world around them. Introducing digital tools in preschool can support children in developing these skills.

To strengthen the argument for using digital tools in preschool, the guardians use expressions such as "good and obvious", "a fun way to learn", "a large part of society", "it's not the 1800s", "the present is digital", and "part of the future". The guardians describe how the use of digital tools has changed and increased since they were children – a trend that will continue into the future. If children

do not receive support in using digital tools, they risk falling behind. Therefore, digital tools should be included in all parts of society.

Digital tools imply screen time, which is harmful to children

I think screen time should be limited as much as possible for children.

In their communication about digital tools in preschool, the guardians use the term "screen time" instead of "digital tools". Further, they write about how children under a certain age should avoid screen time since this may have a negative effect on their eyes and brains. When referring to screen time, the guardians use expressions such as "negative", "unnecessary", "overdose of screens", and "used incorrectly". Together, the guardians' expressions contribute to an image of screen time as something considered harmful to young children.

Implicit in the guardians' communication is a view that all people in society get too much screen time. The guardians express a desire for preschool to refrain from using digital tools and take responsibility for the fact that the children get an "overdose of screens". Mentioning an overdose of screens indicates a view that children are using digital tools in places other than preschool. In their communication about digital tools as screen time, the guardians support their argument by referring to studies showing how screen time is harmful to young children. These first two Discourses, *Digital tools need to be introduced early* and *Digital tools imply screen time, which is harmful to children*, contrast with each other and show guardians' different views on *when* to introduce digital tools.

Digital tools need to be used in the right way

It completely depends on how it is used. It can definitely be positive, but of course it has to be in line with the content.

When using digital tools, children should be producers.

In their communication about digital tools in preschool, the guardians describe how such tools can be an important part of the preschool if they are used in a balanced way and combined with other preschool activities. Hence, the use of digital tools does not appear to be an "either/or" issue since the guardians recognize that they can be used in combination with other activities. The guardians express the use of digital tools in preschool as something positive if they are used "in the right way", referring to *how* digital tools should be used by both children and teachers.

When the guardians express that digital tools should be used in the right way by the children, they mean that the children should be allowed to use the tools creatively and as producers of content. When they express that digital tools should be used in the right way by the teachers, they mean that the teachers should use the tools both to promote children's learning and to vary the teaching. Implicit in the guardians' communication about digital tools is that there is a right way and a wrong way to use them, and only if they are used in the right way can they be viewed positively. The guardians express their doubts about the use of digital tools as a form of entertainment or as a babysitter.

Digital tools take the focus away from what is important

I would have preferred a clearer focus on motor skills, creativity, physical activity, handicrafts.

It is a big question; what type of content is used, and why it is done digitally instead of "for real"?

The guardians describe a risk of overusing digital tools as they may replace other activities and ways to teach. They describe how digital tools are sometimes prioritized over "real" activities. They reveal a view of digital tools as something different and disconnected from play, creativity, physical activity, and social interaction. Implicit in their communication is a view that all preschool activities should preferably be carried out without digital tools.

Further, the guardians express that digital tools may affect how the teachers carry out their teaching. For example, instead of singing with the children, a teacher may choose to show a video of someone singing. Overall, the guardians' communication can be understood as expressing a fear that both the content of the preschool education and how the teaching is carried out will be too much imbued with digital tools. Using digital tools in preschool is not seen as "the right way" to teach and it should therefore not be prioritized. Instead, proper teaching is seen as involving free play and other activities that do not involve digital tools. These last two Discourses, *Digital tools need to be used in the right way* and *Digital tools take the focus away from what is important*, reflect guardians' contrasting views on *how* to use digital tools in preschool.

Discussion

The four Discourses construed in this analysis show different views on digital tools in preschool. This section focuses on implications of these Discourses for mathematics education in preschool.

The Discourses *Digital tools need to be introduced early* and *Digital tools imply screen time, which is harmful to children* reflect contrasting ideas related to *when* to introduce digital tools. If these Discourses affect whether digital tools will be introduced in preschool or not, implications for mathematics teaching are that children might not be given the opportunity to benefit from their use. Children will then not benefit from the support that digital tools can give regarding creative solutions, reasoning, interaction, and communication of mathematical ideas (Palmér, 2015; Trigueros et al., 2014). Further, multicultural schools might not be able to offer the multimodal environment that digital tools can provide and that can be effective in promoting mathematics learning.

The Discourses *Digital tools need to be used in the right way* and *Digital tools take the focus away from what is important* reflect contrasting ideas related to *how* digital tools are used in preschool. In the first Discourse, the meaning of digital tools can be related to previous research about screen time and a consumption-based use of screens at home (e.g. Nilsen & Kjällander, 2023), as digital tools are seen as isolated from other activities in preschool. *Digital tools need to be used in the right way,* the meaning of digital tools can be related to previous research about children exploring such tools in several ways and becoming producers of content (e.g. Nilsen & Kjällander, 2023). In this Discourse, digital tools are seen as something that can be used in a balanced way and combined with other preschool activities. These different views may have implications for how digital tools are used in mathematics education in preschool. For children to benefit from the use of digital tools as a way to promote learning in mathematics, they ought to be producers of content rather than consumers. Further, previous research shows how producing content can contribute to children becoming more critical and reflective about how they use digital tools in the future (Craft, 2012).

In this study, we do not claim that the Discourses construed are the only ones occurring in society or among guardians (especially because of the relatively high dropout rate mentioned earlier), but they occur to varying degrees in the preschools investigated here and are therefore something that the teachers at these preschools need to deal with. Also, Discourses never occur in a vacuum, which is why further studies at other preschools and in other contexts where mathematics in preschool is discussed (for example, the government) could be an interesting continuation of this study. Regarding the dropout rate, another methodological reflection concerns which guardians chose to answer the survey. A large non-response rate in digital surveys is common, but those who answer often do so because the topic is important to them (Bryman, 2016). Thus, we assume that guardians with strong positive or negative opinions about digital tools in preschool have answered the survey to a greater extent than guardians with a neutral opinion. If this is the case, the guardians with a strong negative view on digital tools make up an even smaller part of the total than the results show.

To conclude, 77.8% of the guardians answered "yes" or "partially" in response to the question of whether digital tools are an important part of preschool, and only 15.4% answered "no". The largest group of guardians (49%) answered "partially". This can be related to the Discourse *Digital tools need to be used in the right way*, addressing guardians' opinion on *how* digital tools are used. This indicates that the majority of guardians view digital tools as an important part of preschool, as long as children are producers of content, not consumers. This is in line with research highlighting the importance of focusing on how digital tools are used, rather than for how long (Baki et al., 2011; Nilsen & Kjällander, 2023). In line with Öhman et al. (2024), our study shows the importance of preschools clearly communicating how digital tools are used and why. To ensure such communication, it is important to highlight the use of various types of digital tools, including screen-free options such as robots. Without clear communication about how digital tools are used, guardians may base their views about digital tools on experiences of how such tools are used at home and on what is promoted in media.

Merging or separating mathematics education and play – does it affect learning?

Lena Karlsson

Linnaeus University, Department of Mathematics, Sweden Lena.Karlsson@lnu.se

Keywords: Play-responsive, teaching, preschool, cardinality, MPM

Introduction

Early numeracy is crucial in children's mathematical development. However, few studies have investigated how to teach numeracy in preschool education (Björklund & Palmér, 2019). Additionally, in several European countries there is an ongoing discussion on the relationship between play and education. This study examines the teaching of cardinality through an intervention where mathematics education is merged with play. The aim is to explore how merging mathematics education and play enhances preschool children's learning of cardinality. In this exploration, the Mediating Primary Mathematics (MPM) framework (Askew & Venkat, 2017) is used to compare the quality of instructional sequences that integrate play and mathematics (PRMT) with instructional sequences where mathematics teaching (MT) is separated from play. Through the use of MPM, the learning opportunities in these different instructional sequences are elaborated on. The research question is: What opportunities for learning in mathematics are provided when children participate in a play-responsive teaching (PRT) intervention?

Mediating Primary Mathematics (MPM)

MPM is a theoretical framework developed to analyse and develop mathematics education (Venkat & Askew, 2017). The framework emphasizes that the teacher conveys mathematical content in mathematics teaching through 1) artefacts, 2) inscriptions, and 3) discussions and gestures. The third component is divided into methods for a) generating or validating solutions, b) building mathematical connections, and c) building learning connections through explanations and evaluations. These three aspects of teaching can be categorized into distinct quality levels. High-quality teaching is more profound and more structured, enabling students to learn in the teaching situation. In lower-quality teaching, materials and examples are used in a one-sided or disjointed manner, and children's responses are not considered or developed, which can lead to a reduction or absence of learning opportunities in the situation (Venkat & Askew, 2017).

Methods

The study is conducted through educational design research, which involves a cyclical process of planning, implementation, and evaluation of teaching. Over the course of one year, the researcher and three preschool teachers met every other week to plan and discuss play-responsive activities. These activities were implemented by the teachers with children in various groups. The implementations were video-recorded. In total, four activities were developed and documented through 73 video recordings from the three different preschools. The analysis was conducted using content analysis. In the first step, the focus was on PRT (Pramling et al., 2019) with the codes "as if", "as is", responsiveness, alterity, agency, metacommunication, and intersubjectivity, as well as codes for early

numerical understanding, including cardinality, subitizing, ordinality, wholes and parts, and representations (verbal expressions, gestures, and body language). This coding was performed using NVivo software. The result of this first analysis was three characteristically different sequences in the video documentations: sequences of play (without explicit mathematics), sequences of mathematics teaching (MT, without explicit play), and sequences with merged play and mathematics teaching (PRMT). In the next analysis step, the MT and PRMT sequences were analyzed using the MPM framework. The purpose of this analysis was to delineate the distinct characteristics of cardinality teaching and to examine the mathematical learning opportunities offered to preschool children in these specific sequences.

Result and discussion

The analyses show that MT sequences include more structured artifacts and more connections to mathematical contexts. According to the MPM framework, MT sequences offer richer learning opportunities through structured artifacts, where the teacher systematically emphasizes cardinality and numbers by linking artifacts, contexts, and body language. This structured teaching support can support children's mathematics learning. In MT sequences, the focus is often on one child, providing a more personal learning experience but reducing interaction between children. PRMT encourages an exploratory, playful approach that promotes creativity and agency. Fewer and unstructured artifacts are used in PRMT, sometimes overshadowing the mathematical content. This may be because the teacher needs to be responsive to children's questions, even those not about mathematics, allowing children to influence and make independent decisions during play. PRMT activities often include multiple children, making mathematics relevant to the entire group. The two sequences complement each other by offering different learning opportunities. MT sequences provide clear connections between artifacts and mathematics, improving children's understanding through structured teaching. PRMT sequences encourage exploration and creativity, allowing children to develop their mathematical understanding through playfulness and independence. Together, these sequences can create a balanced learning environment where children benefit from both exploratory play and structured learning with mathematical concepts.

Finger use for addition and subtraction in preschoolers

Stephanie Roesch and Jamine Hartmann

University of Tuebingen, Hector Research Institute of Education Sciences and Psychology, Germany; stephanie.roesch@uni-tuebingen.de

Keywords: Finger use, early arithmetic, embodied cognition.

Introduction

Empirical evidence suggests that numerical cognition has its roots in bodily and sensory experiences, known as embodied numerosity (Moeller et al., 2012). As many children use their fingers to show their age or to do basic arithmetic, finger counting has been claimed a prime example of embodied numerical development. However, its association with early arithmetic can be understood not only by looking at *if* children use their fingers successfully to calculate (Krenger & Thevenot, 2024), but also at *how* they use them (Björklund et al., 2019). In the current study we combined both perspectives by examining for the first time for different task types how many children use their fingers to calculate, (i) in case manipulatives are provided vs. not provided, (ii) in an addition vs. a subtraction task. Moreover, we aimed at investigating (iii) whether finger use is associated with accuracy and (iv) how children use their fingers.

Method

The following analyses are based on data of n=39 German kindergarten children (M=6.2 years, SD=0.3, range 5.7 to 6.8 years), with an even gender distribution. The children were presented with three types of tasks: a verbal addition problem with manipulatives, a symbolic addition problem, and a symbolic subtraction problem. All children were interviewed individually, in a quiet room of the kindergarten. Videos of the interviews were taken with a digital camera on a tripod. In the verbal addition task, the interviewer read aloud the word problem and placed the corresponding number of marbles in front of the child ("Here you have 5 marbles [interviewer puts five green marbles in random order on the desk]. Here I have 4 marbles [interviewer places another four blue marbles on the desk]. How many marbles do we have together?"). For symbolic addition and subtraction, the problems were presented visually (3 + 5, 9 − 5) and were read aloud to children. We analyzed both accuracy and frequency as well as type of finger use. Type of finger use was coded in line with Björklund et al. (2019) as (i) structured (i.e., instantly showing finger patterns without counting single units), (ii) dynamic (i.e., extending fingers successively for counting), and (iii) strategy mix (i.e., aspects of structured and dynamic finger use are combined). We used a Binomial test to examine if children used their fingers significantly more often in case manipulatives were not provided. Furthermore, we used a Chi-Square test to investigate whether finger use is significantly related to accuracy.

Results

First, we examined how many children used their fingers in the verbal addition task with manipulatives vs. the symbolic addition and subtraction tasks. Results revealed that only one child (3%) used the fingers when manipulatives were provided, whereas n=12 children (31%) and n=10

children (26%) used their fingers to solve the addition and subtraction task, respectively. Thus, significantly more children used fingers, when no manipulatives were provided (Binomial test, $p<.001$), while no significant difference was observed for addition vs. subtraction ($p=.30$). Interestingly, most children used fingers for only one task type ($n=6$ for addition only, $n=4$ for subtraction only) and $n=6$ (15.4%) used fingers for both addition and subtraction. Second, we analyzed whether finger use is associated with accuracy. Overall, $n=27$ children solved the symbolic addition task correctly (69%), whereas only $n=10$ children did so for subtraction (26%). As regards finger use, 83.3% of finger users solved the addition task correctly, whereas only 63.0% of non-finger users did so. However, this pattern did not turn out to be significant ($\chi^2(1)=1.62$, $p=.28$). For symbolic subtraction, 50.0% of finger users solved the task correctly, whereas only 17.2% of non-finger users did so. The association between finger use and accuracy turned out significant for subtraction ($\chi^2(1)=4.19$, $p=.04$), indicating that finger users were more successful than non-finger users. In a last step, we examined *how* children used their fingers. For addition, most finger users applied a mix-strategy ($n=5$; four correct), followed by dynamic ($n=4$; three correct) and structured strategy ($n=3$; all correct). For subtraction, most finger users used a dynamic strategy ($n=5$, only one correct), followed by mix ($n=3$; all correct) and structured strategy ($n=2$; one correct).

Discussion

Results revealed that 26% to 31% of children used fingers to solve the subtraction or addition problem when no manipulatives were provided, which is in line with results reported by Björklund et al. (2019) and Krenger and Thevenot (2024). In terms of accuracy, we particularly found a more pronounced advantage in using fingers for subtraction compared to addition. A reason for these differing results might be that children were in general more proficient in addition and finger use might, thus, not have been a major advantage in this case. A closer look at *how* fingers were used for subtraction revealed that dynamic finger use was less successful compared to other strategies. Although our sample size was too small to draw reliable conclusions, this pattern is still in line with results reported by Björklund et al. (2019). However, our conclusions should be substantiated by further studies, as we only looked at one task of each type and a small sample size.

This paper summarises in five themes the 25 papers and 9 posters contributed to the TWG14: University Mathematics Education (UME) at CERME14, and presents an overview of the three thematic discussions conducted in the TWG, before concluding with reflections and suggestions for future research.

Keywords: University mathematics learning and teaching, resources, teaching interventions, mathematics for non-mathematicians, mathematicians and mathematical practices.

Introduction

We opened the activities of the TWG14 at CERME14 by honouring recently departed colleagues who contributed significantly to what we today call UME research: Guy Brousseau, Ed Dubinsky, Simon Goodchild, Anna Sierpińska and David Tall. We also revisited the activities of the group since its launch at CERME7 in 2011, concentrating on an overview of achievements between CERME13 (July 2023) and CERME14 (February 2025). This period saw five special issues related to UME – three in the *International Journal of Research in Undergraduate Mathematics Education* (Dreyfus et al., 2023; Ely & Jones, 2023; Geraniou et al., 2023), which celebrated a decade of contribution to UME research (Dreyfus et al. 2025), one in *Educational Studies in Mathematics* (Martino et al., 2023) and one in *ZDM – Mathematics Education* (Engelbrecht & Borba, 2024); specialised conferences – e.g., the fifth ERME topic conference of the *International Network for Didactic Research in University Mathematics* (INDRUM2024); a book (Bridoux et al., 2023); and, a book chapter (Winsløw et al. 2023). This year, TWG14 received 37 paper and 11 poster submissions. The review process resulted in 25 papers and 9 posters being presented at the conference, all of them published in CERME14 proceedings. This year, we noticed a decrease in the number of contributions compared to previous years, with 36 papers and 17 posters in the CERME13 proceedings. Such decrease was expected due to the emergence of the new TWG25 on "Calculus Teaching and Learning" as well as to the new policy on registration numbers. Contributions address at least one of five themes: *teachers and teaching at school and university level*; d*igital resources*; *mathematics and non-mathematics specialists*; *learning and teaching mathematical topics and practices*; and, *mathematicians and mathematical practices*. Activities included a combination of parallel sessions for paper discussion

and plenary sessions for poster teasers and thematic discussions. The three thematic sessions covered: *digital resources; teachers and teaching at school and university;* and *research methodologies and methods.* In what follows, we summarise contributions in each theme, and the thematic discussions, before concluding with reflections and potential ways forward.

Paper and poster contributions

Teachers and teaching at school and university level

Eleven papers and three posters were classified in this group that proved to be the most popular. Gueudet and Doukhan present a literature review about *Didactic Contract(s)*[1] in UM teaching, particularly teaching characteristics and their impact on students' learning. The review identified three categories of studies that focus on changes of didactic contract at the secondary-tertiary transition; limitations in the students' mathematical activity due to didactic contract rules; and, interventions proposing an 'alternative contract'. Still with attention to teaching environment, and through a commognitive (*Theory of Commognition*, *ToC*) and *Communities of Practice* (*CoP*) perspective, Hooper et al. explore how an inter-community team of mathematicians and mathematics education researchers can redesign an introduction to university mathematics course to facilitate shifts in the lecturer's pedagogical and students' mathematical discourses. Witty et al. discuss the same course from the perspective of the lecturer aiming to redesign the course. Teaching actions towards students' enculturation to university mathematics discourse is the focus of Karavi and Schüler-Meyer, who are interested in *Opportunities to Learn* offered in first-year teaching by four lecturers. The paper exemplifies such opportunities in a session about mathematical proof. Teaching practices towards first year students' introduction to fundamental concepts of Analysis is also the topic of Petropoulou et al. The analysis draws on Radford's *dialectical nature of tensions* to highlight how the lecturer's background in both mathematics and mathematics education contributes to the development of an alternative teaching culture. Butler and Buchbinder use the perspective of *teacher noticing* to study the development of a learning assistant in Calculus over two years. They observe that his noticing shifts from describing particular aspects of student work to reflecting on mathematics generally. With attention to teaching preparation, Canogullari and Radmehr draw on the *Anthropological Theory of the Didactic* (*ATD*) to identify conditions and constraints experienced by lecturers when designing, adapting or selecting tasks. Thorup Eich-Høy analyses mathematics lectures as a way to teach mathematics. Using an original approach based on ethnographic methods and psychoanalytic theory, the paper states that lectures can create situations of resonance, embodiment, and durational pleasure in contrast to the common critiques of lectures as outdated or passive.

This year we welcomed a body of contributions related to the role of mathematics courses (and mathematicians) in mathematics teacher education. Pinto investigates the practices of mathematicians and secondary mathematics teachers when comparing and discussing alternative proofs of the same

[1] Due to space limitations, we do not provide explanation and references to theories, e.g. *Didactic Contract*, *Theory of Commognition* (*ToC*), *Community of Practice* (*CoP*), *Anthropological Theory of the Didactic* (*ATD*), *Cultural Historical Activity Theory* (*CHAT*), etc. We would invite readers to find more in the corresponding contributions in the proceedings.

statement. The study highlights the importance of integrating both mathematical and pedagogical practices in secondary mathematics teaching and showcases how contrasting approaches offer further insights for teacher education. Weith et al., with attention to learning materials, examine the design of resources for pre-service teachers that incorporate theoretical considerations and aim to connect university and school mathematics. The paper presents the design process along with provisional findings on how pre-service teachers draw on their mathematical knowledge to inform their teaching decisions. Viirman et al. bring an international perspective on the role of mathematicians in secondary mathematics teacher education by reporting on the design of a large-scale survey on mathematicians' views and practices towards strengthening mathematics education of prospective teachers. Marchionne et al. examine how prospective secondary teachers judge the value of instructional videos and STACK (System for Teaching and Assessment using Computer algebra Kernel) tasks in learning about secondary students' misconceptions about derivatives. Still in a teacher education context, Hoffman observes how changing the response format of an interface task, from email answers to scriptwriting, led preservice secondary teachers to use overarching lines of argumentation that are more conducive to learning. Finally, with attention to learning materials, Morcos and González-Martín identify inconsistencies in how permutations with indistinguishable objects are presented in secondary and tertiary mathematics textbooks.

Digital resources

Two papers and three posters were classified in this group. Within the emerging field of research regarding the use of genAI (Generative Artificial Intelligence) in UME, Iannone et al. propose a potential research agenda. Using a Delphi method, they collected and classified the research questions considered as most urgent by academics. Miskei-Váradi et al. examine the integration of ChatGPT into a second-year undergraduate numerical methods course and assessed students' perceived usefulness of ChaGPT before and after the course. Findings indicate mixed perceptions on the utility of ChatGPT and its limitations in addressing misconceptions, including risks in accepting false proofs. Du et al. explore university students' mathematical digital competencies in communication in computer-supported collaborative learning and propose a frame that addresses collaborative engagement. Regarding other digital resources, Thoma and Iannone explore a lecturer's perspective on using Lean, an Interactive Theorem Prover, and identify adaptations the lecturer made to his course, the constraints he faced, and the lessons learned in terms of teaching proof with Lean, but also teaching proof more generally. Finally, Markefka et al. describe the development and evaluation of STACK tasks for introductory courses in university mathematics in collaboration with lecturers.

Mathematics and non-mathematics specialists

Five papers and two posters were classified in this group. Dahl et al. explore the integration of virtual reality and problem-based learning to foster engineering students' understanding of the vector cross product. Students reported positive learning experiences, although some of them identified usability issues or/and reported motion sickness. Norris and Noyes compare pre-university mathematics curricula followed by university students of geography, psychology and sociology in England in datasets from 2016-17 to 2019-20, concerning over 90,000 students. Analysis indicates significant differences in the opportunities to study mathematics both between and within the three disciplines,

leading to a complex situation when designing mathematical courses for incoming students.

Several studies in this group take an *ATD* perspective. Šipuš et al. analyse mathematical practices in advanced courses for electrical engineers through interviews with teachers and one master student who point out differences between mathematics and engineering practice. Hitier and González-Martín investigate science students' strategies when solving a non-familiar calculus task, with particular attention to *praxeologies* from mechanics. Students who employed mechanics' or mixed *praxeologies* were generally more successful in solving the task. Florensa et al., also from the ATD perspective, characterise the views of mathematics and engineering teachers about mathematics in the first years of mathematical courses in engineering degrees. Preliminary findings indicate differences in the type of tasks mathematicians and engineers would prioritise (e.g., mathematics-oriented vs practice-oriented tasks). Fernández-Ruano et al. discuss active learning teaching by drawing on *Study and Research Paths* (*SRP*s). The study compares the implementation of *SRPs* instigated by the same problem in three different university-level statistical courses and identifies differences in the ways students engage with statistical techniques. Finally, Kristinsdóttir and Gíslason report on an Icelandic project on the secondary-tertiary transition, aimed at increasing the number of STEM graduates. They discuss similarities and differences in expectations between upper-secondary and university-level mathematics teachers regarding students' mathematical preparation for STEM studies.

Learning and teaching of mathematical topics and practices

Four papers and one poster were classified in this group. Wawro et al. present the design, implementation and analysis of a task introducing the notion of 'least squares' in an introductory linear algebra course. Framed within the *Realistic Mathematics Education* framework the designed task contributes towards student development of graphical intuition with planes and vectors. De la Cruz Benito and Andrews-Larson investigate students' proof methods in the context of linear independence after a course using Desmos, observing that a significant portion of students successfully construct deductive proofs, but others still use empirical proofs. Meanwhile, Wallach and Kontorovich propose a conceptualisation of problem solving based on the *ToC*, distinguishing between *solution generation* routines and s*olution conventionalisation* routines. Rogovchenko and Rogovchenko discuss students' difficulties with differential equations in relation to the general solution. They review influential classical textbooks and suggest an introduction to the notion of the general solution of differential equations as a family of functions. Finally, Veuillez-Mainard studies the teaching and learning of polynomials at the secondary-tertiary transition in France by focusing on students' conceptions of polynomial functions and their graphs.

Mathematicians and mathematical practices

Three papers were classified in this group. Olsen et al. investigate the epistemic tensions associated with the role of programming in the research practices of mathematicians. Drawing on interview data from two mathematicians, one with a background in pure mathematics and the other in applied mathematics, the authors use *Cultural Historical Activity Theory* (*CHAT*) to examine the rules and motives shaping their research practices and the role programming plays within those practices. Goor and Pinto study *positioning acts* of mathematicians and secondary school teachers discussing the practices of a teacher presenting a proof in class, observing that the mathematicians can move from

disciplinary authorities to fellow educators. Finally, L'Italien-Bruneau et al. draw on the *ToC* to study the research discourse of doctoral students in mathematics. They draw on interviews with three such students to describe patterns characterising their specialised mathematics research discourse.

Thematic Discussions

Digital resources: Revisiting UM teaching, learning and assessment

In eight TWG14 contributions, digital resources were the focus or the context of the study. These resources included Virtual Reality, genAI, Programming, Interactive Theorem Provers, Videos, Desmos, Geogebra and STACK. Such attention to digital resources reflects broader trends within UME, as seen in IJRUME's recent special issue on digital experiences (Geraniou et al., 2024), and more generally in mathematics education – especially since COVID-19 accelerated the use of digital resources (Engelbrecht & Borba, 2024). In the discussion, we focused on three digital environments: Interactive Theorem Provers, genAI and STACK. For each of these, we considered: (1) challenges and opportunities they present for learning, teaching and the development of students' employability skills; (2) their influence on assessment, particularly in terms of assessment design; and (3) theoretical frameworks and methodologies that may offer deeper insights into the use of these digital tools.

Concerning the first point, we identified several opportunities and challenges from both student and teacher perspectives. For students, we discussed opportunities for practice, providing applications across different disciplines (e.g., computer science and mathematics), and the development of transferable skills linked to employability. However, concerns were also raised about students potentially becoming overly reliant on digital resources (e.g., genAI) and lacking the appropriate critical engagement allowing for an efficient and effective use of those resources. From the teachers' perspective, the discussion was around the need for targeted professional development and the creation of appropriate teaching materials. It was also noted that support for the teaching implementation of specific digital resources is currently limited, and that some of those resources demand a steep learning curve (e.g., Interactive Theorem Provers). Insufficient availability of appropriate and adaptable teaching and learning materials raises concerns about the practical implementations of these tools in teaching, particularly in contexts where instructors' and students' needs may differ considerably. In terms of assessment practices, we considered tensions between checking correctness and redefining assessment criteria, as well as the contrast between evaluating the final product and placing greater emphasis on the learning process. We also highlighted the importance of rethinking assessment methods to offer a variety of methods but, also, to align better with employability skills. Furthermore, we reflected on potential theoretical frameworks to support research in this area, such as *Instrumental Approach*, *CHAT* and *ToC*. We also discussed how genAI could be implemented within our research process, e.g., as a tool, an agent or a collaborator? Finally, mixed-methods approaches were considered well suited to capture resource-use broadly, as they can provide valuable insights into usage patterns, accuracy, speed and feedback provision.

Teachers and teaching at school and university: A cross-community perspective

In recent CERMEs, TWG14 has seen an increase in the number of contributions related to teachers and teaching at school and university level, and it was a popular theme among contributions also at

CERME14 (see earlier sections). This growing interest is also seen at the INDRUM2024 conference and in recent special issues (e.g., Buchbinder et al., 2023). Given the focus in several TWG14 contributions on cross-community collaboration[2], for instance between mathematicians and mathematics educators, for the second thematic discussion we chose to take a cross-community perspective on teaching at school and university level, including university-based preparation of school teachers and university teacher professional development. The discussion was structured in two parts: (1) reflecting on the affordances and challenges of working with multiple communities in teaching and teacher preparation; (2) considering how can we draw on these affordances and overcome the challenges. Among the studies presented in TWG14 this year, the two main affordances we identified were co-learning partnerships, where members from different communities gain from collaborating on planning and conducting teaching, and benefits for students from cross-community teaching collaboration. However, several challenges were also discussed. Institutional constraints, such as university organisation (e.g., mathematicians and mathematics educators working in different departments or even faculties) might, for instance, lead to a lack of awareness of communities' willingness to collaborate. We also noted potential communication difficulties, stemming, for instance, from different perspectives on teaching and learning in different communities. Finally, the dependence of the 'success stories' on specific individuals involved was pointed out, raising the question of how to make initiatives sustainable. One proposed answer in the second part of our discussion was to conduct research at the 'meta level' on the conditions making cross-community teaching collaboration productive and sustainable. Other proposed strategies are making UME research publications accessible to mathematicians (e.g., through implications for practitioners), and collaborative research on teaching with mathematicians (or other specialists) as co-researchers.

Research methodologies and methods: Specificities, challenges and shared practices in UME

Also, we opted for a discussion on research methodologies and methods, which was motivated by the observation of an increased diversity of methods, including the introduction of methods uncommon in the group, such as a Delphi study and the use of AI tools for coding interview data (see the digital resources theme). The discussion was organised around different interconnected aspects related to methodologies and methods. Discussion revolved around the crucial role methods play, not only in the way research develops, but also in how results are shared and disseminated with close attention to the relation between theoretical frameworks, objects of study, and methods.

One of the issues that emerged from our discussion was the sharing of methodological tools (questionnaires, interview guidelines) within the UME research community, which can become a repository, but which is not sufficiently developed yet. Another topic that was discussed was the need for dissemination of task analysis instruments and approaches, and the possibility for such instruments to be shared with mathematicians – another opportunity for cross-community collaboration between mathematicians and mathematics educators. A further aspect that emerged during the discussion was the international movement towards open data, which may raise issues of

[2]In addition to collaboration within the broader mathematics community (mathematicians, mathematics educators, mathematics teachers, etc.), this could include collaboration with other specialists, like engineers or science educators.

anonymity and confidentiality in our field (typically, for classroom videos). The difficulty of sharing methods and instruments when different theories are employed was discussed as well, a concern that led us to express a need for theory networking towards shared methodologies in UME research. We also discussed the changes in methodological approaches in works presented at TWG14 across CERMEs, noticing a significant development of mixed methods research designs in recent years compared to a dominance of qualitative approaches in the past. Still, access to representative samples for quantitative studies remains an ongoing challenge in UME research.

Many of the issues above could apply to other CERME TWGs. However, specifically to TWG14, UME researchers might be UM teachers as well, which raises issues of balancing priorities and controlling potential biases. For example, a UME researcher who is also a UM teacher might need to reflect on or detach from the teacher's position when doing research. Cross-community collaboration and international/comparative studies were seen as means that might be helpful in this regard. In the latter case, the design of methodological tools that can be used in different cultural and institutional contexts might be an additional challenge. Finally, replication studies were mentioned as an opportunity for transferability, testing and evaluation of methods in different contexts.

Reflections and ways forward

Summarising some of the tendencies we have seen at CERME14 TWG14 compared to previous CERMEs, there is, for instance, an increase in studies focusing on mathematicians' involvement in schoolteacher preparation, and (unsurprisingly, given recent developments in technology and society as a whole) studies on genAI and integration of digital resources more widely. The secondary-tertiary transition is a steady area of interest, as is research on teachers and teaching practices, while this year saw a decrease in papers focusing on the teaching and learning of particular content, and on mathematics for non-mathematics specialist students. This can probably be at least partly explained by the already mentioned new TWG25 on Calculus, as well as by the further consolidation of the TWG26 on mathematics in STEM. This year we returned to contributions around mathematicians' research and teaching practices as well as to their preparation (and pedagogical support) for teaching.

Concerning theoretical perspectives, *ATD* and *ToC* are still widely used in studies presented in the TWG14, while we saw a slight increase in ToC papers this year. Regarding methods, we observed the development of mixed methods, and of innovative methods such as the use of genAI for coding data. There is still a definite lack of contributions focusing on issues of equity and inclusion, despite this being a topic of crucial importance for UME. This lack has been discussed in the group over the years, and one tentative explanation is that researchers focusing on these types of issues, even if their research is conducted at the university level, see themselves more as parts of other research communities rather than of the UME community. This is purely speculative, however, and we would be keen on learning more about how we could attract more contributions from these areas.

In the final session, discussion time was devoted to looking ahead, and thoughts were raised that might serve as inspiration for future work. For instance, for quite some time now, a lot of attention has been paid to the utility aspects of higher mathematics, and its role in other disciplines. Perhaps it is time to also attend to the role of pleasure and enjoyment of pure mathematics? And in connection to this, perhaps it would be fruitful to pay more attention to students' engagement in mathematical

activities as enculturation into mathematical practices? We also discussed the dialectic relation between intuition and rigour. This can be understood both in relation to our common topic of study, namely university mathematics, but also in relation to our own practices as UME researchers. Generally, there seemed to be an interest in further work in the networking of theories and methodologies, in order to see further issues and gain deeper insights.

Learning assistants' development as mathematics teachers: Insights from an undergraduate to graduate teaching journey

Rebecca Butler[1] and Orly Buchbinder[1]

[1]University of New Hampshire, United States of America; rebecca.butler@unh.edu

Learning Assistants (LAs) are undergraduate students who, after completing an academic course, return in later semesters to assist in the teaching of that course. Typically, they are present in class, alongside instructors and/or graduate teaching assistants, and help facilitate student discussions. It has been shown that both students and LAs themselves benefit in LA-supported classrooms. However, few studies have addressed the pedagogical development of LAs as teaching paraprofessionals. We contribute to this line of inquiry by utilizing the lens of teacher noticing to examine how the professional noticing of one Calculus LA, Chase, evolved through his first semester as an LA and into his time as a graduate teaching assistant. Our findings provide insight into LAs' role in undergraduate classrooms.

Keywords: Calculus, learning assistants, professional noticing

Introduction

The Learning Assistant (LA) instructional model was developed in the United States in the early 2000s, to support the facilitation of large introductory STEM courses, like Calculus (Otero et al., 2010). LAs are undergraduates who previously completed a certain course and return to support the teaching of the course. Typically, LAs are present in classrooms alongside the instructor or graduate teaching assistant (GTA) and help to facilitate students' individual or group work by asking or responding to questions, providing hints, and facilitating peer-to-peer interactions. Thus, an LA's classroom role is that of a knowledgeable peer, supporting and advancing student learning. Indeed, multiple studies have shown that in LA-supported classrooms students have better learning outcomes and affective improvements, compared to courses without LAs (Barrasso & Spilios, 2021). These positive outcomes may be surprising, considering that LAs (often non-education majors), receive only minimal pedagogical training. Typically, LAs enroll in a pedagogy course where they learn about teaching and reflect on their practice. To strengthen their content knowledge, LAs meet weekly with the course instructor to refresh their memory of the mathematical topics addressed in that week.

This unique nature of LAs' teaching experience within university classroom environments, combined with the recurring reports of students' success in LAs-supported classrooms, has led researchers to investigate LAs' classroom practices and their professional development as teaching paraprofessionals (Nadelson & Fannigan, 2014). Specifically, it has been suggested that since LAs have only recently learned the course content, they may notice and respond to aspects of student thinking that go unnoticed by other instructors, thus supporting students' success (Wendell et al., 2019). However, to the best of our knowledge, no studies examined how LAs' noticing develops. Our study seeks to contribute to this research gap by examining how LAs' professional noticing evolves as they gain teaching experience. This paper is a case study of one undergraduate calculus LA, Chase (pseudonym). Our research question is: *how did Chase's noticing evolve as he gained teaching experience?*

Theoretical Perspectives

While it has been documented that LAs develop as teachers (Barrasso & Spilios, 2021), the mechanisms behind this development remain relatively unexplored. One promising direction to examine this is the lens of noticing. Teacher noticing has been recognized as an important marker of mathematics teacher development, being developed and widely used for studying the professional learning of practicing and future teachers (Dindyal et al., 2021). Since LAs can also be viewed as teachers-in-training, even if they do not intend to pursue a teaching career, this framework can be appropriately applied to the LA context. For example, Top et al., (2018) observed that as LAs gained experience, their pedagogy shifted from correct students' answers toward attending to students' ideas.

We use van Es and Sherin's (2008) definition of noticing as encompassing attention to events, reasoning about them, and connecting them to broader teaching principles. We additionally use reflective noticing (Buchbinder et al., 2021) to frame this study, examining LAs' retrospective attention to their teaching as opposed to their in-the-moment thinking. While the noticing of LAs has received some attention in the literature (Thompson, 2019; Wendell et al., 2019), these studies do not include the subject-specific nature of development as a mathematics teacher and do not consider development over time, thus allowing for a unique contribution into this under-researched area.

Methods

This study is part of a larger project focused, among other things, on improving Calculus I courses in a large, US public university. Students attend a large lecture (~150 students) taught by a faculty instructor three times a week and learn in smaller (~20 students) recitation sessions, led by a GTA and LA, twice a week. The GTA is primarily responsible for the recitation, including tasks such as: for reviewing the lecture material, proctoring quizzes, facilitating whole class discussions, and interacting with students as they solve problems. The LA assists classroom instruction by circulating the room, asking and responding to questions and facilitating student group work.

Of the four LAs involved in teaching Calculus I in Spring 2022, Chase was a senior mathematics major. He had a strong mathematical background and some tutoring experience. After graduating, Chase taught for a year as a substitute mathematics teacher in a local high school. He then returned to the university for a master's degree in mathematics, and, upon receiving it in 2024, went back to teaching high-school mathematics. Thus, Chase's case is interesting because we were able to examine his long-term teaching development as an undergraduate educator following a novice LA experience.

We examine Chase's development as a teacher by analyzing how his noticing evolved from being a novice LA to an experienced GTA. Data consists of three video-recorded stimulated-recall interviews with Chase, which included reflection on video clips from Chase's recent teaching selected by a researcher based on availability and substance. The first interview took place several weeks into Chase's first semester as an LA (Spring 2022), the second was at the end of his semester as an LA (~13 weeks later), and the third interview was at the end of his final semester as a GTA (Spring 2024). In these interviews, Chase was asked to reflect on his teaching experiences using artifacts like sample student work and short 360-degree video clips of his own recent teaching. These types of reflections have been shown to support pre-service teachers' reflective noticing (Buchbinder et al., 2021). The

interviews were transcribed and analyzed using a coding scheme (Figure 1) based on van Es & Sherin (2008). Each utterance received codes in each of the three categories: actor, topic, and stance.

Category: Actor (Who the LA talks about)
Self: LA talks about their teaching moves, how they think about mathematics, interact with students, their opinions on teaching, or their classroom role. **Student-Individual:** LA talks about a specific student. **Student- Group:** LA r talks about a specific group of students: what they did, how group members interact with each other, or how groups function in class. **Student–Class:** LA talks about students at the class level, e.g., about students they teach or students in general.
Category: Topic (What the LA talks about)
Mathematics: LA talks about mathematics, how someone thinks about or does mathematics, or when they talk about someone's difficulties with mathematics. **Pedagogy:** LA talks about their teaching or teaching in general: their actions or pedagogical decisions. **Climate:** LA talks about social dynamics or social aspects of interactions with others.
Category: Stance (How the LA talks)
Describe: LA details events they see, hear, or experience, but without judging them. **Evaluate**: LA explicitly provides a positive or negative appraisal of a situation or opinion. Or LA provides an alternative action they could have done or could do in the future. **Interpret**: LA explains why or how something happens, or makes connections to underlying concepts, causes, or implications by explaining the meaning or significance of events.

Figure 1: LA Noticing Coding Scheme

This coding scheme was developed based on eight LA interviews. As the LA program expanded, a substantial corpus of LAs' interviews (34 interviews) was collected, making their manual turn-of-talk coding unfeasible. Consequently, we developed a technologically enhanced method. Using Dunivin's (2024) chain-of-thought prompt sequence, we designed a prompting protocol for ChatGPT (OpenAI, 2024) to code the interviews. Chase's first and second LA interviews were coded by a human researcher and AI. Coding disagreements were resolved by the researcher, resulting in an interrater reliability rate of 68.7%, indicating substantial to very good agreement. Chase's GTA interview was coded using this prompting protocol and codes were reviewed by a researcher for accuracy.

Results

Table 1: Summary of Chase's noticing across time, in percentages

	Topic	Mathematics			Climate			Pedagogy

Table 1 shows the summary of Chase's noticing codes. N is the number of utterances that received that topic code for each interview, and P is the corresponding percentage.

Chase's Mathematics Talk

In his first and second interviews as an LA, Chase attended significantly to mathematics, with 30.2% and 38.7% of his utterances respectively coded with this topic. However, in his interview as a GTA, Chase focused on mathematics significantly less, with just 16.2% of his utterances receiving this code. The categories of actors and stances shed light on this change in Chase's noticing focus.

In his first interview as an LA, Chase primarily talked about how students in general thought about mathematics (53.8% of mathematics codes received a *student–class* actor code), offering reasons for student thinking or details of students' solutions (in mathematics category: 38.5% of stance codes described, and 46.2% were *interpret*). For example, when discussing a lesson where students evaluated the truth value of statements about continuity and limits of functions, Chase explained how students "found justifying the first [statement] tough. Because that's just a definition and they didn't want to just say, this is the definition of continuity.") Hence, Chase identified both the problem the students struggled with and the source of their difficulty. He also reflected on the mathematical work of specific student groups (23.1% of actor code were *student–group*), but not individual students. He reflected on one group's interaction: "I think [they were] saying, 'Oh, but there are some functions where the limit exists here and it's continuous.' That's true, but if you say the statement's true, you're saying it happens all the time." Thus, Chase's reflections in the first interview were characterized by a strong focus on mathematics and his descriptions of students' mathematical thinking were general and interpretative. Chase also reflected on his own conceptions of mathematics (23.1% of code *self*), comparing them to students' thinking. For example, he said: "I've been taking math classes for a couple of years. I haven't thought about what someone who hasn't seen [logical] implications before would think about them. So, it kind of got me into their [students] mindset a lot more." This shows Chase's emergent realization that others may think of mathematics differently from him.

In his second LA interview, Chase retained his mathematical focus but became slightly more attuned to how individuals perform mathematics, offering more descriptions and evaluations of student work (47.2% and 19.4% of stance codes respectively). Reflecting on one student's solution to an optimization problem, Chase said: "Some confusion on how to find the area. He says $ax=y$, which isn't right. But he does have the right perimeter form perimeter formula." This quote differs sharply from those in the first interview: Chase offered a confident judgment about the strengths and weaknesses of this individual student's work, showing that he began attending more to individuals.

As a GTA, Chase attended less to the topic of mathematics overall, but when he did, he focused more on students in general and provided more interpretations (66.7% of stance codes) than in his previous interviews. When reflecting on a lesson on partial fraction decomposition, Chase shared his thoughts about general student thinking about this procedure, saying "I think there is confusion about, the variable. Because it changes: (ax) is a variable in your integral, but $a, b,$ and c are variables in your system of equations. And I think that shift is not obvious at all to students". As a more experienced teacher, this reflection is not about specific students or tasks but is a more general inference about how students learn a certain mathematical topic and the challenges students encounter with it.

Chase climate talk

Chase noticed the classroom climate (i.e., social aspects of the classroom) less in his second LA interview than in his other two interviews (1st-LA: 34.9%, 2nd-LA: 23.7%, GTA: 37.8%). While the frequencies were comparable in his first LA and GTA interviews, his stance shifted from descriptive focusing on groups and himself, to more evaluative and focused on the class overall.

In his first interview, Chase's noticing was highly descriptive (73.3%) and focused on his own classroom role and student engagement. For example, he noticed students' (un)willingness to engage with him and one another and referred to some recitation sections being more "talkative", or "vocal" while others were "quieter". Occasionally, he offered reasons for a group's lack of communication (e.g., "The class is at 8:00 AM, so they could be sleepy. I'm sleepy."). He also reflected on his own social role in the classroom (33.3% of climate utterances received an actor code *self*), describing how he thought students felt "comfortable" talking to him and treated him with a level of authority since "it seems like [students] approach [the GTA and I] as relative equals when they're asking questions".

In his second LA interview, Chase's stance about classroom climate became more evaluative and interpretive (31.8% and 18.2% of stance codes repressively). He reflected on learning to socially "manage groups" and interact with "strong personalities" by "extract[ing]" himself from excessively "talkative" students to attend to others. He reflected on gender roles recalling one "bright" female student who rarely interacted with others because "when you're a girl in a Calculus class and it's all men, that's intimidating. I wouldn't want to talk to the guys next to me." He also appreciated the fact that some female students were more comfortable with a female GTA than with him and reflected generally about the differences in his and the GTA's roles and authority in class. Overall, Chase was becoming more cognizant of social aspects of the learning environment, moving beyond describing groups' participation, and reflecting on his social responsibilities in the classroom.

Chase talked most frequently about social issues in his GTA interview (37.8% of utterances from this interview were coded as *climate*), indicating an increased focus on the new responsibilities of his role as a GTA. His focus remained strong on his own classroom role (28.6% of actor codes), saying that now as GTA he has a "responsibility to the students to say, you're going to learn this stuff, or I'm going to try my best to have you learn it". He contrasted this with his LA-ing experience, saying that now students "view me as a little bit more authoritative." He reflected on gender equity, saying that students "tended to push back a little more" against his female LA's answers than they would his.

Chase's Pedagogy Talk

The proportion of Chase's talk focused on pedagogy steadily increased across his three interviews (from 34.9% to 37.6% to 45.9%). This indicates that, as Chase gained experience, he focused less on the particulars of the mathematical content at hand and more on the intricacies of his teaching practice. Unpacking the actor and stance codes sheds light on this shift in his noticing of pedagogy.

Naturally, Chase's talk about pedagogy was frequently accompanied by an actor code of *self* across all three of his interviews (80%, 82.9%, and 76.5%). When discussing pedagogy, he foregrounded himself as a teacher, talking about his actions, opinions, or teaching moves (e.g., "I was talking to them, and I was trying to hint again that it would be false", "I was really trying not to be too explicit

about things and trying to get them to make the connections in their own head"). Occasionally, Chase reflected on pedagogy with respect to other actors. For example, in his second LA interview, Chase commented that students' "homeworks were generally better prepared because [course instructor] is very strict on having your homework well presented." This quote shows Chase reflecting on how the actions of other actors: students and the instructor, affected the teaching and learning processes.

Chase's pedagogical stance changed over time. In his first interview as an LA, his talk was highly descriptive (60% of his pedagogical utterances). For example, recalling his interaction with one group, he said: "I was trying to get them to land on the counterexamples that do exist. So, at the end there I stressed the if-then, like the "always-ness" of that implication." Chase occasionally evaluated and interpreted these descriptions, often by hedging them (e.g., "I think I could have landed on this explanation a little bit quicker", "I'm not sure I did any here, but I think earlier I tried to ask them for cases where the statement didn't hold"). These examples also show Chase's reflection on, and dissatisfaction with, his teaching of a particular mathematical content. In his first LA interview, Chase's pedagogical reflections were filtered through his background as a mathematics major.

In Chase's second LA interview, he became less descriptive, turning towards evaluation and interpretation (40% and 34.3% respectively, in the pedagogical category). Chase began connecting mathematics more explicitly to student thinking. For example, reflecting on his teaching approach to an optimization problem where students had to maximize area for a given perimeter, he said:

> If I just tell them to put y in terms of x in the perimeter equation, that's not really motivated by anything. Instead, I can tell "We have two variables here and that's confusing, but we can figure out how to remove one of them and replace it with some function of that other variable." I think that that gives them [students] a way better idea of the underlying [mathematical] machinery.

While Chase was still concerned with the mathematical content of teaching, he now frames this with respect to student learning, realizing that relating to students may be better than explaining to them. Chase also reflected on how his teaching practices changed over his first LA semester, explaining:

> I was trying not to be too explicit about things and trying to get [students] to make the connections in their own heads. Because it's easy to just kind of go into math mode and say, okay, do this and this and this, and I know why, but if they don't know why, the process is very obfuscated for them.

Chase unpacked specific actions as he tried to move away from his "math mode" approach, explaining that he wanted to "ask more questions and better questions… about the concepts themselves as opposed to just telling them concepts." This indicates Chase is learning to center student thinking in his teaching, realizing the importance of students performing mathematics themselves. He also shared that he initially had difficulty approaching students, saying "I was really confused [about] how I talk to these students without them asking me questions?". Gradually, he became "better at interacting with people unprompted and saying how's it going? Sometimes I look at their paper and say hey, can you explain this to me?". By the end of his first semester as an LA, Chase realized the importance of student agency in the learning process and developed techniques for drawing out student thinking.

In his interview as a GTA, Chase's talk about his pedagogy became primarily descriptive, similar to his talk as a beginning LA (64.7% of his pedagogical utterances were assigned a stance code of

describe), but these descriptions were less content-oriented compared to his first LA interview. Instead, he offered descriptions of his classroom practice and how he managed the classroom (e.g. "I break them up in groups of four", "I try to give them maybe not an answer, but a task, and then I'll check in later and say, hey, how'd that task go?"). This is consistent with the shift in his role from LA to GTA and the new responsibilities for managing classroom dynamics. He shared:

> I was an LA under […] a great GTA. And I remember when I started TA-ing, I was thinking a lot, okay, how would [that GTA] do this? And so eventually I did some things differently, but it was cool to see, I'm running the classroom in a way that I admired. It was cool to see that growth.

Summary and Discussion

Across all interviews, Chase's noticing of mathematics shifted from describing the particulars of student work and relating them to his preferred methods to reflecting on mathematics generally across his teaching. His pedagogical noticing became more specific as he moved from describing his actions in the first interview to critiquing his actions and describing classroom management techniques in later interviews. Similarly, his initial descriptive talk about levels of student participation turned to reflection on issues of equity and authority in the classroom. Overall, Chase's pedagogical development from novice LA to experienced GTA can be characterized as a journey from focusing on how *he* himself understood and explained mathematics to focusing on a more integrated view of mathematics and pedagogy, (e.g., how to communicate mathematics effectively, accounting for individual students' attributes). Chase's experience as a high-school teacher before becoming a GTA likely affected this journey; however, we do not have data evidence that specifies this impact.

Our study contributes to the under-researched area in tertiary education of understanding the instructional dynamics in LA-supported classrooms by considering the development of LAs as teaching paraprofessionals. Chase's case is special because he returned to the same university for his graduate studies, which allowed us to trace his long-term professional development. However, he is not unique in being so deeply affected by the LA-ing experience to switch his career to teaching (Nadelson & Fannigan, 2014). While Chase's case cannot be generalized, examining his learning trajectory, especially through the noticing lens (Buchbinder et al., 2021; Dindyal et al., 2021), aids our understanding of how LAs can grow pedagogically, and how LA-ing experience can affect their teaching. The shifts in Chase's noticing of mathematical content in his first interview to reflecting on connections between mathematics and student thinking in his second interview exemplify how LAs' professional noticing can become more advanced over time (van Es & Sherin, 2008). The increased focus on student thinking as a recent learner could contribute to students' understanding of mathematics, as suggested by Wendell et al. (2019).

Our study also offers a methodological contribution of applying generative AI to code transcripts of interviews about mathematics with a promising degree of agreement with human coding. This technologically aided approach was appropriate for use with the noticing analytic lens because noticing is a construct with mature theoretical foundations (as opposed to other areas of study, which may require prior development of coding schemes). We plan to extend this AI-enabled approach to interviews with 18 other LAs to compare their trajectory to that of Chase to gain additional insight into LA noticing patterns and professional learning trajectories.

Ecology of task design, adaptation, and selection: A phenomenological study with Norwegian mathematics lecturers

Ahu Canogullari[1] and Farzad Radmehr[1]

[1]Norwegian University of Science and Technology, Department of Teacher Education, Norway; ahu.canogullari@ntnu.no

This study aims to investigate the ecology of designing, adapting, and/or selecting tasks for teaching mathematics at the university level by identifying the institutional conditions and constraints that influence lecturers' practice. Drawing on the tenets of the Anthropological Theory of the Didactic, in this phenomenological study data is collected through semi-structured interviews with mathematics lecturers working at a public university in Norway. The findings revealed several conditions at the pedagogy and discipline levels as well as several constraints at the school level. Moreover, instances where conditions and constraints are interrelated were identified. Implications for task design at the tertiary level are discussed.

Keywords: Anthropological theory of the didactic, ecology, task design, mathematics lecturers.

Introduction

Research has investigated task design at the university level from various perspectives. Some studies focus on designing tasks for teaching mathematical topics, such as real analysis (e.g., Gravesen et al., 2017) or multivariable calculus (e.g., Viirman & Jacobsson, 2023), while others emphasize developing skills such as mathematical habits of mind (e.g., Breen & O'Shea, 2019). Despite growing interest, there seems to be a lack of research on factors that explain or influence how lecturers design, select, and/or adapt tasks for teaching mathematics. As Bosch and Gascón (2006) articulated, "when the teacher and the students meet around a knowledge to be taught, what can happen is mainly determined by conditions and restrictions that cannot be reduced to those immediately identifiable in the classroom" (pp. 60–61). It is necessary to consider the conditions and constraints (i.e., ecology) outside of the classroom since they determine activities (i.e., praxeologies) inside the classroom (Chevallard, 2022). This calls for enlarging the unit of analysis, extending it in both directions to encompass more specific and more generic levels (Chevallard, 2002). Since the ecology of a system impacts and explains its functioning, as well as that of praxeologies residing within it (Gascón & Nicolás, 2020), investigating the ecology of task design for teaching mathematics at the university level is important for understanding the system around it and its consequences on lecturers' practice. As such, our study intends to investigate the ecology of task design at the university level by uncovering the conditions and constraints lecturers encounter in their task design practice.

The Anthropological Theory of the Didactic

The Anthropological Theory of the Didactic (ATD) supposes that any human activity can be interpreted as a praxeology, which can further be divided into praxis and logos blocks (Chevallard, 2019). Praxis block refers to the type of tasks and the techniques for carrying out the tasks, while the logos block includes the technologies that explain the techniques and also, theories justifying the technologies (Chevallard, 2019). In this study, we conceptualized the task component of the

praxeology as the practice of designing, adapting, and/or selecting tasks for teaching mathematics. More specifically, it was viewed as a paradidactical praxeology explaining teachers' practices outside of the classroom (Winsløw, 2011). Another important notion proposed within the ATD is called the ecology, referring to "the set of prevailing conditions under which this system lives in actual fact" (Chevallard & Bosch, 2020, pp. xviii–xxxvii). Ecology can be seen as a set of conditions and constraints supporting or impeding the enactment of didactic activities within institutions (Bosch-Casabò, 2018). In ATD, condition is viewed as "anything purported to have influence over at least something" which could "be identified to the state of some system, and therefore to the values of a set of variables that govern this system", whereas a constraint is perceived as "a condition which appears to be unmodifiable by occupants—acting as such—of a given institutional position" (Chevallard & Bosch, 2020, pp. xx-xxi). Chevallard and Bosch (2020) emphasize the importance of identifying the conditions and constraints of an institution (e.g., a university) to explain their influence on the praxeologies (e.g., task design) that are part of a didactic system (e.g., students, university lecturers, mathematics courses) within that institution. They suggest the use of the levels of didactic codeterminancy (LDC) to make this ecology explicit. The LDC, thereby, can be used as a tool to explain the ecology of any didactic organization through the generic and specific institutional levels it offers (Chevallard, 2002). As a tool, the LDC provides researchers a broader perspective to question and study the reality at stake (Bosch-Casabò, 2018). We believe an investigation of such an ecology could help identify significant issues occurring at the different levels of the hierarchy that impact lecturers' task design practice. This research can, therefore, help us to propose more specific solutions to the problems corresponding to a particular level.

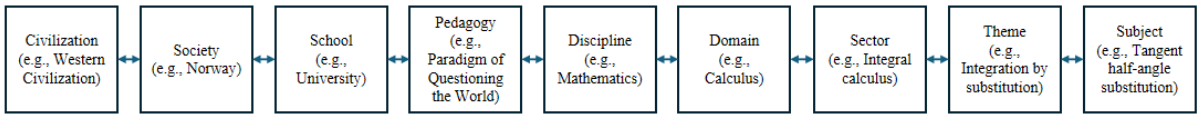

Figure 1: The hierarchy of levels of codetermination with examples, adapted from Winsløw (2011)

In this scale, *society* and *civilization* refer to the highest levels of the hierarchy, with both having their own social norms and values. *School* offers various infrastructures (e.g., buildings, classrooms, and time schedules) for teaching and learning, and *pedagogy* relates to the process of teaching and learning and its organization (Bosch et al., 2021). Align with this view and expanding it further, we perceive conditions and constraints at the school level if they result from or could be addressed by the university stakeholders, such as through setting main policies and regulations. Lower levels structure the *discipline* further into four components (Bosch et al., 2021) (See Figure 1). Against this background, the following research questions are addressed in this study:

> What are the conditions and constraints influencing how mathematics lecturers design, adapt, and/or select tasks for teaching mathematics at the university level? And what consequences do these conditions and constraints have on their task design practice?

Ecology of Mathematics Teaching and Learning at the University Level

Research to date has investigated the ecology of teaching at the university level on various themes. Barquero et al. (2013) studied the ecology of teaching mathematical modeling at the university level

and identified constraints hindering its dissemination across different levels of education. Viirman and Jacobsson (2019) investigated how epistemological differences in the university courses impact the didactical decisions taken by the lecturers and showed that the domain level features influence the decisions made on the pedagogy level. Bosch et al. (2022) designed two study and research paths (SRPs), one in a statistics course at a business administration school and one in an elasticity course for engineering students. One of the constraints they found was the curriculum, which seemed to have an impact on how the questions were generated within the SRPs. Similarly, Hitier and González-Martín (2024) reported the constraints that mechanic lecturers face when working with derivatives in their calculus courses, arguing that lecturers' practices can be accounted for by factors outside of their education and personality. One of the constraints that they found at the school level was the misalignment of mechanics and calculus courses, causing students to attend mechanic courses without having the necessary calculus knowledge and leading mechanics lecturers to adjust their teaching content. Despite the research on the ecology of teaching and learning mathematics at the tertiary level, there seems to be limited understanding of the ecology of task design at this level. Therefore, our study holds a potential for bringing more insights into this understanding, by identifying the issues experienced by lecturers in their task design practice at the university level.

Methods

We employed a phenomenological approach to investigate the ecology of designing, adapting, and/or selecting tasks for teaching mathematics at the tertiary level, considering it a suitable approach for uncovering the experiences of people through in-depth interviews (Creswell & Poth, 2018). Participants were four mathematics lecturers working at a public university in Norway with at least three years of teaching experience. They were selected based on their convenience and willingness to take part in our study. Data was collected by the first author through semi-structured one-on-one interviews as part of her doctoral study. The interview included questions aiming to learn about which principles they consider important in designing, adapting, and/or selecting tasks for teaching mathematics, how they address those principles, and the factors impacting this process. The data we present here focus on the final aspect, aiming to identify the conditions and constraints of task design from the perspective of the ATD. Influenced by the ATD, we conceptualized conditions as situations that lecturers have control over, while we perceived constraints as those beyond their control and cannot be changed immediately. We perceived the LDC in the sense that they have been viewed and defined in the work of Bosch et al. (2021). Their conceptualization of the notions guided our understanding and analysis of our data. The interview transcripts were analysed by the first author at first. Then, the second author analysed 25% of the data to obtain interrater reliability (O'Connor & Joffe, 2020). At the last, we discussed and negotiated our analysis until reaching a full agreement. All names were changed with pseudonyms to maintain participants' confidentiality.

Findings and Discussion

The analysis revealed several conditions and constraints at different institutional levels (see Figure 2). Considering space limitations, here we only present some of the findings that we think are valuable to discuss. Conditions have only been identified at the *pedagogy* and *discipline* levels. One example of a *pedagogy*-level condition was providing individual feedback:

Agnes: We have so many students. We would like to give them […] individual feedback and support them more, but that is impossible. So, we spend a lot of time thinking about tasks that work, that they can do on their own. […] And it [designing tasks that they can work individually] is more important because of lack of resources. If we could follow them closer, I would also make more difficult problems that maybe they do not have a perfect solution.

Agnes expresses the difficulty of offering feedback to each student due to the number of students in her courses, which causes her to design relatively easier tasks that students can work on by themselves. Her concern shows that her task design practice is influenced by the classroom size, something beyond her control. This situation also illustrates how a *pedagogy*-level condition is influenced by a *school*-level constraint. Among others, one suggestion for overcoming such problems could be using peer feedback (Nicol, 2010). Nicol (2010) suggested that feedback should be viewed as a dialogic process, not just a product transferred from teacher to student. This approach allows students to provide feedback to each other and observe peer work, encouraging critical reflection on their own efforts (Nicol, 2010).

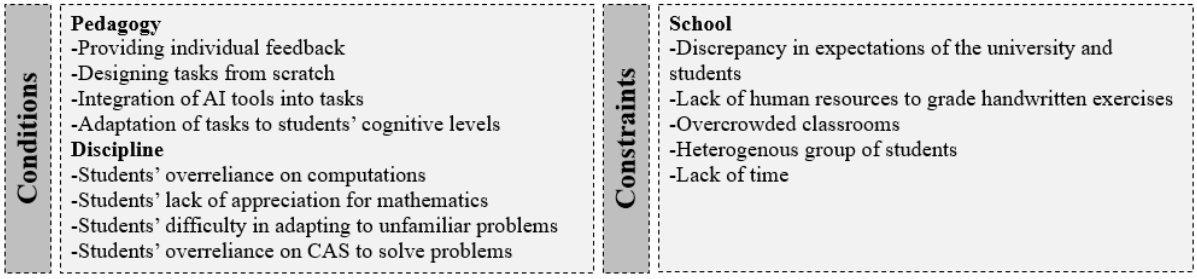

Figure 2: The ecology of task design at the tertiary level

Another condition at the *pedagogical* level was the difficulty of designing tasks from scratch:

Christer: [I use] internet resources or books or things like that because it is really hard to make problems. […] I make some problems myself. I think that sort of making everything yourself and not drawing upon all you know [is difficult].

Christer expressed difficulty in designing tasks from scratch, which often leads him to modify and adapt existing tasks from different resources. He did not mention this difficulty in the context of any constraints influencing his practice; rather, he discussed the challenge of creating problems. Here, it is shown that a *pedagogy*-level condition, although not impacted by a constraint, influences the task design practice of the lecturer. One possible solution to overcome this condition could be to involve different communities in design and implementation of tasks, such as in the form of cooperative engineering (Sensevy et al., 2013). As Sensevy et al. (2013) pointed out, design-based research involving the joint work of teachers and researchers—in this case, mathematics lecturers and educators— enables them to discuss their design and teaching strategies, share their expertise, and translate it into a collaborative knowledge. The collaboration between mathematicians and mathematics educators have been found effective for improving the teaching and learning of university mathematics (e.g., Hernandez-Martinez et al., 2023). The same could also be true for mathematicians. Collaboration among mathematicians could enable them to discuss their design and teaching practices where they could find practical solutions to their common problems.

At the *pedagogy* level, another condition that emerged was the difficulty in integrating artificial intelligence (AI) tools into task design. Important to note is that this challenge could be experienced either at the *discipline* level or at the *pedagogy* level across disciplines. However, from the interview, it seems Christer experienced this at the *discipline* level:

> Christer: If you are going to use this tool [CHATGPT4], it [the task] has to be sort of carefully created, and students have to learn how to [use CHATGPT4], not just use it to get like a copy-paste answer to [their questions] […] but to actually use it to improve their own problem solving and […] construct their own intuition and knowledge […]. But I do not know how to do that.

Christer expressed his thoughts about the need to create well-designed AI-based tasks that would help improve students' problem-solving skills, intuition, and knowledge. He added that he was not sure how to design the kind of tasks that would help him achieve this goal. A recent literature review by MA et al. (2024) argued that there is still a need for research on integration of AI tools into education and identifying effective implementation strategies. In this respect, our findings highlight the importance of investigating this issue at the tertiary level.

At the *discipline* level, several conditions have been mentioned. One issue was students' overreliance on computations and being inattentive to meaningful understanding of mathematics:

> Lukas: They [students] are so focused on solving equations or whatever tasks we give them, but they have no feel really for what it truly means for a function to be continuous or something like that. So, one design principle that we often use is you [students] need to verify something using the definition only. This is very instructive because it means that they really have to think about what the definition says, how you can operate with it, and apply [it] to whatever problem […] at hand.

Lukas perceives that students often prioritize applying procedures over conceptual understanding, which makes him design tasks that require students to use mathematical definitions. This situation demonstrates that a discipline-level condition impacts the lecturer's approach to task design. Our results concur with Breen and O'Shea (2019), who designed a set of tasks for undergraduate level introductory calculus courses, aiming to foster students' habit of mathematical mind and challenge their perception of mathematics as a discipline that solely relies on the application of procedures. Their work proposes six types of tasks that were found to be helpful for this purpose, which are based on example generation, analyzing reasoning, evaluation of mathematical statements, conjecturing and/or generalizing, visualizing, and using definitions.

At the *school* level, one of the constraints was the gap between the expectations of diverse members of the institution:

> Edvard: […] There is often a gap between […] what the students think they should learn and what university or people design the programs think they should learn. And I think it is very important to find a balance there […]. I usually do not like to teach to the test […] [but I give them] exercises [that] will be asked in the exam. We always want them to understand the concepts. So […] a lot of what I do when I choose exercise is sort of concept-driven […]. Sometimes, it is worth doing that [standard procedural tasks], but I do not see sense in […] drilling […] 10 exercises.

Edvard highlighted the difference in the expectations of lecturers, universities, and students, emphasizing the importance of finding a balance to meet those expectations. While he prefers not to

focus solely on preparing students for exams, students typically expect to be well-prepared. As such, he designs tasks in a way that would be similar to the exam so that students' expectations of being ready for the exam would be meet. In alignment with the expectations of the study program of the university and him as a lecturer, he values focusing more on conceptual learning than solely teaching the subject procedurally. A literature review by Struyven et al. (2005) demonstrated that students' preferences of the type assessment determine their learning approaches and vice versa. Therefore, gaining insight into students' assessment and learning preferences is important for designing exam and classroom tasks that meet both students and university expectations.

Another constraint at the *school* level was the lack of tools or human resources for assessing students. For instance, Agnes talked about this constraint in relation to another constraint she experienced:

> Agnes: We do not have the resources to grade handwritten exercises […] This is automatically graded. So that puts […] a limit on what we do. We would like them to also write […] on their own and on a computer. So, like bigger more in-depth problems, and then they could be graded and like getting feedback, but we do not have that. Right now, problems where you need to show reasoning in a better way are not part of this course because we do not have the resources. We cannot grade things [conceptual tasks], so […] more focus [is] on getting to the correct answer.

Agnes lacks the necessary resources for assessing students on more conceptual tasks. Due to this constraint, she is inclined to design more result-oriented tasks. This tendency can also be attributed to the large number of students enrolled to her courses, which affects how she designs tasks and influences her formative assessment of students learning. E-assessment solutions could provide an alternative approach for addressing grading challenges (e.g., Sikurajapathi et al., 2020).

Concluding remarks

This paper investigates the ecology of task design at the tertiary level by identifying the conditions and constraints that lecturers experience when designing, adapting, and/or selecting tasks for teaching mathematics in their courses. As findings showed, there are several conditions at the pedagogy and discipline levels as well as several constraints at the school level of the hierarchy that influence lecturers' practice of task design. One conclusion is that there were instances where a condition was influenced by a few constraints. This situation highlights the complexity of task design, suggesting that effective task design calls for the careful consideration of a range of factors and their potential influence on this practice. Several recommendations are presented in the discussion to address the constraints identified in this study. Finally, the available data provided limited insight into the lower levels of the hierarchy in the ecology of task design. This limitation may be related to the scope of our inquiry, as the study was not explicitly designed to investigate the challenges lecturers faced when designing tasks to teach a particular mathematical topic; thereby, the interview questions did not prompt the participants to delve into this matter in greater depth. Furthermore, care should be taken when interpreting the findings due to small sample from a single Norwegian university.

This paper explores the integration of virtual reality (VR) and problem-based learning (PBL) to enhance engineering students' understanding of the vector cross product in three dimensions. Our design immerses student groups into 3D virtual environments where they collaborate on manipulating vectors representing features of spatial objects. A task is, e.g., that at the outset, the vectors are assigned incorrect values resulting in distorted objects. The setup is tested iteratively at two universities in two different countries. Data are collected through questionnaires. The focus is on students' experiences and perceptions of VR-enhanced learning. Mostly, the students reported positive experiences using the VR environment. It helped them understand the concept of the cross product, see its use in real life, and it was enjoyable. However, some also reported motion-sickness or asked for more control to draw their own vectors.

Keywords: Engineering mathematics, virtual reality, vector cross product, problem-based learning.

Introduction

Mathematics for engineering students and problem-based learning

It is well-known by university teachers that engineering students often find mathematics difficult, and they have little motivation to learn it. This is supported by research showing that engineering students do not develop the mathematics concepts the same way as mathematics students do, and the concepts do not mean the same to them (Maull & Berry, 2000). Bingolbali et al. (2007) found that engineering students see mathematics as a tool and wish to see how mathematics is applied as part of a course. Baillie and Fitzgerald (2000) showed that engineering students who are at risk of demotivation and drop-out, list the level of mathematics and theory as some of the issues. Hence, as argued by Pepin et al. (2021), integrating real-life problems may help engineering students see the use of mathematics.

Christensen et al. (2023) documented a change at Aalborg University (AAU) in Denmark to the first-year mathematics courses in Linear Algebra and Calculus for all students in the STEM-areas by including field specific problems. The study revealed that highlighting the applicability and importance of mathematics in engineering appears to help. However, motivating students to learn mathematics is one thing, understanding mathematics is another. AAU applies problem-based learning (PBL) in projects throughout all curricula and faculties. The AAU PBL principles state that the 'problem' is open and the point of departure of the collaborative project (Askehave et al., 2015). PBL is very beneficial to engineering students (Sukaché et al., 2022), and the usefulness of PBL in mathematics is established at course level using real-life problems (Abou-Hayt et al., 2022).

However, as Dahl (2018) argues, mathematics is an extensive body of abstract knowledge, where the relevance of which to practical, real-world problems is not always immediately evident. This discussion was further developed by Dahl et al. (2023), who argued that both internal and external contextualization can be used in PBL in mathematics projects. In this paper, we therefore apply PBL as the overall theoretical framework for designing the tasks.

Using virtual reality to micro-PBL mathematics concepts

Virtual Reality (VR) is both a learning environment, a motivational tool, and a social medium. As stated above, mathematics education faces challenges due to its abstract nature but also the prevalence of mathematical anxiety (Dowker et al., 2016). However, VR technology offers promising solutions to these issues. VR creates immersive learning environments where students can interact with mathematical concepts. This technology enables visualization of abstract ideas like geometric shapes and functions, enhancing comprehension and problem-solving skills. Thus, VR helps making the inherent abstract world of mathematics concrete. In higher education, VR is already used in medical education (Davidsen et al., 2022). In addition, Timcenko and Thomsen (2023) describe how, using virtual reality, one can expose engineering students to tangible representations of abstract mathematical concepts in support of both students' motivation and their retaining of mathematical knowledge. Moreover, VR can make mathematics engaging by connecting concepts to real-world applications and incorporating them into gaming experiences. It fosters collaborative learning and communication among students and educators, adapting to individual needs. Despite its potential, VR also presents challenges such as accessibility and content quality. Educators need proper training and support to effectively integrate VR into the curriculum and assessment processes.

In conclusion, VR technology offers a transformative approach to mathematics education, addressing the limitations of traditional teaching methods and fostering deeper understanding and engagement. The focus of this study is therefore on how VR can be used to help engineering students understand an otherwise abstract and "invisible" mathematical concept. Hence, we apply the term "micro-PBL" as PBL, in this paper, is used neither to a large project, or a whole course, but to a single concept.

Research question

In this paper, we address the research question: How do engineering students in different countries experience the cross product of two vectors through a virtual reality setup in a micro-PBL setting?

Methods

Which mathematics and in which setting?

This paper is part of the project *myPBL-VRMath* where we focus on visualization and interaction with complex mathematical objects in VR in a PBL environment. The cross product of vectors in $\mathbb{R}^3$ is used as the first example as this is a vector operation essential for understanding direction and magnitude in space. Cross products are used in computer graphics (e.g., computing surface normal), thus representing a crucial tool in 3D graphics visualization, and in physics to describe angular momentum and many other physics phenomena. Given two vectors $u, v \in \mathbb{R}^3$, their cross product $w = u \times v$ is defined as a vector satisfying that w is orthogonal to both u and v; its length satisfies $|w| = |u||v| \sin\theta$ with θ being the angle between u and v; and u, v, and w follows the so-called "right-

hand rule" (Adams & Essex, 2022). One may show that this defines a unique vector, and that the cross product may be computed as $(u_1, u_2, u_3) \times (v_1, v_2, v_3) = (u_2v_3 - u_3v_2, u_3v_1 - u_1v_3, u_1v_2 - u_2v_1)$. Thus, the cross product gives a third vector that is orthogonal to the first two. The length of the cross product is determined by the area of the parallelogram spanned by the input vectors.

We designed a VR PBL environment in which the students are placed in a landscape, Vector Island, where, e.g., they see a sculpture where some facets are wrong because the surface normal is inverted. The students should grab the vectors, using the game controller, and manipulate their positions and magnitudes, observing the instantaneous change in the environment caused by the changed mathematical objects. In this paper, we report a piloting of this VR environment with different types of engineering students in two countries. The testing is done sequentially, in line with principles of design-based research (DBR) where instructional tools are tested, leading to refinements of the design (Sandoval, 2014). Ethical approval has been obtained prior to doing the activities with the students.

Evaluating the students' experiences

We developed a questionnaire to be given after the activities asking about the students' perceptions and experiences. The development was inspired by the Technology Acceptance Model (TAM; Davis, 1985) that explores the acceptance of a new technology using two constructs: perceived usefulness (Q1, Q2, Q5) and perceived ease-of-use (Q3, Q4). Q6 (Recommendation) aligns with TAM's focus on behavioural intention to use technology since recommending the technology to others can reflect a positive experience and intention to use.

- Q1: Usefulness of the activities for own progression of learning
- Q2: Extension of the perspectives over the vector cross product, due to the use of the technology
- Q3: Joy-factors, motivational factors
- Q4: Ease of use of the VR-technology
- Q5: Wish of having VR as a part of several courses during their education
- Q6: If they would recommend other students to try the activities and why
- Q7: Suggestions for improvement of the activities.

The quantitative questions are formulated as 5-point Likert type items (part "a" of questions Q1-Q6). In addition, for each question, we asked the students follow-up questions (parts "b" and "c"), where they should elaborate the answers using own words, thus providing us with qualitative data.

Setup of the tasks

The worked in groups of 3-5 students, where one has a headset, and the others see projections of the environment on their PC flatscreens. The activities are, therefore, designed to encourage dialogues in line with the PBL principles. The student with the goggles sees the 3D world, Vector Island, and can see and manipulate (grab) the vectors that determine the 3D world. Only the students without the goggles can see the underlying formulas needed to compute the cross product, which determine what is rendered in the VR environment. This will make it essential for the students to collaborate as no one has all the information. The students take turns in wearing the goggles.

- If a person in VR changes some of the vectors by grabbing them, the formula and numbers on 2D screens (visible to the other group members) are changed.
- If a change is made from outside the 3D world via an ordinary computer by the other group members, the person in VR sees that immediately.
- The possibility of severe input errors (for instance, caused by a novice VR user performing unexpected moves) is kept to a minimum, i.e., the software checks the input and allows only logical changes so the environment cannot be distorted beyond recovery.

Task 1 – Explore the sun positioning tool

The written material guides the students to: "Enter the virtual world and experiment with the Sun positioning tool. What do you notice? How do the shadows change based on the Sun's position? Try moving yourself slightly (just a little, so you don't get lost!). Observe the statue closely—do you notice anything unusual?" The students should experiment with the tool to move the sun, hence observing a change of the shadows on a sculpture. This task serves as a gentle introduction to the VR environment and using the hardware controllers.

Task 2 – What might be wrong with the triangle and how to fix it?

The written material guides the students to learn that: "An important thing to know is that in Computer Graphics, the objects are made up of triangles. The surface normal of these triangles determine what we can see and how we see it. We can only see the front sides of surfaces, as their normal point towards us. So, how do we (or the computer) calculate the surface normal? That's where our friend, the cross product, comes into play!" The task builds upon Task 1 and the students collaborate on finding a way to fix the sculpture using among other things the right-hand rule.

Task 3 – Fix the problems in the town!

Task 3 is a variation of Task 2 to help the students consolidate their knowledge. However, this is a more open problem where students begin by looking at a picture of a town with many kinds of buildings, mountains at the back, etc. The students should explore and discuss what may be wrong here. This task is designed with inspiration from PBL, asking students to find and solve problems, albeit small (micro) problems. The task is formulated as: "Go down the crossroad. See if you can spot any problems. Observe, talk and act".

Task 4 – Alien attack!

In order to enhance the students' understanding of the cross product, we added a task where the students should not fix something wrong but instead go the opposite direction and create a mistake, a hole, in an otherwise perfect surface. We therefore invented an alien attack, where the students should seek hide from a UFO. The written material stated the following: "Quickly run to safety - The only safe place is under ground. Check the alley between the pizzeria and cafe, to see if there is a way to create a hole to jump in". And later: "Hint: In previous tasks you have learned how to fix the holes in geometry, but now, you need to find a way to make a hole!" See Figure 1 below.

Figure 1: UFO attacking a town on Vector Island

The test sites and the first step of the analysis

Aalborg University as the first testing site – piloting the tool

AAU was chosen as the pilot testing site in the DBR inspired setup as this was where the development of the VR environment took place. This was done before sending the VR tool to other partners. The tool was in a prototype phase, but we needed to catch and fix critical issues, increasing the likelihood of success in broader, out-of-home testing scenarios. The pilot took place during the course "Dynamics and Vibrations" at the 2nd semester of the engineering study programme "Sustainable Design". In the first semester, the students had introductory courses in mathematics, statics and strength of materials. In the course where the test took place, the cross product of vectors was crucial for understanding basic concepts such as angular velocities and angular accelerations of rigid bodies, which are vector quantities in nature. There were more than 10 students present in the class, 7 filled in the consent form, 4 tried the goggles, other observed, several were very engaged in a dialogue, and 4 answered the questionnaire. During this testing, an unexpected bug was detected as well as a need to have written material (mentioned above) with detailed task descriptions for students outside the VR. Those issues were fixed for the second test at Karlstad University (Sweden). However, even this first test on the prototype gave us encouragement that we were on the right track, as can be observed from the selected student comments below:

- I understood it before the VR, but I definitely think that I would have understood it even faster if I had been introduced in VR for it, the first time I had to learn about it.
- I think it is a really nice variation to more traditionally taught ways. It was a cool activity to open up for discussions between students, especially with potential in making small groups.

Karlstad University as the second testing site

At Karlstad University, we tested with 2nd semester civil engineering students, directly after they had finished their first Linear Algebra course. The students participated voluntarily in the activities and no examination or credits were connected to the process. They were first introduced to the study and after that, the students worked together in small groups. We had two groups (4 + 5 students) chosen by taking in consideration their experience of using VR. The activity took about 30-40 min per group. This involved both group cooperation and individual testing for all students in all four tasks. After all activities were finished, the students completed the questionnaire individually. In the rest of this paper, we focus on the analysis of this phase as the VR environment was at a more advanced stage than when piloted at AAU, but we needed the pilot as part of the process. Nine students are not enough to generalise. However, the test serves a purpose of being a step in an iterative DBR-process.

Results of test at Karlstad University

Analysis of quantitative data

Although nine answers are not enough for statistical analysis, a descriptive illustration of their answers should be shown. They clearly lean towards positive attitudes towards our VR tool.

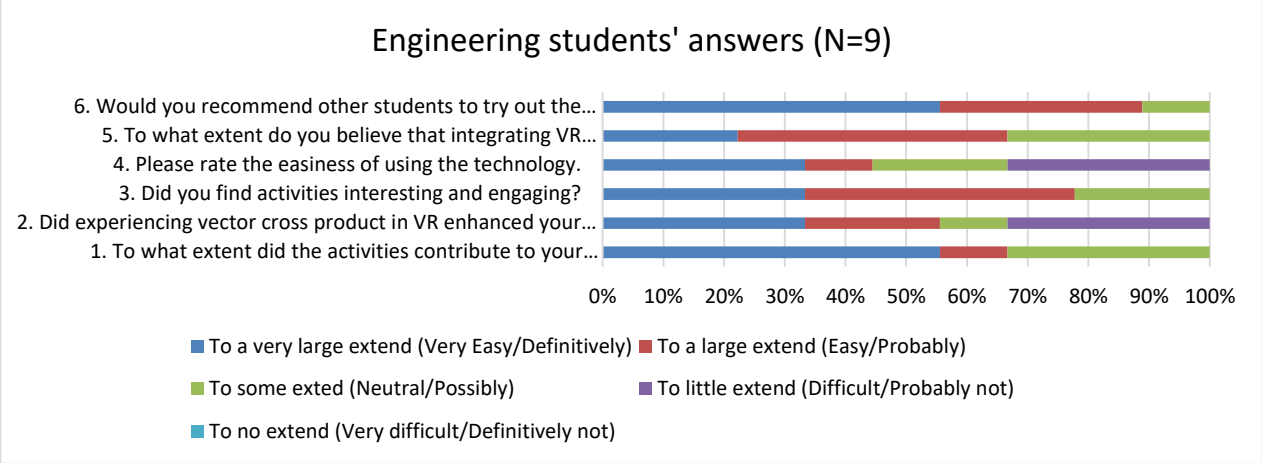

Figure 2: Engineering students' answers at Karlstad University. Questions Q1-Q6 are also seen above

Analysis of qualitative data

We used a data driven approach to analyse the qualitative data since our use of VR is a novel type of activities. As the first step in this analysis, we used ChatGPT to increase the pace of the analysis but also the explore the usability of ChatGPT for such analysis on a relatively small amount of data. Three authors (not from Karlstad University) independently checked ChatGPT's evaluation for mistakes and hallucinations. We found that, mostly, ChatGPT gave valid summaries. However, in Question 1b, asking how the activities (failed to) contribute to their understanding, ChatGPT did not include that a student wrote that the activities were "very funny". Here, "funny" was used in a context of "amusing" not "silly", seen from the context, but ChatGPT might have been confused and then omitted it. Hallucination was seen in the summary of Question 6c, asking if the activities were valuable. The students provided suggestions for significantly more complex mathematics material, while ChatGPT presented it as if this complex material was already present.

In terms of helping students develop understanding of the cross product, the students were positive and experienced the activities as helpful, particularly among students who had not yet fully understood it, while others felt they did not gain any new insights. Particularly the visualisation and interaction with the vectors contributed significantly to their comprehension. This visual approach made complex concepts clearer and more intuitive, which was seen as a significant enhancement compared to traditional methods. Many students also found the interactive and immersive elements of the VR activities enjoyable. The interactivity of the VR environment and the ability to visualize concepts in 3D were strong motivators. In addition, the ability to provide a "big picture" view, showing how mathematical concepts apply in real-life made the abstract mathematics concept more tangible and easier to grasp. Many also stated a wish for more control over the activities to, e.g., draw own vectors, change their sizes, and manipulate them further to see how these changes affect

outcomes. Some students found usability issues and asked for a more intuitive interface. Several students reported experiencing dizziness during use, particularly related to the movement system. Some suggested that teleportation as a movement method could reduce this issue. Some felt that traditional virtual environments or software tools like GeoGebra or Desmos 3D might be more practical and sufficient for certain educational purposes.

Discussion and conclusion

Overall, the results of the testing are promising as students mostly report positive experiences using the VR environment. It helped them understand the concept of cross product, see its use in real life, and it was enjoyable. The observation that students requiring additional time to comprehend mathematical concepts benefit more from VR-based learning environment is unsurprising, given the substantial variation in mathematical proficiency among students. Rather, it underscores the potential of integrating VR technology in mathematics education to assist these students in keeping pace with their quicker-learning peers, ultimately accelerating the overall progress of the class. There are some drawbacks such as motion sickness, and some issues of usability. Motion sickness may be solved by insisting that a student only wears goggles for one task at the time, then rotates. We got ideas for further development such as giving students who may already have a good understanding of the cross product more freedom to play with the vectors. One of the primary limitations of VR integration in education is the significant cost of the equipment. However, since VR is already used in, e.g., medical education and in engineering design, and with anticipated reductions in VR equipment costs in the near future, this research may soon become relevant to a broader range of educational systems. A next step in our project, *myPBL-VRMath*, is to also create VR environments based on rank, eigenvectors and eigenvalues of matrices and explore implementation in courses and with more students as it is a further limitation that our study focused on small groups of students. Building upon the experiences of these two tests, the next step is to do a testing at Azrieli College of Engineering.

Investigating undergraduates' proof methods in linear algebra

Anairis de la Cruz Benito[1] and Christine Andrews-Larson[1]

[1]Florida State University, Anne Spencer Daves College of Education, Health, and Human Sciences, Tallahassee, United States; ad19cc@fsu.edu

Research on student reasoning in linear algebra is extensive, yet few studies focus on linearity and proof (Stewart et al., 2019). This study addresses this gap by examining students' proof methods for a mathematical statement on linear dependence. Data from 54 undergraduates in an Applied Linear Algebra I course were collected using an instructional sequence on Desmos. The sequence introduced intuitive and formal definitions of linear dependence and independence through examples and informal reasoning, progressively building toward formal definitions. Students' proof methods were analyzed and categorized using Stylianides' (2008) framework of reasoning and proving. Most students proved the mathematical statement using deductive, rationale-based, or empirical proof methods, each of which includes various subcategories with distinct characteristics, while some exhibited unclear reasoning or did not respond to the question.

Keywords: Undergraduates, linear algebra, linear (in)dependence, reasoning, proof methods

Literature review on the concept of proof and students' reasoning on linear independence

The process of constructing arguments that meet the standards of a proof is often the final stage in a complex and multifaceted activity known as proving. This activity includes several other processes, including working with examples or exploring specific cases, recognizing patterns, and formulating or refining conjectures or other types of mathematical claims. Additionally, it involves developing informal arguments for these claims that may provide insight or ultimately translate into a proof (Stylianides, 2019).

In advanced university mathematics courses, writing proofs is a key goal (Weber, 2001). Proving is an activity that students are expected to engage in, and it is also a common form of instructional explanation that professors provide for their students, as well as the predominant way mathematics is communicated in university classrooms (Mejia-Ramos et al., 2017). As a foundational course, linear algebra provides students across various disciplines with an early introduction to formal definitions and proofs (Carlson et al., 1993; Stewart et al., 2019). As such, it presents an ideal context for investigating students' proof methods. In recent years, student reasoning in linear algebra has been a rich area of research, but relatively few studies have focused on linearity and proof in this area (Stewart et al., 2019). Linear independence is a challenging concept for students, yet mastering it is crucial for understanding other topics in linear algebra (Stewart & Thomas, 2010). Some research done on student reasoning about linear independence indicates that students tend to lean on procedural approaches, such as using pivots to identify the presence of free variables in reduced row echelon forms, for determining if a set is linearly independent (e.g., Payton, 2019; Stewart & Thomas, 2010). Other research suggests that students can also develop many ways to reason about linear independence geometrically in carefully designed learning or problem-solving environments (e.g., Dogan-Dunlap, 2010; Wawro et al., 2012).

In this study, we addressed the question: What are students' proof methods for linear dependence in the context of a Desmos instructional sequence aimed at supporting their proving activity? To explore this, we developed and implemented an instructional sequence on Desmos focused on linear dependence and independence. Desmos is a free web-based platform for interactive mathematics lessons that offers scalability and accessibility, allowing participants in this study to easily access the instructional sequence activities by clicking a link. Additionally, Desmos facilitated the documentation of students' written work, which was used for the analysis in this study. The

development of the instructional sequence was guided by the Authentic Mathematical Proof Activity (AMPA) framework proposed by Melhuish et al. (2022), which includes components of proof comprehension, validation, and construction. This sequence was carefully designed using examples that engaged students in proof activity, aiming to scaffold their understanding of linear dependence and independence through both intuitive and formal definitions while avoiding outside knowledge, such as row reduction techniques. The instructional sequence consisted of seventeen slides: one outlining the learning goals, three focused on proof construction, two introducing definitions, and eleven dedicated to proof comprehension and validation. This study specifically examined a mathematical statement on linear dependence presented toward the end of the instructional sequence, which required participants to prove: *If a set* $S = \{v_1, \ldots, v_p\}$ *in* R^n *contains the zero vector, then the set is linearly dependent.*

Conceptual framework

In conceptualizing students' proof methods, we draw on the mathematical component of Stylianides' (2008) analytical framework of reasoning and proving (Figure 1). This component categorizes supports for claims into two main types: providing a proof and offering a non-proof argument. Providing a proof is further divided into generic example and demonstration. For this study, we only identified demonstrations in our data; we refer to demonstration as a deductive argument in this manuscript. Stylianides defined a *demonstration* as a valid argument based on accepted truths for or against a mathematical claim. An "argument" refers to a connected sequence of statements. "Accepted truths" is a broad term that encompasses axioms, theorems, definitions, modes of reasoning, and representational tools that a particular community may take as shared at a given time. The meaning of 'valid' in the definition of proof should be understood based on current mathematical conventions.

Stylianides' (2008) non-proof argument category includes empirical argument and rationale-based argument. In our analysis, we found the distinction between empirical arguments and rationale-based arguments in students' reasoning. An *empirical argument* offers inconclusive evidence for the truth of a mathematical claim by checking only a subset of all possible cases covered by the claim. A *rationale* is defined as an argument that is neither proof nor empirical. It either does not explicitly reference key accepted truths used in its reasoning within the context of a particular community or uses statements that fall outside the community's set of accepted truths. This construct was both useful and relevant to our work as in our data set, students were instructed to use definitions in their proofs; some drew on other statements as the basis for their argument.

Figure 1: Stylianides' (2008) framework

Study context and methods

This research took place within the context of a 4-credit introductory applied linear algebra I class, at a public Southeastern Predominantly White Institution (PWI) university in the United States.

This linear algebra class followed a face-to-face format conducted three days per week throughout the 15-week duration of the Fall 2023 semester. The course enrollment included 64 students, with 54 participating in this study, from a variety of applied majors. Class time frequently featured students working on problem-solving activities in small groups; many problems were taken from the Inquiry-Oriented Linear Algebra (IOLA) project (Wawro et al., 2013). The instructional sequence on Desmos on linear independence and independence was assigned as part of students' class work, and they worked on this activity at home.

Stylianides (2019) noted, proving is a multifaceted and complex process, with the proof serving as the final outcome of this activity. In this study, we focus on the analysis of students' reasoning argument to a mathematical statement and particularly on the final product of individual proving activities. During this process, each participant was first assigned an ID from P001 to P054, and their raw responses to the mathematical statement: *If a set* $S = \{v_1, \ldots, v_p\}$ *in* R^n *contains the zero vector, then the set is linearly dependent* were analyzed. The analysis and categorization of proof methods was conducted using the mathematical component of Stylianides' (2008) analytical framework for reasoning and proving but adapted to the context of this study as follow:

Deductive Proof Method: A student' argument was classified as a deductive proof method if it demonstrated that a set containing the zero vector is linearly dependent by appealing to valid mathematical principles emphasized in the instructional sequence. These arguments were grounded in formally accepted truths, such as the definition of linear dependence and properties of the homogeneous vector equation (HVE) $c_1v_1 + c_2v_2 + \cdots + c_pv_p = \vec{0}$. Within this category, students' responses varied in the formality of their reference to the HVE, which resulted in three subgroups: those who used mathematical notation, those who referred to the HVE verbally, and those who did so implicitly.

Empirical Proof Method: A student's argument was classified as an empirical proof method if they demonstrated that a set containing the zero vector is linearly dependent by relying on specific examples. These arguments typically involved selecting a particular set of vectors, one of which was the zero vector, and constructing a non-trivial solution to the homogeneous vector equation. Within this category, two subgroups were identified based on how students referenced the homogeneous vector equation: one group used mathematical notation explicitly, while the other described the equation's structure and logic through verbal explanation.

Rationale-Based Proof Method: A student's argument was classified as a rationale-based proof method if they demonstrated that a set of vectors containing the zero vector is linearly dependent through reasoning that either did not make explicit reference to accepted mathematical truths emphasized in the instructional sequence or relied on ideas outside that instructional sequence. These arguments did not meet the criteria for deductive or empirical reasoning and were therefore categorized as rationale-based.

Unclear Reasoning or Non-Response*:* Some responses did not fit into any of the categories above. These were labeled as *unclear reasoning* when the explanation lacked interpretability or as *response does not answer question* when the student merely restated the definition of linear dependence or addressed a different mathematical statement without proving the one posed in the prompt.

Findings

The following findings represent how students responded to the mathematical statement: **Prove that if a set** $\mathbf{S = \{v_1, \ldots, v_p\}}$ **in** $\mathbf{R^n}$ **contains the zero vector, then the set is linearly dependent.**

Deductive proof methods

Of the 54 participants, 18 constructed arguments using deductive reasoning, invoking general mathematical principles. These students demonstrated understanding of the Homogeneous Vector Equation (HVE) and the formal definition of linear dependence. Their approaches varied in the

specificity and formality of how they expressed this reasoning. I categorized their arguments into three groups based on how they referenced the HVE: 1) explicitly using mathematical notation, 2) explicitly in verbal form, and 3) implicitly in verbal form.

Explicit Reference to the Homogeneous Vector Equation with Mathematical Notation. Seven students made direct and formal use of symbolic notation. These students wrote out the homogenous vector equation ($c_1v_1 + c_2v_2 + \cdots + c_pv_p = \vec{0}$, and clearly stated that a solution exists where at least one scalar coefficient is non-zero. Their arguments were deductive in structure and reflected formal understanding of the mathematical definition of linear dependence. Students in this group explicitly referenced both the equation's structure and its logical implications. For example, P003 stated:

> "The formal definition of linear dependence is that a set of vectors is linearly dependent if there exist weights, not all zero, such that $c_1v_1 + c_2v_2 + \cdots + c_pv_p = \vec{0}$. If a set contains the zero vector, then any real number used as a scalar will still result in the zero vector. Therefore, you can scale every other vector by 0 and scale the zero vector by any non-zero number and get 0 as an answer to the equation every single time."

Explicit Verbal Reference to the Homogeneous Vector Equation. Seven students described the logic and structure of the Homogeneous Vector Equation (HVE) without using mathematical notation. These students used clear verbal reasoning to outline how a linear combination of vectors could result in the zero vector when at least one scalar (typically for the zero vector) is non-zero and the rest are zero. Although these students did not write the equation symbolically, they demonstrated a precise grasp of how the HVE supports a deductive proof. For example, P011 argued:

> "It is always linearly dependent because you can always find at least one nontrivial set of coefficients that satisfies the linear dependence condition. What I mean by this is you can assign values of 0 to the vectors that aren't the zero vector. When you do this, you can assign an infinite number of values to the cp of the zero vector.

Implicit Verbal Reference to the Homogeneous Vector Equation. The remaining four students conveyed deductive reasoning in their arguments without explicitly naming or describing the Homogeneous Vector Equation structure. These students explained that the zero vector can be multiplied by any non-zero scalar while the other vectors are multiplied by zero, leading to a non-trivial solution. Although the homogeneous vector equation was not directly cited, their language reflected a conceptual understanding of its role in proving linear dependence. For example, P010 claimed:

> "If a set contains the zero vector then that vector is free because it can be multiplied by any scalar without changing. This means there must always be a non-trivial solution because it can be multiplied by any scalar while the other vectors are multiplied by 0."

Empirical Proof Methods

Of the 54 participants, 12 students used empirical arguments to show that a set containing the zero vector is linearly dependent. These arguments relied on specific examples, where students selected a set including the zero vector and constructed a non-trivial solution to the corresponding homogeneous vector equation. Within this group, two types of reference to the equation emerged: explicit use of mathematical notation and explicit verbal description.

Explicit Reference to the Homogeneous Vector Equation (with Mathematical Notation). Five students made explicit reference to the homogeneous vector equation using mathematical notation. They wrote out the equation of a form $c_1v_1 + c_2v_2 + \cdots + c_pv_p = \vec{0}$ and provided specific examples showing that not all scalars were zero. Their reasoning was anchored in the formal structure of the equation, even though their proofs were grounded in particular cases rather than general reasoning. For instance, P053 stated:

> " Given $\{v_1, v_2, v_3\}$, where v_3 is the zero vector, we can write the homogeneous vector equation as: $c_1v_1 + c_2v_2 + c_3v_3 = (0, 0, 0)$. We can set c_1 and $c_2$to be equal to 0, and set c_{13} to be any real number, and this would give us a nontrivial solution to the HVE. Similarly, any vector set that contains the zero vector can have a nontrivial solution. By definition, a set of vectors is linearly dependent if is has a nontrivial solution, so any vector that contains a zero vector is linearly dependent."

Notably, one student, P005, in this group went further by assigning specific values to each vector in the set. They stated:

> "Consider a vector set $(1, 1, 1), (3, 2, 1), (0, 0, 0)$. The set is linearly dependent because $0\big((1, 1, 1)\big) + 19(0, 0, 0) = 0(3, 2, 1)$. Since there is a non-trivial solution with not all zero constants, the set is linearly dependent by the formal definition. This same theory applies to any set containing the zero vector because the zero vector can be multiplied by any constant with the other vectors being multiplied by zero."

Explicit Verbal Reference to the Homogeneous Vector Equation. Seven students referred explicitly to the structure of the homogeneous vector equation without using formal notation. These students described the mathematical process of forming a linear combination of vectors with scalar weights and achieving a non-trivial solution. For instance, P027 stated:

> "This is similar to the earlier problem where we were asked if a set was linearly dependent if the solution was $c_1 = 0, c_2 = 0, c_3 = 17, c_4 = 0) = (0, 0, 17, 0)$, given that v_3 was the zero vector. The same solution applies here: assuming that v_3 is the zero vector and $p = 4$, that exact same solution would be true, and since the solution contains at least one nonzero value (17), it is nontrivial and the set is linearly dependent."

This type of reasoning demonstrated awareness of the formal structure of the homogeneous vector equation, specifically, the role of scalar coefficients and their relation to the zero vector, though expressed in verbal or contextual terms rather than symbolic notation.

In this group one student, P046 assigned specific values to the vectors:

> "If a set has solution of only zeros, that doesn't mean the set is necessarily independent. It's only when that is the only solution it can be concluded a set is linearly independent. So, by showcasing there are other solutions to the set in R to the n, it can be proven the set is linearly dependent. For example, the set $(1, 2, 1), (-1, -2, -1), (0, 0, 0)$ contains the solution $(0, 0, 0)$. However, the set also contains the solution (1,1,1). Therefore, the set is linearly dependent."

Rationale-Based Proof Methods

Out of 54 participants, 12 demonstrated that a set of vectors containing the zero vector is linearly dependent by providing arguments that qualify as rationale-based. I identified three nuances in how students employed these arguments: some wrote underdeveloped explanations that omitted explicit references to key accepted truths; others referenced ideas outside the instructional sequence; and a few relied on false assumptions (understood here as statements inconsistent with the accepted truths of the instructional sequence). These issues ultimately prevented the arguments from meeting the criteria for deductive reasoning.

Arguments that were not completely elaborated. Two students showed that the set containing the zero vectors is linearly dependent by communicating the odea of what this will be true but did not really elaborate on their argument. For instance, one student stated:

> "The set would be linearly dependent because the fact that it contains the zero vector indicates it has many non-trivial solutions."

However, the student did not elaborate on the details of those non-trivial solutions or how their existence is known.

Arguments that drew on knowledge external of the instructional sequence. Five students using rationale-based arguments drew on knowledge external to the definitions (and thus external to the Desmos instructional sequence) to prove the that if a set $S = \{v_1, \ldots, v_p\}$ in R^n contains the zero vector, then the set is linearly dependent. For instance, P039 drew on ideas about matrices arguing that:

> "If S contains the zero vector, the matrix would have a line of all 0's, meaning the set is linearly dependent."

Arguments that drew on false assumptions. Five students using rationale-based arguments based their reasoning on false assumptions which are statements that do not belong to the set of accepted truths of the instructional sequence used in this study resulting in an invalid argument. For example, P034 stated that:

> "All linearly dependent sets contain the zero vector, as there is a non-trivial solution to the problem and that can be represented as $0v_1 + 0v_2 \ldots 0v_p = 0$."

Unclear Reasoning

Nine out of 54 students wrote arguments that were classified as demonstrating *unclear reasoning*. These students used idiosyncratic language, making their statements difficult to classify within any of the existing argument types in Stylianides (2008)' framework. For example, P002 stated:

> "If the vs equal zero v's exists and not all that satisfies the equation is a zero."

Response does not Answer the Question

Three students wrote arguments that either stated the definition of linear dependence without proving the statement, or proved a different statement, not the one being addressed. For instance, P035 only stated the formal definition of linear dependence but did not prove the given mathematical statement:

> "The set of vectors $\{v_1, \ldots, v_p\}$ is said to be linearly dependent if there exist weights (real numbers) $c_1, \ldots, c_p$ not all zero, such that $c_1v_1 + c_2v_2 + \cdots + c_pv_p = 0$."

Discussion and conclusion

This study examined undergraduate students' proof methods for a mathematical statement on linear dependence using Stylianides' (2008) reasoning-and-proving framework in an Inquiry-Oriented Linear Algebra (IOLA) class. The findings revealed a range of proof methods. Approximately 33% of participants constructed deductive proofs, drawing on formal definitions and accepted

mathematical structures. This is a promising outcome given that prior studies (e.g., Makowski, 2021) have found deductive proof construction to be rare, even among advanced students. The relatively high proportion of deductive reasoning in this study may be attributed to the design of the instructional sequence, which was grounded in the Authentic Mathematical Proof Activity framework (Melhuish et al., 2022) and emphasized multiple proof-related tasks. Students were guided through comprehension, validation, and construction of arguments, helping them navigate between informal insight and formal expression. Many constructed valid proofs using written language, although few used symbolic notation such as the homogeneous vector equation, consistent with previous findings that students often struggle to incorporate formal mathematical language (Moore, 1994).

Notably, about 22% of students used empirical reasoning, supporting their claims with specific vector examples rather than generalized arguments. While not formally deductive, these responses reflected a strong understanding of the underlying definitions and the logical structure of the proof. Prior work (Weber et al., 2020) suggests that empirical reasoning can serve as a cognitive bridge toward formal proof construction. Students in this category appeared to possess conceptual knowledge but relied on example-based reasoning to express it, which may be understood as part of the natural progression toward deductive thinking. This reinforces the view that proof development is a continuum, not a binary skill (Stylianides, 2008).

An additional 22% of students used rationale-based arguments grounded in informal or intuitive justification. Although these responses did not meet formal proof standards, they suggest that students were engaging meaningfully with the task and attempting to explain why the claim holds. Together, the empirical and rationale-based responses highlight the instructional value of supporting students as they move from informal reasoning to more formal modes of justification. A smaller portion of students, approximately 17 %, wrote arguments that were difficult to interpret due to idiosyncratic language or did not answer the question directly. These responses may still reflect partial understanding, but they point to challenges in translating knowledge into structured argument, an issue also noted by Weber (2001), who found that students often struggle to apply known facts and techniques in proof contexts.

This study has important implications for teaching linear algebra proofs. Instructional sequence approaches that incorporate both informal and formal reasoning, alongside examples and varied proof activities such as comprehension, validation, and construction for enhancing students' engagement in proof activity (Melhuish et al., 2022) may better support their reasoning development and proof construction abilities. Future research should explore students' reasoning processes more deeply through interviews and examine the impact of targeted interventions on proof construction. This research has limitations, including its focus on a single linear algebra classroom, its analysis of only written proofs, and the exclusion of interview data that could have provided deeper insights. Despite these limitations, it offers valuable insights into students' reasoning processes in linear algebra and underscores the importance of supporting their transition from informal to formal proof construction. Its findings contribute to the small but growing body of literature focused on linearity and proof.

A lukewarm defence of the mathematics lecture

Amalie Thorup Eich-Høy

University of Southern Denmark, Denmark; amtho@imada.sdu.dk

The lecture is an often-criticised format of teaching that nevertheless prevails in university mathematics classrooms. This paper offers empirically based perspectives on the qualities of a lecture in advanced linear algebra. Using ethnographic thick description based on third person video recordings, the aim is to examine the analytical relevance of psychoanalytic theories when making sense of lectures. I find that this interpretative lens forefronts how the teacher creates a learning environment that affords durational pleasure, thus highlighting affective values of the lecture.

Keywords: Lecture, university mathematics education, embodiment, resonance, erotics.

Introduction

In the beginning of the semester where I conducted my observations, the vice dean sent out a letter addressed to all teaching staff at the Faculty of Science. He wrote:

> The three-phase model at the Faculty of Science has had its time […] We cannot separate well-being and teaching […] Lectures may well be an element that we continue to use, but as a form of teaching, lectures have their natural limitations. (Nielsen, 2024)

The three-phase model, i.e. lectures, homework and tutorials, has been standard in the mathematics department for decades. In the letter, the vice dean seems to distinguish between forward-looking teaching that promotes well-being of the students, and lectures that are implied to be outdated. This plea for student-centred, active learning approaches is consistent with literature on university pedagogy and general didactics, where the legitimacy of lectures is called into question (Jones, 2007). For example, lectures are criticised for their reliance on transmitting knowledge to students who are rendered passive. Regardless, the lecture prevails in mathematics classrooms at universities (Viirman, 2021, pp. 467–468).

Literature on the lecture is of course not monolithic. Based on interviews on first-year mathematics students' reflections on why lectures matter, Melissa Rodd (2003) forefronts the 'spiritual purpose' of the lecture, in that the lecture may inspire wonder, develop identity, and stimulate imagination. She rejects the 'transmission' criticism as a false premise and highlights instead how lectures direct desire for learning. As such, she problematises the juxtaposition of valid participation and social interaction. Rodd asks the question: "if there were no mathematics lecture, what would be lost?" (Rodd, 2003, p. 15), pointing to how the qualities of lectures are difficult to replicate in other communication or teaching formats. Her sentiment is echoed by Steve Jones: "This live experience cannot be replicated through texts or recorded media; the immediacy, the corporality and the subtle dialogue between students and lecturer are irreproducible and ephemeral" (Jones, 2007, p. 402). This calls for qualitative research on lectures that makes sense of them in more ways than their form. As David Pritchard points out in reference to the debate on the legitimacy of lectures, "different disciplines must be treated differently" (Pritchard, 2010, p. 609). The lecture is a diverse practice, not least across disciplines, and according to Pritchard, some of the criticism of lectures appears

superficial when applied to mathematics. He outlines three functions of the mathematics lecture: communicating, modelling and motivating. This paper follows the path of motivation, although motivation is not the affective term, I will be using. Olov Viirman, who has followed the path of modelling in his work on the function of lectures, inquires after arguments about the value of lectures that are based on empirical investigation:

> [A]ny discussion of the role of the lecture in future mathematics teaching at universities, whether among researchers or practicing lecturers, needs to be informed by research on actual lecturing practice. (Viirman, 2021, p. 487)

Within this choir of lecture-apologists, this paper finds its voice. I contribute with empirical research on the qualities of a university mathematics lecture, making sense of the lecturing practice through a theoretically eclectic interpretative lens of embodiment, resonance, and erotics. By trying out these theories, I contribute with ways of understanding university mathematics teaching practice that forefronts alternative perspectives on it. These perspectives might benefit both the university mathematics education research community as well as the local context of my study.

Methods

The lecture analysed in this paper is part of the data for my PhD project. I work ethnographically (Van Maanen, 2011) in the learning environment of the institution where I studied and am currently employed. This makes my study akin to an autoethnography, which requires both intellectual and political considerations about taking 'native' viewpoints for granted and balancing organisational loyalty (Alvesson, 2003, pp. 167–174). As part of my ethnographic work, I have videorecorded 25 lectures given by four different teachers in courses on calculus and linear algebra for first-year students in pure and applied mathematics. The lectures were recorded with a video camera from the back of the class to my side and a microphone placed on the front row pointed at the teacher. The video and audio files have been synchronised and transcribed. While observing the lectures, I took extrospective and introspective notes to support my later writing.

The lecture is the thirteenth and second-to-last lecture in the course *Advanced Linear Algebra* that took place in the spring of 2024. It was transcribed using four tracks of information: The first records timestamps, the second categorises the situation, the third transcribes the speech, and the fourth holds stills from the video recordings, showing the blackboard, the slideshow, or the teacher. A timestamp was made every time the teaching element shifted in a meaningful way. For example, categories are: Going through a proof, giving examples on the board, answering questions from students, and so on.

The transcription serves a heuristic purpose, since I have worked mostly inductively without predefined categories or codes adhering to a specific theory. Instead, in general terms, my empirical approach is exploratory and descriptive, with a mix of hermeneutic, phenomenological and pragmatic viewpoints: Hermeneutic because I interpret the lecture while trying to be conscious about the context of my observations as well as my own prejudice. Phenomenological because I try to understand the social phenomenon of mathematics teaching from a human perspective. And lastly, pragmatic because I work from the assumption that the methods and theoretical notions I employ, produce the reality I describe (cf. Jackson & Mazzei, 2017). My ideal is to first wonder about the data and then

bring in appropriate theories and their vocabularies. In this way, describing a situation is part of analysing and explaining it (Geertz, 1973).

To make the choice of theories transparent, I interweave the sections on theory and results. In doing so, I write in the style of 'confessional tales' and 'impressionist tales' (Van Maanen, 2011), where one's own lived experiences become part of the object of research. I must emphasise that I do not use my own situatedness as a substitute for the student point of view, but for illuminating the research process as an interpretative act. The lecture that I will analyse was in fact a turning point for the theoretical framework I employ, so the interwoven structure reflects the temporal order of events.

Theoretical outset

My ideal may be to wonder first, but I did not set out theoretically emptyheaded when I began my observations. Having just been a student myself, my initial interest was student-centred, and I directed my attention to the learning environment as a site for experiences where students actively construct knowledge. I drew on the theory of embodied cognition (Lakoff & Núñez, 2000), which remains relatively modest in research on the tertiary mathematics education compared to lower levels, not least in combination with design-based methods (Abrahamson et al., 2020).

The theory of embodied cognition holds that human thought is inseparable from our bodies, and that abstractions are metaphorical and based on primary, bodily experiences (Lakoff & Johnson, 1980). This has several implications for mathematics education, some of them being that learning is situated in multimodal experiences (Shapiro & Stolz, 2019), and that a focus on gesture and other extra-linguistic modalities is beneficial for interpreting students' understanding of mathematics (Edwards et al., 2014). With these perspectives in mind, I went into the empirical phase of my research.

The case of the Jordan Decomposition Theorem

As stated, a turning point in my theoretical framework and research questions happened near the end of my empirical work. In the thirteenth lecture on *Advanced Linear Algebra*, the teacher ('Liam') proved the Jordan Decomposition Theorem, a result so major that it was basically the climax of the course. Liam put it like this:

> Liam: All right. Så lad os se på beviset, for vi har faktisk bygget op til det her bevis over de sidste tre, fire forelæsninger. Faktisk igennem hele kurset.
> *All right. So let us look at the proof, because we have actually built up to this proof for the last three, four lectures. Actually, through the entire course.*

I went into this lecture with a brewing sense of ambivalence toward lecturing as a practice. In last week's lecture on nilpotent matrixes, a streak of eight questions from students ended when Liam, in the interest of time, requested the students hold their questions so that they could move on to an example. I was quick to judge this hushing and disengaging in dialogue as bad pedagogical practice, but at the same time, I noticed in myself an excitement that he would keep on lecturing. I also noticed that the students, unsurprisingly, seemed more hesitant about asking questions, and although the lectures had certainly not turned into a completely monologic practice, elements like proofs seemed to be surrendered to Liam's initiative. Now I sat at the back of the class, ever ready to jot down notes on Liam's metaphors, body language, and visualizations, as the thirteenth lecture began.

About fifteen minutes of prefatory ideas, or what Liam called the 'baby version' of the decomposition, led up to the proof of the theorem. The first minute of the lecture was spent by students requesting two recap lectures, of which he agreed to do one before the written exam. Three minutes went with introductory motivations for the theorem. Liam then spent six minutes presenting both the general and the complex case of the decomposition, showing an illustration of the decomposed matrix:

Liam: Denne her blok nederst til højre […] den her matrix har den egenskab, at den ikke har nogen egenværdier. Man kan tænke på det som at vi har alle de her pæne blokke her, her og her, der går ned, og så har vi en matrix, som består af … skrald. Det her, det er en ubehagelig matrix, som ikke har nogen egenværdier. Det kan vi generelt ikke lide. Det er ikke noget, vi er særligt glade for, så det er sådan, det er der, vi prøver sådan at putte alt vores skrald ned i det her højre hjørne.
This block at the bottom to the right […] this matrix has the property that it has no eigenvalues. You can think of it like we have all these nice blocks here, here, and here, going down, and then we have a matrix consisting of…trash. This one, it is an unpleasant matrix that has no eigenvalues. That is something we generally do not like. It is not something we are particularly pleased with, so it is like, it is where we try to put all our trash, down into this right corner.

After this illustration, two and a half minutes went with students' questions. The next minute, Liam presented the theorem in general, non-matrix terms, i.e. the 'actual' Jordan Decomposition Theorem, after which he declared the proof to begin, as quoted at the beginning of this section. He spent five minutes proving the first lemma needed, and then spent one and a half minutes outlining the idea of the proof of the second lemma needed. Finally, seven minutes of uninterrupted proving followed.

I observed the multimodal aspects of the proof: Liam faced the class at a standing desk with his tablet on it, as the slides appeared on a canvas to his left. The proof manifested one line at a time, and from his desk, Liam moved the cursor as a pointer on the slides while talking. Once, after passing his gaze over the students, he turned to the blackboard to elaborate on a detail.

A recurrent metaphor throughout the proof was 'a matrix without eigenvalues is trash,' which Liam introduced in the quote above. He spat out the word 'trash' with a disgusted facial expression every time he said it, while he spoke of the field of complex numbers with corresponding fondness, since the decomposed matrix does not have a trash corner over this field. Most of the proof was about validating that the lowest right corner did indeed consist of trash over a non-complex field. Apart from laughing at Liam's apparent abhorrence of matrixes with no eigenvalues, the students had turned into mute non-data, until Liam concluded the proof with the remark:

Liam: Så nu har I altså set et af de absolut vigtigste resultater inden for lineær algebra: Jordan-dekompositionen. Ja?
So, now you have seen one of the absolute most important results in linear algebra: The Jordan decomposition. Yes?
Student: Du sagde, nulvektoren kunne aldrig være, hvad?
You said the zero vector could never be what?
Liam: En egenvektor.
An eigenvector.
Student: Men er det vektoren, der består af nuller, eller er det den generelle?
But is that the vector consisting of zeroes or is it the general one?
Liam: Det er nulvektoren for vores vektorrum. Nulvektoren for vores vektorrum er aldrig en egenvektor per definition.

It is the zero vector for our vector space. The zero vector for our vector space is never an eigenvector per definition.
[Six seconds of silence]

Liam: Så der har I altså Jordan-dekompositionen, som fortæller at alle matricer kan skrives som denne her blokdiagonale udgave, som jeg nævnte før. Eller som jeg nævnte i starten af forelæsningen.
So, there you have the Jordan decomposition that tells us that all matrices can be written as this block diagonal version, as I mentioned before. Or as I mentioned at the beginning of the lecture.

Later, I sat at my desk to write up the episode, struggling to describe the nuances of the proof with the vocabulary of embodied cognition. I found that I was missing perspectives on time and affect, and so I realized that embodied cognition was necessary but not sufficient for making sense of the lecturing practice I had observed.

Toward a networked framework of mathematical pleasure

I therefore present a tentative networked theoretical framework to forefront alternative perspectives on the case of the Jordan Decomposition Theorem (cf. Bikner-Ahsbahs & Prediger, 2009). To make sense of my observations, I want to take my framework in the direction of psychoanalysis. The versions of psychoanalysis I find particularly relevant for university mathematics education, are the ones that synthesize with critical theory. Here, Herbert Marcuse is an original torchbearer who dealt with erotics and pleasure as societal matters, relevant outside the private sphere.

Marcuse's pleasure principle arises from a critique of Sigmund Freud's belief that gratification is incompatible with progress (Marcuse, 1955). Marcuse disputes that repressing pleasure is necessary in a functioning society. In fact, he builds his Marxian utopia on a freed principle of pleasure, where the resources afforded by the industrial society, if used wisely, create the opportunities to live in accordance with the emancipated human nature, in an erotic relationship to the world.

A contemporary contribution to Marcuse's school of thought is Hartmut Rosa's notion of resonance, which describes a successful way of relating to the world, in that resonance is the counterpart to alienation in the Marxian sense of the word (Rosa, 2019). According to Rosa, a resonant experience will touch you, move you, and even transform you. Resonance requires self-efficacy but is at the same time uncontrollable: You can never guarantee resonance, but some environments might afford resonance more than others. Rosa formulates a critique of the conditions for resonance in our world, which according to him is characterized by acceleration, competition, and a fundamental attitude of manipulation and control of the world. Hence, to Rosa, the experience of being in the world is intimately related to time.

Resonance is a useful phenomenological term for describing learning situations that 'spark' (Rosa & Endres, 2017). Resonance pedagogy deals with the prerequisites for a resonant didactic triad between the subject, teacher, and students: in short, there must be an atmosphere of trust and genuine engagement with the material from both the teacher and the students. Through Marcuse, Rosa also references the erotic relationship to the world as an exemplary attitude in resonance pedagogy, stating that: "Eroticism, to me, is the opposite of trying to manipulate the world" (ibid., p. 35).

Queering the notion of erotics, I finally network KJ Cerankowski's notion of durational pleasures (Cerankowski, 2021). I find their terminology extremely relevant to my observations because it dethrones the orgasm as the pinnacle of pleasure and explores nonsexual pleasures that do not peak by ending. They write: "I want to stake a claim for an erotics of pleasure, of orgasm even, that does not rely on a teleological model of building tension until one arrives at the release" (ibid., p. 136). By removing the end goal, Cerankowski reframes the temporality of pleasure, broadening our understanding of which pleasures may be legitimate and valuable.

Revisiting the case of the Jordan Decomposition Theorem

In the case of the Jordan Decomposition Theorem, it is clear that Liam's lecture does in fact build on a 'teleological model of building tension until one arrives at the release'. In the first quote, he draws attention to this very build-up, which according to him has lasted through the entire course. It is also noticeable that he spends quite a bit of time on prefatory ideas, motivating the need for the theorem, visually illustrating its meaning and laying down all steps necessary before completing the proof in a streamlined manner. However, the release is disrupted when a student immediately asks a clarifying question at the finish line, afterwards prompting Liam to reiterate the 'ta-da', as it were.

Based on the dramaturgy of the lecture, I interpret that Liam intended for the climax to have a certain impact, brought about by half a semester's worth of prelude. The prefatory elements just mentioned can be seen as efforts to create an environment that affords wonder and vicarious feelings of pleasure. Through speech, slides, body language, and chalk, Liam performs multimodal expressions of embodied metaphors that I would argue create the conditions for a resonant didactic triangle. The 'trash corner', for example, is a metaphor whose function is equal parts communicating the idea and evoking a sense of beauty enabled by the 'trash-free' complex matrix, which excites Liam to a contagious degree. The build-up to the proof can then be seen as a way of persuading the students of its relevance, or "to arouse curiosity and a desire to know" (Sinclair & Watson, 2001, p. 40), instead of immediately stating it as a fact. Liam's lecturing reflects an attitude to mathematics not unlike Marcuse's idea of an erotic relationship, where the proof of the Jordan Decomposition Theorem for quite a while gets to be a potential awaiting realisation. Hence, I would argue that Liam's lecture performance is 'awe-inspiring' (Rodd, 2003, p. 17).

The ruining of the climax in turn disrupts who controls the pleasure, a power-smoothing that is made possible by the immediacy of the lecture, where Liam and the students gather in this specific time and place. With Cerankowski's terminology, the pleasure becomes durational in a temporality where the journey is the act itself. The lecture thus operates on two different teleological models at once, building tension and ending 'not with a bang but a whimper'.

Now, a lot of this discussion has hinged on verbal data, and as already mentioned, the students become non-data to me when they listen. However, it would be a fallacy to then conclude that nothing of note happens. For instance, Liam is evidently not just speaking 'at' the students. His gaze before he turns to the blackboard to elaborate on the proof can be interpreted as subtle communication, and while I do not have access to the students' experience, Rodd's (2003) findings suggest that more might go on in a lecture than meets the eye. It is also worthwhile to question whether looking for observable activity as wholesome learning qua activity is the be-all and end-all. As Miya Tokumitsu argues:

> Many critics dismiss lecture attendance as "passive learning," arguing that students in lectures aren't doing anything. Today, declaring something passive completely delegitimizes it […] under capitalism, anything that doesn't immediately appear as productive, even if only in the most superficial way, is dismissed as a waste of time. (Tokumitsu, 2017)

The students in the lecture analysed in this paper are calm and quiet most of the time. Are they learning? Maybe not this moment, here. But later, somewhere else, the desire to know instilled in them by the lecturer carries on. I argue here that learning is mostly unobservable in lectures on a surface level because learning might be displaced in spacetime. A value of the lecture may thus be excitation, understood as "an elevation in energy" (Porsager, 2021, p. 22). Seen through this lens, the apparent passivity of students instead appears as a build-up of desire for knowledge awaiting satisfaction.

Conclusion

Being an analysis of just one lecture out of the 25 I have observed, this paper serves as a pilot study for my doctoral dissertation. It is nonetheless a feature of ethnographic thick description that "small facts speak to large issues" (Geertz, 1973, p. 23). I have demonstrated the analytical relevance of psychoanalytical perspectives when discussing the value of lectures by reading Liam's proof of the Jordan Decomposition Theorem in its erotic dramaturgy, and further speculating about what goes on under the surface. Combining embodiment, resonance, and erotics has enabled me to appreciate the lecture as a learning environment that affords excitation and durational pleasure. Examining whether this perspective is consistent with students' experience is a relevant endeavour for further research.

Acknowledgments

I would like to thank Martin Hauberg-Lund Laugesen and Olov Viirman for valuable comments on previous drafts of this paper.

Design and implementation of a study and research path for teaching statistics: Impact of the dialectics

Laura Fernández-Ruano[1], Kristina Markulin[2] and Noemí Ruiz-Munzón[2,3]

This paper explores the implementation of study and research paths (SRPs) in university-level statistics courses, focusing on the appearance and impact of dialectics within SRPs built around the same generating question at two universities. By comparing these experiments, similar and different factors influencing the development of university-level modelling are identified. The analysis of three SRPs highlights emerging dialectics, and contrasts how students engage with statistical techniques. Future research could further explore why certain dialectics arise, and how they shape the development of SRPs.

Keywords: Anthropological theory of the didactic, dialectics, study and research path, statistics.

Introduction

In recent years, university teaching has changed through the implementation of a common European framework (Bologna Declaration). This has broadened the focus of the study of didactic approaches, going beyond traditional or theory-practice lectures to include approaches such as inquiry-based, project-based, problem-based learning, service learning, etc. Several studies address the relationship that should exist between the learning process and the methodologies applied from a cognitive perspective (Tan et al., 2019). However, few analyse how teaching research methodology connect with disciplinary or epistemological elements, which has changed little since the Bologna process was implemented at university. This can be seen in the fact that the descriptors of subject content have hardly changed (Bosch et al., 2021). The question to ask is the following: "Does a change in teaching approach lead to a change in the conceptualisation of the knowledge to be taught?" It is postulated that the answer is affirmative because of the emergence of new educational purposes in the sense of Gascón and Nicolás (2021).

This paper assumes the postulate of the Anthropological Theory of the Didactic (ATD) that all human activity can be interpreted as a modelling process to be described in terms of praxeologies (Chevallard, 1999). The Bologna process was a shift from the "paradigm of visiting works" to the "paradigm of questioning the world" (Chevallard, 2015). It may, therefore, be inferred that "doing statistics" in the professional world is to implement a modelling process in which the tools that enable solving an initial problematic situation belong to that discipline. From this perspective, engineering degrees will be focused on the teaching of statistics. A learning methodology based on inquiry processes (Artigue & Blomhøj, 2013) in which statistical concepts and techniques contribute to exploring and solving a problem should be used.

Theoretical framework and research question

The ATD proposes a didactic device called a Study and Research Path (SRP) that enables the development of an inquiry process derived from a previous didactic engineering process (Artigue, 1989). An SRP starts with a generating question Q_0, which arises from a problematic situation, and poses a challenge to a study community. Q_0 is expected to be open-ended, and requires searching information in different sources and studying it to develop and validate a final answer. SRPs can be described by the Herbartian schema: S (X; Y; Q_0) ➥ $A^{\heartsuit}$, where the study community consisting of student(s) X and teacher(s) Y addresses the initial question Q_0 through derived questions Q_i, and intermediate answers $A_j^{\diamondsuit}$ leading to a final answer $A^{\heartsuit}$. The dialectic of questions and answers is the engine for the development of SRPs (Bosch, 2018).

For the *a posteriori* analysis of SRPs, ten dialectics were developed within the ATD to describe the inquiry process (see the latest proposal by Vásquez (2024)): (D1) study and research dialectics: an SRP alternates between study and research moments, evolving through the generation of questions and answers; (D2) individual and collective dialectics: SRPs involve collective responsibility for responses while delegating individual tasks within teams; (D3) dialectics of praxeological analysis-synthesis: students analyse different information sources during the inquiry while teachers make sure Q_0 is answered thoroughly; (D4) dialectics of delimiting and abandoning the topic: mastery emerges when specific knowledge is required to clarify previously misunderstood answers, making it useful for Q_0; (D5) dialectics of the parachutist and the truffle hunter: enquiry alternates between broad brainstorming (parachutist) and focused exploration (truffle hunter) to find relevant knowledge; (D6) dialectics of black boxes and clear boxes: some objects are used without in-depth study (black boxes), leading to grey areas in the inquiry process; (D7) dialectics of media and milieu: the milieu is made up of all the resources, data, tools, and works found in the media (textbooks, the teacher, the Internet, etc.). A rich milieu will allow, for example, the validation of results; (D8) dialectics of reading and writing: information is analysed and integrated into notes and reports, connecting reading with writing; (D9) dialectics of dissemination and reception: the study community justifies and discusses answers in a "common discussion" moderated by the teacher; (D10) dialectics of systems and models: a modelling process refines the initial system and model through intermediate systems to better address Q_0.

The design of an SRP in statistics for engineering degrees, developed in the LABINQUIRY transfer project (Lombard et al., 2024), consists of four phases (Figure 1). In phase 0, the teacher or an external professional presents the generating question Q_0, teams are formed, the SRP methodology is explained, and conditions for delivering the final answer $A^{\heartsuit}$ are set out. In phase 1, brainstorming leads to initial explorations using accessible sources, which are then reorganised and prioritised. Phase 2 involves advanced searches for data, answers, and tools, testing their validity through analyses, experiments, or software, and progress is summarised in an interim report. Phases 1 and 2 may be repeated, if necessary, but within limits. In phase 3, the response to the initial question is presented. Figure 1 shows an outline of the phases of an SRP in statistics.

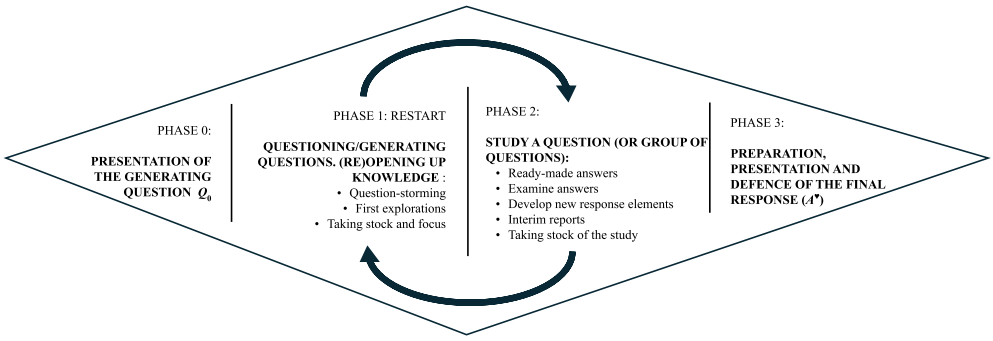

Figure 1: Phases of an SRP in statistics for university degrees

Through the analysis of three implementations of an SRP in statistics, this study aims to identify what elements of the SRP implementation contribute to the emergence and development of different dialectics in statistics at the university level.

Methodology

To address the research question posed, three different implementations of the same SRP, developed during the academic year 2023/24, were used at two different universities (IQS and EUSS) in Barcelona, Spain. The generating question was:

> Q_0: Are the low emission zones (Zonas de Bajas Emisiones, ZBE, after their initials in Spanish) in Catalonia effectively designed, and to what extent does their size affect their efficiency?

A representative of the Department for Transport and Mobility of the Catalan government raised this question. The participating students were organised in teams at the two universities where the SRPs were implemented.

The initial experiment, referred to as SRP-IQS, which was refined over four years, was fully integrated into a second-year statistics course (3 hours a week for 15 weeks) during the academic year 2023-24 in the Chemical Engineering degree at the *Institut Químic de Sarrià* (IQS), Ramon Llull University. The teacher (IQS-T) in charge of the subject is a chemical engineer with extensive experience in both the industry sector and in teaching statistics at the university. In this edition, 43 students organised into seven teams of six members each took part in the experiment.

The experiments conducted for the first time during academic year 2023-2024 in a second-year statistics course at the EUSS School of Engineering attached to the Autonomous University of Barcelona, are referred to as SRP-EUSS. A total of 209 students of statistics for all the engineering degrees (automation and industrial electronic, mechanical, and automotive engineering, engineering in industrial organisation, in renewable energies and energy efficiency) divided into eight groups, participated in the experiment. Two teachers (EUSS-T1 and EUSS-T2) taught four groups each. Both teachers are mathematicians. T1 has extensive experience in teaching mathematics and statistics, while T2, a researcher in didactics of mathematics, has experience in teaching statistics implementing SRPs. The SRP was implemented in the final part of the course in four 2-hour sessions (T1), and six 2-hour sessions (T2).

An analysis was conducted to identify elements and dialectics, and to compare the organisation and nuances of the three implementations. It focused on instructional materials, student team project diaries, and classroom observation notes. Attention was given to statistics topics addressed differently throughout the subject and project. The analysis also included student submissions related to the project. This approach revealed variations in practices and priorities.

Upon completing the SRPs, the students responded to a survey. It concerned the structure of the statistics course, the project in general, its organisation and content, teamwork, and the students' general impression (Fernández-Ruano et al., 2024). Parts of this survey were analysed. From a set of 32 questions (statements), the analysis focused on the four items considered the most relevant to identify the application of the various dialectics outlined and the general impression. They were the following: [Q10] I think the project was related to the content of the subject, [Q12] The project has changed my idea of statistics, [Q25] The descriptive analysis of the variables helped formulate hypotheses, and [Q32] I positively value having carried out this project. As a 5-point rating scale was used, including options from "strongly agree" – 5 to "strongly disagree" – 1, the responses were compared using the Wilcoxon-Mann-Whitney test. A significance level of 10% was applied (Meek et al., 2007).

Results and discussion

This study does not intend to show an in-depth analysis of the different experiments carried out, but a comparative analysis focusing on those dialectics that do not appear in some of the SRPs. They are, therefore, factors that may explain the differences in the students' final assessment. The dialectics (D1, D2, D7, D8) found in all the experiments will not be discussed here, as they are based on a common SRP design.

Experiments at EUSS

The project was implemented *a posteriori* as an application of the content of the course, strengthening statistical and organisational competencies that had not previously been worked on in the course. To implement the SRP, spreadsheets and the statistical software R with its R Commander package, were used earlier than in the previous traditional organisation of the course. This means the students had not used software for descriptive statistics before carrying out the project. The approach and the content used in the IQS implementation were not the same as those at the EUSS implementation. This is mainly because a significant part of the statistics course at EUSS comprises topics on probability, which are not specifically related to data analysis in engineering applications.

At EUSS, in the course taught by T1, the students were limited to applying techniques explicitly covered during the course. In contrast, T2 introduced tools for descriptive statistics and extensions of linear regression techniques that extended beyond the standard course content. As a result, the D4 dialectic cannot be clearly identified in this experiment. In the course taught by T2, regression techniques were developed using software treated as a "black box"; for example, R^2 was referenced and applied without giving the students a clear understanding of its calculation, limitations, or implications, thereby reflecting the D6 dialectic.

An analysis of the studies conducted by the different teams indicates that, at EUSS, T2 provided a broader range of questions (e.g., analysing the number of private cars registered in Barcelona, investigating other regions, and assessing the influence of Barcelona's port area). T1 offered a more narrowly defined scope of study, indicative of a weaker D5 dialectic.

Experiment at IQS

The theory sessions concerned the knowledge the students demanded or needed (through diverse examples that were not related to the project) to advance in the study of Q_0 and derived Q_i, thus combining teamwork and whole-class activities. A detailed account of the design and implementation of those sessions is available in Verbisck et al. (2024). Figure 2 shows a mid-project question-answer (QA) map of the SRP-IQS, constructed in class to show the potential of dialectics D3 and D9. The idea was not for the reader to refer to the exact questions and answers, but to exemplify how the discussions, under the teacher's guidance, resulted in partial answers to Q_0. In Figure 2, dialectics D4 and D6 are identified. The questions in blue are related to the functioning of the ZBE or to general aspects, those in grey to regulations or legislation, the ones in pink to location aspects, purple to seasonal aspects, green to pollutants, yellow to the organisation of the teams, and orange to data (spreadsheet).

During SRP-IQS, tasks characteristic of professional statistics (dialectic D10) appeared. Examples are the delimitation of the system to be modelled (Which radius of influence of the ZBE to consider? Which populations to select?), choosing the variables according to the hypotheses or study to be carried out (Which pollutants to study? During which period?), or all the work of cleaning data, magnitudes, etc. This essential process is absent in traditional statistics courses, where hypotheses and/or data are typically provided in advance, or are directly linked to previously explained techniques.

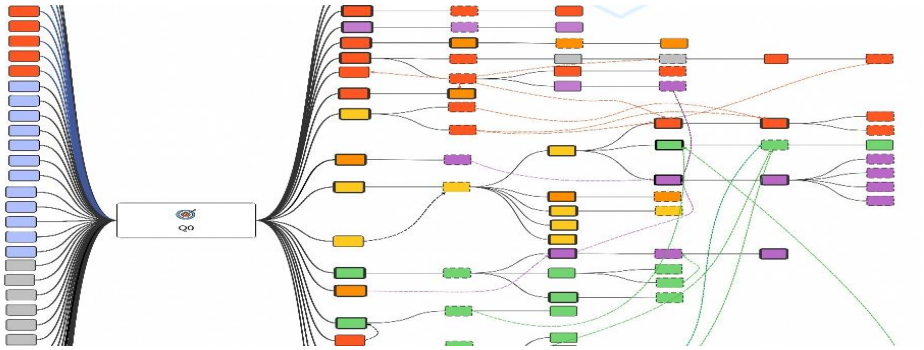

Figure 2: Mid-project QA map of SRP-IQS

The predetermined curriculum was followed (descriptive statistics, probability distributions, inference techniques and parameter estimation, hypothesis testing for one and two samples, analysis of variance, regression models), but some topics were covered in less depth. For example, the study of distributions was reduced due to its theoretical nature, while non-parametric tests were emphasized more, as students explored them through software interaction.

Comparison of group discussions

The moment of collective sharing in the two SRPs at EUSS aligns more closely with a traditional framework of presenting results in which the teacher assumes the role of verifying and validating outcomes (*institutionalisation moment*, as described by Chevallard, 1999). In contrast, in SRP- IQS, this moment of sharing corresponds to the D9 dialectic, as the students actively defend their contributions in front of their peers. They assume knowledge as a response in the strong sense ($A^{\blacktriangledown}$), not as mere reciters of existing works with which they have become familiar, but have not made their own, and have not adapted to the new situation ($A^{\Diamond}$).

This is observed at EUSS, where T1's students limit their world of techniques explained to them in the traditional course and take responsibility for applying them correctly, for example, by replicating the software calculations manually without assessing whether the results answer the questions posed or not. This leads to the fact that the *moment of evaluation* in the case of SRP-EUSS remains the teacher's responsibility. In SRP-IQS, collective sharing aligns more closely with the *technological-theoretical moment* (Chevallard, 1999). Teams debate the most effective strategies, complementary results, or inherent limitations. It is also during this process that, in agreement with the students, the study focuses on the issues that arise from the research. In this sense, the responsibility for validation is shared by the study community.

The epistemological model of statistics challenges the traditional view of the discipline as a hierarchy of techniques, where descriptive and inferential statistics are treated as distinct domains. In SRP-EUSS, this perspective persists, as many students applied inferential tests without first conducting a descriptive exploration that could have guided their work. Conversely, in SRP-IQS, techniques and tests were introduced incrementally, driven by the demands of the investigative process.

Analysis of the student survey

Insight is provided into the students' post-project perspective to highlight some results that expand on the already discussed characteristics of both SRPs. The sample sizes for EUSS-T1, EUSS-T2 and IQS-T are 16, 25, and 32 respectively. When investigating the teacher's distribution of answers in the groups, similar tendencies are observed in the responses to the survey (Figure 3). Regarding Q10, the students whose teacher was EUSS-T1 gave more polarised responses (strong disagreement – 1 and strong agreement – 5 with the statement) in comparison to those of the other groups, but the medians per teacher of 4, 4, and 3.5, respectively, show no significant differences. The same occurs in Q32, where the three medians are 3, and no significant differences are observed (Figure 3).

Figure 3: Survey results per groups and per teacher: Q10, Q12, Q25, Q32

Differences are observed in the responses to Q12. The medians shift from 2 for EUSS-T1 to 2.5 for EUSS-T2, and for IQS-T it was 3 (Figure 3). The difference between EUSS-T1 and IQS-T is statistically significant ($p = 0.04$). In Q25, the medians are 2, 3, and 3, and EUSS-T1 has a significantly lower median than EUSS-T2 ($p = 0.09$) and IQS-T ($p = 0.02$).

These results show that a richer modelling process in dialectics leads to greater changes in students' perception. As they shift from procedural learning to deeper engagement, their stance toward the discipline changes—from learning to be examined to learning to do.

Conclusions

The three experiments compared in this paper are part of an ongoing investigation into the implementation, analysis, and evolution of SRPs for statistics for non-statisticians at the university level. The appearance of dialectics in the implementations and their impact on the study and research process were identified. The SRP design does not guarantee the emergence or effective management of dialectics D4, D5, and D6, as these are linked to the teachers' characteristics. In contrast, dialectics D3, D9, and D10 are related to tools for managing discussions and collecting results (e.g., the QA map, class diary), which influence the redistribution of responsibilities within the study community. These elements should be considered in the design of SRPs to ensure the emergence of dialectics D3, D9, and D10. This aligns with the LABINQUIRY project's objective to provide teachers with the necessary resources for inquiry-based activities.

The analysis highlights emerging dialectics and compares student engagement with statistical techniques. Future research should explore the dialectics' drivers and impact on SRP development.

Disciplinary authorities or fellow educators? Exploring positionings of mathematicians when interacting with secondary teachers

Myriam Goor and Alon Pinto

Weizmann Institute of Science, myriamg@weizmann.ac.il

The communication between mathematicians and secondary mathematics teachers have long been recognized as a critical issue in mathematics education. Yet, such communication remains fraught and limited, in part due to profound communal differences and issues of power and authority. This study is part of long-term research project that investigates how communal differences may be leveraged as a valuable resource in cross-community interactions in mathematics education. In this paper, we draw on Positioning Theory to analyse the positioning acts of mathematicians and teachers as they discuss and evaluate instructional moves of a teacher presenting a proof in a videotaped secondary lesson. Our analysis distinct sets of acts suggesting that a positional shift occurred when the mathematicians were situated as fellow educators rather than disciplinary authorities or pedagogical critics. We discuss the potential affordances of different positionings.

Keywords: *Mathematicians, cross-community communication, boundary encounters, positioning.*

Rationale

The field of Mathematics Education is culturally diverse, encompassing various communities such as mathematicians, secondary mathematics teachers, and education researchers. Among these, mathematicians and secondary mathematics (SM) teachers are particularly influential due to their direct impact on student learning and their roles in shaping policies and curricula. In particular, it has been suggested that improving communication and collaboration between mathematicians and SM teachers is vital for addressing persisting challenges that lie at the intersection of these two communities, such as the double discontinuity in teacher preparation (Lai & Baldinger, 2023) or the secondary-tertiary transition (Pinto & Koichu, 2023). However, partnerships between mathematicians and SM teachers remain scarce, among other things, due to a lack of opportunities for interaction, asymmetric relationships, and profound epistemological and sociocultural differences that hinder communication (Fried, 2014; Goos & Bennison, 2018). This study aims to explain how communal tensions and differences between mathematicians and SM teachers shape their communication, and how such tensions and differences could be leveraged to support dialogical learning between these two communities (Akkerman & Bakker, 2011). Our research is conducted within the M-Cubed Lab (Mathematics Teachers, Mathematics, Mathematicians), a setting specifically designed to generate, document and study dialogical learning between mathematicians and practicing SM teachers (Pinto & Cooper, 2022, 2023).

Prior research has shown that engaging mathematicians and SM teachers in dialogue is not sufficient by itself for generating dialogical learning (Pinto & Cooper, 2023). In many cases, the teachers and mathematicians will initially respond to and build on arguments made by their peers, while only relating superficially to the arguments of the other party (Goor et al., 2023). However,

in certain cases, the dynamics of the discussion seem to shift, affording both parties with rich opportunities for dialogical learning (Goor et al., 2023; Pinto & Cooper, 2022, 2023). In this paper we adopt Positioning Theory to explore whether and how such shifts may be explained in terms of different positionings of mathematicians in their interactions with SM teachers.

Theoretical background

A space in which two communities interact can be conceptualized as a case of a boundary encounter, namely, an environment where communal differences and tensions may lead to discontinuity in communication or in action (Akkerman & Bakker, 2011). However, the literature also suggests that boundary encounters may encourage and support exchange of knowledge and perspectives across communities through dialogical learning, or boundary crossing, specifically in relation to mathematicians and SM teachers (e.g., Goos & Bennison, 2018; Goor et al., 2023; Pinto & Cooper, 2022, 2023). For example, Goor et al. (2023) described how a boundary encounter with mathematicians supported SM teachers in recognizing and exploring alternative mathematical interpretations of a question a SM student raised in class and revisit their perspectives on the opportunities for learning this question afforded. Mytlis and Pinto (accepted) examined professional obligations SM teachers expressed in boundary encounters with mathematicians and found that SM teachers revisited their obligation to mathematical precision when considering the pedagogical merits of SM activities that mathematicians deemed mathematically invalid and therefore inappropriate for SM lessons. Pinto and Cooper (2022) showed how mathematicians and SM teachers may join hands and draw on each other's expertise in formulating a refutation to an imprecise mathematical claim of 8^{th} grade students that is appropriate to an 8^{th} grade class.

In all the above studies, the emergence of dialogical learning was not immediate. The researchers describe various barriers in communication, such as tacit use of incommensurable meanings, colliding professional obligations, or different implicit assumptions about students and their motivation for learning. The literature on boundary encounters identifies various means that may encourage and support dialogical learning, such as artifacts that function as *boundary objects* and facilitators' mindful *brokering* (Akkerman & Bakker, 2011). Boundary objects are characterized as possessing interpretative flexibility that enables different communities to collaborate without achieving prior consensus regarding roles and shared goals. Brokering refers to intentional and purposeful actions that help discussants articulate and negotiate the tacit norms and views of their respective communities. Both boundary objects and brokering are essential for addressing the profound different perspectives of mathematicians and SM teachers towards mathematics and its teaching and learning. However, special attention needs also to be given to the troubled history and asymmetric relationships between these two communities that are known to lead to issues of authority and power that may derail communication (Fried, 2014; Goos & Bennison, 2018).

To address this need we turn in this study to Positioning theory (Davies & Harré, 1990). Positioning theory was developed and has been used in numerous works to explain how the roles individuals take or are assigned within social interactions shape communication. It posits that in every interaction, individuals are positioned by others (interactive positioning) and by themselves

(reflexive positioning) in specific dynamic ways, and this positioning guides action by determining, often implicitly, what kinds of actions are considered appropriate within a given context. Two key terms in Positioning Theory that are prevalent for this study are *positioning acts* (hereafter acts) and *storylines*. Acts refer to the specific actions, behaviors, or utterances that individuals perform in social interactions. These acts are not neutral; they are interpreted and understood within a particular social context, where they carry meaning related to the positions of the individuals involved. For example: Making a statement, asking a question or expressing an opinion. Each act can either reinforce, challenge, or transform the positions of the people involved. Storylines are the broader narratives or frameworks within which acts are interpreted. They provide the context that gives meaning to the acts and help establish the expected roles, behaviors, and power dynamics within an interaction. In the context of boundary encounters between mathematicians and SM teachers, Positioning Theory can help explain how the roles of each community are constructed and how they may affect dialogical learning. In this paper we ask: *How are mathematicians positioned when interacting with SM teachers about SM education?*

Methods

Data collection: The M-Cubed Lab

Data for this study were collected within the M-Cubed Lab (Pinto & Cooper, 2022, 2023), an environment designed in accordance with the knowledge accumulated over the years in research on boundary encounters to encourage mathematicians and SM teachers in bringing their experience and expertise to bear in joint explorations of various issues in SM education. In M-Cubed, small groups of practicing SM teachers and mathematicians meet monthly for 3-hour facilitated sessions where they watch segments from videotaped SM lessons, chosen in advance by the facilitators, the authors of this paper, as boundary objects. The participants identify key teaching moves in the videotaped lesson and explore alternative moves that could have been taken. These explorations serve in turn, with the support of the facilitators who act as brokers, as a basis for boarder explorations of different pedagogical and mathematical perspectives. All SM teachers have over ten years of experience, including in high-track classes, while all mathematicians are actively engaged in academic research and have at least six years of university teaching.

The participants in the M-Cubed session discussed in this paper were three mathematicians (denoted as M1-M3), six SM teachers (T1-T6), and the authors of this paper who acted as facilitators (F1-F2). The session revolved around a 12-minutes segment from a 12th-grade intermediate-track videotaped lesson. In this segment, the teacher, referred to here as Ms. N, presented a proof of the derivative of the natural logarithm function $y = lnx$ by deriving both sides of $e^y = x$ (as illustrated in Figure 1) even though this proof is not required by the intermediate-track curriculum. In her presentation, Ms. N repeatedly tried to prompt students to guess her next step, for example by asking "how can we write the expression $y = lnx$ in a different way?". Generally, the students failed to anticipate the next move, and often made false claims, for example proposing that the derivative of e^y is $(y)e^{y-1}$. The discussion of Ms. N's teaching moves that

followed lasted 40 minutes and was video-recorded and fully transcribed. The discussion primarily focused on: critiques of the presentation of the proof; students' prior knowledge; goals and challenges underlying the intermediate track; and similarities between the intermediate track and university mathematics courses for physics students.

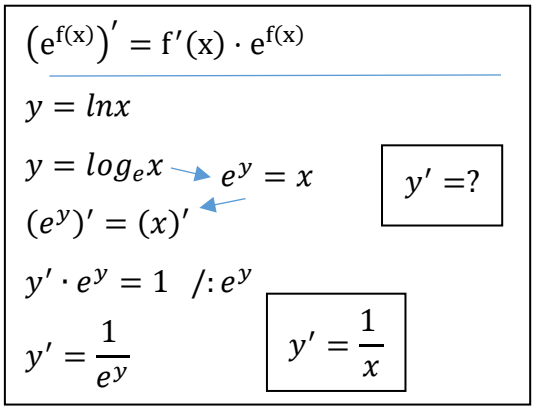

Figure 1: An illustration of how Ms. N wrote the proof on the board during the lesson

Data analysis

Data analysis was conducted in three stages that focused on acts, positioning, and storylines, respectively. In the first phase, we examined participants' utterances and marked repeating acts of the mathematicians or of the teachers at different parts of the meeting. These acts included for example: asking questions; arguing mathematically; making claims about mathematics in general; making claims about the videotaped lesson; making claims about SM education in general; endorsing, challenging or rejecting an observation from a member of the same community, or from the other community. We then refined our initial list of acts to reflect variations of the same act that were observed in the data, particularly when these variations appeared to be communal. For example, the act ‘making claims about the videotaped lesson’ was refined to ‘making critical claims about the videotaped lesson’ and ‘making supportive claims about the videotaped lesson’, with the latter act further refined to additional acts such as ‘defending the instructional actions of Mrs. N. The second phase focused on how participants were positioned within the discussion, based on the identified acts. This analysis distinguished between interactive positioning, where participants were positioned by others, and reflexive positioning, where participants positioned themselves. For example, a participant might be positioned as an authority by making a definitive judgment about the lesson or positioned as an advocate by defending the lesson’s approach. In the third phase, we tried attributing overarching storylines that could explain the different positionings we identified, drawing on the literature. In this paper we present the first two phases of the analysis, and we briefly refer to our initial findings from the third phase at the Discussion Section.

Findings

Our analysis highlights three distinct positioning of the mathematicians in their interactions with the SM teachers: disciplinary experts, pedagogical critics, and fellow educators.

In the M-Cubed discussion, the mathematicians' acts could be initially characterized primarily as making critical and authoritative statements regarding the proof and its presentation. The mathematicians did not identify an error in the proof, but they considered its presentation flawed. One such flaw, highlighted by M2, related to Mrs. N's use of variables throughout her presentation: "It really bothered me that x and y are sometimes treated as independent variables, and sometimes one is a function of the other, and it is not clear what is a function of what". Specifically, M2 pointed out a step in the presentation where Mrs. N. differentiated the expression $e^y = x$, first by differentiating the left-hand side with respect to y, then differentiating the right-hand side with respect to *x*, without addressing the relation between *x* and *y*.

In the discussion of this issue, the mathematicians talked in one voice, reasoning in definite and decisive terms, without inviting the teachers' perspective. For example:

M2: This thing with [the variable] y, why does it bother me? The nonsense [the students] said, that you derive e^y and get ye^{y-1}, it means that they see e as a symbol, which can either be a variable or not, and y, it's just another symbol that can either be a variable or not.

The teachers, for the most part, did not make claims about the mathematical validity of Mrs. N.'s actions, instead asking the mathematicians questions, inviting them to elaborate their perspective:

T2: I don't understand, it's truly the same function [on the two sides of the equation].
M3: I must say that there are crimes in university physics lessons as well.
T2: But why is it a crime?
M2: Functions of the same variable, that's why they remain equal when you differentiate them.
[…]
T1: I must say […] I still don't understand what is the mathematical problem that [the mathematicians] see, that I'm missing.
M1: It starts with that [a student] asks why not look at $\log_a x$ [instead of $ln\ x$] and it was clear that [Mrs. N.] does not know what would happen.

Furthermore, the teachers turned to the mathematicians to ask for their validation:

T1: What would solve all this is to write *f(x)* instead of *y*?
M2: Yes, this would solve it.

The acts of the mathematicians and SM teachers in these exchanges can be seen as positioning the mathematicians as having an authority with respect to quality and validity of the mathematics. On the other hand, when the mathematicians reasoned about pedagogical implications, often critically, the teachers responded with confidence, explaining and defending the instructional choices of the Mrs. N, and pushing back against the mathematicians' claims. For example, T1 defended Mrs. N.'s use of questions, observing that "her questions were accurate for a group that understands just roughly". T1 also defended Mrs. N.'s decision to still focus on the derivative of $ln\ x$ after a student suggested that it may be simpler to look at the more general case of the derivate of $\log_a x$:

M2: [Mrs. N.] just took the function and pushed them in the direction she wanted.
T1: No that's not accurate. The student asked it wouldn't be simpler [to look at $\log_a x$], and she said no, and it's true, it's not simpler […] Students have difficulty with algebra. Anything you add, another number, another multiple of something, it is complicated for them. And so, pedagogically, at the intermediate track, it is really not simpler to prove [derivate of $\log_a x$]; she is right there!

The teachers also rejected alternative instructional approaches proposed by the mathematicians:

M2: In my fantasy, what I would like [Mrs. N.] to say is: let's look at the equation that defines $lan\, x$, at $e^{lan\, x} = x$, that's our fundamental expression, and we are differentiating it.
T1: No way! At the intermediate track? At the high track, maybe, but at the intermediate track?

The acts of the mathematicians and the SM teachers in these exchanges can be seen as positioning the mathematicians as pedagogical critics, who are invited to make positive or negative assessments regarding instructional decisions and moves and offer alternatives, but whose positions can be questioned, challenged, and even rejected.

A third positioning was evident when M3 asked to present on the board a proof from a university ordinary differential equations course he teaches. He wrote the differential equation $y' = y^2$, and presented a series of manipulations of symbols that without explanation is mathematically senseless, even though it yields a solution to the equation. M3 further observed that such an approach is not uncommon in tertiary mathematics courses for physicists, where solutions are obtained without properly defining variables or procedure. He then suggested that the challenge of teaching proofs to physics students may be analogous the teaching proofs at the intermediate level:

M1: Maybe at the intermediate level you teach [students] to do manipulations like physicists.
M3: That's very bad! I think we're raising [at the university] very bad physicists as a result, and intermediate-level [SM] students deserve better as well.

This analogy shifted the discussion from critiquing Ms. N.'s lesson to collaboratively exploring the question what the purpose of presenting a proof in class is, which is pertinent to both parties. At the tertiary level, the mathematicians debated whether physicists need to see valid proofs:

M3: I taught this [course], you can do all of [the proofs] in a way that makes sense.
M2: It's like units in physics, its work hygiene…
M1: I disagree, you have physicists doing their master's in General Relativity, and they learn to work with this staff, and there is no way that you can explain to them mathematically what they are doing and also have them acquire all the analytical skills in three years.

A similar discussion developed around the reasons for presenting proofs at the intermediate track:

M2: What's the point of showing proofs to intermediate-level students if you're saying they will almost surely not understand them? What's the goal?
T1: Look, in every class, there are two who will understand what [Mrs. N.] was doing. And for these two […], it's worth these ten minutes, so that they will understand that it's not because I say so, but really […] there is a proof for it.
T2: Yes? I don't know, it's a question.

T4: Even when you're not showing all the proofs? […] There is no reason in the world to show a proof that have no value on its own, if all the value of the proof is to show that there is a proof.

Notably, in these two last exchanges, in contrast to the exchanges we analyzed before, neither the mathematicians nor teachers are speaking with one voice and with full authority. Both parties have relevant teaching experience to the question that is being discussed, and diverse perspectives. This enables a cross-community dialogue where the mathematicians are positioned as fellow educators.

Discussion

The literature often underlines the important role of mathematicians in SM education as representatives of the discipline (Fried, 2014; Goos & Bennison, 2018). At the same time, the literature also provides ample evidence that SM teachers are generally unclear about how mathematicians' values, norms, and practices could actually inform their teaching and thus may not see mathematicians' expertise as relevant and applicable for them (Lai & Baldinger, 2021; Mytlis & Pinto, accepted; Pinto & Cooper, 2023). These two facets of the relationships between mathematicians and SM teachers could reflect the storylines that underly the first two positionings we identified in our analysis: mathematicians as disciplinary authorities, and mathematicians as pedagogical critics. Both positionings are characterized in that one of the communities speaks in one voice and with authority, in a way that does not invite members from the other community to suggest alternative perspectives that could be compared, elaborated and refined. Thus, these two positionings may be seen as discouraging dialogical learning.

In contrast, the third positioning we identified – mathematicians as fellow educators – reflects a less common narrative, or storyline, which highlights commonalities between SM teachers and mathematicians and their pedagogical challenges and dilemmas. When mathematicians were positioned this way, the dynamics of the discussion was notably different in that it no longer aligned strictly according to communal divisions. Neither side assumed authority, and instead the two sides supported each other in making explicit and negotiating the meanings of tacit notions such as 'mathematics for physicists' and 'intermediate-level mathematics'. The two sides also shared personal experiences regarding a common practice – proof presentation – and jointly explored their goals, in different contexts, when presenting proofs. This positioning also seemed to have helped mitigate the effect of the deficit narratives that the mathematicians expressed about Mrs. N.'s teaching when positioned as disciplinary authorities. Deficit narratives regarding SM teachers and SM education seem to be prevalent among mathematicians, and they have been shown to hinder communication and collaboration between these two communities (Pinto & Koichu, 2023). Our analysis corroborates this finding by showing that SM teachers initially felt compelled to defend Mrs. N. and rejected pedagogical implications proposed by the mathematicians until the positional shift, that turned the focus to the teaching of the mathematicians and the SM teachers.

One potential implication of this study is that it may be beneficial for lecturers in courses for SM teachers to position themselves as fellow educators rather than disciplinary authorities. This can be done, for example, by sharing personal teaching experiences and highlighting analogies to SM

teaching. Further research is needed for investigating whether doing so could help avoid issues of power and authority, disrupt deficit narratives, and reduce teachers' sense of disconnect between mathematics and pedagogy, towards promoting a more effective learning environment.

Research in undergraduate mathematics education using the concept of didactic contract: results and contradictions?

Ghislaine Gueudet[1] and Camille Doukhan[2]

[2] LISEC, UR 2310, Université de Strasbourg, France

The concept of didactic contract is present in many studies about undergraduate mathematics education. Using a review of the literature, we explore the features of didactic contracts identified by research and their consequences for students. Papers investigating the secondary-tertiary transition observe increased expectations, and students struggling to enter a new contract. Other papers reveal contract rules conveyed by teaching practices and adopted by students, but limiting their activity. Some studies proposing interventions introducing an inquiry-oriented didactic contract observe that the 'usual' contract constitutes an obstacle for students' active involvement. We discuss the apparent contradictions in the results obtained by the different categories of studies.

Keywords: Didactic contract, Expectations, Secondary-tertiary transition, Undergraduate mathematics education

Introduction

The concept of didactic contract is present in many studies about university mathematics education. At the beginning of university in particular, some of the students' difficulties can be interpreted as resulting from a change of didactic contract, since: "Secondary school and university have different didactic contracts" (Gueudet, 2008, p. 245). But what do we actually learn from research about the features of the didactic contract(s) at undergraduate level for mathematics, and about their consequences for students? In the context of a research project aimed at uncovering mismatches between the beliefs and expectations of university teachers and those of their students, we reviewed the research literature that used the concept of didactic contract. In this paper we present this review and its outcomes. Recent studies in university mathematics education stress that the diversity of students and its consequences is an essential direction in current research (Pinto & Koichu, 2023). This diversity challenges the existence of a unique didactic contract at university; we claim that this requires to revisit the use of the concept of didactic contract in university mathematics education, and that a literature review on this theme is needed.

The didactic contract: theory

The didactic contract is one of the main concepts within the Theory of Didactical Situations (TDS, Brousseau, 1997). Many different definitions can be found in the literature, even in Brousseau's own work. In our work we refer to the following definition:

"To each precise notion to be taught, the partners in teaching […] associate expectations, obligations that each undertakes and benefits from, and the means by which they envisage (mutually or separately) satisfying these expectations and obligations as well as the consequences of not satisfying

them. A didactic contract is, in the broad sense, an interpretation of the set of these expectations and obligations, be they compatible, explicit, and agreed to or not." (Brousseau & Warfield, 2014, p.1)

The concept of didactic contract is complex; it has been the subject of debates in the French community of research in didactics of mathematics (Sarrazy, 1995). We do not intend here to propose a comprehensive theoretical discussion, but rather to foreground some issues relevant in our context. A first aspect concerns the implicitness of the didactic contract's rules: most of these rules are implicit, and it is neither possible nor desirable to present them explicitly to the students (González-Martín et al., 2014). This raises a methodological issue for identifying the rules of the didactic contract. A second issue concerns what might be called the "level of generality" of the didactic contract. The definition cited above mentions a didactic contract for "each precise notion"; some studies identify didactic contract rules for specific mathematical situations. Chevallard (1988) claims that entering an institution involves a subjection to an institutional contract, which includes a didactic contract for the mathematical contents living in this institution. Balacheff (1988) proposes to distinguish between the didactic contract, corresponding to interactions between a teacher and their students in a situation, and what he calls "custom," which is a set of implicit but more general rules shared in a given classroom for example. This debate concerns the level of generality of the didactic contract, but also a vision of the contract as a set of already existing, stable rules, versus a dynamic process of negotiating the contract along the interactions between the students and the teacher. The research community has not adopted the concept of custom, while at the same time an increasing number of studies has used the concept of didactic contract to study a broad range of implicit features of the teaching and learning processes. De Vleeschouwer and Gueudet (2011) propose to distinguish between three levels of contract in a given institution: a general level, independent of the knowledge at stake ; the level of mathematics as a discipline; and the level of particular mathematical notions.

Drawing on these theoretical elements, we investigate the following research questions:

Which features of didactic contract(s) at the three different levels are identified by research in mathematics education, with which consequences for students? What categories emerge from a grouping of papers according to these features and consequences?

Review of the literature : methods

To answer our research questions, we conducted a review of the research literature in university mathematics education. We were interested in international research using the concept of the didactic contract to analyse teaching and learning features at the undergraduate level. We focused on research conducted in the last twenty years, i.e. research published between 2005 and 2024. We examined books and book chapters concerning university mathematics education; international journals (IJRUME, ESM, ZDM, IJMEST), and the proceedings of the CERME, EMF and INDRUM conferences. We added to this first selection some of the papers cited in it.

We have included in this review only works where the concept of the didactic contract plays an important role. These comprise either synthesis papers that emphasize the concept of the didactic contract, or empirical studies that use this concept in their data analysis methodology and/or present results in terms of didactic contract. We reviewed a total of 40 papers. In each of the selected papers,

we noted the research questions investigated; we examined the features of the didactic contract(s) identified (contract rules in particular, if such rules are explicitly mentioned), and their consequences for students. Moreover, for each study we identified the level(s) of the contract concerned: general (independent of knowledge), disciplinary (related to mathematics) or content-specific (such as calculus or linear algebra).

Results

Three main categories emerged from our reading of the papers; Table 1 shows these categories and the number of papers in each. The length constraints led us to discuss in this text only some selected papers that represent each category.

Table 1. The three categories, and the number of papers in each

Changes of the contract during the secondary-tertiary transition	The 'usual' university contract, adopted but limiting students' mathematical activity	Alternative didactic contract, accepted or not by students	Other	Total

Investigating changes of the didactic contract during the secondary-tertiary transition

A first type of studies concerns the secondary-tertiary transition, the change of didactic contract during this transition, and the difficulties of novice students to enter the university contract.

De Vleeschouwer and Gueudet (2011) observe through a university textbooks analysis didactic contract rules concerning the teaching and learning of duality in linear algebra (content level). In particular, since a linear form is sometimes considered as a function and sometimes as an element of a vector space, students should be able to recognise which point of view is relevant and should be flexible in using either view; this flexibility is typical from university expectations, compared with secondary school. Based on this finding, the authors design an intervention in which a systematic work on this aspect of the contract is organised. The analysis of students' answers to a questionnaire shows that this teaching helped them to develop this contract rule. We note that in this work, an intervention is designed to support the adoption by students of some rules of the university contract.

Studies concerning proof (and thus at the discipline level), synthesized by Selden (2012) show that the didactic contract changes between secondary school and university with increasing expectations, especially in terms of rigour, and that novice students have difficulties linked with this new contract. Bloch and Ghedamsi (2005) study the secondary-tertiary transition concerning calculus. They introduce ten "macro-didactic" variables that characterise the "actual didactic contract", for example: "The degree of formalization"; "The quantity of new notions introduced"; "The status of the tasks proposed: technical application or proof of a general result". The analysis of secondary school textbooks and of lists of exercises used at university (in Tunisia) evidences a change in the values of the ten variables and characterises the didactic contract for calculus in secondary school and at university. Even if used here for a calculus course, these variables can characterise the didactic contract at a disciplinary level; they reveal increased expectations at the beginning of university.

Pepin (2014) investigates students' experience during the secondary-tertiary transition, interpreted as their entrance in a new didactic contract. Referring to the three levels introduced by de Vleeschouwer and Gueudet (2011), she studies in particular the general and the disciplinary levels. Drawing on interviews with students over two years, interviews with teachers and classroom observations, she identifies changes experienced by the students. In secondary school, the students are strongly supported by the teachers, while at university they are expected to find their own learning strategies. Combining the didactic contract and a resource perspective, Gueudet and Pepin (2018) further observe that "discussions with the teacher are not easily available resources for students" (Gueudet & Pepin 2018, p.62) is a general contract rule at university; as a consequence, students develop a rule such as "in case of difficulties, I can find help from my peers" (Gueudet & Pepin 2018, p. 69). At the disciplinary level, there is a mismatch between the teacher's views on the homework to be done (including a work on the text of the lecture) and the actual homework done by the students (focused on exercises, and abandoning the search when the solution is not found quickly). Gueudet and Pepin (2018) also observe that the use of online resources can lead some students to incorporate irrelevant contract rules (here at the level of the content, concerning number theory).

Didactic contract rules limiting students' activity

A second type of studies concerns contract rules conveyed by teaching practices at university, of which the teachers may be unaware, and whose consequence is a limitation of students' mathematical activity. Lebaud (2010) investigates how teachers design mathematics exam texts by using interviews and analysing successive versions of the exam text. She finds that teachers' choices are influenced by didactic contract rules, such as: "The values to be calculated when solving an equation with complex numbers are integers" (content level) or "The answer to the first question of an exercise can appear in the text of the second question" (disciplinary level). González-Martín (2013) investigates the teaching and learning of series. He identifies contract rules through a textbooks analysis. Since the teachers align with the textbooks' content, he hypothesises that the contract rules he identified influence the students' activity. By proposing purposefully designed tasks, he confirms that students have integrated two selected implicit rules (content level): "To solve the questions about series that are given, their definition is not necessary," and "Applications of series, inside or outside of mathematics, are not important" (González-Martín, 2013, p.2328). Dorko (2020) analyses the activity of students using an online homework system proposing exercises about sequences. She identifies that one of the students' strategies is to draw on didactic contract rules at the level of the content, like "when a list of sequences is proposed, some are convergent and some are divergent." The results obtained in such studies reveal implicit contract rules that are conveyed by certain features of teaching and of which the teacher is unaware; González-Martín (2013) describes them as differences between the knowledge to be taught and the knowledge actually taught. Some students leverage contract rules to provide expected answers, instead of reasoning mathematically; moreover some rules limit what is actually expected of students.

Introducing an alternative didactic contract: is it possible?

Most intervention studies using the concept of didactic contract concern inquiry-oriented courses, conveying a specific didactic contract, different from the didactic contract in 'traditional' courses.

We use below the term 'usual didactic contract', which appears in some of these articles, but is not clearly defined by the authors. Grønbæk et al. (2009) study a project-based course, where students work in teams. The authors describe rules of the 'traditional' didactic contract at the general level, e.g. the students have to "do the assigned homework"; the teacher has to "institutionalise good solutions and answer students' questions." In the project-based course, these rules are broken and the teams of students organise their work autonomously. Following two teams of students, the authors observe that what they call an "a-didactic contract" develops in the teams, with rules about the important tasks to be performed and how they are shared within the group. This contract has a positive impact on students' representations about the problem-solving activity. Barquero et al. (2022) note similar changes in the didactic contract, in the context of Study and Research Paths (SRPs: courses starting from an open question where teams of students build their own paths in terms of sub-questions and associated answers). Students have more responsibilities, such as for planning their work or validating an answer. Teachers are no longer the sole holders of knowledge in the classroom. The authors interpret this new contract as a paradigm shift, from 'visiting monuments' to 'questioning the world'. Nevertheless this new contract, very different from the 'usual' one, has to be established in the class and its negotiation can be a delicate process. Dawkins et al. (2019) ask whether or not students adopt the new rules of the didactic contract in an inquiry-based course. Interestingly, they note that some students adhere to the new rules, while others reject them, and this is related to their orientation towards learning mathematics: learning orientation (high buy-in) vs performance orientation (low buy-in).

The study by Ellis et al. (2025) does not concern an intervention; but it evidences the possibility of negotiating different contracts. The authors study the link between students' homework and the didactic contract in the context of a national survey in the US involving 500 institutions. They select 5 universities with successful Calculus I programs and, based on a rich set of data (classroom observations and videos, students' productions, interviews with students and teachers), they observe that the didactic contract regarding homework (at the general and disciplinary levels) in these universities differs from the contract in the other universities. Students are expected to struggle with a more complex content; but they do not struggle alone, they are provided with relevant material to support them in their homework; they are also expected to explain their thinking, and they receive feedback. This study evidences the existence of different didactic contracts in different universities, and the possibility of installing a didactic contract fostering a productive homework.

The papers coded "Other" address specific issues like didactic contract rules when using digital resources, like videos or online exercises. The study by Gill and O'Donoghue (2007) concerns the didactic contract in mathematics service courses in Ireland. Interestingly, the authors identify mismatches between students' expectations and the course delivery. Nardi (2008), interviewing lecturers, notes contradictory expectations which lead her to coin the expression "fuzzy didactic contract", and to expect difficulties for students to understand the rules of this contract.

Discussion

We identified three main categories of papers: (1) papers focusing on the change of didactic contract during the secondary-tertiary transition; (2) papers identifying limitations in the students'

mathematical activity resulting from didactic contract rules; (3) intervention studies proposing an "alternative contract." The features of the didactic contract identified by the studies depend on the category. In category (1), the authors note an increase in expectations of students (e.g. in terms of flexibility, rigor, autonomy). This change creates difficulties for students. Moreover, they are sometimes unaware of this change in expectations; making the new rules explicit can support their entrance in the new contract. The studies in category (2) unveil contract rules conveyed by the teaching practices at university, of which the teachers are unaware. These rules can prevent students from developing a rich mathematical activity. Finally, in the context of research-based interventions, studies in category (3) focus on a didactic contract that is different from the 'usual' contract at university. For such studies, the 'usual' contract can constitute an obstacle, since some students reject the breaches in the rules introduced by the new contract of the intervention.

These answers to our research questions raise some issues, since some of their results can seem contradictory. In the context of an 'ordinary' teaching, studies in category 1 evidence significant expectations at university, while category (2) studies identify limitations in what is actually expected at university, at the level of the discipline and of the content. This apparent contradiction could mean that the expectations and obligations of students at university, although higher than those at secondary school, remain below possible expectations for the mathematics taught. A second issue concerns the entrance of students in the didactic contract: while category (1) studies foreground the difficulty for students to enter into the new contract, studies of the second and third categories, on the opposite, produce results showing that students adopt this 'usual' contract. Moreover this adoption has negative consequences: limitation of the students' mathematical activity, or obstacle for their involvement in an inquiry-oriented teaching. Would the students adopt the 'usual' didactic contract only when researchers want them to act differently? An explanation could be that most students, within a few months, actually comply with rules conveyed by the teaching practices shared in a majority of courses (the 'usual' contract), and that breaking these rules is complex. This leads to a third issue: the existence of a 'usual', dominant contract, regardless of the university, the teacher and the students. Intervention studies proposing an inquiry-oriented didactic contract evidence the possibility, under specific conditions, of negotiating alternative contracts. Even in 'ordinary' conditions, students who have several mathematics teachers at university may experience different contracts. The same teacher may also have different kinds of interactions with different groups of students, and this can produce several contracts in the same class. Elucidating all these issues and apparent contradictions requires further research.

Conclusion

While many studies in university mathematics education refer to the concept of didactic contract, there is still a lot to be learnt about didactic contracts at university. Pursuing in our project the aim of determining implicit expectations of teachers and students, we will not restrict ourselves to the didactic contract but will also consider other theories likely to enlighten such implicit expectations, for example the commognitive theory (e.g. Sfard, 2023). Moreover so far the concept of didactic contract is not associated with a solid method allowing to identify its rules; considering other theories can suggest principles for such a method. Understanding the mismatches between students and teachers at university probably requires a combination of several theories.

Using knowledge from mechanics to solve a calculus task: a study through the lenses of mixed praxeologies

Mathilde Hitier[1, 2] and Alejandro S. González-Martín[1]

[1]Université de Montréal, Département de didactique, Montréal, Canada;
mathilde.hitier@umontreal.ca

[2]Dawson College, Mathematics department, Montréal, Canada

In this paper, we examine the strategies and reasoning employed by students who have completed college-level calculus and mechanics courses as they undertake an unfamiliar graphing calculus task. Adopting a perspective based on the Anthropological Theory of the Didactic (ATD), we analyse students' techniques and justifications, paying particular attention to their use (or non-use) of praxeologies acquired in mechanics. Our findings reveal that students who employed either a praxeology rooted in mechanics or a mixed praxeology combining elements from calculus and mechanics were generally more successful in solving the task. We conclude by discussing the practical and theoretical implications of these results.

Keywords: Differential calculus, mechanics, Anthropological Theory of the Didactic (ATD), college mathematics, mixed praxeologies.

Introduction and research problem

In her literature review on the interconnections between the learning of physics and mathematics, Marrongelle (2004) concludes that "mathematics understanding plays a role in physics learning, and physics experiences seem to have an effect on learning some mathematics concepts" (p. 260). One such concept is the derivative, which (like velocity and acceleration) is central to dynamics. As Stoffels et al. (2022) highlight, dynamics, is "the most common content […] that connects differential calculus and physics, especially in undergraduate mathematics and physics" (p. 235). However, the derivative has been consistently identified as challenging for students, both in purely mathematical contexts (e.g., Fuentealba et al., 2017) and when applied in a physics context such as dynamics (e.g., Stoffels et al., 2022). Moreover, our literature review (e.g., Hitier & González-Martín, 2022) reveals conflicting perspectives on how physics contexts help students understand the notion of derivative.

To explore how students use a physics context to solve calculus tasks, Marrongelle (2004) developed the *Physics Use Classification Scheme*, comprising four categories (Figure 1). However, Stoffels et al. (2022) critique the ambiguity of the *Language-Mixer* category and note that "there is also no evidence that any of the identified user types is more successful [than the others] in solving differential calculus tasks" (p. 238). Additionally, we identify a possible limitation in Marrongelle's study: the participants were enrolled in an *Integrated Calculus and Physics Class* (ICPC), which could influence their use of physics by, for instance, blurring the boundaries between the two disciplines. To our knowledge, since Marrongelle's (2004) work, no subsequent study has investigated how success in solving tasks might vary across the different categories. This gap highlights the need for further exploration of these categories to better understand how students draw on knowledge from calculus and mechanics to solve tasks.

Physics Use	Description
Contextualizer	Student introduces a physical context as a vehicle to solve calculus tasks. Student show evidence of immersing problems in physical contexts in order to solve them.
Example-User	Student evokes examples from physics to help her/him make sense of calculus concepts and problems. Student talks about physics in a way that is disconnected from the problem at hand, often using physics to justify an answer.
Language-Mixer	Student uses language from both physics and mathematics in her/his discussion of solution methods. This classification is applied to a student when there is not enough evidence to classify the student in another category.
Non-User	Student does not use physics, in any recordable written or verbal way to solve calculus tasks.

Figure 1: *Physics Use Classification Scheme*, excerpt from Marrongelle (2004, p. 263)

Theoretical framework

One of the key tools of the Anthropological Theory of the Didactic (ATD) for studying knowledge is that of *praxeology* (e.g., Chevallard, 2019). A praxeology is composed of two blocks. The *praxis* block, or the "'know-how' component" (p. 87), $\Pi = [T, \tau]$, encompasses the *technique* (τ) used to solve a specific *type of task* (T). This technique is supported and explained by a rationale, known as the *technology* (θ), which is embedded within a broader *theory* (Θ). Together, the *technology* and the *theory* constitute the *logos* block, $\Lambda = [\theta, \Theta]$, of the praxeology.

A foundational principle of ATD is that knowledge is institutionally situated. In other words, praxeologies vary depending on the institution in which they are developed or applied. For example, calculus and mechanics, seen as different institutions, may draw on different praxeologies involving the velocity as a derivative (e.g., Hitier & González-Martín, 2022). Recognising this variability, Chevallard (2019) introduces the construct of *mixed praxeologies* for individuals—"praxeologies made up [by an individual] of constituents taken from different disciplines" (p. 98). However, to our knowledge, mixed praxeologies have been described only theoretically in the literature.

Additionally, we consider a task to be *familiar* in a course if the task is part of the *knowledge to be taught* in that course and can be identified in relevant course materials, such as textbooks. Conversely, a task is classified as *unfamiliar* if it falls outside of these parameters.

In this paper, we explore how students draw on a mechanics context to solve an unfamiliar calculus task, through the lens of ATD. Specifically, we address the following research questions: *From which discipline—calculus or mechanics—do students select praxeologies to solve an unfamiliar calculus task? How successful are students at solving this task based on the praxeology they adopt?*

Methods

This paper draws on data from a larger research project that examined the pairing of a differential calculus course with a mechanics course at a large Canadian college, a post-secondary institution that Quebec students must attend prior to pursuing university studies. The regular syllabi of the two courses were not modified, although the teachers collaborated more closely. Therefore, the calculus and mechanics courses were still distinct and not as fully integrated as in Marrongelle's (2004) ICPC. All students registered in the paired courses were part of the college's Enriched Science program, which offers extracurricular activities such as weekly seminars. Our study involved three cohorts of students: one regular or non-paired (R) and one paired (P_1) in the Fall 2019 term, and one paired (P_2) in the Fall 2021 term. No data were collected in 2020 due to the pandemic.

The participants were asked to answer three questionnaires throughout the term, with the last questionnaire submitted during a calculus class near the end of the term. By the time the final questionnaire was distributed, the students had studied one-dimensional kinematics as part of their mechanics curriculum. At this point in their calculus studies, in addition to the usual differential calculus topics (such as derivatives), they had recently been introduced to antiderivatives and had learned how to determine simple antiderivatives symbolically (e.g., determine an antiderivative for a polynomial function). A total of 85 students responded to the final questionnaire (R: 27, P_1: 30, P_2: 28). In this paper, we focus on the question presented in Figure 2. Our previous research (e.g., Hitier & González-Martín, 2022) indicates that this is an unfamiliar task in calculus, but that similar tasks, such as sketching a position-versus-time graph given a piecewise linear velocity-versus-time graph, are familiar in mechanics.

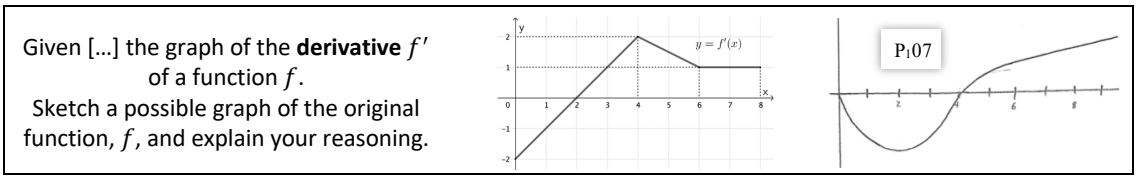

Figure 2: Graphing task (left) and a student's correct sketch of the solution

After an *a priori* analysis of the task, we conducted a praxeological analysis of the students' answers, identifying the techniques and the rationales behind those techniques. We also assessed the graph that each student produced, paying particular attention to their sketching of the four main shapes that comprised it (12 marks in total): decreasing concave up on [0, 2], increasing concave up on [2, 4], increasing concave down on [4, 6], and increasing straight line on [6, 8]. We also assessed three main features (12 marks in total) of the graph: the graph's continuity, its differentiability, and the symmetry of the first parabolic segment on [0, 4] (i.e., $f(0) = f(4)$). Because we asked students to create a sketch and not a precise graph, we did not take into account the use of a scale on the vertical axis and the precision of the values of f with respect to that axis.

A priori analysis of the task

Based on our previous work (e.g., Hitier & González-Martín, 2022), we considered three main approaches in the *a priori* analysis of the task:

1. *AppG*, where the technique consists of identifying relevant features of the graph of the derivative (e.g., its sign), and then attempting to sketch a graph consistent with what can be deduced from the technology. For instance, sketching an increasing graph when the derivative is positive, that is, applying the technology whereby the derivative corresponds to the slope of (the tangent to) the graph of the function, such that the sign of the derivative determines the variation of the graph of the function.
2. *AppE*, where the technique involves determining the equations for the distinct segments of the graph (e.g., $f'(x) = x - 2$) or identifying the form of these equations (e.g., non-constant linear). Subsequently, knowledge related to integration is applied to determine the equations for the corresponding segments in the graph of the function (e.g., $f(x) = \frac{1}{2}x^2 - 2x$) or to establish the form of that equation (e.g., parabola).

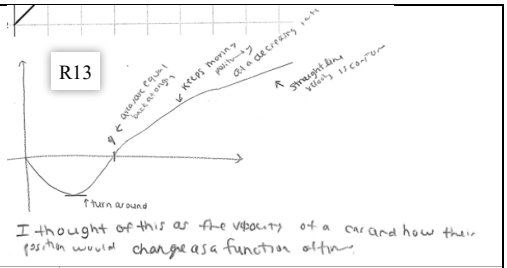
3. *AppM,* where participants clearly draw on their praxeological equipment from mechanics. This could be done explicitly, as demonstrated by student $P_1$24, who explained that they "treated this graph as a velocity-versus-time graph like the ones [they] saw in mechanics, then […] drew the integral of it (position versus time)". In another approach, students could use elements of a praxeology that, according to our previous work, belongs to the mechanics course (for instance, the use of the area under the given graph).

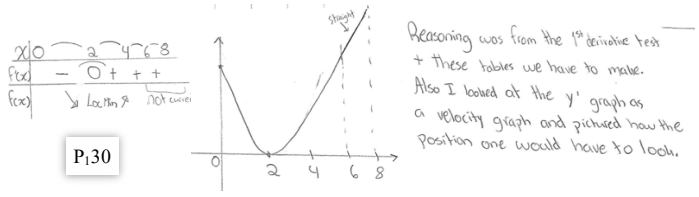
Based on our previous research, we associate the two first approaches with praxeologies from calculus, and the third, by definition, with praxeologies from mechanics. It was anticipated that certain participants' techniques or technologies would be inexplicit or unclear.

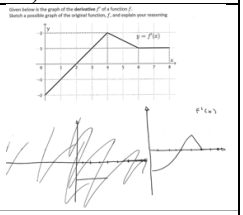
Data analysis

Categorising praxeologies

Following the *a priori* analysis of the task and the praxeological analysis of the students' written work, we grouped the students' praxeologies into four categories (see Figure 3):







<table>
<tr>
<td colspan="2">
</td>
<td colspan="2">
</td>
</tr>
<tr>
<td>Cal</td>
<td>Praxeologies like AppG or AppE with no indication that the student drew on their knowledge from mechanics (this would correspond to Marrongelle's (2004) Non-User).</td>
<td>Mec</td>
<td>Praxeologies associated with AppM (this would correspond to Marrongelle's (2004) Contextualizer).</td>
</tr>
<tr>
<td colspan="2">
</td>
<td colspan="2">
</td>
</tr>
<tr>
<td>Mix</td>
<td>Mixed praxeologies where the praxeology used by the student combines elements from AppG or AppE alongside AppM. These students would likely have been classified as Language-Mixers by Marrongelle (2004).</td>
<td>Unc</td>
<td>Praxeologies too unclear to be classified under the previous categories.</td>
</tr>
</table>

Figure 3: Four categories (and examples) for students' praxeologies

As expected, given the purely mathematical context, most students' praxeologies were classified as *Cal* (68% overall; R: 59%, P_1: 77%, P_2: 68%). Within this group, approximately 17% employed *AppE* techniques despite the graphical context (R: 31%, P_1: 13%, P_2: 11%). Notably, four students out of the 85 ($P_1$03, $P_2$06, $P_2$22, $P_2$25) used mechanics vocabulary in their rationale (as in Marrongelle's study), but applied only *AppE* approaches to solve the task. Their explanations described graph behaviour without referencing a physics context, so these praxeologies were classified as *Cal*.

In contrast, almost a quarter of the students (about 24%, R: 22%, P_1: 20%, P_2: 29%) used praxeologies involving mechanics (*Mec* or *Mix*). Among these, 35% employed mixed praxeologies, although the distribution varied across groups (R: 0%, P_1: 17%, P_2: 75%).

Students' use of *mechanics* and *mixed* praxeologies

Some students employed what we call a *geometric-numerical* approach, calculating areas under the graph of velocity ($f'(x)$) to derive position. In the *Mec* category, $P_1$29, R27 and R14 used this approach. We note, however, that for R27, the resulting graph showed the correct increasing and decreasing intervals but appeared almost piecewise linear. In the *Mix* category, $P_2$12 also tried this approach, as part of a mixed praxeology using elements from *AppG*. $P_1$04 (*Mec*) and $P_2$11 (*Mix*) used only the sign of the area to support their rationale; $P_1$04 based their reasoning on the sign and variations of the velocity, while $P_2$11 used the sign of the area to verify part of their work. $P_2$11 exhibited confusion, "because the area under the curve of f' is negative from $x = 0$ to $x = 2$, which means that f should also be negative [although their graph was positive at first]. However, after $x = 2$ the area under the curve is positive but $x = 2$ is a minimum." In their confusion, $P_2$11 conflated displacement with position and considered segmented intervals rather than cumulative areas. The remaining students who used areas under the curve ($P_2$21, $P_2$24, R13) did so mainly to support the fact that $f(0) = f(4)$. The approach of $P_2$21 and $P_2$24 placed them in the *Mix* category, as they drew on mixed praxeologies using elements from *AppG*. The approach of R13 landed them in the *Mec* category, as they "thought of this as the velocity of a car and how its position would change as a function of time".

The rationales offered by participants who used other mechanics-based praxeologies (*Mec* and *Mix*), excluding those involving the area under a curve, displayed considerable variability in the level of detail provided. While some students supplied only brief responses (e.g., $P_1$24, as noted in the *a priori* analysis), others gave more comprehensive explanations. These included interpreting the sign and variation of velocity, as well as other methods such as recognising that linear velocity results in a quadratic position (e.g., $P_2$05). The three students who drew on mixed praxeologies *not* involving area under a curve took the following approaches:

- $P_1$30 used the first derivative test and noted they "also looked at the y' graph as a velocity graph and pictured how the position graph would have to look".
- $P_2$08 alternated in their rationale between mathematical explanations (e.g., "from $x \in [0, 2]$ the slope is up but closing in on 0") and movement-based descriptions ("it then speeds up from after 2s until 4").
- $P_2$34 drew on all three identified approaches: recognising "$f' \rightarrow$ first degree [implies that] $f \rightarrow$second degree" (*AppE*), using the second derivative's sign to infer graph concavity (*AppG*), and describing movement as "the position goes in the opposite direction quickly at first, then slowly" (*AppM*).

Insights gained from student responses

The responses provided new insights into our *a priori* analysis. Initially, we anticipated calculus approaches to be either graphical (*AppG*) or numerical (*AppE*), but we did not expect to find

differences between praxeologies drawing on mechanics. The analysis of students' answers revealed two distinct mechanics-based approaches. The first is a "geometric-numerical" approach based on the area under the graph, which allowed students to identify specific points on their graphs or recognise symmetry in the first parabolic segment; this approach is similar to *AppE*, as it relies on formula application. The second relies on a graphical reasoning, whereby students used features of the velocity graph to sketch a corresponding position graph; this reasoning aligns with *AppG* in *Cal* but often incorporated covariational reasoning—interpreting the slope of the velocity graph as acceleration to infer the concavity of the position graph. This goes beyond rote memorisation of the link between the second derivative's sign and concavity.

Focusing more specifically on the observed mixed praxeologies (approximately 8.2% of participants, R: 0%, P_1: 3.3%, P_2: 21.4%), we note that the students using this approach combined calculus and mechanics in diverse ways. $P_2$12 used mechanics knowledge to refine their graph, employing the area under the curve to determine numerical values for f. $P_2$11, $P_2$24 and $P_1$30 seemed to switch between disciplines as needed. $P_2$11 explicitly noted the interplay of calculus and mechanics, annotating statements like "used calculus initially, but then mechanics to verify that it was right", or "used mechanics mostly, but I understand that this links to calculus". $P_2$24 started with a sign table (*Cal*) but shifted to interpreting $f'(x)$ as a velocity graph, eventually acknowledging, "in the end, the table helps, it's more systematic". $P_2$24 also provided key hints that indicated their shifting between *Cal* and *Mec*, writing that "maybe [they] had a lot more practice turning $v(t)\rightarrow x(t)$ ($f'(x)\rightarrow f(x)$), so [the] physics approach is easy". The other three participants used mixed praxeologies in a different way: their approach largely relied on technologies from mechanics, which they "translated", at least in part, into calculus terms. For instance, $P_2$34 stated they "thought of it as a position-vs-time graph to make it simpler", but their rationale included sentences like "$f'(x)$ is decreasing but the function remains $\oplus$". We see this as an example of thinking in terms of mechanics but writing in terms of calculus, possibly influenced by the question's calculus context.

Beyond analysing the praxeologies used, we also examined the participants' success. Figure 4 displays the median and average score for each group (R, P_1, P_2), categorised by praxeology discipline (*Cal*, *Mix*, *Mec*, or *Unc*), along with the proportion of students in each group using these praxeologies.

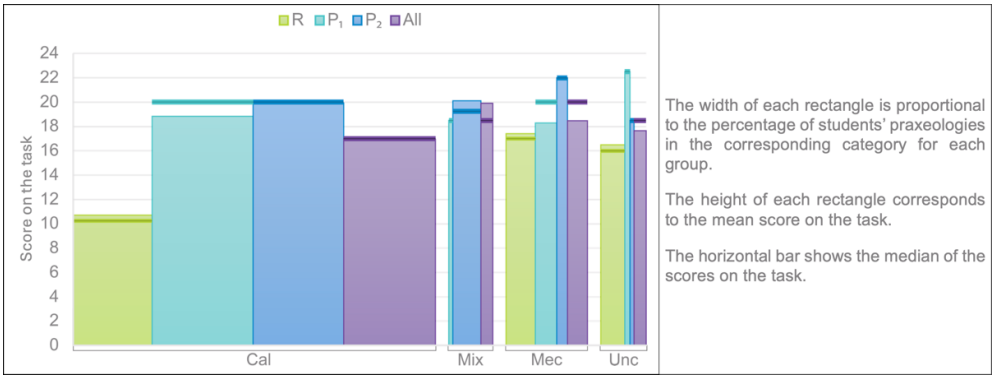


Figure 4: Results of the task for each group depending on the category (average and median)

Differences are more readily discerned among the groups of students than between the disciplines underlying the praxeology:

- Group R achieved overall lower scores than P_1 and P_2, with no mixed praxeologies observed in R. Group R also displayed the greatest disparity in their scores, depending on the type of praxeology used.
- In P_1, scores were consistent across praxeologies, with mixed praxeologies (*Mix*) scoring slightly lower on average. In P_2, students using *Mec* praxeologies outperformed their peers.
- Across all groups, students who used *Cal* praxeologies generally scored lower compared to students who employed *Mec* or *Mix* praxeologies. Additionally, mixed praxeologies yielded the highest average scores, while *Mec* praxeologies produced the highest median scores.

In short, students leveraging mechanics-based praxeologies (*Mec* or *Mix*) generally performed better on this unfamiliar task, underscoring the value of interdisciplinary reasoning. However, the variability in how students integrated mechanics and calculus highlights the importance of enhancing teaching strategies to explicitly connect each discipline—as seems to have been achieved in the paired classes.

Concluding remarks

In this paper, we analyse students' responses to an unfamiliar calculus task resembling a task from their mechanics course. This context allowed us to observe praxeologies drawing on calculus, mechanics, or a combination of the two. When both disciplines were involved, we identified praxeologies that either employed numerical procedures or relied on properties of the given graph and the relationship between the derivative and the original function (or the velocity and the position functions in mechanics). Our findings build on Marrongelle's (2004) work. Students employing praxeologies strictly from calculus were categorised as *Non-Users*, while those using mechanics-based praxeologies were labelled *Contextualizers*. However, in identifying students using mixed praxeologies, we were able to refine the *Language-Mixer* category. Specifically, we observed two distinct ways in which students integrated their knowledge from calculus and mechanics. On the one hand, some students "translated" concepts between calculus and mechanics; while their rationales included calculus-based vocabulary, their reasoning was grounded in mechanics. These students could be considered *Contextualizers*, as their main conceptual framework remained tied to mechanics. On the other hand, certain students seemed to draw flexibly from both disciplines, choosing the most suitable technology or reasoning strategies regardless of their disciplinary origin. Interestingly, we did not classify any participant as an *Example-User*. This may be because our questionnaire offered students limited opportunities to provide examples, unlike Marrongelle's (2004) interview method.

Regarding task performance, students in the non-paired course who explicitly used mechanics knowledge achieved higher scores. However, our results support the conflicting views in the literature (e.g., Hitier & González-Martín, 2022) concerning the role of physics contexts in learning calculus notions. For instance, although $P_2$11 successfully drew on both calculus and mechanics to sketch a reasonable graph, their use of areas under the curve led to confusion. This confusion was traceable to gaps in their understanding of certain mechanics concepts.

Our study also makes a theoretical contribution to the literature. The use of knowledge from one discipline to solve a task in another is often framed as a transfer of knowledge (e.g., Roorda et al., 2015). However, here we adopted Chevallard's (2019) construct of mixed praxeology, which, as far as we know, has never been explored empirically. This enabled us to observe how some students

integrate knowledge from both disciplines to tackle an unfamiliar task, revealing two key patterns: 1) Some students successfully combined knowledge from both disciplines, aligning with literature suggesting that interdisciplinary reasoning fosters a deeper understanding of concepts (e.g., Jones & Watson, 2017); 2) Conversely, other students appeared to use mixed praxeologies as a coping mechanism. For example, $P_1$30's graph resembled a parabola that transitioned into a straight line after 6. This outcome reflected their difficulty in determining the graph's shape on [4, 6].

Finally, we acknowledge limitations in our study. First, although many participants provided written rationales explaining their reasoning, task-based interviews would have provided clarification. For instance, some students may have fully translated mechanics reasoning into calculus terminology, obscuring their reliance on mechanics. Moreover, students from paired courses outperformed those in group R. This may reflect the benefits of pairing, but it could also indicate differences in student profiles; the Enriched Science program could attract students with higher motivation and curiosity, leading them to explore beyond the standard curriculum. Lastly, in contrast to Marrongelle's (2004) broader investigation, our study focused on a single calculus task, which, although graphically contextualised, was relatively accessible to students familiar with similar mechanics tasks.

Using scriptwriting as a response format for interface tasks: Exemplary analyses in the context of symmetry

Max Hoffmann

Paderborn University, Germany, max.hoffmann@math.upb.de

This paper investigates so-called interface tasks as a means to bridge academic mathematics and school mathematics in university courses for pre-service teachers (PSTs). While prior research has focused on the development, implementation, and theoretical foundations of such tasks within a geometry course, less attention has been given to response formats. This study examines the scriptwriting format (as an alternative to the letter/mail format used before), where PSTs are tasked with responding to a student's question about symmetrical figures. I explore the theoretical potential of scriptwriting as a response format and present initial findings from a qualitative analysis of the scripts produced by PSTs.

Keywords: pre-service teachers, interface tasks, scriptwriting, symmetry

Introduction: Interface tasks

The transition from university mathematics to school teaching poses significant challenges for upper secondary pre-service teachers (PSTs), often called the *second discontinuity* of teacher education (Klein, 2016). One way to counteract this problem in university mathematics courses is to use special tasks (e.g., Bauer, 2013; Biza et al., 2007; Eichler & Isaev, 2023; Hoffmann & Biehler, 2023, 2024) that aim to show and reflect on connections between academic mathematics and mathematics in schools. In literature, various theoretical approaches for such task concepts can be found, which have a certain degree of situatedness regarding typical activities of a mathematics teacher in practice as a common design element. In Hoffmann and Biehler (2023, 2024), we provide a theoretical foundation for situated tasks in the context of the framework of content-specific teacher expertise (e.g., Prediger, 2019) and understand so-called *interface tasks* "as learning opportunities whose design is based on identified [jobs] with the following objectives: first, to enhance the probability that PSTs will use their academic CK [content knowledge] and skills in future teaching situations and second, to foster the attitude that their academic CK and skills are relevant by broadening and deepening PSTs' views on future typical requirements." In this, the term "job" is understood as "typical, often complex situational demands of subject-matter teaching […]" in the sense of (Prediger, 2019, p. 370).

While there are some works on the selection and characteristics of suitable situations/contexts/links (Prediger, 2013; Wasserman, 2018; Weber et al., 2023), research on different response formats remains scarce. However, thinking about proper response formats seems to be important in that – at least in university mathematics courses – interface tasks are, to a certain extent, fictitious, usually being completed in written form as homework. For example, there is no real oral discussion with an actual student. This means that no matter how realistic the situational setting of an interface task is, the processing is always somewhat contrived, and suitable response formats are, therefore, essential.

This paper aims to provide a small exploratory contribution to this area of research. A previous study focused on an interface task (Hoffmann & Biehler, 2024) where PSTs were asked to respond to a

high school student's symmetry-related question in an email or letter. For the current study, the response format was modified to *scriptwriting tasks*, which have been successfully applied in other projects (e.g., Zazkis & Kontorovich, 2016).

My primary research interest is to explore how this alternative response format influences typical PSTs' solutions. Before presenting the study, I will introduce the interface task and highlight key findings from the initial research, indicating that changing the response format to scriptwriting could improve the task concerning the intended objectives.

An interface task on 100°-rotationally symmetric figures

The following subtasks are those parts of an interface task we researched as part of Hoffmann and Biehler (2024) that are relevant to the present article.

> Consider the following student statement, "Except for circles or circular disks, there can be no other 100◦-rotationally symmetric figures."
>
> a. Mathematize the statement and clarify the question based on your academic mathematics background.
> b. Respond to the student statement (grade 7) in letter or mail form in a differentiated manner that promotes learning. Feel free to use visualizing elements as well.

The task is part of a sixth-semester course, "Geometry for PSTs". The course is attended by pre-service teachers (PSTs) who will later teach primarily at the upper secondary level. It should be noted that such courses are relatively uncommon in German teacher education, as upper secondary PSTs typically attend mathematics courses together with mathematics majors. Additionally, PSTs participate in courses on mathematics education during their studies. Thus, our interface tasks do not primarily promote pedagogical content knowledge. In particular, the course had no new input on competencies in this area.

The PSTs complete the subtasks presented above after treating the topic of symmetry in the course where the symmetry properties of n-gons were not explicitly discussed. However, it was explained that symmetries of a figure generally form a group. Based on previously proven statements about the concatenation of reflections and rotations, various statements about necessary constellations for the existence of reflectional and rotational symmetries in a symmetry group were shown. This includes a lemma that every α-rotationally symmetric figure is also $(k \cdot \alpha \bmod 2\pi)$-rotationally symmetric for every $k \in \mathbb{Z}$. Thus, an important task in developing a response to the student is to reduce the algebra-oriented university perspective on symmetry didactically into school mathematics.

To complete the interface task, the PSTs must analyze and relate the student's statement to their CK, particularly the course content. We refer to this step as *mathematical clarification*. Building on this, the PSTs must use both their general pedagogical and pedagogical content knowledge, as well as their experience and intuition, to carry out an *elementarization* that is sensitive in terms of content and language to the student's level of understanding (Hoffmann & Biehler, 2024, p. 1449) to answer the

student's question. This step-by-step approach is an established structure of interface tasks, as used, for example, by Biza et al. (2007, p. 303).

In the definition of interface tasks provided above, one central focus is on the *job* that underpins the given situation. For the interface task presented above, this *job* is *examining students' contributions and mistakes and reacting to them in a way conducive to their learning*. Of course, this job can be focused on in university teacher training from various perspectives. The mathematics-focused and idealized approach of *mathematical clarification* and *elementarization* specified by the subtasks is one such perspective ("model job", Hoffmann & Biehler, 2024, p. 1446) that aligns with the course context and content.

In Hoffmann and Biehler (2024), we reconstructed the mathematical arguments of the PSTs and then evaluated them further using qualitative methods. One focus of the analysis was identifying the so-called 'overarching lines of argumentation'. This refers to a holistic description of the mathematical argument underlying a PST's processing of a task part. A corresponding way of categorizing PST responses according to general mathematical approaches can also be found, for example, in Biza et al. (2007, pp. 304-305, 307-308.). In analyzing the answers on a) and b), the correct answers could be assigned to one of two categories: Obviously, the student's statement on the existence of 100°-rotationally symmetric, non-circular figures is incorrect. This can be shown by giving an example (such as a suitable regular n-gon, e.g., n = 18, 36, 72, 360, ...). The two subcategories that work in our analysis for assigning different overarching lines of argumentation are the following: Either the 100° rotational symmetry is justified for a specific n-gon without explaining how this example is found (*Cat. A*), or it is explained how a suitable example of a 100°-rotationally symmetric figure can be constructed systematically (*Cat. B*) (Hoffmann & Biehler, 2024, Sect. 5.2.1).

Regarding subtask 2b, we found that most PSTs' responses fell into Category A: they provided an example of a 100°-rotationally symmetric figure (typically a regular 18-gon or 36-gon). However, they did not explain how this example was found to the student. However, such an explanation would be important from the perspective of the desired "learning conduciveness" of the reaction to the student's contribution. Furthermore, from the perspective of the lecturer and the researcher, it offers an opportunity to observe the PSTs acting mathematically in a school-related situation to diagnose individual strengths and weaknesses and explore the general processing of interface tasks (see also Biza et al., 2007, p. 302).

From a research perspective, this result remains unsatisfactory. It is unclear whether the PSTs themselves did not employ a systematic method to construct a 100°-rotationally symmetric figure—perhaps relying on trial-and-error or internet searches—or whether they had a systematic approach in mind but, for reasons not evident in the data, deemed it irrelevant to include in their letter or email to the student. This article focuses on how a modified response format can help address this open aspect.

Theoretical Background: Scriptwriting tasks in teacher education

In literature, *scriptwriting* in mathematics teacher education describes activities in which fictitious dialogues (often between teacher and student) must be continued from a given beginning of a conversation (e.g., Zaskis & Marmur, 2018). A variety of objectives can be addressed for PSTs'

learning, such as “examining a personal response to a situation, exploring erroneous or incomplete approaches by a student, revisiting and possibly enhancing personal understanding of the mathematics involved, and enriching the repertoire of potential responses to be used in future ‘real’ teaching” (Zaskis & Marmur, 2018, p. 294). In addition to such instructional objectives, scriptwriting is also a helpful research tool because “scripts form a rich data source that can be examined from various perspectives and provide a lens for examining images of teaching and insights into the scriptwriters' understanding of mathematics” (Zaskis & Marmur, 2018, p. 294).

Zaskis and Marmur (2018) used scriptwriting tasks to, among other things, promote the understanding of PSTs on the concept of function and to establish connections between university mathematics and school mathematics. They gained insights into the PSTs’ personal example space on functions and described differences in connectedness and richness. These results formed the basis for follow-up instructions for the PSTs. This underlines the dual usefulness of the scriptwriting format for teaching and research. Campbell and Baldinger (2022) also used scriptwriting tasks in PST training. They could identify and analyze various resources that PSTs used when responding to a student error about the concept of polygons. The resulting scripts helped to reveal “patterns of teaching moves”, the way new mathematical ideas were “introduced”, how the PSTs “represent student’s voice,” and “whether or not the [student’s] error was resolved” (Campbell & Baldinger, 2022, p. 516).

An important commonality in these and other projects (e.g., Buchbinder, 2018; Shure & Rösken-Winter, 2022; Zazkis & Kontorovich, 2016) is that scriptwriting is used as a productive “approximation of practice” for teacher training, which includes “opportunities to rehearse and enact discrete components of complex practice in settings of reduced complexity” (Grossman et al., 2009, p. 283; Zazkis & Marmur, 2018, p. 294). The "reduced complexity" mentioned in the quote fits the definitional idea of grounding interface tasks on *model jobs* (Hoffmann & Biehler, 2024; see above), which, due to their deliberately narrowed perspective (mathematics-focused) compared to the actual job in the classroom, are also of reduced complexity. However, this allows a “focus on individual aspects of teaching” (Campbell & Baldinger, 2022, p. 509), which in the interface task above is the mathematical clarification and subsequent elementarization.

Interface tasks and scriptwriting match well on a theoretical level, which means that the use of scriptwriting activities as a response format seems appropriate in the first instance. I described above the problem that many PSTs used an “overarching line of argumentation” that was not optimal for the fictitious student from the perspective of promoting learning when responding to the student's question about the existence of 100° rotationally symmetrical figures and did not explain how to construct a suitable n-gon systematically. If the PSTs are already aware of such a procedure but do not consider it relevant to the task, this could be due to a possible non-identification with the situation (explain in a letter/email). If the student question is instead used as the starting point for a dialog between teacher and student to be written, the result is a format that is much closer to real classroom interaction (“approximation of practice”). When developing their dialogs, PSTs need to think about how they represent the student's voice and, thus, indirectly think about the learning value of the teacher's response. In addition, new mathematical ideas must be deliberately placed in the dialog for the fictitious student. Both are aspects that, according to Campbell and Baldinger (2022; see above), can be revealed in scripts, i.e., they also play a role during the PSTs’ scripting process.

Overall, the use of scriptwriting activities as a response format for the existing interface task presumably offers advantages for the PSTs in their role as learners as well as for research. In the first step, it can be more validly checked or excluded whether/that individual PSTs are actually unable to construct a 100°-rotationally symmetric n-square systematically, which would illuminate a blind spot in the original study. Furthermore, according to the four features of scriptwriting activities identified by Campbell and Baldinger (2022), there is the potential to gain further insights that can be used to develop and refine design principles for learning opportunities in profession-oriented mathematics courses for PSTs. However, this is not part of this paper.

Research Design

As part of a revision of the interface task introduced at the beginning of this paper, subtask b was modified using scriptwriting, following the considerations in the previous section.

> b. Write a fictitious dialog between a teacher and an interested student at an intermediate level. The dialog starts with the student's contribution and then extends over at least four parts per person.

Following the above analysis of the potential of scriptwriting activities, I expect that the framing of the task by the PSTs as more of a dialog situation will lead to it being more typical to first explain how one arrives at the example that is then further used, rather than it simply falling out of the blue. Accordingly, this paper is intended to contribute to answering the following research question:

How does the interface task's modified response format (scriptwriting) influence the overarching lines of argumentation that can be reconstructed in the PSTs' responses, specifically in terms of their conduciveness to learning?

The formulated dialogs of 19 PSTs are available to answer the research question. These were prepared as part of the homework for the course “Geometry for PSTs” in 2023, and the PSTs have consented to pseudonymized use for research purposes. The dialogs were analyzed using the evaluation method described by Hoffmann and Biehler (2024). The underlying mathematical argumentations were reconstructed and evaluated using qualitative content analysis methods. Initially, the categories from the previous analysis were used, with the option of expanding the respective subcategories inductively if necessary. Of course, this also prepares the way for answering further exploratory research questions on different response formats, which are not part of this paper. Nevertheless, I will make a few comments in the following presentation of the results, which show potential for exciting further analyses.

Selected results exemplified by Nick's dialog

Except for three PSTs, all others (16 PSTs) have formulated an appropriate dialog in terms of content. Only two PSTs gave an example of a 100° rotationally symmetrical figure in their dialog without clarifying how the example was derived (*Cat. A*, see above). Conversely, almost all PSTs (14 of the 16 PSTs) have opted for the second overarching line of argumentation (*Cat. B*, see above), which is that in their dialogs, it is discussed how a suitable example of a 100°-rotationally symmetric figure can be constructed systematically. The following excerpt from the dialog created by PST Nick serves as a typical example of this category:

2 Teacher: […] Do you remember the definition of rotationally symmetric figures?

3	Student:	Yes, well - a figure is rotationally symmetric if we rotate it by an angle and the figure looks the same again, i.e., the rotation does not change the figure.
4	Teacher:	That's right. Then why can a 100° rotation only leave the circle or the circular disk “unchanged” and no other figure?
5	Student:	Yes, that's logical because the rotation angle must be a divisor of 360°. And 100° does not divide 360°. So, only the circle or the circular disk, which is rotationally symmetrical to every rotation angle, can do that.
6	Teacher:	You have already understood the role of the divider very well. However, 100° does not necessarily have to be a divisor of 360°. We have to find a figure that is rotationally symmetric to both 100° and 360°. We would, therefore, have to check whether there is an angle of rotation to which the figure is rotationally symmetric in such a way that if we perform this rotation several times in succession, we get a total rotation of 100°. Then, the figure would not “change”. Do you have any idea how we can achieve this?
7	Student:	That would be the greatest common divisor of 100 and 360, which is 20.
8	Teacher:	Right. What does that mean for your assertion?
9	Student:	Well, then a 20° rotationally symmetric figure would also be 100° rotationally symmetric.
10	Teacher:	Correct. Does such a figure exist? Think about it yourself first, a sketch can also help here - or you can use GeoGebra.
11	Student:	A regular 18-gon! That's right! That means there are other figures besides circles and circular disks that are 100° rotationally symmetric. Thank you!

In Nick's dialog, the teacher first asks about the student's understanding of the concept of rotational symmetry and, building on this asks him to explain how the student comes to his statement. It becomes clear that the student thinks that every angle of rotational symmetry must always be a divisor of 360° [5]. The teacher takes up this contribution appreciatively and then introduces the central argument from a mathematical perspective (rotational symmetry from which 100° and 360° can be generated [6]), which is then completed by the student [9], who names the 18-gon himself [11]. Thus, in accordance with the analysis category, the student's statement is not merely refuted by giving a counterexample. However, the student's misconception is also addressed in a way that is much more conducive to learning, and by building on this, an argument for the correct solution is provided.

Beyond this insight, Nick's dialog can be used to show how the "features of scripts" (Campbell and Baldinger, 2021, p. 516, see above) also represent insightful perspectives for further analysis in the context of the interface task at hand: For instance, we can see relevant mathematics-related teaching moves such as the explication of definitions that are essential for the discussion [2-3]. There are also transcript passages in which the teacher takes up the student's statement to sow the seed for a new mathematical idea (explicitly using the greatest common divisor) [5-7]. In [5], Nick anticipates a very expectable misconception (which still occurs even with PSTs, cf. Hoffmann & Biehler, 2024), namely that non-existence follows because 100 is not a divisor of 360. In addition, the dialogue design also shows (in the sense of Nick's understanding of the underlying mathematics, cf. Zaskis & Marmur, 2018, p. 294, see above) that Nick succeeds in connecting the algebraic perspective on symmetries taken in the university geometry course with the question and elementarizing it appropriately.

Discussion

This paper presented parts of a study in which scriptwriting was used as a format for answering an interface task that had already been developed. A comparison with the analysis of the original

response format (letter/mail) shows a clear shift in the "typical" overarching line of argumentation. Of course, no generalizable statement can be made based on the available data, especially as two different groups with few students are compared. However, both groups had very similar study prerequisites, and apart from the change in the response format, no changes were made to the geometry course's concept. Altogether, the data strongly supports at least stating the hypothesis (in line with the theory-informed assumptions) that the scriptwriting format in the context of the interface task under consideration here leads to many PSTs using overarching lines of argumentation that are more conducive to learning.

Furthermore, the exemplary analysis of Nick's script shows that the categories used in other studies on and with scriptwriting activities (e.g., Campbell & Baldinger, 2022) can also be profitably applied for analysis here. For example, the representation of the student's voice is virtually impossible to evaluate in the original response format. Nick's script also indicates a close connection between the elementarized arguments and his university mathematics background.

For PSTs for whom these links are not so clearly recognizable in the scripts, scriptwriting seems to be both a diagnostic tool and a starting point for individual feedback to the PST. It allows the lecturer and the PST to jointly reflect, for example, on whether there are still gaps regarding the course content or whether specific mathematical concepts and relationships are considered irrelevant to the PST's design of the fictitious dialog. However, valid statements on the instructional potential in the context of our interface tasks require further investigation. Nevertheless, all these considerations point to the initially described research-related and instruction-related potential of using scriptwriting within interface tasks.

Acknowledgment

I would like to thank Igor' Kontorovich for the initial suggestion to try the scriptwriting response format in the context of our interface tasks. I would like to thank the TWG co-chairs and reviewers for their critical reading and the resulting instructive comments.

From "chalk and talk" to active learning: inter-community partnerships and shifts in pedagogical and mathematical discourse

Owen Hooper, Elena Nardi, Irene Biza and George Witty

University of East Anglia (UEA), Norwich, United Kingdom; O.Hooper@uea.ac.uk

Emergency remote teaching (ERT) during the Covid-19 pandemic exposed lecturers to new pedagogical challenges in which alternative active learning approaches were implemented to manage the absence of "chalk and talk". We explore how an inter-community (Mathematics, Mathematics Education) team can redesign a university mathematics course titled Mathematical Skills (MS) to facilitate shifts in the lecturer's pedagogical discourse and in students' mathematical discourse. Through a commognitive/communities of practice analysis of research design team interviews, we present preliminary findings that evidence shifts: from object-level to meta-level learning features in tasks posed by the lecturer; in the explicitness of lecturer goal setting routines; and, towards tasks that encourage active student participation. We conclude with noting the potential benefits to the students' learning experience emerging from the inter-community partnership.

Keywords: Active learning, Commognition, Communities of Practice, inter-community partnerships.

Introduction

In recent years, research related to Active learning (AL) pedagogies and practice orientated interventions in university mathematics has grown (Biehler et al., 2022). However, the adoption of AL approaches in tertiary mathematics has been gradual, with chalk and talk (C&T) remaining the pedagogical norm amongst mathematics lecturers (Cevikbas & Kaiser, 2023). The Covid-19 lockdowns forced universities to shift teaching online, labelled by Engelbrecht et al., (2023) as emergency remote teaching (ERT). In this new environment, lecturers needed to adapt their teaching approach to keep students engaged (Hooper & Nardi, 2021), as C&T pedagogies were incompatible with ERT. A shift to AL environments with flipped / blended pedagogy elements – including tasks such as problem posing, group work, presentations and time for class discussions – seemed to address some of the challenges of ERT (Hooper & Nardi, 2021), but a reported limitation was the lack of time and resources for effective planning and execution, with much left to trial and error (Engelbrecht et al., 2023). However, conditions are now more conducive to a shift towards AL pedagogies (Engelbrecht et al., 2023), with learned societies such as the Institute for Mathematics and its Applications in the UK funding professional development initiatives for mathematicians on said approaches (Thorogood, 2024). In this paper, we explore how establishing a research design team (RDT) can facilitate a collaborative inter-community partnership (ICP) between mathematicians and mathematics education researchers. The formation of an ICP serves two purposes– the first is to generate innovative pedagogical practice by redesigning a first year (Mathematical Skills, Sets, Numbers and Proof, thereafter MS) course that is infused with AL tasks. The second is to implement this redesign to facilitate shifts in the lecturers' pedagogical discourse, and the students' mathematical discourse. We present preliminary analysis of RDT data, reporting on the shifts in the lecturer's pedagogical discourse and the potential impact these may have on the students' mathematical

discourse. We first outline key elements from the AL and RDT literature before introducing the theoretical framing and methodology of our study.

Literature Review

The relationship between mathematics education researchers and academic mathematicians has been described as fragile (Nardi, 2016). However, the structure and dynamics of this relationship are shifting, as evidenced by the growth in ICPs (Biehler et al., 2022; Nardi, 2016): see, for example, the implementation of a research design cycle towards upscaling an intervention in an abstract algebra course in Biehler et al. (2022). Our study aims to build effective ICPs between mathematicians and mathematics education researchers that are "non-deficit, non-prescriptive, context specific and example centred" (Nardi, 2016, p. 365) and have the potential to spark communications that are "jargon-free, even though their construction is fundamentally driven by mathematics education research findings" (Nardi, 2016, p. 372). By establishing this ICP, we aim to find common ground between the two communities and facilitate a redesign of aforementioned MS course.

Active learning is defined by (Freeman et al., 2014) as a pedagogy that "engages students in the process of learning through activities and/or discussion in class, as opposed to passively listening to an expert" (p. 8413). The broadness of this term is beneficial for adopting a flexible, non-prescriptive approach that may blend various tasks and environments. For example, the diversity of AL approaches is evident in research on flipped/blended classrooms (Cevikbas & Kaiser, 2023). Additionally, research has focused on specific types of AL tasks, such as example generation (Kinnear et al., 2023) or solution sharing (Biehler et al., 2022). The recent growth in AL approaches in university courses may potentially be attributed to exposure to alternative pedagogies during ERT, which highlighted the potential effectiveness of AL to improve student engagement in university mathematics (Engelbrecht & Borba, 2024). Research on AL environments has highlighted benefits regarding student engagement, mathematical understanding and class discussion. However, such environments are time consuming to plan and rely on student buy-in to be successful (Cevikbas & Kaiser, 2023). A critique from Deitrich & Evans (2022) is that the reported benefits have not been consistently demonstrated in practice yet. Additionally, there is a growing body of research exploring specific AL tasks. For example, Kinnear et al. (2023) explored how example generation tasks support students' understanding of challenging concepts such as injective, bijective and surjective functions. Space constraints do not allow us to explore each type of task used in the project; yet, we note that a variety of AL strategies have been included in the redesign of the course to foster student understanding and engagement. Whilst not an exhaustive list, there are four types of tasks regularly incorporated into our course intervention: quizzes, example generation, group work and solution sharing. The ICP that our project is building is underpinned theoretically by networking two theories (Commognition, ToC; Communities of Practice, CoP) which we briefly outline in what follows.

Theoretical Framework

ToC, introduced by Sfard (2008), is a discursive approach to learning, with emphasis placed on the various acts of communication: with oneself, with peers, verbal and non-verbal (e.g. writing on the board). These communicative acts form part of a community's discourse, with mathematics discourse defined by four characteristics: word use, visual mediators, endorsed narratives and routines. Sfard

(2008) notes that mathematical learning can be at object-level (learning about the objects that make up the mathematical discourse, for example, learning the Fundamental Theorem of Arithmetic, what symbols such as ∃ and ∀ mean, and so on) and at metal-level (learning about how discursants are expected to behave within the discourse community in, for example, formulating and substantiating object-level narratives). As students transition to university mathematics courses, they shift from being governed by the rules of school mathematics to new, university mathematics rules. One such rule change students experience is the different expectations for what consistutes an acceptable mathematical argument (or proof). For students, just writing a solution with the correct final answer is insufficient at university level; the lecturer expects evidence of mathematical literacy, developed explanations and logical structure. At university, the rules of the mathematical game change, and engaging with university mathematics involves not merely learning about new mathematical objects (object-level learning) but, crucially, about these new rules (meta-level learning). To facilitate both types of learning, our MS course intervention incorporates variety of AL tasks which are designed to give students the opportunity to explore and engage with these new rules. The ToC was selected to capture shifts in student's mathematical discourse (Sfard, 2008) and the lecturer's mathematical pedagogical discourse (Hooper & Nardi, 2021). Using the ToC as a foundation to inspire our AL tasks, we can see from the examples below how well-designed tasks can facilitate shifts in the student discourse and create opportunities for our lecturer to undergo shifts in their mathematical pedagogical discourse. In this project, we utilise the ToC as a tool to analyse the data and inform the design of our intervention. This will be expanded upon in subsequent sections.

According to Wenger (1998), CoPs are established overtime where a group is defined by the ways members have a shared relationship, beliefs, values, and tasks. In the MS course, we define the community by the beliefs (in this case their view of mathematics, and what it means to them to be a mathematician), the pursuit of shared goals (e.g., gaining skills to be a successful mathematician at university) and the tasks that make up the course (e.g., using proof by induction, deciding if a function is injective or not). Within the CoP, we have two distinct players – the old-timers who are experienced, fully active members of the community (e.g., the lecturer) and the newcomers, those that are yet to engage with the community, its goals and tasks (e.g., the first-year students), but by participating in its practices they aim to become old-timers. In this CoP, Witty is the lecturer of the MS course with the CoP shaped by his previous teaching experiences, his beliefs, the goals he wants students to achieve and tasks. As a researcher in UME, Hooper's role in shaping the CoP is to highlight relevant research literature (e.g., as mentioned in the literature review above) as well as experiences as an old-timer on a similar course. To facilitate the students' transition the new rules of university mathematics, we implement what Wenger (1998) calls an inbound learning trajectory: this involves designing a sequence of tasks and goals for newcomers to engage with during the semester. The concept of a learning trajectory provides a framework for the MS intervention to scaffold tasks that support students from the periphery to the centre of the CoP.

As Biza et al. (2014) note, in CoP there is often a lack of detail regarding the fine-grained elements of the learning trajectory. Networking CoP and ToC provides the nuance needed to trace the aforementioned learning trajectory (CoP) in the terms of what ToC labels as discursive shifts. Defining the MS course community provides us with a boundary to operate within. We root our

definition of the MS community in the meta- and object-level rules we essentially want the students to engage with throughout the semester. So, with the boundary now set, we help the newcomers navigate through it. The construction of a learning trajectory gives a structure for students to engage, peripherally at first, with this new community and its associated meta-rules. The learning trajectory consists of a sequence of tasks, with an underlying goal of shifting students' mathematical discourse. We, therefore, design a learning trajectory which attends to the goals of the community whilst also facilitating students' object-level and meta-level learning. We also use the four characteristics of mathematical discourse both to inform the tasks and to analyse the students shifts along the learning trajectory. By networking these two theories we achieve both a macro and micro level perspective to analyse and inform the redesign of the MS course.

Context, methods, and participants

The ICP is redesigning and implementing an intervention in a 12-week face to face, year 1 MS course with 100% summative coursework. The course offers students an introduction to concepts in Set theory, Number theory, Proofs and mathematical skills. The ICP has two key brokers: Hooper (doctoral researcher supervised by Nardi and Biza, representing the community of mathematics education researchers) and Witty (representing the community of mathematicians). The team held regular bi-weekly meetings lasting 60-90 minutes which were open ended, with discussion informed by goals set and tasks completed by each broker between meetings. Hooper gave a brief overview of ToC and CoP (to ensure transparency and openness on how the analysis of Witty's teaching will take place). These meetings are the focus of the data analysis in this paper. The aim of these meetings is to provide opportunities for discussion, debate and decision making regarding the learning trajectory, AL tasks and the selection of resources. However, the "ultimate substantiator" (Sfard, 2008, p.243), in this case Witty, effectively made the final decision on the content of the learning trajectory. During the design phase, there were two central data collection points: the five RDT meetings (recorded and transcribed by Hooper) and resources uploaded on the shared RDT OneDrive. Hooper conducted a partial analysis of the transcripts using the ToC to identify shifts in the lecturer's pedagogical discourse. Resources shared on the drive included draft session plans which Hooper also analysed. We present three examples in this paper that have emerged from our preliminary data analysis. Example one concerns the lecturer shifting the focus of tasks from object-level learning goals towards meta-level learning goals, with reference to an excerpt on quantifiers. Example two explores a shift in Witty's goal setting routine, where session goals hitherto tacit to students are now made explicit. For example, Witty's session plans began to include a written explanation of what students should achieve from engaging with the various tasks. Example three focuses on a pedagogical shift as Witty seeks to implement tasks to facilitate legitimate student participation in the lectures. In tandem, we try, where possible, to identify potential shifts these changes may have on students' mathematical discourse.

Results

Example One: Shifting task focus from object-level to (also) meta-level learning

The partial analysis of Witty's previous course materials revealed an emphasis on object-level learning, specifically on introducing new definitions (e.g., of a set), theorems (e.g., the Euclidean

algorithm) and notation (e.g., ∃ and ∀). These are important mathematical objects for student participation in the community of university mathematics. However, such participation also requires attending to a new set of meta-level rules which Witty is responsible for introducing. Disproportionate attention to object-level learning may stifle student engagement with these new meta-level rules, potentially hinder students' discursive shifts and limit opportunities for legitimate participation in the MS course. The example Hooper and Witty discussed concerned challenges with making sense of, and using, the notation ∀ (for all) and ∃ (there exists).

> Witty: ...it's weird the notation *for all* and *there exists* then just becomes sort of like I dunno a barrier, it's something they have just seen and are like "I need to comprehend that and I'm trying to do some maths as well".

This highlights challenges students have in engaging with new symbols, deciphering their meaning and use whilst the lecturer has already introduced more mathematical content. This density of content may be overwhelming for new community members. The new rules of the game demand students understand such notation. However, without the opportunity to explore and endorse these new narratives, students are prevented them shifting further than the periphery of the CoP (Wenger, 1998) in the MS course. Therefore – whilst they are engaging with new mathematical content (object-level, quantifiers), their participation in the mathematical discourse of university mathematics is hindered by not being able to utilise notation to solve mathematical problems. Student challenges with quantifiers is highlighted in research, for example, students attempting to solve problems that involve quantified statements without acknowledgement of the quantifiers (Sellers et al., 2021). We discussed this challenge in our RDT meetings as another lecturer (occasionally present at these meetings) stated:

> …my biggest thing when I was an undergraduate especially in analysis was the fact, I literally learnt *for all epsilon greater than 0…* and I didn't, I wasn't registering the for all epsilon I was just registering the sound *for all epsilon greater* and not really understanding what it meant.

Discussing AL tasks that may address problems such as these, the lecturer drew on their experience and suggested utilising tasks such as "fill in the gaps" or "mix and match" style exercises. The aim of these tasks is for students to engage with the new symbols to explore their differences and the implications their use has for the mathematical meaning of a statement – as well as realise how communicating in this new way makes them more central participants in the practices of university mathematics. This example highlights the potential of the intercommunity partnership to identify challenges students may have with these new rules of the game and utilise research and literature to incorporate AL tasks to facilitate meta-level learning where previously the focus had been on object-level learning. By utilising Witty's previous course materials, we leveraged a context driven, jargon free discussion that facilitated reflections, discussions, and modifications which informed the design of the learning trajectory.

Example Two: Shifting from tacit to explicit lecturer's goal setting routines

> Hooper: This [course] is titled maths skills but there is no…this is the point of this module…, this is why we are doing maths skills, these are the things you'll be expected to engage with.

Despite being named Mathematical Skills, it was not explicit to students what these skills were, how they were expected to engage with them, or why they were important for newcomers to the community of university mathematics. If we want students to engage beyond the periphery of the community, it is important they have a clear and explicit trajectory to do so. The comment by Hooper was aimed to spark a discussion on the aims and goals of the course and how this could inform our learning trajectory and build our sequence of tasks. As a result of these discussions, a shift occurred in the lecturer's pedagogical discourse: Witty's goal setting routines shifted from tacit to explicit student goals within the MS course. In practice, this sparked an overhaul in the design of the opening lecture sequence. The above comment likely prompted a re-evaluation of the lecturer's pedagogical choices (e.g., order of the sequence of tasks) and the importance to the students of clarity in terms of what is expected of them. As a result, Witty in Lecture 1 aimed to discuss and explore students' meaning of mathematical skills and their importance.

> Witty: for example, this exercise here leads into them submitting something as well, like having a goal […] by the end of this you're gonna like have solved these problems and written them up.

Additionally, the explicit goal setting extended to Witty's own pedagogical routines as for each AL task included it had an associated goal (or purpose). As Witty notes,

> there are so many things we could do…it's trying to not like, I don't know, just do them for the sake of it. But, also like make sure there is a purpose.

By our fourth meeting, these utterances had become routine and Witty's desire for purpose in each task became regular goal setting. In the above extract, we see the lecturer develop a routine of self-questioning and justification, related to their selection of tasks. As the lecturer engages in this inter-community partnership, they have started adjusting their pedagogical routines. The discussion, sparked by Hooper's CoP informed observations regarding the lack of explicit goals on the MS course, has helped facilitate a shift in the lecturer's goal-setting routines. This shift is crucial for the intervention design, as these goals form the foundation of our learning trajectory that will guide students' engagement throughout the semester. The engagement with this inter-community partnership has the potential to not just produce an intervention to facilitate students' shifts in mathematical discourse but also present opportunities for lecturers to shift their pedagogical discourse as they are exposed to propositions emerging from mathematics education research.

Example Three: Pedagogical tasks to encourage legitimate student participation

As mentioned earlier, one motivation for redesigning the MS course was to help student engagement by shifting from a largely C&T approach to one infused with AL opportunities. Where deemed appropriate, Hooper proposed transformation of previously used teaching materials that were familiar to Witty (e.g., replacing giving examples to students with an example generation task). In response, on one occasion Witty commented that

> Witty: with the quiz they have to think about it, but they are not writing it down and you know maybe that is quite a powerful thing that they need to be doing.

This is a key moment where Witty endorses a change in students' engagement routines to encourage legitimate student participation in lectures. This concept of legitimate participation became a regular theme across our meetings with Witty reinforcing narratives on student participation in the lectures.

> Witty: I guess for a quiz that they might interact with notation, but sometimes it could be we want you to write that down because that's what you're going to be doing in a bit, writing it down. It's good to recognize it, but also like being able to, using it straight away allows you to go "I'm using this correctly."

This provides insight into Witty's aspirations to shift the students' engagement routines from passive observers to legitimate participants in the MS course. The aim is that both object-level and meta-level learning emerges as students are allowed time for exploration and practice when introducing content.

Concluding Remarks

The examples above have highlighted how inter-community partnerships (between mathematics education researchers and mathematicians) can facilitate the design of an AL infused MS course through engagement with research findings, prior experiences and practice. Networking the ToC and CoP provide the theoretical foundations for the RDT, for designing the intervention and for data analysis. The ICP facilitates a shift in the lecturer's pedagogical discourse from C&T to AL pedagogies, exemplified by the three examples above. Example One illustrates a shifting in the focus of tasks set by the lecturer from object-level to (also) meta-level learning. These discussions (in a jargon-free way) provided opportunities for the lecturer to re-evaluate the tasks (and their goals) that have shaped the course previously. Example Two illustrates shifts in the lecturer's goal setting routines, ensuring the aims of the course were now explicit to the students. Example Three illustrates a shift towards designing tasks that encourage legitimate student participation. So far, we have seen how the ICP can facilitate a redesign of a mathematics course and the shifts this presents in the lecturer's pedagogical discourse. Whether and how these changes result in shifts in students' mathematical discourse is the next and imminent phase of our ongoing study.

Acknowledgment

This paper draws on Hooper's UEA funded, ongoing PhD study. We extend our gratitude to the participants involved in this ongoing project.

This paper reports preliminary results of a study employing the Delphi method to ascertain the consensus of stakeholders regarding the role and use of generative artificial intelligence (genAI) in teaching and learning undergraduate mathematics. Participants to the study included mathematicians, mathematics educators, and learning designers. The data consists of responses to an online survey which asked participants to state the most urgent research questions related to the use of genAI in university mathematics. We obtained 41 research questions by 34 participants from 23 institutions. We grouped these questions under two broad thematic headings: "questions concerning students' interaction with genAI" and "questions concerning teachers' interaction with genAI". These themes indicate what participants deem a pressing research agenda concerning genAI in university mathematics to be. We conclude with a description of the next steps for this study.

Keywords: University mathematics, genAI and large language models, Delphi method.

Introduction

The debate about the potential of generative artificial intelligence (genAI[1]) and the perceived threat it poses to the teaching and learning of mathematics at university level is pervasive. Opinions are divided (Kramm & McKenna, 2023): many believe that genAI is a threat to the way in which we teach and assess academic performance – and in particular mathematics – and to the delicate relationship between students and teachers (Luo, 2024). Others argue that integration of genAI in teaching and learning at university is unavoidable and indeed desirable (Rane, 2023). In any case, genAI has and will influence teaching and learning processes in higher education at a global scale. Higher education research communities have rapidly responded to these techno-educational shifts. For example, a recent meta-review identified 66 review studies conducted about genAI in higher education alone, exemplifying the urgency of research to help communities of practice to cope with the surge of genAI technologies (Bond et al., 2024).

We see it crucial to produce disciplinary, mathematics-specific research about genAI amid such broader shifts in higher education studies. Research in mathematics education on the affordances and drawbacks of genAI for teaching mathematics has so far spanned from investigating the mathematical

[1]We use the term genAI to indicate all large language models (LLM) such as ChatGPT, Claude, Gemini and others which may be available to students and teachers.

capabilities of a genAI (Green, 2024) to the comparison of the perceptions of teachers and students on the role of genAI in university mathematics (Fuller & Barnes, 2024). A rapid review of the higher education literature beyond mathematics (Lo, 2023) reveals how much of the attention devoted to the use of genAI in higher education concerns issues of misconduct in assessment. However, we could find no coherent research agenda in the work we reviewed, especially with focus on university mathematics, and the current research seems to remain disconnected. We, therefore, have attempted to develop a coherent research agenda regarding the role of genAI in university mathematics using the Delphi method (Hsu & Sandford, 2007). In this paper, we report results from the first phase of this study by focusing on the research questions it generated, and on what these questions tell us about the interests and priorities of stakeholders in university mathematics education.

Data collection: the Delphi method

The Delphi method (Hsu & Sandford, 2007) has recently been used productively to seek consensus on information from stakeholders from a certain community in a relatively new field. The first part of the method requires identifying who the stakeholders are in the chosen community and inviting their contributions. The Delphi method then proceeds in four stages of data collection and analysis. In the first stage, an open-ended questionnaire is sent to potential participants, to gather information about the chosen area. If an extensive review of the literature has been carried out, this stage can be replaced by a structured questionnaire. The second and the third stages of the method consist in asking stakeholders to rank the items obtained from the first stage, for example, via a questionnaire or focus group interviews, to gather consensus about the importance of the items found in stage 1. This iterative process usually produces a high level of consensus that, in the fourth stage, is refined to arrive at a final ranking of the items proposed by the participants.

In our implementation of this method, we followed the study of Kinnear et al. (2024) who, by adopting this method, outlined 55 research questions that represent the interest of mathematicians, mathematics educators, teaching designers and technicians regarding the use, design and research on e-assessment of university mathematics. As in this study, we also choose to gather research questions proposed by stakeholders who, in the case of the use of genAI in teaching and learning university mathematics, were mathematicians teaching university mathematics, mathematics educators researching the teaching and learning of mathematics at university, and/or those academics in positions related to teaching administration such as Directors of Teaching. Firstly, we contacted potential participants thought our extended professional networks; we are part both of Mathematics and Education departments, and our extended network comprises both mathematicians and mathematics educators. After the first contact we employed a snowballing recruitment strategy. We then caried out a rapid review of the literature (Wollscheid & Tripney, 2021) on the use of genAI in university mathematics. In this review we found very few mathematics education studies related to this topic; therefore, we started the Delphi process by distributing an open-ended questionnaire to those who had agreed to take part in the study. The questionnaire comprised some biographical data such as their role in the higher education institution, reason for interest in the study, and the three open-ended prompts: “(1) Please enter details about your first research question. (2) What motivates this question? (3) How would one go about researching this question?”

Participants were encouraged to enter more than one research question with justifications if they wished. These prompts resemble those used by Kinnear et al. (2024), where participants were also asked to propose research questions related to the topic of interest. Ethical approval for the study was sought and obtained at the University of Edinburgh.

We distributed the questionnaire between January and March 2024 to colleagues from 72 institutions in 15 countries. We received responses from 34 individuals from 23 institutions in 12 countries who offered 41 research questions (one verbatim example is in Figure 1). Of those, 21 participants described themselves mainly as mathematicians teaching university mathematics, 9 as mathematics educators and 4 either as learning designers or just interested in the topic.

Question

How can LLMs be used to generate bespoke automated feedback to student-produced text in tertiary mathematics?

What motivates this question?

Recent years have seen substantive efforts committed to generating such automated feedback using established platforms like STACK. Some research suggests that "elaborated feedback" is more useful than simply giving correct/incorrect feedback (Attali & van der Kleij, 2017)* but is it worth the up-front effort for the teacher to devise all this feedback?

How would one go about researching this question?

Initially, a qualitative analysis of LLM generated feedback to students' responses can provide an initial indication of the value and scope of such feedback across different mathematical contexts. Down the line, (quasi)-experimental designs might compare the impact of different feedback types on student learning, behaviour or perceptions.

*(Attali, Y., & van der Kleij, F. (2017). Effects of feedback elaboration and feedback timing during computer-based practice in mathematics problem solving. *Computers & Education, 110,* 154–169. https://doi.org/10.1016/j.compedu.2017.03.012)

Figure 1: Example of one answer in its original form. Here LLM stands for Large Language Models, one of the terms used by participants which we then included in the general 'genAI' category when we made the language of the research questions proposed consistent.

After we collected the data, we worked within our team to make the language of the questions uniform so that they would create a coherent body of research questions for later consideration, and to avoid repetition between questions. We note that this is a departure from the method as described in Hsu and Sandford (2007) but given the variety of educational contexts represented by participants, we deemed it necessary to find a unifying language for the research questions. To be faithful to the intentions of the question setters, we consulted the answers to the second and third questions when editing the text. For example, we decided to use genAI as a collective name for all the large language models mentioned in the questions (LLM, ChatGPT, Claude, Gemini etc.). Once we reached a uniform language, we sought to identify themes among the questions. We held three meetings, each comprising a subset of the authors of this paper. In each of the meetings we collaboratively carried out thematic analysis (Attride-Stirling, 2001) to identify themes and sub-themes, iteratively refining the analysis in each meeting. Through this process, we identified three broad umbrella themes:

'questions regarding students' interaction with genAI', 'questions regarding teachers' interaction with genAI'. A third theme comprising only three questions on the role of genAI in mathematics education research will not be discussed in this paper. The first and the second umbrella themes each contained a number of subthemes, as shown in tables 1 and 2. Overall, it can be said that the larger umbrella themes were rather pedagogical in nature: they concerned the day-to-day practices of teaching and learning of mathematics rather than addressing broader ethical, philosophical or technological conversations as in the bulk of general higher education studies (see Bond et al., 2023). Below we elaborate on the findings of our analysis of the research questions, and what they tell us about the community's perceptions of the role of genAI in university mathematics education.

Theme 1: Questions about students' interaction with genAI

We clustered 17 questions in this umbrella theme (see Table 1). The dominant concerns for participants were how critical students are in respect to genAI's mathematical output (5 questions) and how students use these tools as a resource for their studies (6 questions).

Table 1: List of sub-themes, with examples, within the 'students' interaction with genAI' group. The number in brackets indicate how many questions were found in each subtheme

Students' interaction with genAI (17)	
Sub-theme (number of questions)	**Examples of questions**
genAI as a resource for studying (6)	How do students use genAI to support their independent study? What support do students expect with respect to the use of genAI in mathematics?
Critical evaluation of genAI (5)	How do students evaluate the reliability of mathematical solutions produced by genAI? Does engaging with genAI support students in developing critical evaluation of tasks and their solutions?
Feedback (3)	How do students experience interactions with genAI-based automated systems for formative feedback? How is feedback on a mathematics task generated from a genAI received by students compared to feedback from their teachers?
Student-centred task design (2)	How can students develop a deeper understanding of mathematical concepts by teaching them to genAI? In what areas of undergraduate mathematics is genAI more effective for supporting students' learning? And why?
Support for use of genAI (1)	What support do students expect with respect to the use of genAI in mathematics?

Studies on the accuracy of genAI responses to advanced mathematics questions have shown that, for most topics typically included in a first-year mathematics degree and with the exclusion of proof-related questions, genAI can often provide accurate answers, but they are occasionally subject to hallucinations (Green, 2024). Hallucinations are instances when genAI's output refers to, or directly quotes, material that is incorrect or non-existent (e.g., research papers which seem plausible by their title but have in fact not been written, or a proof following the pattern of a similar proof but in a context where such pattern is not applicable). Therefore, being able to appraise output provided by this tool becomes important for students.

It is interesting to note that participants in our study seem to recognise that genAI is a tool which must be incorporated critically in the teaching/learning interaction and is not something to be banned, as some of the papers in the review by Lo (2023) suggested. This is evidenced by the 11 questions concerning building students' critical skills and orchestrating support for learning which constitute the largest sub-theme in this group. The need to develop students' critical skills to appraise genAI output has been addressed in the literature before (see Drushlyak et al., 2024, for an example of a study in mathematics education concerning proof). Criticality towards the output – if not already developed – needs to be fostered with classroom activities, hence the research question regarding the evaluation of the most effective support that can be offered to students and of the activities that can be devised to this end. Related to the support for students' use of genAI were the two questions directly concerning task design and the three questions about how students respond to automated feedback provided by genAI.

Theme 2: Questions about teachers' interaction with genAI

The sub-themes concerning teachers' interaction with genAI are also revealing. We found 21 questions here (see Table 2). The impact of genAI on assessment design and the threat of assessment misconduct were hardly mentioned by participants, contrary to our expectations. Only five questions were dedicated to assessment, and of those, only one ("How can educators detect AI-generated responses from students?") concerned prevention of assessment misconduct involving genAI. This is contrary to what the general literature on the use of genAI in higher education reports, where the preoccupation with misconduct is pervasive (e.g., Lo, 2023).

Instead, the dominant concern of our participants was with determining how genAI can support the design of tasks aimed at encouraging and supporting students' learning (10 questions). These questions detail the involvement of genAI in practices the literature recognises to be beneficial to students. For example, the question "What are the benefits of asking students to use genAI to generate their own questions on a given topic?' refers to the idea that asking students to generate their own mathematical questions is conducive to conceptual understanding (Voica & Singer, 2013) and the need to find out whether this is the same when the questions are directed to genAI. Another interesting aspect is represented by questions about the use of genAI to support teachers' own practice by rendering some of the tasks related to teaching more effective and less time consuming. For instance, there are questions regarding whether genAI can support lesson planning or writing lecture notes, or even support providing illustrative examples of complex mathematical concepts. Similarly, the assessment sub-theme included questions about how genAI can be used for exam marking or to help

teachers interpret the large datasets that are produced by assessment results. Such questions show again the wish to include genAI in teachers' practice as a supporting and potentially time-saving tool, but to do so responsibly and aware of the capabilities of the tool.

Table 2: List of sub-themes, with examples, within the 'teachers' interaction with genAI' group. The number in brackets indicate how many questions were found in each subtheme

Teachers' interaction with genAI (20)	
Sub-theme (number of questions)	**Examples of questions**
Student-centred task design (10)	What features of genAI-supported tasks have most potential for advancing learning? To what extent can genAI be used to generate examples illustrative of particular topics/concepts?
Assessment (5)	How can genAI be used to support the efficient marking of exam scripts? How can genAI be used to interpret large assessment datasets?
Curriculum design / statistics (2)	How can genAI be used for the teaching and learning of statistical data analysis? What are the implications of recent advances with genAI for priorities in the statistics curriculum?
Feedback (2)	To what extent is genAI-produced feedback reliable? How can genAI be used to support digital scaffolding by providing them with appropriate individualised feedback and hints?
Support for use of genAI (2)	How do we help students learn to make productive use of genAI?

Statistics teaching has a special mention in our dataset. This may be because some of the participants may be involved in teaching statistics, but also it could be the case that our participants believed that genAI is 'better' at solving statistics questions than at providing proofs in pure mathematics (see for example Lo, 2023), at least for now. One surprisingly missing topic regarded the use of genAI for coding. Coding has become a more significant part of university mathematics teaching in the past 10 years (Iannone & Simpson, 2022) where the most used programming languages are Python and R for statistics (Sangwin & O'Toole, 2017). The computer science literature indicates that genAI is very efficient at producing code in these programming languages with a recent study showing that ChatGPT4 achieved an accuracy of 86.2% on the sample used for testing Python coding (Coello et al., 2024). We hypothesise that such questions, which indeed regard university mathematics teaching, are missing from our list of questions due to the composition of our group of participants.

Final remarks and next steps

The categorisation and analysis of the questions presented above shows a picture of engagement with genAI and of preoccupation with how to better shape such engagement, both for students' learning and for teachers' practices. Our participants recognised the potential of genAI tools and the need to explore how they can be productively used by their students. The preoccupations that are manifested by some policy makers and university administrators (see Williams, 2024, for an example in the UK sector) regarding assessment misconduct seem not to be reflected in the priorities of those who teach and research university mathematics. This finding may indicate that stakeholders believe that responsible use of a tool – in this case genAI – achieves better outcomes for teaching and learning than banning or restricting its use. One of the limitations of our study is that the questions posed depended on the expertise and interest of the participants. Although we strived to have a diverse group in our sample, both geographically and in terms of expertise, we have inevitably missed some aspect of the interaction between teaching university mathematics and genAI, as the absence of questions concerning coding suggests. For the next steps of our research, and to produce the research agenda we set out to outline, we will analyse focus group discussions with participants and move to the last step of the Delphi method. This consists in asking participants to discuss the research questions obtained in previous stages and rank them in terms of importance to them and to their community. This will allow us to finalise the research agenda both in terms of what questions will finally be included amongst the ones found, and in terms of outlining what the priorities for the community are. The final research agenda will also contain suggestions on how the research questions may be investigated. Such suggestions will be drawn both form the original questionnaire and from suggestions emerging from the focus group interviews.

Acknowledgment

We would like to thank the colleagues who contributed their time to take part in this research.

Opportunities to Learn as entry points to university mathematical discourse: The case of proof in introductory lectures

Thomais Karavi[1] and Alexander Schüler-Meyer[1]

[1]TU Eindhoven, Eindhoven, the Netherlands; t.karavi@tue.nl

The transition from school to university mathematics is associated with many student difficulties and dropouts. This study investigates Opportunities to Learn (OTLs) offered in university mathematics lectures. We conceptualise OTLs as the lecturers' attempts to invite students' participation by suggesting entry points in the university mathematical discourse. We explore the OTLs in university mathematical discourse that appear in the overlap of lecturers' mathematising and identifying. For this study, we used data from the first lectures of four first-year courses offered to mathematics bachelor students. We discuss our initial exploration of OTLs through an example from the teaching of proof in an introductory set theory course. By investigating the OTLs, we unfold how they shape expectations towards students' participation in the discourse and the demands for students to meet these expectations. Future research should investigate the impact of OTLs on student participation.

Keywords: Opportunities to learn, university mathematics lectures, discourse, mathematising, identifying.

Introduction

The transition from school to university mathematics, known as the secondary-tertiary transition (STT), presents challenges, often leading to difficulties and dropouts (Di Martino et al., 2023). We view STT not just as an academic shift but as a process of learning the "rules of the game" in university mathematics (Sfard, 2014; Pinto & Koichu, 2023). While resources like textbooks, peers, and bridging courses support this transition, lectures remain a key resource for students. Although lectures typically do not promote active participation, lecturers create entry points for students to participate in the respective mathematical discourse. For instance, Weber (2004) describes a lecturer who began an analysis course by emphasising the logical aspects of proving. This choice stemmed from the assumption that students would struggle with analysis without a foundation in formal proving. By introducing proving through topics like sets and functions, the lecturer provided an entry point for students to grasp proving in analysis. Such opportunities in lectures serve as invitations for students to participate in university mathematical discourse, helping them develop the necessary skills and understanding to navigate this new academic environment.

Nevertheless, whether these entry points in lectures are beneficial for students' learning, or even their STT, remains unclear, preventing us from understanding the contributions of lecturing to a successful STT. Sfard (2014) argues about the great distance between school and university mathematical discourses with respect to reliance on formal rules and the increased level of rigorousness, which would make it doubtful whether entry points in lectures can bridge this distance. At the same time, during STT, the students are expected to reapproach the mathematical practices that they are familiar with from school. From this perspective, providing entry points that explicate how to engage with the presented mathematics could help students to better engage in the university mathematical discourse

during their studies, e.g., during engagement with proving tasks independently. In this paper, we investigate these entry points and how they take shape during lectures.

Theoretical considerations and literature background

Opportunities to Learn as a place of identifying students

From a discursive standpoint, and focusing specifically on university mathematics, the entry points offered in lectures can be conceptualised as Opportunities to Learn (OTLs) (Remillard, 2014). We regard these entry points as invitations to participate in the university mathematical discourse. Building on this perspective, we explore how OTLs emerge in mathematics lectures and are related to lecturers' perspectives on students' participation in mathematical discourse. Chan and Sfard (2020) see OTLs as "circumstances that call for, and support, *a change* in the learner's participation in a discourse, a transformation that would bring him or her closer to the [intended] discourse […]" (p. 3). OTLs can be of two types. Firstly, OTLs call for a change in the "learner's command of the discourse" (p. 4). Here, the lecturers identify students in their talk in a certain way, suggesting "how this participation builds on and is being built by, that of other participants" (ibid, p. 10). Secondly, OTLs invite a change "in the discourse itself" (p. 4). Here, we combine these views and conceptualise OTLs in university mathematics lectures as entry points in lectures aiming at a change in students' participation in the university mathematical discourse. For example, a lecturer might introduce a new mathematical concept by posing a question to raise prior knowledge related to the concept's formal definition. This OTL may allow students to enter the discourse through their prior knowledge.

OTLs are an expression of how lecturers want their students to participate in the university mathematical discourse, so lecturers identify their students in a certain way when explicating the "rules" of the discourse in their teaching. In other words, having access to OTLs is essential for students' participation in the university mathematical discourse as it supports their initiation to the "rules" of the discourse that are otherwise often tacit among expert participants of the discourse. This initiation is particularly important in becoming independent and agentic participants within the mathematical discourse. For example, a lecturer might demonstrate how to construct a mathematical proof by explicitly focusing on a logical style (e.g., Weber, 2004), creating OTL that may allow students to internalise "rules" about how to start and how to structure a proof.

University mathematical discourse in shaping OTLs

Mathematical discourse is distinguishable by a community's word use, visual mediators, endorsed narratives, and routines (Sfard, 2008). Participation in the discourse distinguishes from ritual to explorative (Lavie et al., 2019). Ritual participation in a mathematical discourse appears to be the first necessary step when a person tries to enter a discourse (Heyd-Metzuyanim, 2015). The person focuses on the process and tries to replicate the actions of more experienced participants of the discourse. When the person starts having some experience and can explore independently in the discourse, then the participation becomes more explorative.

University mathematical discourse contains both mathematising and subjectifying talk. Mathematising refers to the talk of mathematical objects. In contrast, subjectifying is the talk about the participants in the discourse. For instance, when lecturers introduce students to mathematical

routines—such as proving or defining—they are not only engaging in mathematising but often also in subjectifying. For instance, they ascribe particular ways of being, which shape participants' identities within the discourse (Heyd-Metzuyanim, 2015). Subjectifying operates subtly, involving statements about who the participants are within the discourse and how participants perceive each other in the discourse (Heyd-Metzuyanim, 2015). Accordingly, an OTL can be conductive to support students' STT when it supports students' subjectifying – their identification of themselves – as members of the university mathematical discourse (Sfard, 2008). Through such social and affective processes of assigning students with identities that are constructed for them by the lecturers, OTLs might contribute to a group's success or failure in learning mathematics (Heyd-Metzuyanim, 2013).

For this study, we focus on identifying a subtype of subjectifying (Heyd-Metzuyanim, 2015) that describes narratives about participants in their talk. Behaviours or ways of being often stay opaque to participants and only become evident when not adhering to them. These characterisations are often implicit, becoming noticeable primarily when participants deviate from them. To uncover such implicit *identifying*, researchers analyse recurrent identifying narratives in the talk of lecturers (Heyd-Metzuyanim, 2013). Overlaps of mathematising and identifying in university mathematical discourse may bring the "researchers closer to understanding how mathematical learning is shaped by students' identities and how students' identities are shaped by mathematical talk" (Heyd-Metzuyanim, 2015, p. 512). Thus, these overlaps highlight how the processes of mathematising and identifying are intertwined in shaping OTLs for students.

Research question

Particularly for the case of proving, OTLs call students to participate in the proving routines when, at the same time, they are trying to familiarise themselves with them (Remillard, 2014). Remillard (2014) identified discursive entry points when students worked on proving tasks. Examples of entry points were the raised questions about managing the proof process and tackling the ambiguity of what needs to be proved. In this study, we ask: *How are students identified in OTLs to allow students' participation in university mathematical discourse, particularly proving, during STT?*

Method

Data collection

This study is exploratory and part of an ongoing project. The project aims to provide understanding and suggest ways to reduce the dropout numbers of first-year mathematics students. We follow a multiple-case study approach where the cases are set by experienced lecturers teaching in four first-year university mathematics courses offered within an applied mathematics bachelor's program in the Netherlands. The four lecturers were chosen as they teach the introductory, proof-oriented courses in the first semester (consisting of two quartiles) of the applied mathematics bachelor and are described as the foundation for the next courses of the curriculum. The selected courses cover introductory topics in the mathematics curriculum.

The primary data set of this study consists of video recordings of the lectures. The courses were video-recorded by the university of the study, and the videos remained online for archive reasons. Each lecture lasted 90 minutes and was transcribed. Captures from the blackboard were also implemented

in the transcripts. A supplementary data set included course notes and other shared material (i.e., homework exercises and extra reading material).

Data Analysis

For this study, we focus on the first lecture of each course as an initial investigation of the data set, as we assumed that OTLs would be particularly prominent here. We aim for a micro-level characterisation of OTLs in the overlap of mathematising and identifying talk. For that, we related them with how they may allow students' participation in the discourse from the lecturer's perspective.

For the first step of the analysis, we started with episode separation. Each episode was related to the presentation of a narrative (e.g., proof, definition, example) or a block of related narratives (e.g., examples). The episodes were coded using in vivo, descriptive, and theoretical codes. The assigned codes aimed to characterise the lecturers' mathematising. At the same time, discourse analysis took place for the characterisation of the identifying. We concentrated on moments that are attached to certain identifications about the person, aiming for the development of a manageable set of identity narratives (Heyd-Metzuyanim, 2015). For instance, "You are in a good shape", "You seem convinced" are examples of moments that were related to certain identifications assigned to the students by the lecturers.

In the second step of the analysis, the episodes were closely examined for the identification of OTLs in lecturers' discourse, doing discourse analysis. In particular, the focus was on the instances, later characterised as OTLs, where the lecturers' identification of students related to their mathematising towards the participation of the students in the discourse. We characterised the OTLs as entry points for explorative or ritual participation in the university mathematical discourse. For instance, phrases like "you immediately see this should be true" were characterised as normative, assigning a membership to the students and considered as an indication of explorative participation from the students to the university mathematics discourse as the lecturer asked for students' independent participation in the discourse, exploring on their own why the narrative is true. We considered these instances as indications of OTLs and compared them among the lecturers (Charmaz, 2014).

Findings

In the following, we present two episodes (consecutive) from the first lecture of the introductory, proof-oriented course in set theory. The course aims to introduce students to formal proof and functions as the foundation for future courses in university studies. The lecturer is an experienced mathematician who taught the course more than five times before the time of the data collection. The following excerpts are from the proof of the first distributive law for sets: Let A, B, C sets. Then the following holds: $A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$. The exploration of OTLs gives insights into the lecturer's attempts to support students' transition from school to university mathematical discourse while suggesting the lecturer's expectations regarding students' participation in the discourse.

Introduction to the theorem and proof

> For example, let's try to do this first distributive law [the lecturer draws Venn diagrams – Figure 1].
> A, B, C, and I intersect A with B, intersection with C…

So, from these Venn diagrams, you immediately see this should be true. But a picture is never a proof. Yeah, it only helps you.
Now, I've seen this picture. And now, I am quite confident that it is true. So, I have to give you a proof.

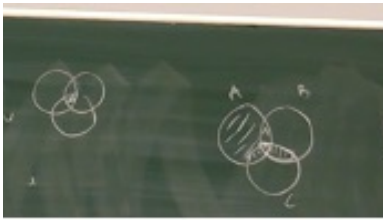

Figure 1: Visual mediator for distributive law

As seen in the excerpt, the lecturer introduces students to the distributive law for sets by presenting the statement of the theorem and subsequently initiates the proof by drawing Venn diagrams. The diagrams offer an initial understanding of why the theorem is true. In the excerpt, we gain initial insights into the lecturer's identification of students as both ritual and explorative participants in the university mathematical discourse, providing OTLs in both cases. On the one hand, the lecturer identifies them as aware of the statement's truth through the presence of the narratives about mathematical proofs (i.e., "you immediately see this should be true", "confident that it is true"), assigning explorative participation for the students as independent participants in the discourse, exploring on their own why the narrative is true. On the other hand, narratives in the lecturer's discourse bring up what counts as valid proof ("a picture is never a proof… it only helps you"), with the lecturer assuming that some students may not see the necessity of providing proof after the lecturer's drawing the diagrams, suggesting a ritual participation for students. The lecturer then continues to the proof of the statement:

Okay, I have to do two sides, I have to prove that A intersects B union C is a subset, the left-hand side is a subset of the right-hand side. And I have to do the same proof but then the other way. Yeah, but let's concentrate on this one.
Proof: let x be an element of the left-hand side.
Then I argue and argue. And I end: so x is on the right-hand side.
This is my goal, yeah. I just have to fill in the details.

In this excerpt, the lecturer starts the formal proof of the distributive law. The lecturer outlines the proof process (i.e., "the left-hand side is a subset of the right-hand side", "I have to do the same proof but then the other way"). Then, the lecturer starts the proof with the main argument, which is to show that an element x from the left-hand side is also on the right-hand side. The lecturer describes the argument as the goal and the process towards this goal as the details in between. In this case, the OTL reflects the outcome of the proving process, suggesting an explorative, outcome-oriented participation in the university mathematical discourse. The lecturer continues with the proof and concludes as follows:

That's a proof of that statement. I take my x in here and prove that it is there.

In the same way, or, similarly, you can do the other statement that if you have an element from A intersect B union A intersect C, that is A intersect B union C.
But that's how you approach this.

In the excerpt, the lecturer concludes the first part of the proof, showing that an element x from the $A \cap (B \cup C)$ is also an element of $(A \cap B) \cup (A \cap C)$. Then, the lecturer identifies that the students have enough information to attempt the proof of the statement that an element x from $(A \cap B) \cup (A \cap C)$ is an element of $A \cap (B \cup C)$, providing them with an OTL to work on their own, following the proof that was presented to them. This OTL is suggesting students' explorative participation as the focus is shifted from the proving process back to the statement that is needed to be proven.

Commentary following the proof

The lecturer continues with a commentary following the proof.

What do you notice? It reads like a novel. Yeah. Yes, you can read this as full sentences. Of course, they are very short and obtain formulas. […] I wrote down some of these identities. Look at the identities in the lecture notes, take one or two of them. And try maybe to draw these Venn diagrams, whether you understand that that is true. Or try to prove them in this way, or read the proof of some of the statements as given in the notes. And really not only try to understand it, but also see how it's formulated. How to make a good text out of it, where all the reasons are in there, look at these words, assume, suppose, let, therefore, then, ands. Yeah.

The lecturer asks the students about the proof on the blackboard, focusing on what they notice. Then, the lecturer mentions that the proof can be read like a novel, has whole sentences, and that the proof's length is short but contains formulas. The lecturer identifies the students as being able to read the proofs and produce similar examples based on the lecturer's presentation of the proof. However, we interpret that at the same time, the lecturer recognises them as newcomers to formal proving because, following this identification, and continues by explicating narratives about proof writing, reading, and understanding ("try to prove them in this way", "draw these Venn diagrams", "read the proof of some of the statements"). In this excerpt, the OTL suggests ritual participation, where the focus is on the process and less on the procedure's outcome. The lecturer adds:

So, don't forget to put in all these words.
That's, that's really important. That's the heart of mathematics is words, not these formulas. But these words give you your assumption, your conclusion, and so on. And that is giving a proof? Explain the reasoning.
And the further you get? Of course. Less detailed you have to be. But right in the beginning, you need to be very detailed because you're building up your knowledge.
Really be prepared. Write on all these.

The final excerpt highlights the lecturer's identification of students as newcomers to proof writing and the suggested ways of producing formal proof. The OTL in this excerpt is related to students' ritual participation in the university mathematical discourse. Within this identification, the lecturer brings up that the "heart of mathematics" is in the words of the proof. The lecturer adds that the students need to be in the beginning "very detailed because you're building up your knowledge".

Then, the lecturer suggests ways to be prepared and write these proofs on their own, allowing an entrance point to the discourse for the students who start engaging with mathematical proofs.

In the example, we unpacked the OTLs in university mathematical discourse that appear in the overlap of mathematising and identifying in the talk around the teaching of proof. The OTLs the lecturer offers to the students are based on the mathematising that is taking place while proving, the students' intended participation in the university mathematics discourse (i.e., "very detailed because you're building up your knowledge"), and the lecturer's identification of students (i.e., "confident that it is true"). The OTLs reveal how students are expected to participate in the discourse. In particular, while the OTLs in the presentation of the theorem and its proof suggested more explorative participation, the OTLs in the commentary following the proof were interpreted as indications of ritual participation. In both cases, the students were interpreted as newcomers in the proving process, suggesting ways of facilitating their independent work with similar proofs. In the example presented here, the lecturer, through the OTLs, seems to emphasise what an independent and agentic participant in the university mathematical discourse is expected to do. Yet, considering that students are not yet independent or agents in the new (for them) university mathematical discourse, it remains questionable whether and how they can benefit from such OTLs.

Discussion

This study is an initial investigation of OTLs offered in university mathematics lectures. We conceptualise OTLs as the lecturers' attempts to suggest a change in students' participation by allowing entry points in the university mathematical discourse. We asked, "*How are students identified in OTLs to allow students' participation in university mathematical discourse, particularly proving, during STT?*". We focused on an example from the teaching in an introductory set theory course, and we provided an exploration of the OTLs that appear in university mathematical discourse in the overlap of the lecturer's mathematising and identifying talk. Thus, the OTLs found in our study may suggest how one should participate in the university mathematical discourse, and depending on the student' success in following the OTLs, their participation in the discourse might develop very differently, potentially reducing the dropout numbers of first-year mathematics students.

The OTLs appeared as entrance points to the university mathematical discourse as they indicated how a student is expected to participate in them. In this case, the OTLs did not focus on proving styles (e.g., Weber, 2004) but more on the ways of studying independently. Similarly to the cases explored by Remillard (2014), the lecturer shared identifying narratives of how students are expected to participate in the discourse. The students are expected to familiarise themselves with the "rules" of the lecturers' discourses, entering the new university mathematical discourse while starting to work independently. Sfard (2014) argued about the importance of students' independent journey in the university mathematical discourse, highlighting it as a difference between school and university mathematical discourses. Yet, considering that students are at the beginning of their university studies, it is unlikely that they will benefit from OTLs that emphasise becoming agentic and independent participants.

STT is a complicated and challenging period for students, and this study is the starting point for further exploration of introductory university mathematics lectures as a resource to support STT. As

Pinto and Koichu (2023) also mention, STT and supporting STT have many interpretations in mathematics education field. Future steps include analysing a larger corpus of data that would allow the refinement of the OTLs for STT. Moreover, students' input would allow a further understanding of the lectures' historical involvement in the STT, enabling characterisation of the OTLs with respect to the shared "rules" but also relating it to their actual agency development.

The research communication of doctoral students in mathematics

Rox-Anne L'Italien-Bruneau[1], Igor' Kontorovich[2] and Ofer Marmur[1]

[1]University of Auckland, Department of Mathematics, New Zealand;
r-a.litalien-bruneau@aucklanduni.ac.nz

[2]Faculty of Education, The University of Hong Kong, People's Republic of China

Doctoral students hold a particular position in relation to mathematics and mathematical learning. This unique position is central in the work presented here as we explore doctoral students' experiences of mathematics through the investigation of their communication of research. Building on the commognitive framework, this paper is a first step in characterising the mathematical research discourse of doctoral students. Our analysis of interviews with three doctoral students in mathematics highlighted three patterns characterising our participants' mathematical discourse. We conclude this paper by discussing how these patterns inform how doctoral students construe their mathematics.

Keywords: Doctoral students, mathematical communication, commognition.

Introduction

Transitions to, across and from university mathematics have been widely examined in recent years (Hochmuth et al., 2021). In the case of the transition *across* university mathematics, two main areas of research were explored: the transition between courses about the same topic (such as analysis) and the transition from general to disciplinary courses (such as engineering) (Hochmuth et al., 2021). Although the transition to higher degrees in mathematics was identified as a possible transition across university mathematics (Hodgson, 2015), doctoral students at the heart of the specific transition from undergraduate to research mathematics received little attention (Edwards, 2010). Yet, as part of this transition, doctoral students play a unique role in mathematics and mathematical learning.

On the one hand, doctoral students can be seen as mathematical students who successfully went through undergraduate mathematics courses and programs. As illustrated by Alcock and Inglis (2008), turning to these students could yield impactful results regarding the "skills needed for success in advanced mathematics" (p. 127). Accordingly, research on doctoral students could inform the sort of habits that foster the learning of mathematics in university courses.

On the other hand, doctoral students can be seen as "becoming mathematicians" (Herzig, 2004, p.171) and, more precisely, as learning the practices of research mathematics. In particular, the process of becoming a mathematician entails learning how to solve "a problem with an 'unknown' solution and no definite 'direction' towards its successful solution" (Geraniou, 2010, p. 288). In other words, doctoral students are not only expected to learn mathematics as part of their program but also to learn how to solve problems for which no solution is known by the mathematical community.

These expectations put doctoral students in a unique position in terms of their experience of mathematics and mathematical learning. Accordingly, in her doctoral project in mathematics education, the first author of this paper seeks to characterise how doctoral students in mathematics experience research and participate in mathematical research activities. Contributing to this broader project, this paper focuses on the mathematical research discourse of doctoral students.

Theoretical background

Building on systematic functional linguistics (SFL) and commognition, Morgan and Sfard (2016) develop a discursive framework that approaches mathematical experiences through the lens of the *ideational* function of mathematical discourses. In SFL, language and communication are described as functional, not representational (Halliday, 1985). In that sense, the *ideational* function of communication pertains to the way we share our experiences of the world by communicating. Similarly, commognition describes communicating and thinking as two sides of the same coin, the former being the public version of the latter. In this sense, Morgan and Sfard (2016) claimed that studying the use of language is a "means of understanding the ways in which participants in communication may construe their 'reality'" (p. 100). Leveraging the work of Morgan and Sfard (2016), we draw on the commognitive framework to explore how doctoral students construe their mathematical reality.

In commognition, the use of language is captured with the fundamental construct called *discourse*. Mathematical discourses correspond to different types of communication and are distinguishable through the *words used* (e.g., the names of mathematical objects and properties), *visual mediators* (e.g., symbols and figures), *narratives* (e.g., definitions and claims), and *routines* (e.g., methods and techniques) (Sfard, 2008). Additionally, discourses define "different communities of communicating actors" (Sfard, 2008, p. 93). Members of a community of discourse, called *insiders*, are said to be able to participate in a given discourse: they are able to communicate with other insiders.

In our work, we view research in mathematics as a form of participation in what we call a *specialised mathematical discourse* (SMD), a discourse corresponding to a specific mathematical field such as dynamical systems, graph theory, or topology. As illustrated in Madsen and Winsløw (2006), pursuing research in mathematics asks for what the authors have called *extensive prerequisites* due to the level of sophistication of the mathematical theories and methods. Commognitively speaking, this means that participation in SMDs relies on discursants' familiarity with distinctive and technical keywords, narratives, visual mediators, and routines.

Additionally, mathematical discourses, specialised or not, are often characterised by what Morgan and Sfard (2016) called the level of *objectification*. Objectification is a process through which participants in a discourse talk about objects and properties instead of people and processes (Sfard, 2008). Objectification occurs through *reification* and *alienation*: in the former, a talk about processes becomes a talk about objects (e.g., talking about fractions as dividing vs fractions as numbers) while, in the latter, all signs of human agency are removed from the discourse. As a result of *objectification*, statements about mathematical objects appear as the "state of the affairs in the world" rather than "a statement about our own commognitive activity" in specialised mathematical discourses (Sfard, 2008, p.107). For instance, a definition appears as a fact about an object instead of a discursive activity.

Building on Morgan and Sfard's (2016) framework, the wider project investigates doctoral students' mathematical discourse as a way to explore their experience of mathematical research. Accordingly, the work presented here is a first step in answering the following question: *How do doctoral students participate in the specialised mathematical discourse of their research?*

Methods

The data for our study were collected from interviews conducted by the first author in the Department of Mathematics at a research-intensive university in New Zealand. These interviews were designed for the first author's doctoral research project. As part of this project, eight doctoral students were invited to a series of individual semi-structured interviews in which they answered questions about their work and progress in research.

As part of the interview, doctoral students were prompted to talk about their research on several occasions. Acting as the interviewer, the first author encouraged the participants to talk about (the state of) their research at the beginning of each interview. Second, she asked participants to provide specific examples from their research to support their answers to interview questions about their participation in research activities. Last, the interviewer occasionally asked clarifying and follow-up questions about the mathematics discussed. For example, when a participant said that "some groups [the mathematical structure] have been explained", the interviewer asked him to detail what he meant by "explained". Additional data was also collected through 30-minute seminars in which students were invited to present their research to other students participating in the study. Accordingly, we view the interviews and the seminars as two settings where doctoral students communicate their research projects and participate in the specialised discourse of their research. However, due to space constraints, we only discuss findings from the analysis of the interviews in the next section.

More particularly, we report on interviews with three doctoral students who provided detailed explanations about the mathematical objects and processes involved in their research. These students are Isaac, Patrick, and Charles (pseudonyms). Isaac and Patrick both work in the field of dynamical systems, and Charles's research is at the intersection of group theory and graph theory.

In total, nine interviews (three for each participant) were analysed. Working with the transcripts of the interviews, we proceeded with a three-stage analysis of the keywords and expressions participants used to talk about and refer to the mathematics of their research. The first stage involved identifying all the instances where participants talked about objects, routines or visual mediators of their SMDs in the interviews. To do so, the first author read the transcripts multiple times and sought clarifications from participants about their use of certain expressions. In the second stage, we looked at the specific words and expressions that participants used. For this paper, we were concerned with the *levels of specialisation* (Morgan & Tang, 2016) and *objectification* of the discourse (Morgan & Sfard, 2016). The *level of specialisation* pertains to the use of specialised and non-specialised keywords and expressions. This categorisation was based on follow-up conversations with the participants and consultations of mathematical references such as books, research papers and conference posters. For example, the names of mathematical objects or properties, such as "wild chaotic attractor" or "fragmentally asymptotically stable", are specialised expressions since they appeared in instances of SMDs found in the references consulted. Conversely, expressions that are not part of the SMDs and could have been replaced with SMD keywords and expressions were classified as *non-specialised*. The *level of objectification* concerns the actors brought into the conversation and what is said about them. A narrative was categorised as *objectified* if it corresponded to a talk involving mathematical objects and properties, and it was categorised as *disobjectified* if it corresponded to a talk involving

people and processes. In the last stage of the analysis, we identified patterns in how our participants used different forms of talk characterised by their level of specialisation or objectification.

Findings

When looking at the levels of specialisation and objectification of our participants' discourse, we found three patterns that characterise their participation in their respective SMDs. We detail and exemplify each of these patterns in the following.

Doctoral students talk about mathematics with non-specialised expressions

The first pattern we identified in our data pertains to the level of specialisation of the discourse generated as part of the interview. In our analysis, we found that our participants talked about specialised mathematical objects with non-specialised expressions. The first example of this pattern occurred in Isaac's interviews when talking about stability and perturbations of a dynamical system:

> So my supervisors talk a lot about stability and perturbations, […] so perturbations, the idea that I have a system, I shake it a little bit and then check again if the system behaves the same or not.

In this excerpt, Isaac elaborated on the object "perturbations", which, in the field of dynamical systems, is a controlled variation of the parameter values in the differential equations characterising a dynamical system. However, Isaac did not talk about this change of parameters when explaining "perturbation" and described it as "shaking [a system] a little bit" (underlined). In particular, "shaking" a system can be seen as capturing the variations of the parameter values, and "a little bit" as capturing the fact that these variations are controlled. Accordingly, we categorised the expression "shake it a little bit" as non-specialised since it builds on the everyday discourse and was not used in the references we consulted.

The second example of the use of non-specialised expressions when talking about mathematics comes from Charles. Here, Charles explains that he builds on the work of other mathematicians to find a specific family of graphs for a proof in his research:

> So, what I am trying to do is to kind of apply a similar idea, so what they did, they were able to build graphs with these groups as local groups, and their stabilisers just explode, they grow super super fast, we call that exponential, you can think of it as a very wild example.

In the excerpt above, Charles offered details about what his discourse community calls "exponential". Even if "exponential" is used in school mathematics (e.g., when talking about functions), Charles used it in a specific way in his SMD: "exponential" is used as a category of groups when associated with the local action of a graph. In short, "exponential" groups correspond to groups for which, when acting on a family of graphs, the size of the stabiliser grows exponentially with the size of the graphs. In the excerpt, Charles talked about this specific type of growth of the size of the stabiliser by first describing the stabiliser as "exploding" and "growing super super fast" and then introducing the specialised keyword "exponential". In particular, these two expressions are not part of Charles' SMD and are closer to the everyday discourse.

The two examples above illustrate how doctoral students used non-specialised expressions when describing or explaining specialised objects or properties from their research. While "perturbations"

and "exponential" could be discussed with specialised words and expressions, Isaac and Charles elaborated on these keywords with non-specialised expressions. More importantly, in the case of Charles, he used expressions similar to "explode" and "grow super super fast" or "wild graphs" again when talking about groups or stabilisers later in his interview. For example, in the following excerpt, Charles talked about how challenging it is to find the family of graphs he needs for his proof:

> […] you just give me a group and I'm supposed to make a graph that has this local action, and on top of that, you are asking me to make this stabiliser explode. That's even harder.

In this excerpt, Charles talked about the stabiliser as "exploding" like in the previous excerpt. However, as opposed to the first excerpt, Charles did not use the specialised word keyword "exponential" as a reformulation of "explode" and only talked about the stabiliser with the non-specialised expression this time. In that sense, this suggests that our participants also use non-specialised expressions outside of explanations of specialised words.

Doctoral students talk about mathematics by talking about people and processes

The second pattern we identified in the data concerns the objectification of the discourse, or more precisely, the *disobjectification* of the discourse. Our data showed that our participants adopted a talk about people and processes when talking about objects and properties. The first example of this pattern comes from Charles' interview, in which he talked finding a family of graphs with specific numerical parameters. When talking about the value of one of these parameters, Charles said:

> Ideally, I would find a family [of graphs] which has the numbers I like.

The numbers that Charles talked about here pertain to the size of the eigenspace for a graph, which is a specific parameter associated with each graph in the family. In particular, Charles wants to find a family of graphs for which this parameter grows linearly with the number of vertices of each graph in the family. In other words, Charles is looking for a family of graphs that will satisfy some numerical conditions. However, when talking about these numerical conditions, Charles did not name the parameters he studied or talk about the numerical value he was looking for. Instead, he talked about "the number [he likes]". An alternative and objectified version could be: "Ideally, I would find a family in which the size of the eigenspace grows linearly with the size of the graph". In a way, Charles referred to the properties of the number by talking about people in the excerpt above.

Similarly, Patrick also talked about people and processes when describing the object at the heart of his research and the sort of work he does:

> We can sort of represent these [heteroclinic cycles] as like a directed graph, and then what you can do is you can do something like stick two of them together, right? And […] this is a heteroclinic network. […] And you take an object like this […], you stick it in a four-dimensional dynamical system, so you just say you have $\mathbb{R}^4$, you stick this [heteroclinic network] in it and then you ask what does this thing's presence in the system do to the nearby points?

In this excerpt, Patrick introduced heteroclinic networks to the interviewer. In Patrick's field of research, heteroclinic networks are the union of heteroclinic cycles and they are said to define dynamical systems as they affect the behaviour of nearby points. In other words, heteroclinic

networks are unions of heteroclinic cycles, and they define the long-term behaviour of nearby trajectories in dynamical systems. Yet, when describing heteroclinic networks to the interviewer, Patrick focussed on the manipulations of mathematical objects and talked about "stick[ing] two [heteroclinic cycles] together" to obtain a heteroclinic network and then "stick[ing]" the resulting object in a four-dimensional system. He then detailed the questions one can "ask" about heteroclinic networks. Accordingly, by talking about people and their manipulations and questions about mathematical objects, Patrick implicitly talked about the properties of heteroclinic networks as the union of heteroclinic cycles and a structure affecting the behaviour of nearby trajectories.

Doctoral students signal their use of specialised expressions with discursive markers

When analysing the level of specialisation of the discourse, we noticed that our participants signalled the use of specialised expressions with a specific kind of markers, that is, markers highlighting the discursive nature of mathematics. For example, in the following excerpt, Patrick detailed some of the functions he works with as part of his research and introduced the names of such functions:

> Then, what we consider is this map or this rule or, as we call it, the flow function [which] is a function that takes where you start and how far forward in time you want to go and spits out where that point will be at the next time.

In this excerpt, Patrick introduced the mathematical object "flow function" as a "map" or a "rule" he studies as part of his research. In particular, this function returns the position of a given point after it moves for a certain amount of time in the dynamical system. When referring to this object, Patrick first used the words "map" and "rule" before introducing the specialised counterpart "flow function". Additionally, we note that just like Charles with "explode" in the first pattern, Patrick also used the non-specialised expressions "map" and "rule" instead of "flow function" later in his interview. However, with this example, we want to illustrate the expression "we call it" with which Patrick introduced the specialised expression "flow function". By highlighting the specialised character of "flow function" with the expression "we call it", Patrick also shed light on the discursive process of defining and naming "flow function" in his discourse community.

Similarly, in the following excerpt, Isaac signalled the particular status of "bifurcations":

> In the world of dynamical systems and in particular, in differential equations, there are different objects that behave differently. So, there are equilibrium points, there are periodic orbits, there are invariant tori but recently people um found out about wild chaotic attractors. The way that these objects are created is through some things that are called bifurcations.

In this excerpt, Isaac introduced bifurcations as something that "creates" the objects that he previously listed. In particular, Isaac detailed that the "things" that created these objects "are called bifurcations". Like in the case of Charles, Isaac used a marker and signalled a specialised expression to the interviewer. Additionally, this marker also highlights the discursive nature of mathematics. As opposed to presenting descriptions of mathematical objects as "a state of the affairs in the world" (Sfard, 2008, p.107), Charles and Isaac both shed light on the processes of naming and defining mathematical objects.

Discussion

In this paper, we investigated doctoral students' participation in research mathematics through the communication of their research projects to a mathematics education researcher. Through our analysis of these interviews, we identified three patterns characterising the discourse of doctoral students when talking about their research in this context. In particular, we found that our doctoral students (1) talked about mathematics with non-specialised expressions, (2) talked about mathematics by talking about people and processes, and (3) signalled their use of specialised expressions with discursive markers.

To our knowledge, the mathematical communication of doctoral students has never been studied before. Our findings are a first step in characterising how doctoral students communicate their research, but also in characterising how doctoral students "construe their [mathematical] 'reality.'" (Morgan & Sfard, 2016, p.100).

The first pattern highlights that doctoral students draw on non-specialised discourses when talking about their research. In this sense, our findings align with the work of Barwell (2013, 2016) who highlighted that learning mathematics might not only be transitioning from what he called the *everyday* or *informal* discourse to the *mathematical* or *formal* discourse. For him, learning mathematics involves a dialectical relationship between various discourses and entails the extension of one's discursive repertoire. Our analysis illustrates that our doctoral students not only drew on their SMDs when talking about their research, but also on the everyday discourse. This suggests that the everyday discourse might be part of the discursive repertoire associated with their research. Additionally, the objectification of discourse is often described as an important stage in learning mathematics: replacing a talk about people and processes with a talk about objects and properties is described as essential for the development of mathematical discourses (Sfard, 2008). Yet, our second pattern indicates that our participants talk about processes and people when describing mathematical objects and properties involved in their research. In addition, our third pattern highlights the discursive processes of naming and defining mathematical objects as part of doing mathematics. In other words, the discourse of our participants sheds light on their involvement and the involvement of other mathematicians in mathematical research.

This suggests that the everyday discourse, but also a talk about people and processes, might be part of the SMDs of our participant. Since commognition claims that communicating is the public version of thinking, it is possible to wonder about the role these ways of talking and thinking play when our participants engage with mathematical research. In other words, when our participants work on their research and try to progress on some of their problems and proofs, what are the contributions, if any, of the everyday discourse and talk about people and processes? More investigations across different contexts, such as conference talks or research meetings, could yield more insights about these contributions. While our preliminary analysis of the seminars suggests that our participants adopted similar patterns when presenting their research to other doctoral students in mathematics, more work is needed to investigate how different discourses and forms of talk play a role in our students' mathematics.

The role of mathematics in advanced electrical engineering courses: a typical case of numerical integration

Željka Milin Šipuš[1], Matija Bašić[1] and Jelena Pleština[2]

[1]University of Zagreb, Faculty of Science, Department of Mathematics, Zagreb, Croatia; mbasic@math.hr

[2]University of Split, Faculty of Science, Department of Mathematics, Split, Croatia

This study, framed within the Anthropological Theory of the Didactic, explores the role of mathematics in advanced courses for electrical engineers. It examines the connection between mathematics and advanced electrical engineering courses through interviews with teachers and a master's student, alongside a didactic and praxeological analysis of teaching and learning about spectrum of laser emission, which relies on integration. The results indicate that mathematics courses mainly provide theoretical foundations, while advanced courses develop techniques specific to electrical engineering. Advanced courses can inform mathematics courses in terms of knowledge selection, adaptation, and organisation, as well as inquiry-based learning. A pedagogy in which the teacher is primarily responsible for knowledge, while the student applies given models, is also a characteristic of courses beyond mathematics.

Keywords: Mathematics for engineers, Numerical integration, Anthropological theory of the didactic, Didactic transposition.

Introduction

Mathematics might be considered a fundamental, but subtly integrated part of many other disciplines. Hence, it is a big challenge to determine the scope and the tools with which one might study the math-related topics in the university education of non-mathematics professionals. There is a growing interest in research of teaching mathematics for students in other disciplines, such as physicists, chemists, engineers, economists etc. (Winsløw et al., 2018, p. 67). Analysing the epistemological relations between mathematical knowledge in mathematics courses and specialised professional courses (Hochmuth & Peters, 2022; Rønning, 2021) enables an understanding of the transitions students undergo, reveals potential gaps, and provides a foundation for didactic interventions.

In this study we wish to explore how mathematical knowledge appear in a more professionally oriented (advanced) course for electrical engineers, with the goal to uncover the requirements of the mathematics discipline that are coming from the subject discipline. This is a continuation to our previous investigations (Bašić & Milin Šipuš, 2024) on the role of the notion of integral in the university education of future mathematicians, economists and physicists, in which we are especially interested in methods and their (dis)advantages in educational research.

Theoretical framework and research questions

Anthropologic Theory of the Didactic (ATD) is a theoretical framework that, in the broadest sense, examines the factors for the diffusion of knowledge through an epistemological, ecological and didactic analysis within a given institution (Chevallard & Bosch, 2020a). The epistemology of knowledge at stake can be explored using the tool and methodology of *didactic transposition*

(Chevallard & Bosch, 2020b). The basic unit for analysing and modelling knowledge is praxeology, which is represented by an ordered quadruple $[T/\tau/\theta/\Theta]$, where: τ is the technique used to solve a task of type T, θ is the technology, the discourse of the praxeology and explains the technique, and Θ is the theory that is a justification of the technology (Chevallard & Bosch, 2020a). The ordered pair $[T/\tau]$ is called a *praxis (block)* of the praxeology and $[\theta/\Theta]$ is called the *logos (block)*. Praxeological analysis enables the understanding of the organisation of knowledge and reveals the purpose of the observed knowledge within the observed institution.

The analysis of the *ecology of knowledge* focuses on *conditions and constraints* set by the various *levels of didactic co-determinacy*: ⋯↔*Schools* ↔ *Pedagogies* ↔ *Disciplines*↔⋯ (Chevallard & Bosch, 2020a). ATD views individuals in relation to the *positions* they hold within the observed *institution* (Chevallard & Bosch, 2020a). In a typical didactic system, the key positions are those of the teacher and the student.

Furthermore, ATD identifies the *paradigm of visiting works* as the dominant educational paradigm, where pedagogy is based on teaching pre-established pieces of knowledge (Chevallard & Bosch, 2020a). The movement towards inquiry-based learning, often seen in research and educational systems, is regarded by ATD as a push for a shift in the educational paradigm—from the *paradigm of visiting works* to the *paradigm of questioning the world* (Barquero et al., 2018; Chevallard & Bosch, 2020a).

In general, we are interested in the epistemology and ecology of praxeologies related to integrals that appear in advanced engineering courses, the role of (both established and new) mathematics praxeologies in such courses and, the relationship between introductory mathematics courses and advanced engineering courses. In this study, we aim to explore potential methods for addressing these broad questions by examining teaching and learning about the spectrum of laser emission. Teachers and experts in the domain of electrical engineering suggested this theme because it includes integration, which poses mathematical challenges to students. Accordingly, our research question is: What insights can praxeological, didactical, and ecological analyses of this theme provide for teaching mathematics to engineering students or for adapting mathematics-related praxeologies to the needs of advanced engineering courses?

Methods

To gain insight into current practices involving the use of integrals in advanced electrical engineering courses, we conducted short semi-structured interviews with two teachers and a student from a faculty of electrical engineering in Croatia. The first interviewee is a professor of Optical Communication Systems with about 20 years of experience teaching electromagnetic courses to students pursuing a specialized study track, typically with about 10 students enrolled. The second professional is a PhD student who also works as a teaching assistant for various courses, such as Antenna Systems. The student participant is in the final year of the Master's programme in Information and Communication Technology, having successfully completed all required courses up to that point.

Our research began by asking teachers to identify content they found particularly interesting as examples of using integrals in electrical engineering. They have selected the theme about the spectrum of laser emission and provided accompanying lecture notes for the students. Our review of

these materials aimed to assess how the mathematical content was addressed in the course. Additionally, interviews with teachers were conducted by the first and second author, focusing on the relevance of the tasks in engineering education and methods for calculating integrals when working with discrete data. We were also interested in determining whether the students were expected to have specific prior knowledge of numerical integration, their use of technology, and any potential difficulties related to mathematics. The interview with a student aimed at the same information but from a student perspective. A praxeological analysis has been performed based on the lecture notes and the interview, while the didactical and ecological considerations are drawn based on the interviews – full transcripts to selected answers and our interpretation is given in the following section.

Analysis

We consider a task in electrical engineering concerning the spectrum of laser emission (Saleh & Teich, 2019). The spectrum consists of many wavelengths and for each wavelength one can measure the corresponding spectral power of the source. The width of the laser spectrum is the distance between wavelengths at which the power is half the maximal power, see Figure 1a.

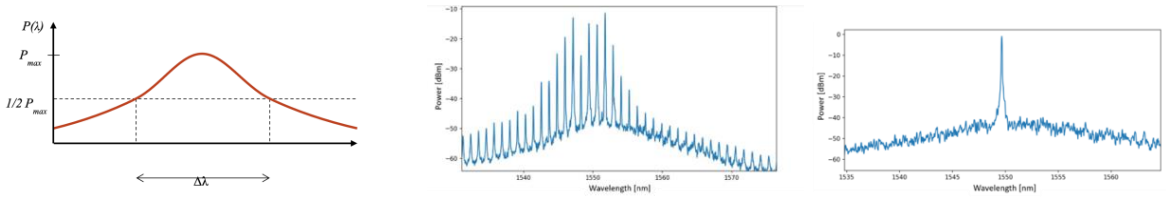

Figure 1: The width of a spectrum (a) and typical spectrum of a multimodal (b) and of a single-modal (c) laser diode

For multimodal (Fabry-Pérot) lasers, the spectrum of possible wavelengths is highly irregular (Figure 1b) and to determine the width, the mean square spectral width is calculated using the formulas:

$$\sigma_\lambda^2 = \frac{\int_0^\infty (\lambda - \bar{\lambda})^2 P(\lambda) d\lambda}{\int_0^\infty P(\lambda) d\lambda}, \qquad \bar{\lambda} = \frac{\int_0^\infty \lambda P(\lambda) d\lambda}{\int_0^\infty P(\lambda) d\lambda},$$

where the second formula describes the average mean of possible wavelengths. The same formulas are used to determine the spectral width of single-mode lasers (Figure 1c) because the spectrum is very narrow, and it is difficult and inaccurate to determine the distance between $1/2\ P_{max}$ points.

In practice, it is common to obtain measurements for a (very dense) set of wavelengths. A typical dataset contains about 20000 entries given as pairs of a wavelength and the corresponding source power. The task for the students is to calculate the spectrum width based on this discrete set of data. The students are not given any further instructions, and the solution of the task should be handed in a form of a report. Since the data is discrete, this is a typical task in numerical integration. In numerical mathematics, numerical integration is usually performed using software which is programmed based on the 'trapezoidal rule' to obtain precise values, but sometimes a less precise 'rectangle rule' is used. The rectangle rule is a very simple approximation technique that is closely connected to the definition of the definite integral using Riemann sums. The integral is approximated by the Riemann sum, i.e.

the ‘area under the graph’ is approximated by a sum of areas of rectangles of certain width of a small interval and height given by the value of the integrated function in one point of that small interval.

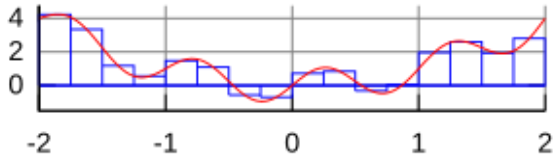

Figure 2: Rectangle rule is based on the approximation of the definite integral by Riemann sum (“Numerical integration,” 2024)

In the interview, the professor (P) explains the task with the specific details about the data provided to the students and the responsibility that is left to them as a small inquiry assignment.

> P: The task is to calculate the mean square spectral width… related to the area under the curve. The definition is classical, and the only thing we do is to apply to a concrete spectrum. This is a fundamental example in our field. The spectrum is given as a discrete sample of data obtained by measurement. The instrument that we use does not give the mean square width, although some other instruments do, so the students need to calculate the integral from the given data numerically. It is left up to students to choose what method and software they will use, but they need to present their work. For the students this is one of the first encounters with real data and for the first time they need to make a calculation using numerical methods.

We observe that the professor expects the students to make connections between the formulas and the data based on their previous mathematical knowledge about the notion of an integral. In the interview, he provides more inputs which explain the students’ praxeologies, i.e. the technology of the ‘area under the curve’ and the ‘rectangle rule’ which the students use as a common technique.

> P: Some students have nice approaches. In general, they interpret the integral as the area under the curve and they use the rectangular approximation, which we also call step or piecewise constant approximation. Trapezoidal approximation would be a step further, but since datasets are large there is no need for it. The students recall how to calculate areas under the graph from their mathematics courses... they don’t have difficulties and provide correct results. Probably the students also exchange basic ideas about integration among themselves. The only problems that occur in some students’ report is related to the fact that the instrument provides data on a logarithmic scale (in decibels), so some students fail to take that into account, but this is a very concrete and manageable problem.

In addition, the professor explains that this task is very special because this specific spectrum can be well approximated by the Gauss curve. It is taught in the lectures that this approximation is related to the numerically calculated integral by a fixed factor (square root of 2), so the professor concludes that this might show students that “their work is meaningful and that the students use this result to check their own work”. Hence, validation of the praxis is also possible in this task using another logos. The professor also comments that the data is such that the issues of numerical approximation (such as floating point error) does not occur in this setting, but this is not discussed with the students, as most of them have not taken the elective course in numerical mathematics and are even unaware of such issues.

The interviewed student (S) recalled immediately the task and described it in the following way.

S: We were given the data about the power of a laser, and we needed to calculate the mean square spectral width. I did not have difficulties because I remember the notion of the integral from my previous courses. An example with integration has been shown in the exercises class and the formulas [of the model] with integrals were provided during the lectures.

We see that the retention of what was the task is very strong, and that the student was interested during different parts of the course. She proceeds by explaining how she solved the task.

S: We have learned in mathematics courses that the integral from somewhere to somewhere is the area under the graph and we saw that we have something similar here…erm… the spectrum of the laser is like a function given by data. So, we didn't need to integrate, I have just simply calculated the data as the small individual areas…and I used the 'for-loop' in Python to sum that up. Of course, there is an error, but as we increase the number of data the error is smaller.

From this quote we see that the student interprets the integral as the area under the graph and uses the technique of approximating that area by 'rectangle rule'. The student also mentioned that they did not take a course on numerical mathematics, and that they "have heard there are numerical methods for integration but have not seen or used them". This indicates that it is possible that the students make connections between the discrete and continuous aspects of the integral based only on intuitive justifications and possibly on the definition of the Riemann integral (theory developed in earlier courses on integrals), and for them numerical integration is an ad hoc technique that they discover while solving this task, not a standard technique from numerical mathematics.

The teaching assistant (TA) brought the focus of the interview to techniques that the students use in a broader sense. He mentions one task with which many students show different techniques than expected regarding taught knowledge. The task reduces to integration in one variable and since integration is not the focus on the exam, the primitive function of the integrated function is provided in the task as a hint. It is noticed that the students do not use that hint and instead plug in the whole integral into a calculator.

TA: For a few years now, I notice that at the exams 80-90% of students rather use the calculator than the antiderivative given in the task to finish the calculation. We suspect they feel safer this way and find it a faster way. I have asked them why they do it but never received a reason. They probably get used to using calculators during their first or second year. Although the mathematics courses in the first year force all the students to integrate well, we might notice that integration becomes less frequent in the higher years. For example, even when the students need to compute Laplace or Fourier transforms, they learn ready-made rules for these transforms, and they stop integrating "by hand" after the second year.

Moreover, the assistant emphasized that the students focus more on the engineering and physics notions while mathematics is an auxiliary tool, and new mathematical notions are not introduced in the course. He confirms that the course on numerical mathematics is elective, and students develop techniques based on intuitive justifications, but believes that for many students the main notions are developed during the course Mathematical Analysis 1 in the first year. He tells the story of his mathematics professor at this course: 'Imagine you are in the woods without a calculator and must estimate the area of an irregular part of wood. You could cut the wood into small rectangles and

measure them with a ruler.' He also discusses students' techniques and mathematical praxeologies, in general.

> TA: Concerning the interpretation of results or making conceptual calculations, such as using that the function is even or has some other symmetry, or a trick using a shift of the graph by $\pi/2$, we see that there are two classes of students. Some students easily do such tricks and others almost never do it, there is no in between. We also see that students often use online graphic calculators, but the professors never teach them to do that – it must be that one student comes to others and shows them what they discovered and that is how some use of software spreads.

Discussion and conclusion

The interviews with the two teachers have suggested the analysis of teaching and learning about the spectrum of laser emission. The analysed theme serves as an example of the interaction between the disciplines of engineering, didactics and mathematics. We see the analysed task as significant in the study programme of future electrical engineers because it is (1) fundamental to the discipline of electrical engineering according to experts, (2) providing learning opportunities for autonomous activities which is shown in the students' freedom to choose techniques for solving the task, (3) providing first encounters with calculations based on real data and establishing connections between theoretical mathematical knowledge and practical domain knowledge, and (4) leads to evolution of the mathematical praxeology of calculating definite integrals.

The extension of integration praxeology is two-folded. First, the task requires students to formulate and justify the technique of calculating the integral of a function given in discrete arguments (table representation). The technique is justified by reinforcing the logos from basic mathematics course: the definition of the Riemann integral and its interpretation as area under the graph. Hence, the praxeology is enhanced in the logos block. Second, the techniques of integration change over the years. At first, in mathematics courses, the main integration techniques are induced by the logos of the integral as an antiderivative and the Newton-Leibniz formula, and through specialised courses numerical integration and the use of software become the more dominant techniques. This evolution of the praxis block is also explained and supported by the episode mentioned by the teaching assistant – the students use calculators to evaluate integrals even when the antiderivative is given as an instruction in the exam task. Exact integration techniques learnt in mathematics courses are not crucial in specialised courses. This aligns with González-Martín's (2021) conclusion that integrals are used to introduce notions in engineering courses, but the techniques in these courses do not heavily rely on calculus techniques (p. 211). Analysing specialised courses from a mathematical perspective can more efficiently guide the didactic transposition of knowledge from mathematics courses. In this case, one may question whether it is necessary to introduce the indefinite integral before the definite. To what extent should numerical mathematics be integrated into the education of engineers, and how should it relate to the knowledge transposed from mathematical analysis? Furthermore, it is crucial to consider how the logos of numerical techniques can be constructed to prevent a disconnect between praxis and logos in engineering praxeologies, Current evidence suggests that while logos is grounded in mathematical analysis, praxis primarily relies on numerical techniques.

From the interviews with the teachers, it is indicated that the students manage in the given conditions, i.e. the economy of the didactic system is evaluated positively from all institutional positions. This is

confirmed also by the interviewed student, not only for herself, but for her colleagues. The ecological analysis spans beyond the local didactic situations to include reasons for its success in: (1) the praxeological equipment that the students attain during their earlier stages of study, and (2) the stability of the implementation of the programme (including the described task) over a period of at least few years. Nonetheless, we may note that the teachers do not formulate all the didactical goals of the task explicitly and the professor clearly emphasizes that the choice of the task is governed by the requirements of the discipline of engineering.

Institutional positions shaped by the specific academic and professional background of teachers who are not mathematicians, enrich the didactic system even beyond the specialised courses these teachers teach, by informing mathematics courses. In the paradigm of visiting works, specialised courses can provide justifications for learning and organising knowledge. In the paradigm of questioning the world, analysing specialised courses, as well as fostering collaboration between mathematics teachers and teachers of specialised courses, can support design of inquiry-based activities (SRPs) even in mathematics courses. Moreover, despite the learning potential of such activities, the pedagogy and ecology of knowledge in specialised courses is within the paradigm of visiting works. The teacher is responsible for providing techniques, assessing their efficiency, and delivering the formula, which can be understood as a model that students must apply (Barquero et al., 2018). This points to the entrenched nature of the pedagogy of visiting works as the dominant institutional pedagogy, imposing constraints on the diffusion of knowledge in non-mathematics disciplines.

Each interviewed participant might be considered to occupy multiple positions. The professor makes academic decisions based both on his position as a teacher and a professional in engineering, while the teaching assistant provided answers in the interviews using his experience as a student and as a teacher. The interviewed student confirms hypothesis about the study programme and the perspective of other students (i.e. from the institutional perspective of a student we confirm that the didactic transposition was successful for some students), but she also explains some of her behaviour based on personal preferences, aware of her differences from other students, and points to her unsatisfied needs for more meaningful connections with other domains of mathematics. This is, of course, one more instance of the personal-institutional dialectic, well-known in ATD, but shows some clear advantages and limitations of the methods in our study – as much as we gain from learning about the personal perspective of a student, we unavoidably lose the power of generalisation of our findings.

To conclude, our study informs us about the role of mathematical tools and notions in electrical engineering that provides opportunities for students' learning on different levels and illustrates a complex relationship between the disciplines that happens in a university study programme for engineers. It might be seen that the strong impact of the discipline is seen in the reduction of the logos block in the discourse from mathematics, which is complemented by the technologies and theories in the discourse of the discipline to justify the established praxis block. We also note the importance of considering different institutional positions, whose disregard, such as considering mathematical notions only from the perspective of the discipline of mathematics and ignoring the epistemology of other disciplines, might lead to methodological limitations. Similarly to some other insights in the discipline of physics (Bašić & Milin Šipuš, 2024), we see that non-mathematics disciplines contain very intricate positions of teachers who, alongside with professional content of their course, teach

domains of mathematics and use their experience as professionals in didactic decisions. The didactic transposition present in their courses shows many positive aspects that certainly would justify the attention of further research in mathematics education.

[3]ELTE Eötvös Loránd University, Budapest, Hungary; miskeiferi@gmail.com

This study examines the integration of ChatGPT in a second-year undergraduate numerical methods course with 32 mathematics major students. We evaluate the perceived usefulness of ChatGPT before and after regular use in a numerical methods course, its correlation with students' willingness to use it in high- and low-stakes environments, and with exam outcomes. Findings indicate mixed perceptions of ChatGPT's usefulness, particularly its limitations in addressing misconceptions and the risk of students accepting false proofs. Correlation data (N = 22) suggest that students who initially viewed ChatGPT as useful were more likely to use it, and frequent users found it more beneficial. A slight positive correlation may exist between ChatGPT usage and exam performance, but its use during the exam correlates negatively with overall performance. Small sample size limits the generalizability of the results.

Keywords: Chat GPT, LLM, attitudes, numerical methods, university mathematics education.

Introduction

The use of technology for educational purposes is as old as education itself. With the emergence of advanced and widely accessible Large Language Models (LLMs) – computer programs that generate human-like text based on training data – we may face a major paradigm shift in education.

The AI Boom triggered by the release of ChatGPT 3.5 by OpenAI in November 2022, and GPT 4.0 in March 2023, was a significant development which have reached a vast number of users. To incorporate ChatGPT into mathematics education, we believe that it must 1) provide reliable mathematical content – so that students may learn valid mathematical content – and 2) learners must perceive them as credible sources of information – which is a critical component of technology acceptance. The fulfilment of these two conditions is not inherently guaranteed. These models may return false or misleading information – a phenomenon called AI hallucination. Hicks et al. (2024, p. 37) explain that ChatGPT is "in an important way indifferent to the truth of their outputs" because they are intended to mimic human language rather than critically evaluate their outputs. Moreover, ChatGPT is often unable to adequately correct misconceptions, as pointed out by Wardat et al. (2023).

Frieder et al. (2023) examined the mathematical capabilities of ChatGPT 3.5 and 4.0 using the GHOSTS and miniGHOSTS datasets, which contain 728 prompts covering various university-level mathematics topics and are designed to benchmark the higher mathematical capabilities of LLMs. Frieder et al. (2023, p. 1) write that "ChatGPT can be used most successfully as a mathematical assistant for querying facts, acting as a mathematical search engine and knowledge base interface."

Furthermore, GPT 4.0 can assist students with undergraduate-level mathematics questions. However, both versions performed poorly on graduate-level mathematical problems.

Kashefi and Mukerji (2023) showed that ChatGPT can generate, debug, and translate code of various advanced algorithms between programming languages, but is prone mistakes like those of a human programmer. Kabir et al. (2023) conducted an analysis with 517 programming questions to evaluate ChatGPT's answers and found that "52% of ChatGPT answers contain incorrect information" (Kabir et al. 2023, p. 1) while the users "overlooked the misinformation in the ChatGPT answers 39% of the time" (Kabir et al., 2023, p. 1) which underlines the importance of user caution when using ChatGPT.

Kelly et al. (2023) conducted a systematic literature review utilising the frequently used extended Technology Acceptance Model (TAM) with 60 articles. TAM explains how users come to accept and use technology, with key constructs such as perceived usefulness (the belief that the technology enhances performance), ease of use (how effortless it is to use), performance expectancy (expected benefits from use), and effort expectancy (anticipated effort required). They conclude that

> perceived usefulness, performance expectancy, attitudes, trust, and effort expectancy significantly and positively predicted behavioural intention, willingness, and use behaviour of AI across multiple industries. (Kelly et al., 2023, p. 1)

Abdaljaleel et al. (2024) administered a ChatGPT-specific modification of TAM called TAME-ChatGPT to 2240 participants from Arabic countries in the context of higher education and found that "ease of use, positive attitude towards technology, social influence, perceived usefulness, behavioural/cognitive influences, low perceived risks, and low anxiety" (Abdaljaleel et al., 2024, p. 1) affected positive attitudes towards the adoption of ChatGPT in higher educational settings.

Given the current known extensive capabilities of ChatGPT as well as its limitations, research was conducted with second-year mathematics major undergraduates at Eötvös Loránd University as part of an introductory numerical methods course, attempting to find answers to the following questions.

- How do students' perception of ChatGPT's perceived usefulness (both before and after the course), their autonomous use of ChatGPT in low-stakes and high-stakes academic situations, and their exam performance (exam scores) correlate?
- How does students' perception of ChatGPT's perceived usefulness for learning numerical methods change because of regular use over the semester?

Based on the literature cited, we believe that answering these questions is critical in establishing the usefulness and applicability of LLMs in university-level mathematics education.

Impact

This study explores how students' perceptions of ChatGPT evolve with experience and how it affects engagement and learning outcomes. Higher levels of acceptance are expected to correlate with higher levels of use, but it is unclear whether more ChatGPT use correlates with better performance, as inaccurate answers might confuse students. However, exposure to erroneous answers may facilitate better long-term knowledge retention and self-correction in some cases (Adams et al., 2014; Große & Renkl, 2007; Paulovics et al., 2023). Establishing such correlation should be a prerequisite to any

argument about the expected benefits of integrating LLMs into the teaching of numerical methods. By examining the correlation between students' perceptions of ChatGPT, and their willingness to use it in varying academic situations, including in examination situation, we can identify some of the potential impact of integrating LLMs on both learning efficacy and assessment practices, thus contributing to their integration in teaching numerical methods, and mathematics in general.

Methods

This study was conducted at Eötvös Loránd University, Hungary (ELTE), which is recognized as the leading institution for mathematics education in Hungary, with 22 male and 10 female second-year mathematics undergraduate students. Participants had previously studied three semesters calculus, two semesters of linear and abstract algebra, and one semester of Python programming. They had not previously studied numerical methods and began their studies in this subject in the spring of the 2023/2024 academic year. Their interests in mathematics are diverse. Not all 32 participants took part in every activity administered during the semester, but all 32 students took the end-of-semester exam.

The course is titled Introduction to Numerical Methods, which includes a 45-minute lecture and a 90-minute lab session for 12 weeks. The course topics include floating point arithmetic, numerical differentiation, interpolation, numerical integration, solving systems of equations numerically, estimating eigenvalues of matrices, and solving ordinary differential equations numerically.

At the end of the semester, students are evaluated based on a complex four-part exam:

- Qualifying Section (50 mins): Three easy, practical programming questions, any non-human assistance allowed. Those who fail this section will fail the whole exam.
- Definitions and Theorems (30 marks),
- Algorithm Comprehension (20 marks): Programming/debugging,
- Proofs (50 marks): State and prove three theorems.

Categorising the research participants based on their prior mathematical and programming skills is not justified due to the high degree of homogeneity in their previously earned grades. Given the sample size and the nature of the research questions, students were not separated into groups of any kind. During the semester, a higher level of diversity in programming skills was revealed than previously suggested by the grades of the Introduction to Scientific Programming (Python) course.

During the 12 weeks of instruction, students completed 5 quizzes (questionnaires) in weeks 2, 3, 5, 10, and 12 to explore how they used ChatGPT for assistance, whether they used it without being prompted to do so, how helpful they found it for solving numerical methods exercises, and whether they find its mathematical claims convincing. They were specifically asked to try and use ChatGPT only before answering Quiz 1 and Quiz 2. It is important to keep in mind that given the same prompt twice, LLMs will most likely return different answers, and thus it is impossible for teachers to plan for every conceivable answer that students may encounter when working with it. Here follow the quizzes and related activities that are discussed later.

Activity before Quiz 1: Students were asked to consider a basic difference scheme and determine which derivative of f it approximates and in what approximation order. Then, they were told to ask ChatGPT for help in any way they like. Finally, they filled out Quiz 1 with the following questions:

1. Did you ask ChatGPT for assistance before being told to?
2. How useful do you feel it was to attempt solving the exercise with the help of ChatGPT? (0 = Not useful at all, 1 = Mostly not useful, 2 = Mostly useful, 3 = Very useful)

Activity before Quiz 2: Students were asked to calculate the Lagrange interpolation polynomial given four input-output pairs and then write a Python code that would find the coefficients of the interpolation polynomial and plot it together with the interpolation points. Then they were told to ask ChatGPT to help them write the code. Finally, students filled out Quiz 2 with the following questions:

1. Did you check the output of the code generated by ChatGPT?
2. Did ChatGPT provide correct code?
3. How useful do you feel it was to attempt solving the exercise with the help of ChatGPT? (0 = Not useful at all, 1 = Mostly not useful, 2 = Mostly useful, 3 = Very useful)

Activity before Quiz 3: Students were asked to prove that if the matrix norm is induced by a vector norm, then the inequality $\|A\| \geq \varrho(A)$ holds, where $\varrho(A)$ denotes the spectral radius of the matrix A.

ChatGPT provided the following answer to this question:

> According to the definition of the induced matrix norm, $\|A\|$ is the maximum rate of proportional increase of a linear transformation performed on a matrix, relative to a given normalized input vector. Formally: $\|A\| = \sup_{x \neq 0} \frac{\|Ax\|}{\|x\|}$. The spectral radius is the largest absolute value eigenvalue of the matrix, which means the norm applied to the matrix is the maximum of the absolute value of the matrix's eigenvalues. Therefore, for any induced matrix norm, $\|A\|$ can be greater than or equal to the absolute value of the largest eigenvalue, i.e. $\|A\| \geq \varrho(A)$. Thus, the spectral radius is always less than or equal to the induced matrix norm. Hence, the inequality $\varrho(A) \leq \|A\|$ is valid for any induced matrix norm.

What is your opinion on the solution ChatGPT provided?

a) There are no usable parts in the answer (either in terms of definition or reasoning).
b) There are correct parts, but the reasoning is mostly incorrect.
c) The reasoning is basically good, but some steps are not perfect.
d) The proof is fully valid

Note that ChatGPT's solution was to merely quote the definitions of the matrix norm and spectral radius and then restate the claim to be proven. It did not make any logical steps to connect the two definitions. The actual proof is rather easy compared to how much text ChatGPT returned: it requires the application of equivalent definitions stringed together.

After the exam, we provided an opportunity for the students to fill out a voluntary questionnaire:

1. How much did you use ChatGPT's assistance independently during the semester (outside of the seminars)?
2. How useful did you find ChatGPT's assistance for independent exercise solutions during the

3. semester? (0 = Not useful at all, 1 = Mostly not useful, 2 = Mostly useful, 3 = Very useful)
4. Did you use ChatGPT to solve the test questions in the qualifying section of the test today? If yes, for which questions?

Findings

Results from Quiz (questionnaire) 1 and 2 – completed by 25 students altogether – aimed at measuring students' perceived usefulness of ChatGPT at the beginning of the semester show slightly positive perceptions. Averaging each student's two answers given one week apart yielded data of 25 scores with an average of 1.98 and a standard deviation of 0.57 on a scale from 0 (not useful) to 3 (very useful). The after-exam answers of these same 25 students regarding the perceived usefulness of ChatGPT at the end of the semester show a slight increase in average (2.36) and decrease in standard deviation (0.49), possibly indicating better attitudes towards ChatGPT's usefulness.

Figure 1 summarizes five key correlations (R) and their corresponding p-values between the variables described below, calculated for the 22 students who answered all the questionnaires. All omitted correlations are negligible (|R|<0.3).

- **PPU** (previously perceived usefulness) – the average score for the perceived usefulness of ChatGPT given in response to Question 3 of Quiz 1 after the first ChatGPT session and Quiz 2 after the second ChatGPT session (0-3),
- **P** - the score achieved by the student on the exam (0-100),
- **UDS** - ChatGPT use score during the semester based on the after-exam survey (0-3),
- **PUA** - perceived usefulness of ChatGPT at the end of the semester (0-3),
- **SCR** - the use of ChatGPT during the qualifying part of the exam (0-3) – how many of the three exercises the student asked ChatGPT about.

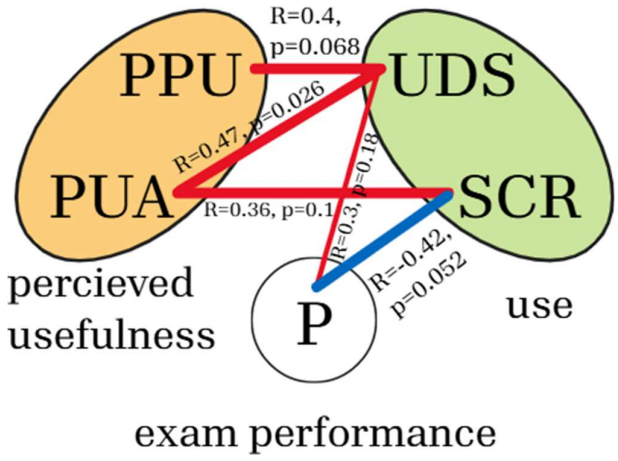

Figure 1: Correlation values and the corresponding p-values between the variables defined above

Based on the data gathered, the previously perceived usefulness of ChatGPT (PPU) may have (p = 0.068) a weak positive correlation (R = 0.4) with individual use during the semester (UDS), and individual use during the semester probably (p = 0.026) has a moderate positive correlation (R = 0.47)

with students' perceived usefulness of ChatGPT after the semester (PUA). Moreover, PUA may have ($p = 0.1$) a weak positive correlation ($R = 0.36$) with students' willingness to try to apply ChatGPT in a high-stakes academic environment, during the qualifying section of the exam. However, this willingness possibly ($p = 0.052$) has a moderate negative correlation ($R = -0.42$) with overall exam performance. Furthermore, students' individual ChatGPT use during the semester might have ($p = 0.18$) a weak positive correlation ($R = 0.30$) with overall exam performance. Finally, there appears to be no noteworthy correlation between students' perception of ChatGPT's usefulness - either before the semester or after the semester - and their exam performance.

The answers for question 3 of Quiz 3, regarding ChatGPT's attempt at solving the theoretical exercise, among the 23 students that answered are as follows:

- 0% (0/23) - There are no usable parts in the answer (either in terms of definition or reasoning).
- 52% (12/23) - There are correct parts, but the reasoning is mostly incorrect.
- 39% (9/23) - The reasoning is fundamentally good, but some steps are not perfect.
- 9% (2/23) - The proof is fully valid.

Given that ChatGPT's answer for this exercise was to quote the definitions of the matrix norm and spectral radius, and then twice restate the claim to be proven, the fact that 11 out of 23 students found this answer either "fundamentally good" or "fully valid" underscores ChatGPT's ability to mislead large fractions of novice students with reasonable-sounding non-answers.

Discussion and conclusions

This study aims to explore the perceived usefulness of ChatGPT in a second-year undergraduate numerical methods course. The findings provide insights into how students interact with and perceive AI-based assistance, highlighting both its potential benefits and limitations.

Results from Quiz 1 and 2, as well as the after-exam survey show mixed perceptions with regards to ChatGPT's usefulness, possibly reflecting the known issues of the current limited mathematical capabilities of ChatGPT when it comes to undergraduate and graduate level mathematics, and its inability to correct misconceptions, as discussed by Frieder et al. (2023), Kashefi and Mukerji (2023), and Kabir et al. (2023). The increase in mean and decrease in the standard deviation between these two measurements may be interpreted as an improved perception of ChatGPT's ability to assist students with numerical methods exercises. Although, this increase may also be the result of several psychological biases, such as the familiarity bias (a preference for what one has been exposed to) or the sunk cost fallacy (continuing an effort because of past investment), as detailed by Greul et al. (2023); rather than ChatGPT's convincing mathematical ability.

In several seminar sessions, students were encouraged to use ChatGPT independently. The after-exam survey revealed many students found ChatGPT useful for solving exercises outside of structured seminar activities. The correlation data suggest that students who found ChatGPT to be useful after a couple of seminar sessions used ChatGPT more frequently during the semester, and that those who used ChatGPT more frequently during the semester perceived it as more useful by the end of the semester. This latter correlation may likewise be due to psychological factors such as the wish to justify effort or mere familiarity bias and is not necessarily caused by ChatGPT's performance.

The data indicates a slight positive correlation between the independent use of ChatGPT and exam performance, suggesting some possible benefits in understanding and application of numerical methods. The numerical values of the correlation coefficient and the p-value are far from showing a significant positive benefit, especially with a moderate-size largely homogeneous pool of participants. Nevertheless, they justify further investigation, which may establish such a benefit more clearly, especially as LLMs are likely to become more powerful in the future.

The notable negative correlation between ChatGPT use during the qualifying section of the exam and the final exam scores ($R = -0.42$) may have at least two explanations. Either ChatGPT reliance for immediate problem-solving without deeper comprehension may hinder performance, or simply those who were less prepared and consequently went on to earn a lower score tended to rely on ChatGPT more heavily in the qualifying section of the exam. It is important to keep in mind, however, that the generalizability of these findings is rather modest due to the small sample size of the study.

In Quiz 3, it is alarming that almost half of the students thought that restating the two definitions and the claim to be proven constitutes an "at least mostly sound." This result is congruent with the findings of Kabir et al. (2023) in the field of programming, and Frieder et al. (2023) in university mathematics, and underscores the possible benefit of including methodology based on students' error correction, such as employed by Adams et al. (2014); Große & Renkl, (2007); and Paulovics et al. (2023).

Integrating ChatGPT into mathematics courses with care and emphasis on its known weaknesses may prove to be beneficial, as it can function as a data-querying tool extremely well, students appear to respond positively to integrating it into courses, and correcting mistakes is also known to increase understanding. This is especially true, as AI tools are likely to get more powerful soon. Several students reported that using ChatGPT is a great tool for them to get their codes to work, suggesting that courses that involve programming might benefit from integrating ChatGPT more.

Permutations with indistinguishable objects: inconsistencies in the university mathematics training of prospective secondary teachers

Jonathan Morcos[1] and Alejandro S. González-Martín

Université de Montréal, Canada,[1] jonathan.morcos@umontreal.ca

In this paper, we examine how content related to permutations with indistinguishable objects (PIO) is presented in tertiary and secondary mathematics textbooks. Using tools provided by the Anthropological Theory of the Didactic, we observe a compartmentalisation of approaches and missed opportunities to form connections between permutations and combinations in the context of PIO. Our findings highlight important gaps in the rationales presented in tertiary textbooks regarding PIO, as well as inconsistencies between the content studied by prospective teachers and the content presented in secondary mathematics curricula. While the tertiary textbooks studied often rely on a single formula-based technique, the secondary textbooks use a broader range of problem-solving approaches and include tasks with constraints that are absent from the tertiary-level textbooks.

Keywords: University mathematics for prospective teachers, combinatorics, textbook analysis, Anthropological Theory of the Didactic (ATD), Klein's second discontinuity.

Introduction and research problem

Recent years have seen an increase in the number of studies examining the teaching and learning of university mathematics for students outside mathematics programs (Biza et al., 2022). Two major avenues of inquiry can be observed. First, the relevance of mathematical training for various professionals, including prospective teachers, is facing growing scrutiny (Wasserman et al., 2023). In particular, research shows that secondary teachers rarely use their tertiary mathematics knowledge in their teaching, due to a lack of connections between university content and secondary teaching practices, as part of a phenomenon known as *double discontinuity* (Klein, 1908/2016). Second, recent studies highlight the potential of combinatorics to enhance teaching and learning at both secondary and tertiary level. For example, Lockwood et al. (2020) advocate for greater integration of this branch of discrete mathematics into school curricula, noting its potential to foster deep mathematical reasoning and encourage computational thinking, among other benefits. That said, the authors recognise the significant challenges that combinatorics pose for students of all ages and the limited research on teacher training that specifically addresses these challenges.

The first author's Master's thesis explores the intersection of these two topics by identifying consistencies and inconsistencies between the university training of prospective teachers and secondary mathematics. In this paper, we focus on a specific type of task: permutations with indistinguishable objects (PIO). In PIO-related tasks, the goal is to arrange a set of objects in a specific order, where two or more objects are indistinguishable, provided there are at least two distinct types of objects. Lockwood et al. (2018) identify two possible approaches to solving PIO tasks: using permutations or using combinations. They note that students tend to favour permutations, and that textbooks often fail to make explicit connections between these two perspectives. Therefore, while PIO tasks have the potential to draw links between various approaches to combinatorics problems, textbooks often fail to connect related concepts. To better understand this situation, and in line with

our objective to systematically investigate consistencies and inconsistencies between tertiary and secondary combinatorics content, we seek to analyse the mathematical practices related to PIO tasks in university mathematics and compare these practices to those observed in secondary mathematics.

Theoretical framework

We adopt an institutional approach for this study, specifically, the Anthropological Theory of the Didactic (ATD – Chevallard, 1999). ATD situates the teaching and learning of mathematics within the broader context of human activity. Through a process known as *didactic transposition* (Chevallard, 1985), scholarly knowledge is shaped to align with the institutional context in which its teaching and learning take place. *External transposition* describes the process of selecting and organising knowledge to be taught in various didactic institutions, which may result in different reorganisations of the "same" content (Castela, 2017). *Internal transposition* takes place within schools, and occurs when teachers mobilise and transmit knowledge and students acquire it. We are interested in analysing the organisation of PIO-related knowledge in two different institutions: 1) secondary mathematics and 2) tertiary mathematics in teacher-training programs, with the goal of identifying potential gaps. We therefore focus on institutional mathematical practices rather than on teachers' practices. Examining our research problem through the lens of ATD allows us to consider the institutional characteristics that may influence how PIO is addressed in each of these institutions.

ATD provides a tool for analysing this transformation of knowledge: the *praxeology*. Knowledge is mobilised by a task T, which is solved using a specific technique τ. A rationale θ, called a *technology*, explains and justifies the technique, supported by a general theory Θ. This quadruplet $[T/\tau/\theta/\Theta]$ is what is known as a praxeology. It can be broken down into two blocks: the practical block $[T/\tau]$, called the *praxis*, and the theoretical block $[\theta/\Theta]$, called the *logos*. In our case, we aim to analyse and compare the mathematical praxeologies related to PIO in two given institutions. We formulate our research questions as follows: RQ1) *What are the mathematical praxeologies related to PIO in university mathematics courses in a training program for prospective secondary mathematics teachers?* RQ2) *How do these mathematical praxeologies relate to those in secondary teaching?*

Methods

Data collection for the first author's Masters' research is taking place at the Université de Montréal in two phases: 1) textbook analysis and 2) interviews with prospective teachers. This paper focuses on the first phase, as the interviews are still in progress.

Building on previous research (e.g., González-Martín et al., 2013), we analysed textbooks to investigate knowledge to be taught at university and secondary levels. This allowed us to formulate conjectures about the potential difficulties faced by teachers and students using these textbooks, as textbooks provide valuable insights into mathematical practices (e.g., Stylianides, 2014). To identify consistencies and inconsistencies in praxeologies related to PIO content at the university and secondary levels, we examined three secondary textbooks (STs) approved by the Québec government for use in all secondary schools and compared them with two university textbooks (UTs) used in *Discrete Mathematics* and *Probability* courses in a teacher training program. The textbooks analysed are as follows: ST1) Ledoux et al. (2008); ST2) Guay et al. (2008); ST3) Miloudi et al. (2008); UT1)

Ross (2014); and UT2) Rosen (2002). The full bibliographic references for these textbooks are available here. Excerpts from the textbooks were translated for this paper.

We analysed the textbooks and identified the praxeologies related to PIO using open coding methods (Saldaña, 2013), focusing on chapters that explicitly address combinatorics. In the secondary textbooks, this content appears in the chapters on probability; we analysed only the combinatorics aspects of the relevant tasks. Across all textbooks, we identified tasks that involve PIO and examined the recommended techniques for solving them (the praxis block). We also identified content that provided rationales for these techniques (the logos block). The first author conducted the initial analysis and the second author carried out an independent review of the results. Minimal disagreements were resolved collaboratively, resulting in the findings presented in this paper.

Data analysis

PIO in tertiary textbooks (RQ1)

Both UT1 and UT2 dedicate a specific section to PIO, presenting what can be considered "pure" PIO tasks. These tasks involve ordered arrangements of all n objects in a collection, where some objects are indistinguishable. In both textbooks, the first task serves to introduce the concept of PIO. Both textbooks subsequently present the same theorem accompanied by the formula for PIO (UT2, p. 275):

> The number of permutations of n objects, where there are n_1 indistinguishable objects of type 1, n_2 indistinguishable objects of type 2, …, and n_k indistinguishable objects of type k is $\frac{n!}{n_1!n_2!\cdots n_k!}$.

Both university textbooks emphasise the centrality of the formula for PIO tasks.

However, each university textbook supports this theorem with a different logos. In UT1, the combinatorics chapter begins with the multiplication principle, which justifies the formula $n!$ for the permutation of n distinguishable objects. PIO is then introduced as a specific case of permutations: "Example 1.9: How many permutations of the letters in the word PEPPER are possible?" (p. 5). The solution outlines the following steps: 1) calculate $6!$, the number of permutations assuming all six letters are distinguishable; 2) identify and compute the cases where indistinguishable letters can be rearranged to form the same "word" ($3!\,2!$); 3) conclude that the number of distinct permutations is $6!\,/\,3!\,2!$. This example leads directly to the above theorem, accompanied by two solved tasks that use the same technique: applying the PIO formula (τ_{AF_PIO}). However, the "proof" for the PIO formula is based solely on the given example: "Applying the same reasoning as in Example 1.9, we establish the following theorem […]" (p. 5). The reasoning is task-specific and does not lend itself to generalisation. Furthermore, the division principle applied in the final step, which justifies dividing the total number of permutations by the number of distinct permutations that yield the same final "word," is not explicitly stated. Lastly, after introducing PIO, UT1's chapter on combinatorics transitions to combinations without linking either of these concepts to permutations or to PIO.

In contrast, UT2 introduces PIO in a section titled "Generalised permutations and combinations", which follows a subsection on combinations with repetition. The example used is mathematically similar to the task in UT1: "Example 8. How many distinct arrangements of the letters in the word SUCCESS are possible?" (p. 274). However, the proposed solution uses a different technique than

the one presented in UT1: 1) calculate the number of possible ways to arrange the three *S*'s in the seven positions ($\binom{7}{3}$); 2) calculate the number of possible ways to arrange the two *C*'s in the remaining four positions ($\binom{4}{2}$); 3) similarly, calculate the number of arrangements for U and E, using $\binom{2}{1}$ and $\binom{1}{1}$, respectively; 4) use the multiplication principle to find the total number of arrangements: $\binom{7}{3} \cdot \binom{4}{2} \cdot \binom{2}{1} \cdot \binom{1}{1} = 7!\,/\,3!\,2!\,1!\,1!$. This approach justifies the PIO formula while making explicit links to combinations, parameters, and the multiplication principle. However, Example 8 is the only solved PIO task included in UT2, and it is immediately followed by the statement of the theorem, which overshadows the reasoning. As in UT1, despite the initial rigour, the application of τ_{AF_PIO} ultimately emerges as the dominant technique.

While UT1 and UT2 provide distinct approaches—UT1 grounds PIO in permutations and UT2 in combination—the absence of connections between the two technologies perpetuates the compartmentalisation of knowledge. This aligns with Lockwood et al.'s (2018) observation that students may perceive combinatorics techniques as disconnected. Moreover, while an explicit reference to "PIO" could theoretically bridge this gap, UT2 further complicates matters by using different terminology for mathematically identical tasks. Indeed, the subsequent section in UT2, "Distributing objects into boxes", addresses tasks that are mathematically equivalent to PIO. An example is provided of a task that involves organising distinguishable objects in distinguishable boxes, and the conclusion leads to the stating of a theorem for this type of task using the same formula as PIO. Mathematically speaking, distributing n different objects into k distinct boxes with specific numbers of objects in each box is equivalent to PIO.[1] However, the connection between both sections of the textbook is explicit only in a note that follows the resolution of the task. Expanding the discussion from distributing distinguishable objects into distinguishable boxes to distributing distinguishable objects into indistinguishable boxes (Dubois, 1984) could have unified these concepts and clarified PIO as a subcase of distribution problems, but UT2 fails to seize this opportunity.

Both textbooks reveal a compartmentalisation of related praxeologies. In UT1, PIO is isolated within permutations, while in UT2, it is disconnected from related tasks involving object distributions. Neither textbook establishes links between the various possible approaches to PIO tasks. Denied the opportunity to connect the rationales underpinning these practices, students may struggle to integrate their understanding across the two textbooks and courses.

PIO in secondary textbooks (RQ2)

None of the three secondary textbooks has sections dedicated to specific pieces of combinatorics content. Rather, each textbook features a chapter in which combinatorics content is scattered throughout, appearing in various types of tasks. Therefore, we rely on two criteria to identify tasks related to PIO: the presence of an ordered sequence of objects, and the presence of indistinguishable

[1] It can be approached as follows: 1) label each box, assigning identifiers corresponding to the specific number of objects to be placed in each box; 2) arrange the n indistinguishable identifiers (PIO); 3) assign each object a number corresponding to its position in the sequence of identifiers, and place the objects into their corresponding boxes. Thus, the total number of ways to distribute n distinguishable objects into k distinguishable boxes is equal to the number of ways to permute n objects with k distinct types of indistinguishable objects, which aligns with PIO.

objects in the collection. Five tasks—three in ST1 and two in ST2, 6.2% of all combinatorics tasks[2]—meet these criteria and can be classified into four types (see Table 1).[3] In addition to pure PIO tasks (as seen in the tertiary textbooks), these two secondary textbooks also include PIO-related tasks in which an additional constraint must be considered. Moreover, the PIO formula is never explicitly stated. Rather, both ST1 and ST2 rely on a broad range of techniques, which we discuss below.

Table 1: Classification of PIO-related tasks in secondary textbooks

Task classification		Task statement (our translation)
T_{PIO}	"Pure" PIO, i.e., an ordered sequence of indistinguishable objects	ST1: A team of six athletes is competing in a triathlon. Two different athletes must participate in each event. In how many ways can the roles be assigned? ST2: A Christmas garland has ten lightbulb sockets. In how many ways can eight green and two red lightbulbs be arranged?
T_{CP-PIO}	PIO with constraints on the positions of the indistinguishable objects	ST1: In how many ways can three couples sit around a table if the members of each couple must sit across the table from one another?
T_{r-PIO}	A partial PIO: an ordered sequence of certain objects from a collection containing indistinguishable objects	ST2: The numbers 1, 2, 2, 3, 4 are written on individual pieces of paper and placed in a bag. How many distinct numbers can be formed by randomly drawing one, two, three, or four pieces of paper?
$T_{\odot-PIO}$	A circular (as opposed to linear) arrangement of indistinguishable objects	ST1: In how many ways can three boys and three girls be seated around a campfire such that all boys are seated together (assuming rotations of seating arrangements are considered distinct orderings)?

For T_{PIO}, ST1 describes its technique for solving PIO as taking the total number of permutations of all objects and dividing it by the number of rearrangements of indistinguishable objects. That said, as seen in UT1, the rationale does not explicitly address division and equivalence. Concerning $T_{\odot-PIO}$, ST1 uses pictograms to illustrate the six possible outcomes and counts the number of drawings to calculate the total number of possibilities. In doing so, ST1 does not explicitly draw any links between this task and combinations: the number of possible arrangements of three boys and three girls sitting around a fire, with the condition that the three boys must be seated together, is equivalent to selecting one of the six positions around the fire for the "first" boy, i.e. $\binom{6}{1}$, with the other two boys seated immediately after him.[4] Regarding T_{CP-PIO}, ST1 gives the expected final answer, 48, merely providing the following as a justification: "The number of permutations must be multiplied by 2 to account for the fact that two members of the same couple can sit on either side of the table" (p. 359). ST1 does not provide any additional details to reconstruct a technique, but based on the given rationale, we hypothesise that ST1 considers the following approach for this task: 1) choose a pair of

[2] This is a rather small proportion of tasks. We address this situation, as well as the fact that ST3 does not include tasks related to PIO, in the *Discussion and concluding remarks* section.

[3] It could be expected that an analysis of other sections and chapters of STs and of a larger sample of textbooks would lead to even more types of tasks.

[4] In the case of a "linear" PIO (for example, if the people were seated on a bench), this situation would be equivalent to choosing one of four possible places for the "first" boy, leaving room for the other two boys, but this "extra room" is not needed in a circular arrangement. This is also why we consider this task to be different from T_{CP-PIO}: changes occur when considering $T_{\odot-PIO}$ linearly, whereas T_{CP-PIO} can be solved in a linear fashion (with restrictions on the possible arrangements in a sequence rather than around a table) with no mathematical change in the task.

opposite seats for the first couple (three possibilities); 2) from the remaining options, choose a pair of opposite seats (two possibilities) for the second couple; 3) from the remaining options, choose a pair of opposite seats (one possibility) for the third couple; 4) for each couple, multiply by 2 to account for the fact that members of a same couple can switch seats; 5) using the multiplication principle, there are $3 \times 2 \times 1 \times 2^3 = 48$ possible arrangements. We note that this method does not align with other practices in the textbooks that make up our sample, where indistinguishable objects are linked to a division step. Moreover, we believe that a rigorous explanation would indicate that a multiplication by 2 is required *for each couple*, as this would illustrate the use of multiplication for indistinguishable objects and would link this PIO-related task to combinations. However, this detail is absent in ST1.

To solve T_{PIO}, ST2 first gives $\frac{10\times9}{2}$ as the expected answer, but with the sole explanation that "because the number of possible arrangements is determined solely by the colour of the lightbulbs, there are half as many possible arrangements due to repeated permutations" (p. 538). Subsequently, ST2 suggests another technique (Figure 1), asking teachers and students to identify a pattern based on the systematic listing of possible outcomes and the partition into subsets. This approach is absent from all the other textbooks, and the fact this new technique is applied to only one task highlights an inconsistency, both within the secondary textbooks and between ST2 and the university textbooks.

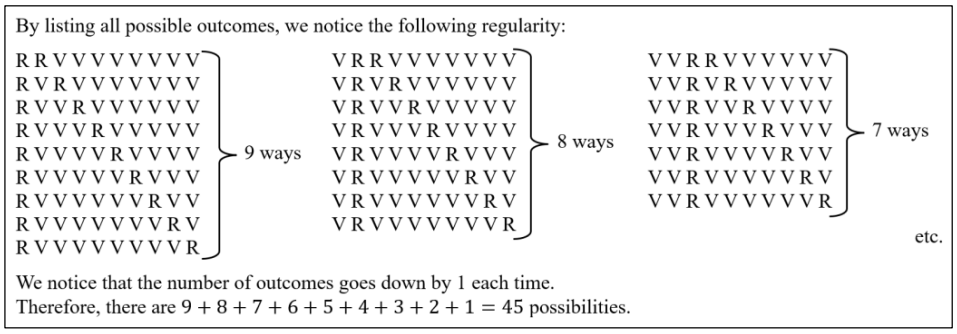

Figure 1: Solving technique suggested in ST2 for T_{PIO} (Guay et al., 2008, p. 585D)

ST2 also includes τ_{r-PIO}, a task related to the permutation of r of the n objects (some but not all objects) from a collection with indistinguishable objects. The suggested technique is to build a tree diagram of all possible outcomes to "make sure that students do not forget possible outcomes or repeat some possibilities" (p. 536). Despite the interesting points about repetition in the diagram, we question whether this technique is practical for a secondary mathematics classroom, as it includes a tree-diagram covering all 60 possibilities.

Discussion and concluding remarks

In this paper, we analyse praxeologies related to PIO in university and secondary mathematics textbooks to identify consistencies and inconsistencies between the training of prospective secondary teachers and secondary mathematics curricula. This analysis is carried out using tools provided by ATD, which yields interesting results concerning the praxis (the tasks and the techniques used to solve these tasks) and the logos (rationales) related to PIO in both institutions.

The two university textbooks provide the same formula for PIO, emphasising the direct application of the formula in solving PIO tasks. This reliance on τ_{AF-PIO} in the tertiary textbooks could help explain prospective teachers' shift towards a formula-based approach to combinatorics during their university training, as observed by Lamanna et al. (2023). On the other hand, we observe differences between the two university textbooks in the way content and rationales are presented: UT1 introduces PIO as a particular case of permutations, while UT2 treats PIO as an application of combinations. UT2 also relies on τ_{AF-PIO} to solve tasks categorised as distributing distinguishable objects into distinguishable boxes. This results in mathematically similar tasks being placed in different sections while establishing little explicit connections between them. Furthermore, neither university textbook provides any rationale for the connections between the permutational and combinational aspects of PIO, which aligns with Lockwood et al.'s (2018) hypothesis that the organisation of textbook content impedes the connection between permutations and combinations in cases where both approaches could be applied. Additionally, our analysis highlights the weakness of rationales provided for PIO content in university textbooks. Although PIO provides opportunities to connect combinatorics concepts, approaches, and broader practices—potentially enriching mathematical thinking—these connections are left implicit and underdeveloped. We conjecture that this could also pose problems for prospective teachers (and potentially for university teachers as well), who may find themselves unable to explain or justify practices related to PIO. In particular, this could prevent prospective teachers from acquiring the necessary tools to address secondary students' difficulties regarding PIO.

When comparing the praxeologies in the university textbooks to those in the secondary textbooks, we observe a number of inconsistencies. In particular, the PIO-related tasks in the secondary textbooks sometimes include constraints that are absent in the university textbooks. The variety of tasks in secondary textbooks is paired with a variety of techniques: formulas, tree diagrams, the listing of outcomes, and the identification of patterns. This suggests that certain aspects of PIO-related knowledge covered at the secondary level might not be addressed in tertiary mathematics education. It also raises questions about whether tertiary mathematics praxeologies related to PIO should be broadened to encompass the variety of tasks covered in secondary mathematics.

Finally, we acknowledge that PIO-related tasks represent only a small percentage of tasks in secondary textbooks. This poses a limitation while also calling for a continuation of this study. Although our analysis of secondary tasks draws on a small sample, there is potential for improvement, especially considering that one of the three textbooks does not include any tasks related to PIO. This also suggests a mismatch between the time allocated to PIO in university education and the time devoted to it in secondary teaching; however, this is difficult to ascertain from a textbook analysis alone, as the amount of in-class time allocated to specific content depends on many other factors. We anticipate that our interviews with prospective teachers will shed further light on this issue, in addition to clarifying the other conjectures that we formulate in this paper.

Mathematical provision across subjects in the pre-university curriculum: Comparing geography, psychology, and sociology undergraduates in England

Jennifer Norris[1] and Andrew Noyes[1]

[1]University of Nottingham, School of Education, Nottingham, UK;
jennifer.norris@nottingham.ac.uk

Pre-university mathematical provision in England is now distributed across a number of advanced level subjects. However, due to the complexity of subject choices and inconsistency in university entry requirements, it is not easy to determine the potential effect on undergraduate cohorts. Taking geography, psychology, and sociology as illustrative cases, we compare the quantitative curricula followed by undergraduates prior to university using national administrative datasets for secondary and higher education for academic years 2016/17 to 2019/20 (n=90,745). We find variation in prior opportunities to study different types of mathematics both between and within these three disciplines. This study highlights the complexity of the mathematical provision for incoming undergraduates in England, and hence the need for a common mathematical framework across the pre-university curriculum to clarify what students can be expected to know and do at the transition to university.

Keywords: Competences, curriculum, non-mathematics degrees, transition.

Introduction

The question of how to prepare students for the mathematical demands of undergraduate degrees outside of the areas of science, technology, engineering and mathematics (STEM) is of international concern (MacInnes et al., 2016). In Germany, lecturers of non-science subjects agree that students should arrive at university with mathematical prerequisites, which vary widely between subjects (Neumann et al., 2021). Similarly, in the UK, the university disciplines of business, economics, geography, psychology, and sociology all require some prior knowledge of mathematics or statistics (Hodgen et al., 2014). A common issue is undergraduates' difficulty with "applying familiar mathematical concepts in unfamiliar contexts" (Bowyer & Darlington, 2016, p. 2), that is, with transferring the mathematics they know to the new context of their undergraduate discipline.

In England, academic advanced level (A-level) qualifications are taken during the upper secondary (16-18) phase of education, and are the most common pre-university qualifications, although technical and vocational routes are also possible. A feature of the A-level system is that the range of subjects studied is narrow, with most students taking just three subjects, while there are also no restrictions on subject combinations. Students are therefore not confined to specific pathways and can choose a mixture of STEM and non-STEM subjects. A-level Mathematics is optional and has consistently been the most popular A-level subject over the last ten years (Plaister, 2022). Research has used participation and attainment in A-level Mathematics as the primary measures of undergraduates' mathematical backgrounds (Hodgen et al., 2020). However, students could also have opportunities to develop mathematical skills across multiple A-level subjects, depending on their subject choices. For example, a student taking A-levels in Physics, Chemistry, and Computing has clearly studied at least some mathematics. While aspects of mathematics were previously embedded informally within other subjects, reforms to A-level curricula between 2015 and 2018 formalised the

mathematical content of nineteen A-level qualifications. There is now a requirement that quantitative skills form a proportion of the assessment for these nineteen subjects, ranging from 5% for A-level Physical Education to 40% for A-level Physics. Hence, it is now possible to broaden the definition of pre-university mathematical provision to include all 'quantitative' A-level subjects.

This paper uses this broader definition to present an initial exploration of how these curriculum changes affect undergraduates in three higher education disciplines in terms of the mathematics they are expected to have studied prior to university. Geography and psychology are both located at the boundary of the sciences and social sciences, while sociology is a more typical social science. In England, there are no required A-level subjects for entry to university to study geography, psychology or sociology, and all three have the same average entry grades, although grade requirements vary between universities (Universities & Colleges Admissions Service, 2024). While not required, A-level Mathematics is recommended for entry to psychology degrees, but not for degrees in geography or sociology. For all three disciplines, it is also possible, and sometimes even recommended, to take the subject at degree level without having the corresponding A-level. In practice, students enter these disciplines with a variety of different subject combinations, including both quantitative and non-quantitative A-levels. This research therefore seeks to address the questions: what are the mathematical opportunities provided to undergraduate geography, psychology, and sociology students by their pre-university (A-level) curriculum, and how do these vary within and across disciplines?

Conceptual framework

The language of mathematical competences has been used in a number of international contexts to draw attention to "doing" mathematics, rather than simply "knowing" mathematical terms, concepts, methods and topics (Boesen et al., 2014). Frameworks such as those created by the Danish Competencies and the Learning of Mathematics (KOM) project and the Programme for International Student Assessment (PISA) focus on the competences developed within the school subject of mathematics (Niss, 2014). Since our focus is on mathematical competences across subjects, we make use of a framework of nine General Mathematical Competences (Table 1) originally designed to describe the "doing" of mathematics within real, complex situations in a range of different vocational contexts (Advisory Committee on Mathematics Education, 2019), and subsequently adapted for use with academic school subjects.

Table 1: General Mathematical Competence (GMC) framework

Drawing on Communities of Practice theory, participants in school subjects (and university disciplines), including students and teachers, can be viewed as separate communities of practice (Wenger, 1998). By definition, we therefore expect some level of discontinuity for students moving between the mathematical practices of different subject communities, as well as when moving from school to university. However, there are also ways in which communities connect and communicate with one another, including through concepts or terms that make sense within both practices, known as "boundary objects" (Wenger, 1998, p. 105). The GMCs are intended to function as boundary objects that make sense within different subjects and disciplines, as well as at different difficulty levels and phases of education. Hence, we were previously able to map these GMCs within the intended, written curriculum for quantitative A-levels, providing a common language for discussion of the types of mathematics present in different subjects (Norris & Noyes, 2023). In adapting the framework for use with academic subjects, the number of GMCs was reduced from ten to nine and each GMC was divided into four sub-competences highlighting different aspects of the competence. For example, GMC 1 *measuring with precision* has the four components: (1a) *measuring physical objects and processes*, (1b) *measuring constructs*, (1c) *units of measurement*, and (1d) *accuracy of measurement.* Full details of this expanded framework can be found in Norris and Noyes (2023). While intended to make sense across subject areas, the applications of these GMCs clearly vary between subjects. For example, GMC (1d) *accuracy of measurement* appears in the A-level Geography curriculum as a requirement to "demonstrate the ability to interrogate and critically examine field data in order to comment on its accuracy" (Department for Education, 2014), whereas in the A-level Psychology curriculum the same GMC sub-competence is represented by the requirement to "use an appropriate number of significant figures". Although researching the curriculum cannot tell us what students know or can do in practice, it does provide an indication of the maximum set of mathematical competences that we can expect students to have experienced. That is, where a GMC is not present at all within a students' subject choices, we cannot expect this competence to be well-developed at the transition to university.

Methods

This quantitative analysis uses data from the Higher Education Statistics Agency (HESA) database, with our population consisting of undergraduate students enrolled at universities in England from 2016/17 to 2019/20 to study geography, psychology, or sociology as their first (single honours) or second (joint honours) degree subject. These were linked to data on prior attainment from the National Pupil Database (NPD), with only those students with at least one A-level passing grade retained in the analysis. Subjects achieved at A-level were translated into a binary measure of students' opportunity to study each GMC sub-competence using the results of the curriculum mapping reported in Norris and Noyes (2023). Students are counted as having had the opportunity to access a given GMC sub-competence where that sub-competence is found in the written curriculum for one or more of their A-level subjects. Combining the previous curriculum analysis with national student data from the HESA and NPD thus allows us to investigate the prevalence of GMC sub-competences in the intended pre-university curriculum for different groups of undergraduate students. Since we have whole population data statistical hypothesis testing is not appropriate, so we use frequency analysis only. To prevent the possibility of disclosing individual personal information all counts are rounded to the nearest 5 and percentages are calculated using rounded values.

Findings

Among the population studied (n=90,745), the largest discipline was psychology (50%, n=45,650), followed by sociology (including social policy and anthropology) (37%, n=33,850). Geography (including general and human geography but not physical geography) made up the smallest cohort (12%, n=11,245).

Figure 1 shows the distribution of GMC sub-competences for the undergraduate geography cohort. That is, the proportion that had taken one or more A-level subjects where GMC sub-competences were intended to be taught and assessed. Opportunities to study GMC sub-competences were highly concentrated within A-level Geography, taken by 93% of geography undergraduates. Hence, a core of 15 sub-competences were provided in the pre-university curriculum for almost all geographers, being the same 15 sub-competences previously found to be present within the A-level Geography curriculum (Norris & Noyes, 2023). However, for a small number of undergraduates, these core sub-competences were only present in subjects other than geography, and a few did not have the opportunity to study them at all. Other common quantitative A-levels taken prior to undergraduate geography were Biology (19%), Economics (19%), and Mathematics (18%). Overlap in GMC sub-competences between Geography and other subjects at A-level was somewhat varied. For example, while (8a) *reason with mathematics/ logic* and (8c) *draw conclusions from mathematical information in context* were included in the pre-university provision for similar numbers of undergraduates, the proportion for whom these sub-competences appeared in multiple A-level subjects varied from 16% for (8a) to 67% for (8c). In addition, over half had taken A-levels containing (3a) *working with numerical proportion* (68%) and (2b) *use of number* (58%), which are not present in A-level Geography and so can only have come from other quantitative subjects.

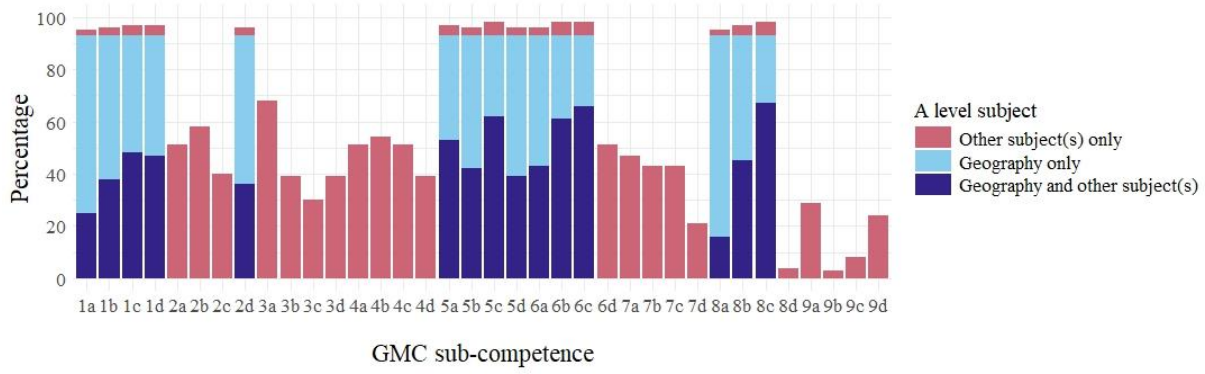

Figure 1: Prevalence of GMC sub-competences in the A-level curriculum followed by geography undergraduates prior to university, by A-level subject

Pre-university provision for the undergraduate psychology cohort similarly included opportunities for most to study a core set of sub-competences (Figure 2), which in this case were the same 18 sub-competences found to be included in the A-level Psychology curriculum (Norris & Noyes, 2023). The proportion of psychology undergraduates who had taken the corresponding subject at A-level was slightly lower than for geography (86%), with a slightly larger proportion of opportunities to study these core sub-competences located in subjects other than A-level Psychology. Of the sub-competences common among psychologists, GMCs (8c) *draw conclusions from mathematical*

information in context and (6c) *establish relationships and make predictions* had the greatest overlap between A-level Psychology and other A-level subjects (54% and 53% respectively), with (2c) *order of magnitude calculations* and (4d) *select appropriate data and units* having the least overlap (both 23%). The opportunity to study (8b) *communicate using mathematics* was offered in A-levels other than Psychology for over half of psychology undergraduates (66%), with their most common other A-level subjects being Biology (27%) and Sociology (26%). Only 13% of psychology undergraduates had taken A-level Mathematics, which therefore provided only a small proportion of opportunities to study GMCs.

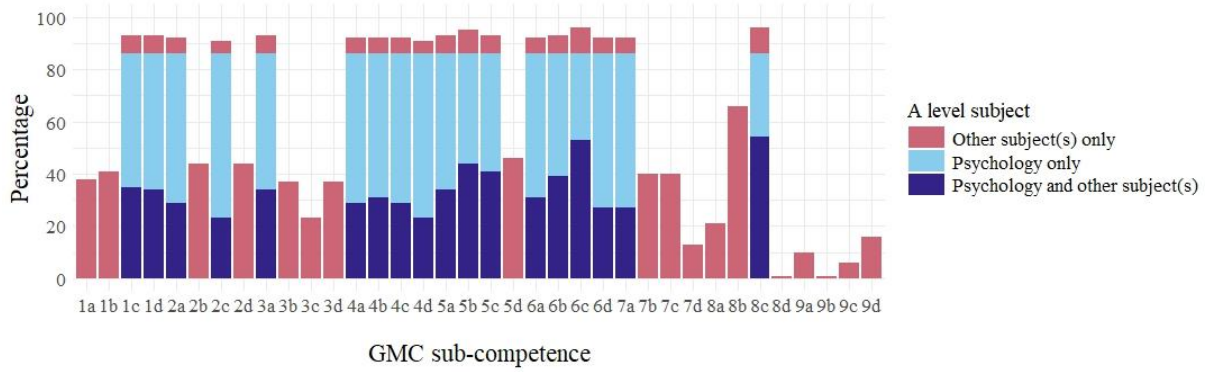

Figure 2: Prevalence of GMC sub-competences in the A-level curriculum followed by psychology undergraduates prior to university, by A-level subject

Most sociology undergraduates had opportunities to study the four core GMC sub-competences found to be present in the A-level Sociology curriculum (Norris & Noyes, 2023), despite the fact that less than half had taken A-level Sociology (49%)(Figure 3). Many undergraduates therefore only had opportunities to access core sub-competences in A-levels other than Sociology, while very few were offered access in multiple A-level subjects. The most common other quantitative subjects taken were A-level Psychology (36%) and Geography (11%), while just 7% had taken A-level Mathematics. Moreover, for the four core sub-competences, between 16% and 31% of sociology undergraduates did not have the chance to study them at all, so they form a much weaker 'core' of mathematical provision than those for geography and psychology.

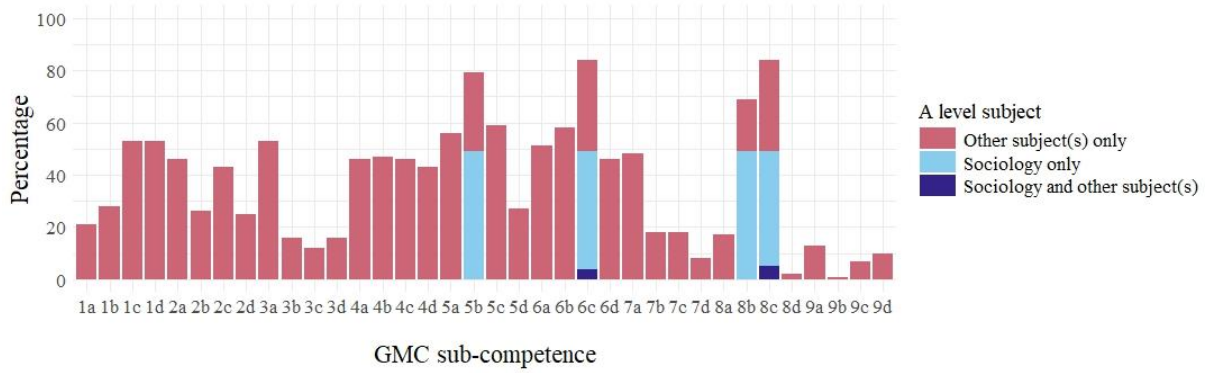

Figure 3: Prevalence of GMC sub-competences in the A-level curriculum followed by sociology undergraduates prior to university, by A-level subject

Discussion

The General Mathematical Competences (GMCs) intended to be taught across the A-level curriculum seem to align reasonably well with the quantitative content of geography, psychology, and sociology degree programmes, which have a common focus on statistics (Hodgen et al., 2014). For geography, psychology, and sociology undergraduate cohorts, core GMCs covered by their pre-university curriculum included some elements of *processing data* (GMC 5) and *understanding data and risk* (GMC 6), which are clearly relevant for further study of statistics. For all three cohorts, this also included aspects of *communicating using mathematics* (GMC 8) that are closely related to statistics, such as data presentation and drawing conclusions from statistical information in context. Core sub-competences prevalent among the pre-university curricula of geography undergraduates had an additional focus on *measuring with precision* (GMC 1), which may link to collecting data through fieldwork (Harris, 2020). In contrast, psychology undergraduates instead had greater opportunities to *use rules and formulae* (GMC 4) in their pre-university qualifications, suggesting that the approach to statistics is perhaps more process-oriented and less practical than for geography. In A-level Psychology, formulae are often used in the context of statistical calculations, although this may not be the case within other A-level subjects. While the English A-level system appears to have offered undergraduate geography and psychology cohorts opportunities to study a wide range of GMCs relevant to their university studies, further work is needed to establish the amount and level of these mathematical competences across subject curricula. In contrast, sociology undergraduates had less opportunity to study a range of data-related competences prior to university, which is perhaps reflected in the low starting point of statistics teaching within sociology degrees (Scott Jones & Goldring, 2017). This suggests that there is perhaps scope to increase the range of mathematical competences provided in the pre-university curriculum for sociology undergraduates, whether in A-level Sociology or in other subjects.

While statistics is an area of common ground, the three disciplines differed in the extent to which their cohorts shared a common set of mathematical opportunities prior to university. Over 90% of geography and psychology undergraduates had previously had opportunities to access a core of GMC sub-competences. Psychology degrees are overseen and accredited by the British Psychological Society, so there is a higher level of consistency in the statistics curriculum across universities than for other university disciplines (Field, 2014), and it therefore makes sense that incoming undergraduates had similarities in the types of mathematics in their pre-university curricula. The consistency among geography undergraduates is perhaps more surprising, as geography degrees are more variable in their quantitative content (Hodgen et al., 2014). This may be because the total geography cohort is relatively small, so universities can select for students with A-level Geography.

The sources of undergraduates' prior mathematical opportunities are also important, as previous exposure to mathematical competences within a particular disciplinary context may aid students' transition to university by making both mathematical concepts and the context of application more familiar (Bowyer & Darlington, 2016). Our findings suggest that sociology undergraduates could face additional challenges in transferring their mathematical experience to university, since a large proportion only had prior opportunities to study core sub-competences in the context of A-levels other than Sociology. Similarly, there are a small number of psychology undergraduates who only had the opportunity to study core sub-competences in other, non-psychology, A-level subjects and therefore

had to transfer these competences across disciplinary boundaries. It is possible that the mathematical transition from school to university may be much smoother for geography undergraduates, the vast majority of whom have already had opportunities to experience mathematical competences within a specifically geographical context. It may therefore not be a matter of great concern that A-level Mathematics is not a major source of access to mathematical competences for any of these cohorts, as a more useful focus could be on encouraging closer connections between university disciplines and their corresponding A-levels.

Conclusion

The contribution of this paper is an increased understanding of who is affected by the curriculum requirement to teach and assess quantitative skills in multiple advanced-level subjects, and therefore how this could contribute to the mathematical preparation of science and social science students for undergraduate study. We find that the current system of advanced-level qualifications in England provides many geography, psychology, and sociology undergraduates with opportunities develop a range of mathematical competences, even without taking A-level Mathematics, by choosing other quantitative A-level subjects. While geography undergraduates primarily gain access to core mathematical competences through A-level Geography, either on its own or alongside other quantitative A-levels, sociologists rely much more on the mathematical competences in subjects other than A-level Sociology. In both cases, there are a number of students who were not provided with these opportunities, either as a result of choosing non-quantitative subjects or because their chosen quantitative subjects provided types of mathematics not relevant to their university disciplines. Filling these 'gaps' would require substantial systemic change, such as moving away from an entirely free-choice system to introduce mandatory subjects of study, or further curriculum reform to embed mathematical competences in subjects that currently have no quantitative requirement. Before such dramatic changes are considered, we argue that there is a need for further development of a common mathematical curriculum framework across advanced level subjects to fully understand the mathematics already provided to students, including not only types of mathematics as presented here but also the amount and level of mathematical content, since there is no existing framework designed for this purpose. These are necessary foundations for informing university lecturers about the pre-university mathematical opportunities available to their incoming cohorts. As well as recognising students' prior mathematics qualifications, we need to find ways both to acknowledge and take advantage of the mathematical opportunities within other subjects to prepare students for studying science and social science subjects at university.

Between the trivial and the impossible: CHAT as an analytic lens to study the role of programming in mathematical research

Jan-Fredrik Olsen[1,2], Elise Lockwood[2,3], Tor Ole Bigton Odden[2]

[1]Lund University, Sweden; jan-fredrik.olsen@math.lu.se

[2]University of Oslo, Norway

[3]Oregon State University, USA

In this study, we explore how Engeström's Cultural Historical Activity Theory (CHAT) can be applied to analyse epistemic tensions related to the role of programming in the practices of mathematicians. Drawing on interview data with two mathematicians from a northern European university, we investigate how our use of CHAT highlights tensions between pure and applied mathematics. The analysis allows us to identify dialectic contradictions between motives and rules governing mathematicians' research practices, demonstrating CHAT's potential for studying epistemic tensions. In future research, we plan to incorporate additional data to study tensions between mathematicians' use of programming in their teaching and in their research.

Keywords: Mathematics, mathematics education, Cultural Historical Activity Theory, programming

Introduction

Over the last decades, there has been an ongoing discussion on the impact of increasing availability and capacity of high-performance computing on mathematics research and education (see, e.g., Buzzard, 2024). However, despite the apparent relevance of computing to mathematics, the epistemic status of programming in mathematicians' practices is unclear. In a survey of 302 Canadian mathematicians, Buteau et al. (2014) found that 43% reported using programming in their research, compared to 18% in their teaching, revealing what we see as a potentially significant gap. In a follow-up study, Broley et al. (2018) found that mathematicians use programming mainly to obtain intuition and numerical results where analytic methods fall short. This is in line with the only other interview study we know of on this topic (Lockwood et al., 2019). Mathematicians' lower use of programming in their teaching is mainly attributed to institutional constraints and the lower epistemic status of programming in teaching (Broley et al., 2018).

Taking a broader view, we note that tensions in the practices of mathematicians have been well-established by philosophers of mathematics and researchers in mathematics education. For instance, Hersh (1991) and Burton (2004) pointed out a gap between the importance mathematicians attribute to intuition, curiosity and experimentation in their research and the more classical and rigid Platonistic image often conveyed to the general public. Hacking (2014) discusses tensions between pure and applied mathematicians from a historical and philosophical perspective, noting that while the distinction between pure and applied mathematics is a recent invention, some mathematicians argue that applied mathematics is not mathematics at all.

In this paper, we give the first report from a PhD project in which we interviewed mathematicians from a northern European university on their research and teaching practices. In this preliminary step, our research aim is to critically evaluate the use of Engeström's Cultural Historical Activity Theory

(CHAT) (Engeström, 2015) as an analytic lens to study tensions related to the use of programming in mathematics. Our choice of CHAT is in line with our view of mathematics as a field whose development is driven by tensions. Specifically, we address the research questions:

RQ 1. What features of mathematicians' programming-related research practices are foregrounded (and not) when we draw on CHAT as an analytic lens?

RQ 2. What additional data sources are needed to substantiate and triangulate findings, and how can we refine our operationalisation of CHAT to promote rigour and transparency in the analysis?

Theoretical perspective

Engeström's Cultural Historical Activity Theory (CHAT) builds on the activity theory of Vygotsky and Leon'tev (see Engeström, 2015) and has been adapted to mathematics education research in different ways (see, e.g., the survey of Núñez, 2009). We adopt the concept of activity as our unit of analysis. We understand activity to be anything humans come together to do collectively that is motive-oriented, enduring over time and situated (e.g., the activity of mathematical research – or teaching - situated at a mathematics department).

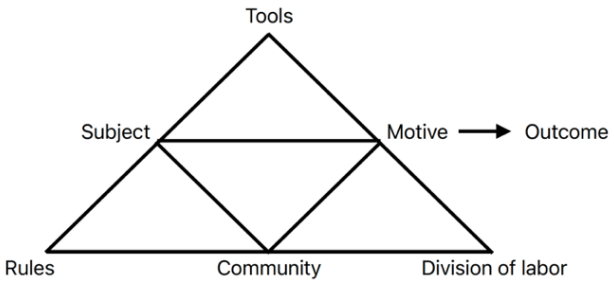

Figure 1: Engeström's extended activity triangle (Engeström, 2015).

We draw on two key constructs of CHAT: the extended activity triangle (Figure 1) and dialectic contradictions. The **extended activity triangle** can be thought of as the anatomy of an *activity*. At the top sits Vygotsky's mediating triangle, which frames the *subject* as using *tools* to pursue a *motive* directed toward a 'tangible' *outcome.* The bottom nodes represent the collective and social nature of the activity, which frames the subject as operating within a community that shares the motive, is regulated by *rules* and norms and is shaped by power structures reflected by the *division of labour*. Following Mwanza and Engeström (2005), we operationalise the extended activity triangle as a checklist of questions we ask the data (see Table 1). The nodes thus provide (overlapping) vantage points that we use to analyse and subsequently synthesise a description of the activity. As the description draws on multiple data sources, it likely contains contradictory information that indicates tensions. Following Engeström (2015), we view the motive as the reason 'why' of the activity and make it the focal point of our analysis as it shapes, and is shaped by, all parts of the activity.

If we think of this operationalisation as a diagnostic tool to examine the well-being of an activity, then **dialectic contradictions** could be thought of as the underlying conditions we seek to diagnose and the underlying causes of the observed tensions. However, dialectic contradictions are not defects

to be removed. Instead, they are intrinsic cultural forces driving the historical development of the activity and have the potential to provide mechanisms for change when understood.

Table 1: Operationalization of the extended activity triangle.

Node	Examples of questions
Subject	What role does the subject identify with as part of the activity?
Motive	Why is the subject pursuing the activity?
Tools	With what means does the subject pursue the activity?
Outcome	What is the 'output' of the activity as perceived by the subject?
Community	Who does the subject see as supporting their pursuit of the activity?
Rules	What rules and norms regulate the subject's pursuit of the activity?
Division of labour	What power structures affects who does what in the activity?

To operationalise dialectic contradictions, we follow Ilyenkov (2009), who defines them as intrinsic properties of the activity that are "the concrete unity of mutually exclusive opposites" (p. 185). We propose the following more explicit operationalisation:

- **Dialectically related observations:** A pair of interrelated observations that provide complementary or contrasting properties of a situated activity that neither can do separately.
- **Dialectic contradiction:** Dialectically related observations that are mutually incompatible and are a cause of tensions that drive change or development in the activity.

Radford (2021), working within mathematics education research, provides an accessible account of material dialectics, where he points to dialectically related observations, such as those between an object's inner nature (or essence) and its material appearance, between what an object is and what it is not, between its history (concrete) and its logic (inner), or between the individual and the collective. Radford takes a less structured view of the concept of activity than Engeström (2015), who, based on the extended activity triangle, classifies contradictions as arising from dialectic observations made within nodes (primary), between nodes (secondary), between old and new versions of an activity system (tertiary) or between activity systems (quaternary). These types of contradictions all concern the inner nature of the activity and resonate with what Radford would call inner contradictions. Here, we restrict our attention to primary and secondary contradictions. A primary contradiction might involve multiple conflicting motives for a single activity. In contrast, a secondary contradiction would be if this conflict of motives leads to, say, a schism within the community in which the activity is situated.

Methods

This study focuses on interviews with two participants, selected from a group of 15 mathematicians interviewed at the department of mathematics at a major northern European university. The broader participant group included researchers from pure and applied mathematics and was purposefully sampled to represent all research groups and capture variation in the use of programming in teaching.

Semi-structured interviews (1.5 to 2 hours each) were audio-recorded and later transcribed and addressed programming in research and teaching, as well as views on institutional context. Interviews were conducted by the first author, a research mathematician, to facilitate communication. Additional participant selection ended when our capacity for analysis was reached. We acknowledge that data saturation was not achieved, as each interview provided new and interesting perspectives.

In this paper, we focus on two participants – given the pseudonyms Mats and Lars – who represent opposite ends of the pure–applied spectrum and offer contrasting perspectives on programming in teaching. To maintain their anonymity, we edited the transcripts to obscure their research fields.

A deductive thematic analysis based on CHAT was initially conducted on the full data set (Braun & Clarke, 2006). During the process, we narrowed our focus of the analysis to the research part of the interviews with Mats and Lars to engage more deeply with the data and better evaluate and refine our operationalisation of CHAT. The analysis produced a set of codes, themes and the set of questions in Table 1. Based on these, we developed two contrasting yet interrelated accounts of mathematical research activity, one for each participant. We then examined the codes, themes and accounts for signs of tensions that met our criteria for dialectic contradictions. The analysis was conducted by the first author and reviewed collaboratively with co-authors and experts in mathematics and mathematics education research.

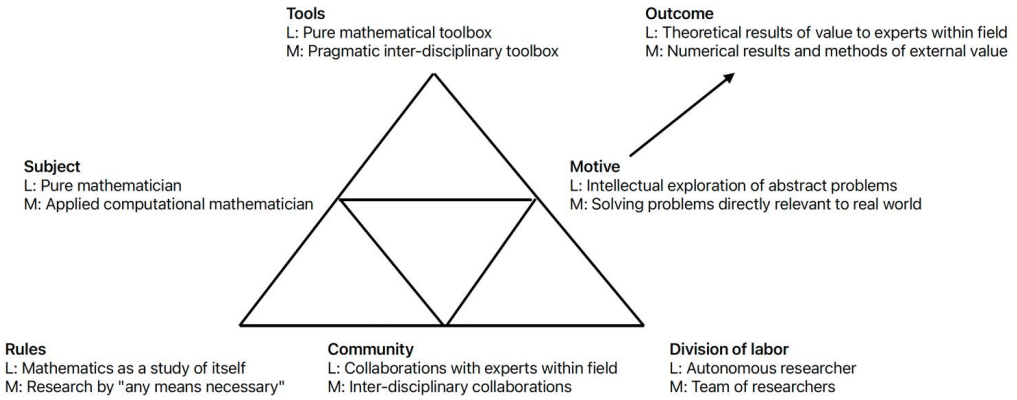

Figure 2: Description of the mathematical research activity in terms of the CHAT triangle. Under each node, Lars' activity corresponds to the top line and Mats' to the bottom line.

Findings from the interviews with Mats and Lars

Here, we present the findings from the analysis of the interviews with Mats and Lars in two parts. First, we provide an account of mathematical research activity based on our analysis of the interview data using CHAT as an analytic framework. Then, we examine signs of dialectic contradictions through the lens of our operationalisation of CHAT. The findings are summarised in Figure 2 below.

The activity from the perspectives of Lars and Mats

Regarding the *subject* of the activity, Lars describes himself as a *classically oriented pure mathematician* who does not involve computers in his research. "I have approached it quite theoretically, meaning there is little in my research that uses programming or that uses any type of

computer-based tool at all." In contrast, Mats identifies as an applied computational mathematician. For him, "it is not possible to imagine doing much without a computer".

Regarding the *motive* of their work, Lars conveyed his passion for mathematics by declaring, "I do love theorems". He describes his motivation as an intellectual exploration of a mathematical landscape in a Platonistic sense: "The mathematically interesting is a very thin membrane that lies between the trivial and the impossible. [...] This is the only place where you can solve problems using mathematics." Mats, in contrast, is driven by solving real-world problems involving real-world data. "Solving that damn problem, that is the important thing." As he sees it, if the link to real-world data is severed, then something is lost: “It becomes like chess. And chess is nice and interesting and everything. But it is just chess."

Regarding *tools*, Lars speculates that "had I been stronger in terms of programming, it is possible that [...] I would have been open to other kinds of solutions and opportunities." However, he does not think he would have wanted to do it any other way. His interest in mathematics is firmly rooted in the use of analytic tools: "[programming] could have helped me, given me some insight, I could have experimented a bit, put together models, and so on. But what I really cared about, ultimately, was theoretical results." Mats, on the other hand, views mathematics and programming as deeply intertwined: "You only get so far by only the tools of mathematics. Simply put, you need to combine the tools of mathematics and programming to have a proper toolbox […] modelling, combined with programming is just insanely powerful." Mats elaborates that analytic tools are necessary to verify computational results because if not, he says, “you could always end up doing things on a computer without having a clue of it is correct or not."

In terms of *rules*, Lars shares a story from the start of his career in which he worked on a project that involved computations on real-world data: "The power series of the solutions were completely incomprehensible, so we had to program a bit […] and compute how these things actually behaved.” So, Lars’ lack of interest in programming is not due to a lack of experience. Instead, he seems to view the use of programming as belonging to a different ‘game’ than the one he is interested in, one with a different set of rules. Mats, in contrast, expresses a rather agnostic view of disciplinary boundaries: "It is solving that damn problem that matters. [...] it is not the discipline as such." As noted earlier, he has little interest in mathematics as an abstract “game of chess”.

Their *communities* also differ. Lars primarily collaborates with other pure mathematicians and PhD students. He estimates that around half of mathematicians in his community know how to program, including some of the best researchers. While he reports that colleagues who focused on numerical approaches broke off and formed a separate community, he now sees a softening of this divide, with computational researchers becoming more engaged in theory. However, Lars indicates that the tensions between pure and applied mathematics persist:

> "There are still communities in pure mathematics who […] look down on purely numerical mathematics. [...] But then you go to the applied computational mathematicians [who are] a bit condescending from the other direction."

Mats positions himself as part of an interdisciplinary community, where most of his colleagues program. When asked about fellow applied mathematics who avoid programming, he says that “I am sure have they have done some programming a long time ago and then put it away. And in that sense, they are not half blind, it is just that they have chosen to close their eyes in that direction."

With respect to the *division of labour*, both Mats and Lars report a strong sense of autonomy. Lars expresses the freedom to explore any ideas he finds interesting, consistent with his view that mathematics is an enterprise of intellectual exploration. As he puts it, “Everything […] is just ideas that are in your head - you want to do this; you want to do that. And then there is something that triggers it, that you follow this trail instead of that." Mats describes having a similar experience in his research group, where this autonomy is extended to PhD students, who are asked whether they prefer analytic work or programming when hired. However, he emphasises the importance of a balance within the group: “It needs the whole package. There is nothing that stands out as more important than anything else.”

Finally, their perceived research outcomes differ in scope and orientation. For Lars, the outcome consists of theoretical papers aimed at fellow experts. If any programming is used, it primarily serves cosmetic purposes. Mats, by contrast, views software implementing numerical methods, usable by the wider community, as a key outcome alongside more traditional research papers.

Dialectic Contradictions

Based on the above descriptions, we indicate two dialectic contradictions in our data: a primary contradiction concerning the participants’ motives for doing mathematics and a secondary contradiction caused by friction between their motives and rules for mathematical activity.

The primary contradiction in motive lies in Lars and Mats’ fundamentally different sense of the purpose of mathematical research. Lars describes his interest in mathematics to be the intellectual exploration of “the thin membrane that lies between the impossible and the trivial”, driven by a curiosity about mathematics itself. Mats, on the other hand, sees mathematics disconnected from real-world data as being just like a game of chess - perhaps interesting, but ultimately just a game. These opposing motives satisfy our criteria for a primary dialectic contradiction: they are (a) complementary and interrelated, (b) mutually incompatible in how they define legitimate mathematical activity: for Lars, the motivation is intrinsic to mathematics, while for Mats it is extrinsic, and (c) a source of tension. Mats’ ‘game of chess’ analogy and Lars’ account of mutual condescension between theoretical and computational mathematicians point to a deeper struggle over epistemically valid ways of pursuing mathematics.

The secondary contradiction arises from the tension between these opposing motives and the corresponding rules of mathematical practice. Lars adheres to the norms of his notion of classical mathematics, where programming has little or no place. His earlier experience with programming was framed as a side-step or a deviation from this norm. Mats, by contrast, insists that his job is to solve that "damn problem" *by any means necessary.* For him, this requires a flexible approach that integrates classical mathematics with modelling and programming. From this perspective, disciplinary boundaries are less important, and success depends on being able to draw on multiple

domains. These conflicting views on rules qualify as a secondary dialectic contradiction as they are (a) complementary and interrelated, (b) mutually incompatible *in light of the contradiction in the motive node*: Lars' motive for doing mathematics is intrinsic to mathematics, while for Mats it is rooted extrinsically, and (c) a source of tension and change, as evidenced by Lars' account of the split between computational and theoretical factions in his field.

Discussion

Above, we used CHAT as the basis for a deductive thematic analysis of interviews with two mathematicians, Lars and Mats, who represent opposite ends of the pure–applied spectrum. As part of this process, we refined our operationalisation of CHAT (see Table 1). We now connect back to the research questions from the introduction and consider implications for our future research.

RQ1: Our operationalisation of CHAT provided an analytic lens with motive as a focal point. In analysing the interview data, this led to us identifying two contradictions. (1) A primary contradiction related to motive: Lars' intrinsically oriented motive of theoretical exploration versus Mats' extrinsic focus on solving real-world problems. (2) A secondary contradiction related to the interaction between friction between motive and the epistemic rules seen as governing mathematical activity: For Lars, programming lies outside the norms of classical mathematics, while for Mats, it is essential for solving real-world problems. These contradictions are not merely a question of incompatible views but reflect a source of tension and conflict and, thus, a force for change in the collective social activity that they are part of. Lars' sense of individual autonomy and disinterest in programming aligns with the norms and division of labour in the community of pure mathematicians that he associates himself with, while Mats' integrated computational approach reflects those of his interdisciplinary community of applied researchers. These findings resonate with findings from the philosophy and history of mathematics that identify such contradictions as driving forces in the historical evolution of mathematics (see, e.g., Hacking, 2014) and mathematics education research where Buteau et al. (2014) connects mathematicians' use of programming to disciplinary norms.

RQ2: Our structured use of CHAT, drawing on Engeström (2014) and Mwanza and Engeström (2005), allowed us to produce a systematic account of Lars and Mats' activities and highlighted dialectic contradictions. However, our focus on two interviews limits our ability to assess collective aspects (rules, community, division of labour). For instance, at the department of Lars and Mats, is a diversity of motives and approaches among mathematicians generally viewed as an asset, a source of conflict, or both? In further work, we, therefore, see it as necessary to include interview data from the broader participant group and other data sources to triangulate findings (such as site visits, background interviews with administrative staff and students or surveys).

While our explicit operationalisation of CHAT, in response to criticism of the use of CHAT by Núñez (2009), promoted transparency and analytic rigour, it may have reduced the flexibility of our analysis. We recognise this tension as similar to the contrast between Engeström's structured framework for CHAT (2015) and Radford's more flexible interpretive approach (2021). So, while Engeström's structured framework was helpful in the early stage of this project, Radford's materialist dialectics may have the potential to allow for more analytic depth in the long run. Going forward, we see a need to balance these perspectives.

The next step of this project is to further refine our use of CHAT, drawing on both Engeström and Radford. We will then apply this evolving framework to the broader set of interview data to shed light on the interplay between mathematicians' teaching, research, and programming practices.

An alternative approach to teaching the fundamental concepts of Analysis to first-year university students

Georgia Petropoulou[1], Angeliki Mali[2], Theodossios Zachariades[1] and Despina Potari[1]

[1]National and Kapodistrian University of Athens, Greece; gpetrop@math.uoa.gr

[2]University of Crete, Greece

Teaching fundamental concepts of Analysis in the first year of university is crucial for students' success in university-level mathematics. This study investigates how a lecturer, with research expertise both in mathematics and mathematics education, introduced these concepts to first-year undergraduate mathematics students. Data collection included observation notes, audio-recordings of lectures and interviews with the lecturer. Through iterative cycles of data analysis, we identified a four-level pattern in the lecturer's teaching approach which we exemplify in the case of the limit of a sequence. We illuminate the meaning of the identified pattern by reflecting on the development of an alternative teaching culture through tensions and attempts of their synthesis. We highlight the role of research experiences in mathematics education in shaping an alternative teaching culture and explore ways to influence the overall teaching culture at the university.

Keywords: university mathematics teaching, concept introduction, tensions, teaching culture.

University mathematics teaching to first-year mathematics students often faces challenges in initiating students to advanced mathematical processes and concepts (Lew et al., 2016; Breen & O'Shea, 2016; Di Martino et al., 2023). While extensive research has focused on teaching proofs, less attention has been given to teaching practices for introducing essential concepts like the concept of limit (Lew et al., 2016) - a fundamental threshold in Analysis which students must grasp to succeed in more advanced mathematical topics (Breen & O'Shea, 2016). In most countries, the expectations at the university level differ from school mathematics which primarily focuses on procedural understanding (Di Martino et al., 2023). In a bachelor's program in Mathematics, students are required to shift their focus towards increased abstraction and rigor (Vollstedt et al., 2014), along with the introduction of advanced mathematical concepts (Hitt & Dufour, 2021). As a result, students may experience situations of a "culture shock" as they are introduced to advanced mathematical language and culture (Burazin & Lovric, 2018). Hence, how key mathematical concepts are introduced is crucial for students' initiation into mathematical culture and success in higher-level mathematics.

In this case study, we investigate the teaching approach of a lecturer during the introduction of the Analysis concepts (limits, continuity and derivatives) in first-year undergraduate mathematics lectures. There is a body of research that points to the mathematical gap between secondary school and university (Di Martino et al., 2023) and values what we can learn from mathematicians' practices. Even more, how their research can influence their teaching in university courses as well as in teacher education programmes (Mali et al., 2021). The lecturer in this study teaches in a mathematics department where the established teaching culture is the presentation the definitions, theorems and proofs. He himself is not only experienced in teaching and research in mathematical Analysis but also has a strong research background in mathematics education (e.g., in teaching in secondary and tertiary

level and teachers' knowledge). This combination of expertise makes him an information-rich case, offering valuable insights into how teaching culture could be shaped by research experience. Therefore, we ask the following research question: How does a researcher in mathematics and in mathematics education approach teaching the fundamental concepts of Analysis to first-year mathematics students?

Theoretical considerations

We adopt a dialectical materialist perspective of culture (Radford, 2021), in which individuals create cultures and cultures create individuals. Radford emphasised the interconnected and dynamic nature of culture. In his view, culture is an integrated system where material and intellectual dimensions interact within a web of societal relationships. These relationships are not static or universally consistent; they shift based on context and circumstances, creating tensions and conflicts that drive cultural change. We also view culture as a polyglot relation of conflict, resistance, and meaning making between individuals and societal practices they engage in. When examining the teaching culture of a lecturer involved in both research and teaching, culture embeds, and is embedded, in the set of practices that influence their approach to teaching and research within the university's affordances and constraints. In this context, we specifically consider the teaching of Analysis and the lecturer's research background, seeking insights into how the dominant university culture could be affected. However, culture is not merely a static set of practices. It is a living, evolving process shaped by the lecturer's interaction with students, colleagues, and the broader academic community. This process is formed through their engagement in societal practices, including how they teach, how they communicate mathematical concepts, and how they integrate research into teaching. In return, this culture influences the mathematician's own thinking behind teaching and research. This thinking includes considerations of how best to enable students to think mathematically, how they work within university affordances and constraints, their own educational history, their views of mathematics and what it means for students to learn mathematics (Potari et al., 2023).

Shedding light on tensions inherent in teachers' doing and thinking has the potential to offer deeper insights, on the one hand, into the source of these tensions, and on the other hand, whether teachers attempt their synthesis (Potari et al., 2023). For example, mathematical rigour and insight are seen as being in tension, and this tension can offer insights into why some teachers prefer giving up some rigour in exchange for insight when teaching mathematical proofs (Sangwin & Kinnear, 2024). The dialectical nature of tensions (Radford, 2021) emphasizes that they are not just obstacles but can also be productive forces that drive deeper engagement and development in the educational context. Culture also serves as a site of tensions and their synthesis towards meaning making, suggesting that the lecturer's teaching practices might involve navigating the differing expectations and challenges that arise during students' enculturation into advanced mathematics and the new university environment. Thus, the teaching culture involves not only the presentation of mathematical content but also facilitating students through this enculturation, so they become successful in higher-level mathematics. The teaching culture would, therefore, be shaped by these broader societal processes, including the difficulties students encounter during their transition, institutional norms and the evolving field of mathematics education itself. Ultimately, we view teaching culture as encompassing teaching practices, teacher thinking and the societal context in which they are situated. We examine

how this teaching culture is developed through tensions handled by drawing on the mathematician's own research background.

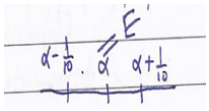
Methods

This is a case study focused on teaching the fundamental concepts of Analysis at a university in Greece. The Analysis course under investigation was proof-oriented and its content included limits of sequences and functions, continuous of functions, derivatives and the related theorems. The course was offered to a large cohort of 200 mathematics students in the first semester of their bachelor's programme. The usual way of introducing mathematical concepts in this department was rather traditional, in the form of teaching the formal definitions followed by some examples. The third author was the university lecturer, who held a Ph.D. in mathematical Analysis, and had conducted research in mathematics education as well. He was a well-regarded lecturer among students, with 30 years of teaching experience at the university level.

Data for this study included observation notes and transcripts of audio-recorded lectures covering the concepts of the convergence and the limit of a sequence, as well as the limit, continuity, and derivative of a function. These observations were made by the first and the fourth author. Data also includes transcribed discussions between the lecturer (the third author) and the two researchers (the first and fourth author). Each discussion followed each of the observed lectures, during which, the planning for the next lecture was also addressed. In the retrospective analysis, the second author was involved and further reflections of the lecturer took place that were also part of the data. In this way, the data analysis became systematic. The iterative cycles of analysis began among the three researchers with a grounded study of the data, involving collaboration among the three researchers and the lecturer. Together, they reviewed the transcripts and discussed their remarks, focusing on what the lecturer did and intended during his teaching. In the initial cycles of analysis, a combination of open coding and theoretical coding, informed by extant literature, was used to identify specific teaching practices. For example, uncovering the limitation of students' current content knowledge, coordinating intuitive and formal explanations, providing alternative representations, highlighting a mathematical practice (e.g., abstraction), etc. As the analysis progressed, the researchers identified a four-level pattern in the lecturer's approach to teaching the concepts mentioned above. Following the initial cycles of analysis, the researchers engaged in discussions with the lecturer about his underlying considerations for teaching. They presented him the descriptive names of the identified teaching practices and corresponding examples from the data. The lecturer reflected on how his own background and research expertise influenced his approach to designing and implementing his teaching of the concept of limit. These discussions were audio-recorded and transcribed for identifying tensions.

In the following section, we present examples of observational and interview data concerning the teaching of the limit of a sequence, that were coded as teaching practices and tensions as well. The teaching practices are discussed in the order of the four-level pattern. At the end of the section, we give an account of the identified tensions and their role in the development of an alternative teaching culture comparing to the one described above that had been established for many years in this department.

Findings



A four-level pattern of a concept introduction was identified by the analysis of our data: *setting a familiar problem unsolvable with known techniques, adopting an intuitive approach to address the problem, decontextualising the solution process to introduce the new concept, making the new concept transparent*. We exemplify this pattern by drawing on data from the teaching of limit of a sequence. At the end of the section, we give an account of the identified tensions and their handling, as they are also findings of the study.

At the first level of concept introduction, a familiar problem was usually introduced and the limitation of students' previous knowledge for solving this problem was established. The selection of an appropriate problem accessible to students was crucial because, in this way, they were encouraged to start thinking about how they could solve it and the lecturer facilitated them in uncovering the limitation of what they knew. The problem he selected to introduce the limit of a sequence was the following: "How we could calculate the area of a circle of radius 1". The students knew from school how to calculate the area of polygons and one student remarked that this method does not work because "the circle does not have a straight section". Thus the limitation of the known measurement process emerged.

At the second level, students were encouraged to adopt an intuitive approach, drawing on their arguably limited knowledge to find a solution method for the problem set. The lecturer asked, "How could we possibly link the area of the circle with the area of regular polygons?" When one student answered, "We could fill the circle with polygons!" the lecturer commented: "Yes, but there [on the circle] will always be something left over." This intuitively obvious comment prompted another student to get the idea, "Let's take polygons inside and outside [the circle]." For the lecturer, this intuitive idea represented students' arrival at a second, crucial for the solution, step: confining the unknown quantity, that is the area of the circle, between two known quantities, that is the area of an inscribed and a circumscribed polygon to the circle. He proceeded to substantiate the student's idea on the board by drawing the simple case of an inscribed and a circumscribed square around the circle, as well as a corresponding number line with the symbols $E1$, E, $E1'$ (representing the areas of the square in the circle, the area of the circle and the area of the square outside the circle, respectively) and the symbolic representation of the inequality $E1<E<E1'$. Then, he asked students another crucial question: "Could we reduce the interval where the number E lies"? This question aimed to lead students pave another crucial step: to think of a way for an increasingly better approximation, arbitrarily close to the intended quantity E. A student immediately responded, "Yes! By increasing the number of the sides of the polygons". Then, the lecturer invited students to "look numerically" at what they had been discussing earlier in a Geogebra environment, where two sliders adjusted the radius of the circle and the number of the sides of the inscribed and circumscribed polygons. After increasing the number of the sides with the slider, he concluded, "The difference in the areas can be made as small as we want and approaches zero." The entire teaching approach intended to ease students' shifts between vital mathematical ideas, such as confinement and approximation through mathematical inquiry and was characteristic for this lecturer's teaching.

At the third level, the solution process was decontextualised from the initial problem and, in this way, students were gradually introduced into mathematical abstraction, as presented in Table 1:

Table 1: A Teaching episode from the introduction to the limit of a sequence

<table>
<tr><td>1</td><td>Lecturer:</td><td colspan="2">The areas are sequences. Let the midpoints of the polygons be considered. We can get as close as we want to the area of the circle.</td></tr>
<tr><td>2</td><td>Lecturer:</td><td colspan="2">If we wanted an approximation to the nearest tenth:
$a-\frac{1}{10}, a+\frac{1}{10}$
[he draws the following figure for the approximation process].

If we wanted an approximation to the nearest hundredth:
$a-\frac{1}{100}, a+\frac{1}{100}$. In other words, the distance is the radius.</td></tr>
<tr><td>3</td><td>Lecturer:</td><td colspan="2">How can we express any distance in a general way?</td></tr>
<tr><td>4</td><td>Student:</td><td colspan="2">With a positive number.</td></tr>
<tr><td>5</td><td>Lecturer:</td><td colspan="2">Let's take a positive number and call it ε (epsilon). We said [he divides the board in two parts]:</td></tr>
<tr><td rowspan="4">6</td><td rowspan="4">Lecturer:</td><td>As close as we want,</td><td>For every $\varepsilon > 0$</td></tr>
<tr><td>there exists a polygon</td><td>there exists $n_0 \in N$</td></tr>
<tr><td>such that the distance between its area and the area of the circle is less than ε.</td><td>$|\alpha_n - \alpha| < \varepsilon$</td></tr>
<tr><td>This property is not only true for this particular polygon but also for all polygons with a greater number of sides.</td><td>for every $n \geq n_0$</td></tr>
<tr><td>7</td><td>Lecturer:</td><td colspan="2">When all these conditions are met, we say that the sequence (α_n) converges to the number α. … [the formal definition followed]</td></tr>
</table>

In the above teaching episode, the approximation process was decontextualised from the initial problem of finding the area of a circle to a more objectified form, applicable in other cases as well. Through a detailed translation of the intuitive approach into mathematical terms by the lecturer (turns 3–7), students were gradually introduced to mathematical abstraction at this level. Then, the definition of the limit of a sequence was formulated symbolically, graphically and verbally. The entire process transformed intuition into concrete, interconnected mathematical ideas until the new concept was introduced.

At the fourth level, the introduced concept was made transparent through appropriate examples, counterexamples and non-examples [e.g., the sequence $(-1)^n$]. In parallel, the lecturer addressed potential students' misconceptions (e.g., the convergence implies monotonicity), drawing on his familiarity with such misconceptions from his experience in mathematics education. Furthermore,

the connection of the new concept to expressions from everyday life (e.g., “speed limit”) and to other mathematical concepts (e.g., the density) was discussed, further contributing to the transparency of the limit concept.

Intuition, inquiry as well as pedagogical concerns about how students come to understand mathematics, are all components of this lecturer’s research culture both in mathematics and mathematics education. These components are poles opposed to mathematical rigour, exposition of the advanced content as well as restrictions resulting from the large number of attendees. Attempting to balance these poles creates dialectical tensions of epistemological, pedagogical and institutional nature, identified in this lecturer’s teaching. For instance, we saw above an interplay between intuition and mathematical rigour (epistemological), the inevitable exposition of mathematical content alongside questions calling for students to “do” mathematics (pedagogical) and the large number of students (institutional), which prevents interaction or restricts inquiry in using available technological tools. Thus, the other cultures in which this lecturer participates, like the mathematical, research and university cultures, create tensions in teaching. In his own words:

> “In teaching, you try to arrange ideas in an order so that they come across somewhat naturally. In research, ideas don’t come like that; sometimes a light for something turns on your mind! In teaching, you try for the questions to come as naturally as possible: we have a problem, we try to solve it with what we know, it doesn’t work, we try to think of something else, and that’s how we can connect the knowledge we have and start thinking. Of course, trying to think of something else isn’t easy for students to do in class. For example, I think I had told them to take the regular polygons inside and outside the circle. Then narrowing the interval within which what we are looking for lies—that was relatively easy. Some students mentioned it, like increasing the sides, and that’s how it progresses. But you put things in order. Students should be able to answer smaller questions or at least think about them, even if they don’t give the answer.” [59:31]

We took a step further to ask how these tensions were handled. Our analysis showed flexibility in adapting his teaching to the prevailing conditions in any way possible. For example, the poles of the epistemological tension—intuition (e.g., at the second level) vs. rigour (e.g., at the third level)—were dialectically synthesised in the four-level approach for the introduction of mathematics concepts. This synthesis approach is what develops an alternative teaching culture in this lecturer’s case.

Discussion

In this study, we closely examined the teaching approach of a researcher during the introduction of the concept of limit of a sequence. His goal was to introduce students into how we "do" mathematics. We identified a pattern in his first-year undergraduate mathematics lectures, characterised by four levels: *establishing the limitation of current knowledge for solving a particular problem, adopting an intuitive approach to address the problem*, *establishing the new concept*, and finally *making the concept transparent*. This approach provides a nuanced, inquiry alternative to the conventional model, which often relies on a mere exposition of formal definitions.

Reflecting on the development of an alternative teaching culture, we illuminated the meaning of the identified four-level model and its potential for students’ learning. Despite the culture that dominates

university mathematics teaching of a new concept, which includes only the last part of the third level i.e. the presentation of the typical definition, the lecturer in this study forms a teaching culture which includes all four levels and this might be indicative of increased learning opportunities for students. This alternative teaching culture, represented by (but not restricted to) the four-level model, is developed through tensions and attempts of their synthesis. We observed epistemological, pedagogical, and institutional tensions in agreement with previous studies (e.g., Potari et al., 2023). The difference in this study is that the lecturer was aware of the culture of research in mathematics education, the culture of traditional university teaching, and the culture of mathematical research, and he attempted to synthesise his experiences from these existing cultures. In this attempt tensions arose, which he sought to balance, thereby initiating a new, alternative teaching culture.

The findings are particularly relevant when considering the dual roles of research mathematicians who also serve as university mathematics lecturers. Often, there is a perceived disconnect between their roles as researchers and lecturers. However, bridging this gap between mathematical production (research) and teaching could provide students with a more authentic and integrated experience of mathematical inquiry, which is crucial during their initiation into higher-level mathematics. In our case study, the lecturer leveraged his own research expertise both in mathematics and mathematics education to shape the four levels of his teaching practices. By connecting research and teaching, his students may become better equipped to do university mathematics, ultimately being more successful and productive in their mathematical thinking and activity (Lynch & Lockwood, 2019).

The teaching culture that the teacher initiated was further shaped by his own research background in mathematics education. This expertise played a vital role in informing him of students' misconceptions and difficulties in areas such as quantifiers or infinite processes. To address these challenges, he dedicated lecture time to explain these areas through examples and graphical representations. By drawing on his mathematics education expertise, the lecturer created a learning environment which could not only address common misconceptions and difficulties but could also promote a deeper conceptual understanding, essential for student success in university mathematics.

Building on this foundation, the study enhances the understanding of concept introduction practices by increasing awareness of how a lecturer's research background can play a pivotal role in cultivating an inquiry teaching approach. This emphasises that a lecturer's research background both in mathematics and mathematics education serves not just as a source of content knowledge but also as a valuable resource for developing teaching practices towards making abstract concepts more accessible and understandable. Such insights enrich students' learning experiences and ease the mathematical gap identified in the transition literature (Di Martino et al., 2023). Future research will need to investigate the impact of such research-informed teaching practices on students' learning and engagement across diverse student populations and learning environments. While this single case represents a small shift in the existing teaching culture, changing the overall culture of a department is difficult. However, in the context of how the individual shapes the broader culture, it raises the question of how and through which collaborations these research-informed experiences can contribute to shaping the overall teaching culture at the university. In a setting where the context limits significant change, such an approach could still influence how students learn and, consequently, how they develop their teaching as future educators.

Is this a different proof? Mathematicians' and secondary mathematics teachers' practices when comparing alternative proofs

Alon Pinto

Weizmann Institute of Science, Israel; alon.pinto@weizmann.ac.il

There is a growing interest in how teachers in academic mathematics courses can identify and explore connections to their practice. Despite early indications that teachers value examining how their instructors' practices can inform their own, research in this area remains limited. This study addresses this gap by contrasting the practices of a secondary teacher and a mathematician as they analyse the pedagogical affordances of teaching more than one proof in a specific instructional situation. Data were collected in the M-Cubed Lab, an environment designed to study dialogical learning between these two communities. The analysis reveals markedly different practices that lead to opposing pedagogical conclusions, illustrating how exploring mathematicians' mathematical and pedagogical practices in relation to secondary mathematics teaching can be both nuanced and insightful, and underscoring the potentially significant role of such explorations in teacher education.

Keywords: Secondary teacher education, mathematicians, dialogical learning, alternative proofs.

Rationale

More than a century has passed since Felix Klein drew attention to the discontinuity that secondary mathematics (SM) teachers experience when taking academic mathematics (AM) courses, yet the mathematics education community still grapples with delineating the potential affordances of AM courses for SM teaching and how they may be realised in practice. Klein's approach to addressing this discontinuity emphasised connections between specific mathematical concepts and practices in the tertiary and secondary mathematics curricula (Wasserman et al., 2023). Over time, this approach has been implemented, refined, and expanded through numerous capstone courses, teaching modules, and textbooks. Despite these substantial efforts, the double discontinuity persists, and may even be widening (Biza et al., 2022). In response, the past decade has seen growing interest in connections between AM learning experiences and SM teaching that extend beyond curricula to the pedagogical practices of SM teachers (Wasserman et al., 2023). Following an extensive review of the literature, Wasserman et al. (2023) introduced a framework that explicates various distinctions in teacher preparation programs and highlights connections across these distinctions that so far received less attention and remain underdeveloped. One such connection is between the mathematical and pedagogical practices of AM instructors and those of SM teachers. These connections represent how AM instructors may intentionally model certain practices that they deem beneficial for SM teaching. While research on such *modelled-instruction connections* is limited, there are initial indications that they are appreciated by teachers and can influence their practice (Wasserman & McGuffey, 2021).

This study aims to further explore the nature of modelled-instruction connections and their potential affordances for SM teaching by contrasting the practices of mathematicians and experienced SM teachers as they compare alternative proofs in the context of SM multiple-proof tasks. Multiple-proof tasks are tasks that invite students to produce or compare alternative proofs of the same mathematical statement (Dreyfus et al., 2021). Scholars have long advocated for the teaching of alternative proofs,

particularly in teacher preparation programs. However, research suggests that in practice SM teachers rarely present alternative proofs, either because they do not recognise their value, or because they lack knowledge and skills related to the practices of proof and proving (Dreyfus et al., 2021). This makes multiple-proof tasks an intriguing context for investigating modelled-instruction connections.

Theoretical background and research question

The literature suggests that the mathematical and pedagogical practices of AM instructors may play an important role in teacher education by facilitating prospective teachers' learning about teaching through an 'apprenticeship of observation'. Thus, these connections may help future teachers develop productive pedagogical practices (Wasserman et al., 2023). First, prospective teachers may incorporate into their own teaching certain teaching practices and strategies that they experienced and appreciated as learners. Second, prospective teachers may also draw on their instructors' mathematical and pedagogical practices as a resource for informing their own future teaching. Wasserman and McGuffey (2021) introduced the concept of *pedagogical-mathematical practices* to describe practices that are an amalgam of mathematical and pedagogical practices, for example acknowledging and revisiting assumptions and mathematical limitations, or using boundary cases to test and illustrate mathematical ideas. Observing how AM instructors engage in pedagogical-mathematical practices may inform teachers about how to engage with these practices in the future.

Zazkis (2020) observed that teachers' accounts of how they utilise their experiences in AM courses in teaching suggests that such utilizations are often personal and tacit, and thus often remain invisible, not only to outside observers but often also to the teachers themselves. These characteristics, which pose a significant methodological challenge in studying the affordances of AM for SM teaching (Biza et al., 2022), are likely to be even more pronounced in the case of modelled-instruction connections due to the tacit and personal nature of pedagogical and mathematical practices. To address this challenge, Pinto and Cooper (2022, 2023) proposed that boundary encounters between mathematicians and experienced SM teachers may be used as a methodology for generating and studying utilizations of AM in SM teaching. The premise of boundary encounters is that communities are separated and defined by social, cultural, and epistemological discontinuities in action or interaction, which can make the exchange of knowledge across communities difficult (Akkerman & Bakker, 2011). However, the literature on boundary crossing highlights mechanisms that can help boundaries serve as a powerful catalyst for dialogical learning across different communities. This study takes place within the M-Cubed Lab, an environment specifically designed to study boundary encounters between mathematicians and practicing SM teachers (Pinto & Cooper, 2022, 2023). In this setting, this paper investigates the following research question: *How do the practices of mathematicians and secondary mathematics teachers differ when comparing alternative proofs?*

Methods

Data collection: The M-Cubed Lab

Data for this study were collected in the M-Cubed (Mathematicians, Math teachers, Mathematics) Lab. In M-Cubed, small groups of mathematicians and experienced SM teachers convene once a month to view videotaped SM lessons and jointly inquire into mathematical and pedagogical issues

that they recognise therein. This research setting serves as a laboratory for generating and studying the implications of ideas and perspectives from AM in consideration of authentic instructional situations. This paper focuses on two M-Cubed participants: Benjamin, a research mathematician with extensive teaching experience in undergraduate courses, and Daniel, an experienced SM teacher.

Data for this paper comprise a videotaped 2-hour discussion that included Benjamin and Daniel, and an article that Daniel wrote after the meeting for his teacher blog where he reflects on this discussion. The M-Cubed discussion concerned the teaching of multiple-proof tasks, and it followed 15 minutes of individual work where Participants tried to locate different proofs to the Three-Squares Problem:

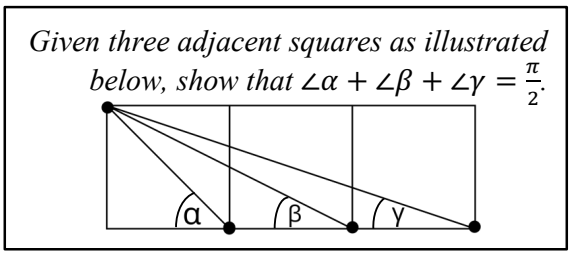

Figure 1: The Three-Squares Problem

The Three-Squares Problem, often attributed to Martin Gardner, has many elementary solutions in various mathematical fields, making it particularly suitable as a multiple-proof task (e.g., Hoseana, 2024). After engaging with the problem individually, participants discussed their proofs in small mixed groups and then watched a 20-minute section from a videotaped lesson in an advanced-track 11th-grade class where six students presented their six alternative proofs of the problem. Three proofs are in planar geometry (presented below), and the other three are in trigonometry, analytic geometry, and complex numbers[1]. Then, the group reflected on the lesson they just watched, comparing how alternative proofs were presented and discussed, and exploring the opportunities for learning that may have been afforded for the students. The M-Cubed meeting was videotaped and fully transcribed. After the meeting, Daniel wrote a ~3000-word article, intended for a blog for SM teachers, reflecting on Benjamin's and the other mathematicians' observations regarding the opportunities for learning that the different proofs afforded, and contrasting them with his own perspective as a SM teacher.

Data analysis

The first stage of the analysis focused on identifying different threads in the data where a thread refers to a sequence of utterances, though not necessarily continuous, that address a common issue and relate to and build on each other. This paper focuses on the thread: "Are the three planar-geometry proofs different and is there merit in teaching more than one of these proofs?" This thread was chosen since it was central in both the M-Cubed session and Daniel's article. Analysis of the practices that Benjamin and Daniel engaged in while addressing this question were informed by Wasserman et al.'s (2023) framework and by Wasserman and McGuffey's (2021) descriptions of pedagogical-mathematical practices. Since such practices are neither strictly mathematical nor purely pedagogical, this paper considers any practice that could reasonably belong to one or both these categories.

Findings

During the M-Cubed meeting, several participants observed that the teacher in the videotaped lesson did not explicitly address what students were supposed to learn from seeing multiple proofs. This

[1] All six proofs are presented in detail here: https://stwis.org/5gylx8.

observation raised the question of what the affordances of multiple-proof tasks are and how teachers can help students realise these affordances, focusing specifically on the opportunities for learning that were afforded by engaging students with the three planar geometry proofs:

Proof A: Add three auxiliary squares and connect the points A and C to the point *G,* as in Figure 2. The triangles ACG and AFE are similar as right angled isosceles and thus $\sphericalangle ACG = \sphericalangle\alpha$. Since $\sphericalangle GCB = \sphericalangle\beta$, we can conclude that $\sphericalangle\alpha + \sphericalangle\beta + \sphericalangle\gamma = \frac{\pi}{2}$.

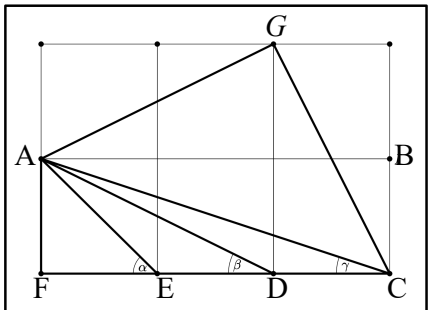

Figure 2: AGC is similar to AFE

Proof B: The triangles AED and CEA are similar since the two triangles share the angle AEC and since $\frac{AE}{ED} = \sqrt{2} = \frac{CE}{EA}$. It follows that $\sphericalangle EAC = \sphericalangle EDA = \sphericalangle\beta$, and since $\sphericalangle\gamma$ and $\sphericalangle CAB$ are alternating angles, $\sphericalangle\alpha + \sphericalangle\beta + \sphericalangle\gamma = \frac{\pi}{2}$.

Proof C: Similarly to Proof 1, add three auxiliary squares and two edges to a point H as illustrated in Figure 3. The new right-angled triangle AHC is similar to with a similarity factor $\sqrt{2}$. It follows that $\sphericalangle ACG = \sphericalangle\beta$ and since $\sphericalangle BCG = \sphericalangle\alpha$ we can conclude that $\sphericalangle\alpha + \sphericalangle\beta + \sphericalangle\gamma = \frac{\pi}{2}$.

Before reading further, the reader is invited to pause and reflect on whether these three proofs are 'different' and on the value of teaching all three proofs in SM classes.

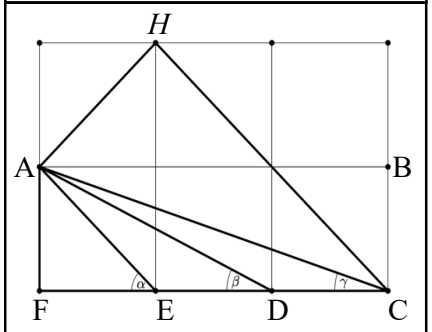

Figure 3: AHC is similar to AFD

Benjamin's analysis of alternative proofs

Benjamin was generally critical of the presentation of alternative proofs in the videotaped SM lesson:

> I don't think we saw different solutions here. I think we saw the same solution several times in different costumes. What could have been valuable was to tell [to the students] that in geometry, the way to show that angles add up to 90° is by embedding them in a right angle. That's what common to all the solutions […] For me, it was boring to see all these solutions […] There is no principal difference, one student looked at this triangle, while another looked at another triangle.

This criticism suggests that Benjamin assess the added value of alternative proofs according to whether the represent fundamentally different *principal ideas*. Since he viewed the three planar-geometry proofs as representing the same principal idea, he saw little added value in teaching more than one proof. However, Benjamin did recognise merit in teaching more than one proof in this case:

> I think it's important to emphasise the difference between a geometric construction, which provides a better explanation but requires innovation, and computational methods […] This is a tactical difference in problem solving, maybe even strategic, that should be pointed out.

When asked to elaborate, Benjamin explained the strategic differences he observed:

> When working with trigonometric functions, or slopes, or complex numbers, you represent the angles as numerical objects in some way, and then … then you compute a sum or a product […] You compute, you just sit down and compute. In geometry, you can't just sit down and compute, you need to find something to compare. It's comparison, not computation.

Benjamin also highlighted a subtle mathematical issue in the computational solutions, which further justified comparing the geometric and computational approaches. He noted that in some of the

computational proofs, the students concluded the sum of the angles without explicitly addressing the fact that this sum was determined up to additions of $\pm 2\pi$. For example, in the trigonometric proof, a student determined that $\beta + \gamma = \arctan(1)$, but did not reason why the sum was not $\pi/4 + 2\pi$. Benjamin noted that the proofs are still valid because all the angles were acute, but this was a geometric argument that needed to be made explicit. He concluded:

> I think it's nice that you don't entirely get away from the geometry. Everyone thinks that you can just compute, compute, compute, but it doesn't really work that way.

In sum, Benjamin's practices of comparing alternative proofs and determining their pedagogical value were focused on the principal ideas each proof illustrated. Specifically, he emphasised the general proving strategies that are exemplified by the different proofs. He considered the three planar-geometry proofs to be essentially the same and saw no value in teaching more than one of them. He did see value in comparing a planar-geometry proof with a computational proof to highlight and contrast two general problem-solving strategies in mathematics and discuss their relative advantages.

Daniel's analysis of alternative proofs

During the M-Cubed session, Daniel opposed the idea that teaching alternative proofs inherently benefits students and agreed with Benjamin that the proofs need to be compared in some way:

> A lesson needs to have content! […] The teacher could have said, wait a minute, let's look at the three [planar geometry] solutions. In all of them we found similar triangles; In all three, our anchor was finding a right angle. This… this would have been a completely different lesson!

However, Daniel did not fully endorse Benjamin's analysis of the proofs and his conclusion, as he observed additional aspects of alternative proofs that he considered valuable for SM students:

> I think, something really nice that you could do is to try to find in each proof the, like, some cues […] What was it in the problem that led us in this particular direction? […] You could ask, now that we've seen a proof [using complex numbers], what in the problem could have made us think in the direction of complex numbers? […] What are the clues at the 'scene of the crime'?

In the Daniel's article, he developed this idea further. He focused on the planar-geometry proofs and explored why Benjamin viewed them as equivalent while the M-Cubed teachers generally considered them different. First, he created a table where he identified the principal ideas in each proof:

Table 1: Daniel's analysis of the principal ideas in the three planar-geometry proofs

Principal idea	Proof A	Proof B	Proof C
Completion to a right angle	V	V	V
Using a known proportion		V	V
Identifying similar triangles	V	V	
Using an auxiliary construction on a grid	V		V

Recapping his analysis, Daniel appeared to agree with Benjamin that all these proofs share a big idea:

> You can see that all solutions use 'completion to a right angle', which they accomplish […] either by using proportion considerations, referring to known proportions, similar triangles, or a grid. Thus, [the] big idea is positioning the three angles at the same vertex to create a new angle that equals their sum, then using a geometric argument to justify that this angle is a right angle.

Yet, Daniel's analysis also highlighted differences between the proofs, particularly the 'cues' in the Three-Squares Problem that could guide SM students towards each proof. Regarding Proof 1, Daniel observed that SM students could recognise that triangle AFE is a right-angled isosceles, which is a well-known auxiliary construct, and use it to identify where it can be placed in the figure to provide useful information. In relation to Proof 2, Daniel suggested that SM students could first look to identify which angles in the figure are or could be equal to α, β and γ, and then 'think backwards':

> We first conjecture which triangles are similar because that would help us, then we identify the proportional edges, then we identify the proportion, and then we prove the similarity.

Regarding Proof 3, Daniel noted that a student could recognise that the triangle AFD has a 1:2 ratio when using the square's edge as a unit of measurement, then replicate this ratio on a grid with the square's diagonal as the unit. Based on this analysis, Daniel concluded that each of the three proofs emphasises a different initial consideration that could guide students towards the proof. He further observed that the different conclusions drawn by the mathematicians and SM teachers might reflect a deeper distinction between AM education and SM education. Specifically, Daniel suggested that the term 'different solutions' might hold different meanings to mathematicians and to SM teachers:

> In [AM], a solution is a proof, and a proof is a sequence of arguments, each one is either known to be true or follows from previous arguments. From this perspective, solutions are equivalent if they represent equivalent lines of reasoning […] In contrast, SM teachers […] may be viewing a solution as be viewing a solution as a process, a sequence of actions that students need to learn. From this perspective, different starting points represent a significant difference [between proofs].

Daniel further suggested that explicating these different meanings could help inform teachers' decisions about teaching alternative proofs. He concluded his article by connecting the different interpretations of 'different solutions' to pedagogical practices of AM instructors and SM teachers:

> In class, mathematicians might ask, "Is there another solution?" while SM teachers might ask, "Did anyone solve it differently?". This difference is not merely semantic but reflects distinct views on the value of [teaching] multiple solutions to mathematical problems.

Daniel further observed that at AM education, the focus is on mathematical products that are independent of the proving process or the identity of the prover, whereas in SM schools the focus is almost entirely on the learners. Hence, for SM teachers, a student's solution is rarely disconnected from the individual solutions process of the student, because "problems, proofs, and [proving], are first and foremost pedagogical tools". Whereas in AM education the 'same' solutions by different proofs are expected to receive the same feedback, the 'same' solutions by difference students may receive different feedback. One student might be praised, while another might receive feedback on subtle errors, all because the students are at different learning stages.

Discussion

The literature suggests that SM teachers may benefit from examining their instructors' pedagogical and mathematical practices (Wasserman et al., 2023). However, the process by which such practices may be transformed into resources that inform SM teaching remains unclear. This study offers further

evidence that this transformation is not straight forward (cf., Pinto & Cooper, 2022, 2023). Daniel did not mimic Benjamin's approach to evaluating the pedagogical productiveness of presenting more than one proof, but instead analysed the proofs differently, reaching an opposing conclusion. While Benjamin argued emphatically that there is no merit in teaching more than one planar-geometry proof while Daniel argued just as strongly that there is. At first glance, this finding might seem discouraging. If this observed difference is, as Daniel suggested, not merely anecdotal but indicative of a deeper distinction between AM education and SM education, then one might question the benefits for SM teachers of examining AM instructors' practices when teaching alternative proofs. However, a closer examination of how Benjamin's observations influenced Daniel's analysis of the three alternative proofs underscores the potential value of modelled-instruction connections.

When comparing the different proofs of the Three-Squares Problem, both Daniel and Benjamin sought to draw insights extending beyond the specific proofs themselves. Notably, the insights Benjamin derived align well with key aspects of proof comprehension that mathematicians expect university students to develop, such as identifying the proof framework, summarising the proof via high-level ideas, and making implicit warrants explicit (Mejia-Ramos et al., 2012). Benjamin's analysis highlighted a single overarching proof strategy common to all three planar-geometry proofs, leading him to conclude that there is no merit in presenting more than one proof.

While Daniel did not endorse Benjamin's conclusion, it served as a catalyst for his own analysis, which was guided by a question more aligned with the pedagogical practices of SM teachers: What cues can an SM teacher highlight in the problem that might direct SM students towards each proof? Daniel's question explicitly intertwines mathematics and pedagogy, as evidenced by his analysis of the three proofs – unlike Benjamin's strictly mathematical approach. Drawing on his knowledge for teaching, Daniel identified three additional heuristics that were differently represented in each proof (see Table 1). In contrast to Benjamin's more general strategy, Daniel's heuristics were specific to SM students and SM planar geometry. In this sense, Daniel's practices and conclusions can be seen as extending and refining Benjamin's rather than conflicting with them.

The question remains: how can the potential affordances of modelled-instruction connections be realised in practice? Analysis of Daniel's approach and practices highlights two significant resources typically not accessible in AM courses. First, the analysis shows how Daniel, an experienced SM teacher, drew extensively on his knowledge for SM teaching when exploring, criticising, and refining Benjamin's practices. This finding adds to growing evidence that SM teaching experience – generally inaccessible in AM courses to both instructors and students – can be a valuable resource for identifying and explicating connections between AM teaching and SM teaching (Even, & Mytlis, 2024; Pinto & Cooper, 2022, 2023). Second, in M-Cubed, Daniel was not only exposed to Benjamin's mathematical practices but was also able to engage in a dialogue with him about his mathematical and pedagogical perspectives. In fact, Daniel noted that what triggered his analysis was the realisation that while Benjamin's exploration of the 'sameness' of the planar-geometry proofs was purely mathematical, the question whether the proofs are the same is not purely mathematical but also pedagogical – meaning that Benjamin's conclusions could be challenged by SM teachers. Creating more opportunities for mathematicians, prospective teachers, and practising teachers to share, explore, and revisit their tacit mathematical and pedagogical perspectives and practices could help

make these resources more accessible in teacher preparation programmes, thereby reducing the perceived disconnect between secondary and tertiary mathematics education.

On the conceptual understanding of the notion of a general solution

Yuriy Rogovchenko[1] and Svitlana Rogovchenko[2]

[1]Department of Mathematical Sciences, University of Agder, Kristiansand, Norway; yuriyr@uia.no

[2]Department of Engineering, University of Agder, Grimstad, Norway

Many mathematical models for real-life phenomena are based on differential equations. Their importance in applications makes differential equations one of the core subjects in most engineering programs. Empirical studies reveal students' difficulties with the conceptual understanding of the fundamental notions of a differential equation and different types of its solutions. In this paper, we review the presentation of the notion of a general solution as a process in widely recognised classical texts suggesting a pedagogical strategy that can help improve students' understanding of the concept.

Keywords: Differential equations, general solution, conceptual understanding, genesis of differential equations, process-object duality.

Introduction

Differential equations (DEs) are used for modelling a wide spectrum of problems in engineering, physics, economics, biology, medicine, social sciences. The subject is regularly taught to large cohorts of students in mathematics, physics, natural sciences, economics, and engineering. Engineering students traditionally face difficulties with the mathematics subjects, and the course in DEs is not an exception. Mastering different methods of solution is not the only goal of DEs courses – "in the end, it is not the number of tricks that the student has learned, but rather the understanding of the concepts and awareness of the relevance of the techniques, which is important – and, finally, his approach to the new learning which an encounter with a new problem may demand" (Bickley, 1964, p. 383). Rota stressed that by reducing the course difficulty and turning the subject into a "bag of tricks," we impact both students' interest in learning and learning outcomes because "a course taught as a bag of tricks is devoid of educational value" (1997, p. 9). Current educational research on DEs mainly focuses on (i) students' difficulties in understanding DEs and their solutions and (ii) methodological and pedagogical approaches in teaching and learning DEs. In this paper, we are concerned with the important notion of a general solution and teaching strategies that promote its conceptual understanding. The research question we address is: *How presentation of the concept of a general solution through the genesis of differential equations can facilitate students' learning?*

Educational research on students' conceptual understanding of a general solution

The reasons for students' confusion with the notion of "solution to a DE" are well understood.

> Consider the numerous words that are used as prefixes to the word solution – the general solution, particular solution, unique solution, superposed solution, fundamental solution, etc. According to the definition – solution to a DE is a differentiable function that satisfies the DE in some domain, any of the aforementioned would be a solution to the DE. But with the defining process pushed to the background, each of them may stand alone in students' minds. (Raychaudhuri, 2008, p. 175)

The concept of solution as a function has a much broader meaning in DEs compared to the concept of solution as a number for algebraic equations, yet equilibrium solutions to DEs are still numbers (or 'constant functions'). Raychaudhuri (2008) noticed that a small group of high achieving students

demonstrated the reliance on the general solution. When students were asked to validate a given function as a solution to a given DE, they first found the general solution and then verified that it belongs to a given one-parameter family of solutions. Raychaudhuri (2008) argued that the reliance on the generating process could be explained by students' confusion about which solution should be used in the task. If students believe that the general solution should include all solutions to a given DE, they can simply opt for finding it and using it in their reasoning. She contended that although students might have seen examples of DEs possessing solutions which cannot be obtained from the general solution, they may discard them as non-examples of the concept. Singular solutions are often difficult to find, and they are seldom discussed in modern textbooks on the subject. Existence of singular solutions is one of the reasons why the concept of a general solution is often introduced only for linear DEs. The lack of conceptual understanding of the notion of a general solution for nonlinear DEs may result in its wrong use, even for linear DEs with variable coefficients, or in no use at all.

Arslan (2010) found that "the students were successful in algebraic solutions of DEs, but not in conceptualizing DEs and the solution of DEs concepts" and "algebraic solutions of DEs can be found even without a deep understanding and conceptualization of DEs, which is why students do not feel any need to understand DEs and related concepts" (p. 887). Students ignored the presence of a constant in the general solution, substituted the general solution of one DE into the general solution of another DE, viewed it as a slope, and even as an equation of a tangent line. Arslan (2010) concluded that the most striking difficulties were related to the concept of a DE, the general solution, solution, and a particular solution of a DE. Camacho-Machín et al. (2012) reported that "students experience difficulties in identifying the different meanings of the concept of solution to a differential equation" (p. 76). Lacking conceptual understanding of solutions to DEs, students solved a DE and compared the obtained solution with a given function to verify that it satisfies the DE, cf. (Raychaudhuri, 2008). In general, students tend to concentrate attention on specific solution techniques and "often fail to relate them to other concepts or ideas" (Camacho-Machín et al., 2012, p. 76).

Assessment task

We came across students' difficulties with the understanding of the concept of the general solution in a course Mathematics for Mechatronics (MfM) for senior engineering students based on a popular textbook written by Boyce and DiPrima (2012) and taught by the second author (Hernandez-Martinez et al., 2024; Rogovchenko et al., 2020). Several nonstandard tasks were designed for a graded assessment to explore students' understanding of the Existence and Uniqueness Theorems (EUTs) and related notions. A sample problem is presented below.

Problem (a) Verify that

$$y(x) = C_1 + C_2 x^2 \qquad (1)$$

is the general solution of a DE

$$xy'' - y' = 0. \qquad (2)$$

(b) Explain why there exists no particular solution of DE (2) satisfying initial conditions $y(0) = 0$, $y'(0) = 1$.

(c) Suggest different initial conditions for this DE so that there will exist exactly one particular solution of a new initial value problem. Explain your choice.

Although the focus in this problem is primarily on the students' understanding of EUTs, we noticed that nearly all students verified that the function (1) satisfies the DE (2), but the overwhelming majority did not provide a valid reasoning to justify that (1) is the general solution (Hernandez-Martinez et al., 2024; Rogovchenko et al., 2020; Rogovchenko & Rogovchenko, 2022b; Treffert et al., 2018). Students learned that solutions to linear DEs exist and are unique on the intervals of continuity of the coefficients. Writing DE (2) in the standard form $y'' - (1/x)y' = 0,$ one concludes that solutions of this DE exist on two disjoint intervals, either for $x < 0$ or for $x > 0$. When the initial conditions are considered at $x = 0,$ the coefficient $(1/x)$ is not defined and thus there exists no particular solution of this DE satisfying initial conditions $y(0) = 0,\ y'(0) = 1$. We purposely asked students to verify that the function (1) is the general solution of (2) to create the situation when the general solution is well defined for all real values of x but initial conditions cannot be met because the coefficient in the DE (2) is discontinuous at zero and the corresponding system of linear algebraic equations for finding the constants C_1 and C_2 is inconsistent. Students correctly addressed parts (b) and (c), verified that the given function (1) satisfies the DE (2), but did not explain why (1) is the general solution.

By the definition, the general solution for a second order DE is a function of the variables x, y and two constants C_1 and C_2 containing all particular solutions of this DE. This can be established either by analysing the structure of the general solution and demonstrating that there are no particular solutions that are not contained in the two-parameter family of functions (1), or by solving the linear DE (2). The latter includes an intelligent guess of a particular solution of the DE (2), substitution reducing the order of the DE, and integration of the obtained first order DE. This technique was not studied in the MfM course; therefore, the task in part (a) became a stumbling block for students, although they possessed sufficient knowledge on linear DEs needed for answering the question.

To address students' difficulties, we analysed relevant literature finding out that Arslan (2010), Camacho-Machín et al. (2012), and Keene et al. (2011) suggested relevant problems, but only one of five problems in the cited papers contributed to the development of the conceptual understanding of the notion of the general solution engaging students into an exploration of an open-ended task (Rogovchenko & Rogovchenko, 2022a). We also posit that the course textbook discusses in sufficient detail only one approach to the notion and advocate complementing it by the definition of the general solution rooted in the genesis of DEs. We believe that the combination of these two process-oriented approaches can facilitate students' conceptual understanding of this fundamental notion.

Process-object duality in mathematics learning

Sfard (1991) argued that abstract notions "can be conceived in two fundamentally different ways: structurally - as objects, and operationally - as processes" (p. 1). Although "we have good reasons to expect that in the process of concept formation, operational conceptions would precede the structural" (p. 10), "the terms "operational" and "structural" refer to inseparable, though dramatically different, facets of the same thing. Thus, we are dealing here with duality rather than dichotomy" (p. 9). According to Sfard, the process of concept formation has three steps: interiorisation, condensation and reification. A learner first performs a process on familiar objects, then starts thinking of the process as a whole, and finally sees a familiar object as a "fully-fledged object." The last step is a rather complex phenomenon often defined as "an ontological shift, a qualitative jump" (p. 30).

In this light, one can define a general solution of a DE as a mathematical *object* (a family of functions depending on n parameters corresponding to the order of a DE and containing all particular solutions of a DE). On the other hand, a general solution can be introduced as an outcome of a *process* of solving a given DE with one of available methods and assuring that it has no other solutions not included in the obtained solution. We argue that a complementary definition of a general solution as a *process* rooted in the *genesis of DEs* can facilitate understanding of this important concept.

The concept of the general solution in the MfM course textbook

For the first time, the general solution is informally introduced in Example 1 (Boyce & DiPrima, 2012, p.11) as the expression that contains all possible solutions of a given DE. It is interpreted geometrically as "an infinite family of curves called integral curves. Each integral curve is associated with a particular value of c and is the graph of the solution corresponding to that value of c. Satisfying an initial condition amounts to identifying the integral curve that passes through the given initial point" (p. 12). This definition includes several important concepts in the Theory of Differential Equations: family of curves, an integral curve, a particular value of an arbitrary constant, an initial condition, a solution to an initial-value problem. Among all these notions, students usually focus their attention on the term '*solution*' and pay much less attention, if at all, to its combination with the terms '*particular*' and '*general*.' Most students encountered the notion of 'solution' earlier in Calculus courses whereas other notions associated with it in a DEs course were not familiar to them. According to Sfard (1991), the notion of '*solution to a differential equation*' is introduced by Boyce and DiPrima using both ways: there are examples which ask to show that a given function is a solution of a given equation (an object) and there are straightforward methods for finding solutions (a process). There is only one problem in Chapter 1 where one has to find a general solution of a very simple first-order linear DE and there are no problems asking students to verify that a given function is a general solution at all. Therefore, the explanation of how one can show that a given family of curves is a *general solution* is not provided, while there are numerous problems asking to verify that a given function is a *solution* of a given DE. This inevitably focuses students' attention on the latter notion. In Chapter 2, a first order linear DE with variable coefficients is solved and its solution, obtained as a result of integration, is explicitly named 'general' (Boyce & DiPrima, 2012, pp. 36-37). Later in this chapter the difference between the general solutions in linear and nonlinear cases is explained, and the justification for the specific use of the term "general solution" is provided.

> For a first order linear equation it is possible to obtain a solution containing one arbitrary constant, from which all possible solutions follow by specifying values for this constant. For nonlinear equations this may not be the case; even though a solution containing an arbitrary constant may be found, there may be other solutions that cannot be obtained by giving values to this constant. ... Thus, we will use the term 'general solution' only when discussing linear equations. (Boyce & DiPrima, 2012, p.74)

The discussion of the terminology for nonlinear DEs remains open because general solutions of nonlinear first order DEs were neither computed directly in examples nor suggested for solution in the exercises. Since students did not see a single example of a general solution to a nonlinear DE, they usually mistakenly associate the concept only with the linear DEs. Although the DE (2) in our assessment task is linear, students did not know how to demonstrate that the function defined by the equation (1) is its general solution. In fact, one can derive this conclusion from the basic properties

of linear DEs. Since the DE (2) is linear, any linear combination of two functions, 1 and x^2, each of which is a solution of this DE, is also a solution of the DE (2). By Theorem 4.1.2 (Boyce & DiPrima, 2012, p. 223), it suffices to check that these two functions are linearly independent and thus form the basis for the solution space for the given equation, so that (1) is the general solution of the DE (2). Linear independence can be easily verified either by the definition or by computing the Wronskian.

The concept of a general solution in terms of the genesis of DEs

A search for a good explanation for the concept of a general solution to a DE brought us to the genesis of DEs thoroughly described in a highly regarded classical book by Ince (1926), where "Dr. Ince has set a new standard for English books on differential equations" (Book review, 1934, p. 357). We also analysed the texts by Forsyth (1885) and Page (1897) that influenced Ince, as well as relevant material in widely recognised books by Boole (1859) and Johnson (1896). Although we tried to make the search as comprehensive as possible using the sources available at https://archive.org/, it is possible that some texts have been missed, especially non-English literature; however, a comprehensive search of all sources is not our focus in this paper. To the best of our knowledge, it was George Boole, an English mathematician widely known as a father of modern symbolic logic, who initiated the discussion of the genesis of DEs. He argued that even though the theory of the genesis of DEs from their primitives is to certain extent explained in treatises on Differential Calculus, there are some points of great importance "which need a distinct elucidation" (Boole, 1859, p. 8).

We explain the idea of the genesis of DEs following Page (1897). Consider an equation of the form

$$\omega(x, y, C) = 0 \qquad (3)$$

relating the variables x, y and a constant C. Differentiate (3) to obtain

$$d\omega \equiv \frac{\partial \omega}{\partial x} dx + \frac{\partial \omega}{\partial y} dy = 0. \qquad (4)$$

Elimination of the constant C after differentiation using equations (3) and (4) leads to a first order DE of the form

$$F\left(x, y, \frac{dy}{dx}\right) = 0. \qquad (5)$$

Equation (3) is called a *complete primitive* (Page, 1897) for a DE (5); it always coincides with a general solution for linear DEs. For nonlinear DEs, singular solutions not described by (3) may exist.

A similar procedure applies to equations involving two, three, or n constants (Ince, 1926, pp. 4-5). The advantage of this explanation is that one starts with a one-parameter family of functions (3) and arrives at a DE (5) satisfied by any function from the family (3). In most cases, the first order DE (5) has no solutions other than those defined by equation (3), and the meaning of a general solution becomes very clear. Boole (1859, p. 15) argued that if one applies the above procedure to a relation containing n distinct constants, there will exist only one DE of the order n which is free of constants. Johnson (1896) emphasised that "any equation containing arbitrary constants is the primitive of a certain differential equation free from these constants" (p. 6), whereas Ince (1926) pointed out the need for "certain conditions of differentiability and continuity of derivatives" (p. 11). Due to its transparency and rigour, Ince's book remained one of the main texts on DEs for over forty years until another influential text by Tenenbaum and Pollard (1963) changed the way the concept of a general

solution is taught today. Focusing attention primarily on teaching students how to use DEs, the authors "have abandoned the use of the terminology "general solution" of a differential equation unless the solution is in fact general, i.e., unless the solution actually contains every solution of the differential equation" (p. xv). This influenced the presentation of the concept in most modern textbooks on DEs and, unfortunately, led to students' difficulties rather than facilitating their understanding of a general solution.

We believe that the idea of the genesis of DEs developed in the texts by Boole (1895), Page (1897), and Ince (1926) can help to resolve the issue with the understanding of the notion of a general solution by complementing the definition of the general solution as an object with the explanation of two processes, the integration of a DE and the derivation of a DE from an algebraic equation relating the variables x, y and the constants C_1, C_2. Indeed, to prove that the function (1) in the assessment problem is a general solution of the DE (2), one differentiates (1) twice (Page, 1897, pp. 2-3) to obtain

$$y'(x) = 2C_2x, \qquad y''(x) = 2C_2. \qquad (6)$$

Replacing $2C_2$ in the first equation in (6) with $y''(x)$ from the second equation, one obtains the DE (2) which, in virtue of linearity, has no singular solutions not described by (1). This simple technique reversing the integration and differentiation not only provides an alternative argumentation that the two-parameter family of functions (1) is a general solution of the given linear DE (2) but, importantly, also applies to many nonlinear DEs. Differentiation is intensively practised in Calculus and is in most cases easier than the integration methods for DEs. In our opinion, this explanation to how a DE can result from a given equation relating x, y and n constants after differentiation and some algebraic manipulations should positively impact students' development of a concept of a general solution of a DE and facilitate learners' ontological shift to its perception as a structural object.

Conclusions

Empirical research reported by Arslan (2010), Camacho-Machín et al. (2012), Raychaudhuri (2008), and the authors (Hernandez-Martinez et al., 2024; Rogovchenko et al., 2020; Rogovchenko & Rogovchenko, 2022b; Treffert et al., 2018) points towards students' difficulties with the conceptual understanding of the notion of a general solution of DE. Assessment tasks may test differentiation skills without contributing to students' conceptual understanding of this notion (Rogovchenko & Rogovchenko, 2022a). The course textbook (Boyce & DiPrima, 2012) and most contemporary texts on the subject do not emphasise the importance of the general solution for DEs other than linear, and students often associate it only with this class of DEs.

We explored how the presentation of the concept evolved in influential textbooks published from the late nineteenth century and came across lucid and rigorous explanations in classical texts by Boole (1859), Page (1897), and Ince (1926). In Calculus courses, solutions to DEs are introduced primarily for the illustration of the differentiation and integration techniques. Therefore, students first approach the notion of a general solution as a *process* (Sfard, 1991). On the other hand, in DE courses, presentation of the notion of the general solution for nonlinear DEs as an *object* receives very little attention, if at all, with the focus shifted to linear DEs. We argue that students can better understand the concept of the general solution if it is based on the genesis of differential equations from equations relating two variables, x and y, and n distinct constants. When students are first presented with an explicit description of a family of solutions containing all solutions (there is no need to verify this)

and then see a DE derived by the repeated differentiation of the original equation and algebraic elimination of all constants, they may better understand the concept. Students know from Calculus that the differentiation of a given equation is technically not as complex as the integration of a DE. Following the idea of the genesis of DEs, students can get a better grip of the concept of a general solution, especially for nonlinear DEs. This approach to the design of conceptual tools for understanding a general solution addresses the claim that

> Teachers at all grade levels tend to view mathematics in terms of "subject matter" (e.g., definitions, theorems, proofs, problems and their solutions), not in terms of the conceptual tools that are necessary to construct such mathematical objects, and that cognitively, pedagogically, and epistemologically both categories are needed. (Harel, 2008, pp. 268-269)

This paper is the first step towards the design of what we believe should become a more effective pedagogy facilitating students' learning and understanding of the concept of a general solution of a DE which we plan to test both in a standard and advanced courses on DEs.

"How should we solve it?" and "How should we write it down?" Two tacit hurdles in university mathematics discourse

Miriam N. Wallach[1] and Igor' Kontorovich[2]

Learning tertiary mathematics requires students not only to develop new ways to solve mathematical problems but also to communicate their solutions. In this conceptual paper, we use the commognitive framework to construe problem solving as a discursive activity whose metarules are inseparable from the situation and the community within which it unfolds. Then, we distinguish between the processes students go through when generating a solution for themselves (i.e. the solvers' community) and the conventionalization of this solution to make it sharable with a broader community. This distinction raises the question of how solution generation and conventionalization are taught and learned. As a first step towards this question, we present a vignette from student-centred first-semester tutorial in linear algebra. Our analysis delineates didactical routines the instructor implemented to support her students during problem solving in tertiary mathematics.

Keywords: Problem solving, instructional interactions, commognition, linear algebra.

Introduction and research background

The challenges of learning tertiary mathematics have been explored broadly and widely (e.g., Winsløw et al., 2018). Our interest lies with the challenges of problem solving. To justify this interest, let us quote Halmos (1980), who wrote, "what mathematics really consists of is problems and solutions" (p. 519). Similarly, the final report of the Higher Education Curriculum Summit claims, "problem-solving is the most useful skill a student can take with them when they leave university" (Rowlett, 2011, p. 19). A complementary justification is more pragmatic: in the tertiary setting, students' learning of mathematics is mostly occasioned through problems and evaluated through (usually written) solutions students submit for assessment by course instructors. Thus comes the question – how is problem solving learned and taught in tertiary mathematics.

Problem solving processes include linking tentative solutions with a problem situation and appropriate resources (Selden & Selden, 2013). In a classroom, the instructor determines if a tentative solution is acceptable, and this changes according to the level of mathematical rigor required (Stylianides, 2007). Thus, what is an acceptable solution is dependent on the context –the audience, the setting, and the constructed socio-mathematical norms.

Communication of the solution can unfold in different media, including oral and written. Some studies (e.g., Fukawa-Connelly et al., 2017) suggest that oral communication includes mostly informal mathematical content, while written communication is often formal and symbolic. The conversion process from the informal argumentation to a formal written one can be a challenge for undergraduate students, with some of the difficulty stemming from knowing what is acceptable (Selden & Selden, 2013). While a search for literature regarding learning and teaching problem solving yields fewer contemporary publications than may be expected (e.g., Badger et al., 2012),

relevant insights can be borrowed from prolific research on the didactics of proof. Indeed, close relationships between proving and problem solving have been acknowledged (Selden & Selden, 2013). This relationship stems from problem solving generally referring to solving "non-routine" problems necessitating proving (e.g., Selden & Selden, 2013), from considering a proof as a solution to a problem (e.g., Badger et. al., 2012), and from the alignment of the challenges of communicating a solution with the challenges of communicating a proof (e.g., Weber, 2008).

Part of proof research attends to the social process of sanctioning an argument as a proof, foregrounding the key role of communication and audience (e.g., Weber, 2008). For instance, Harel and Sowder (1998) distinguish between the processes where a prover ascertains the validity of a mathematical statement for themselves and where they persuade others in its validity. Famously, Mason et al. (1982) construe proving as an act of convincing not only a friend but also an enemy. Another insight highlights the contextuality of proof. As a process that solves a problem, a proof can be viewed as an event that occurs in a specific time and place (e.g., Goguen, 2001).

The above findings can be complemented by insights from broader problem solving literature. One regards students' challenges with learning to solve non-routine problems, as opposed to exercises that mimic previously demonstrated worked examples (e.g., Selden & Selden, 2013). The literature also points out the difficulties of teaching to solve problems systematically (e.g., Badger et al., 2012). Our aim is to introduce a conceptualization of problem solving that foregrounds some implicit hurdles that students navigate when learning to solve problems in tertiary mathematics. The conceptualization is grounded in the commognitive framework. We put the conceptualization into action in a vignette to cast light on how instructors can respond to students' requests for help with these hurdles.

Commognitive foundations

Commognition is a socio-cultural framework that has been broadly used to make sense of instructional interactions in tertiary mathematics (e.g., Kontorovich et al., 2024). The framework views learning as a process through which learners develop and refine their participation in the target *discourse* to become agentive participants in the corresponding *discourse community* (Sfard, 2008). The framework construes university mathematics as a discourse with characteristic *metarules* that define "patterns in the activity of the discursants" (Sfard, 2008, p. 299).

Language transforms discourses into multilayered structures, enabling discursants to communicate about anything, including the discourse itself. Accordingly, discourse components (e.g., metarules) can be not only enacted implicitly but also articulated, becoming an explicit object of communication (Sfard, 2008). For instance, Kontorovich et al. (2024) explore how metarules of proof can be discussed in a classroom. The researchers contend that ascending to the meta-discursive layer is potentially useful for instructors to spell out how the target discourse compares to what students are accustomed to and for students to specify their challenges with the yet-to-be-familiar realm.

Lavie et al. (2019) position *routines* as a commognitive unit of analysis. Routines are viewed as <*task*, *procedure*>-pairs, where the latter are implemented to achieve the former. Routines are context-sensitive since they are performed in *task situations*. These are defined as "any setting in which a person considers herself bound to act—to do something" (Lavie et al., 2019, p. 159). Sfard (2023)

differentiates between two types of routines. *Algorithmic* routines involve procedures with a well-defined sequence of steps and yield an expected sort of outcome (e.g., solving a quadratic equation). *Heuristics* encompass non-deterministic procedures that "do not specify the basic steps in a unique way. [They] increase chances for a successful performance […] but they do not ensure it" (Sfard, 2023, p. 4). Sfard (2023) contends that most instructional routines are of the second type. Sfard (2023) notes that routines, when taken together, constitute a tightly interconnected *network*. One example of interconnections stems from routines coming in different sizes: from 'extra-large' to 'atomic,' whereas 'smaller' routines serve as building blocks for the 'larger' ones. In this way, routine networks are recursive and have "a fractal-like nature [that] finds its expression in the fact that when you repeatedly zoom into this network, you discover ever new, smaller routines" (Sfard, 2023, p. 5).

Before considering problem solving through the commognitive lens, let us acknowledge that we are not the first to do so. Using the framework, Koichu (2019) conceptualizes problem solving in mathematics instruction as "a socio-culturally shaped process of not-immediate achieving a chosen or imposed goal, in which the involved individuals enact, through private or public exploratory discourse, individual or shared resources that they interpreted, even for a short while, as appropriate for achieving the goal" (p. 7). Koichu builds his conceptualization on cognitive research as well, and acknowledges that "being a discursively oriented, [the conceptualization] is not fully compatible with the 'strong' discursive perspective" (p. 61). We attempt to offer a more compatible version next.

Solution generation and conventionalization in problem-solving task situations

Problem solving can be commognitively construed as a discursive activity that unfolds in a certain task situation where an individual or a group draw on routine networks to produce a *solution*. We borrow Koichu's (2019) definition of solution as "a public narrative, which becomes endorsed, by the problem solvers or the problem proposers, as the one that achieves the goal" (p. 49) or 'a task' in commognitive terms. Consistently, we distinguish between two tasks of problem solving. One is to generate a narrative that the solvers consider as solution to the problem. The other task is to modify this narrative so that the problem proposers consider it a solution as well. That is, the proposed solution must adhere to the conventions of a target discourse community. Modifying an initial *solution-narrative* can go beyond merely "writing it down" and using appropriate notation. Mathematical solutions are comprised of both content and form (Byers & Erlwanger, 1984), which are barely distinguishable from the discursive viewpoint.

The construct of task situation in our conceptualization foregrounds the contextual circumstances of an initial problem-solving task (e.g., Goguen, 2001), since they shape the expectations from the solution-narrative. In tertiary mathematics, course instructors, i.e. the discourse experts, are often the ones to set up mathematical problems for students, discourse newcomers. Then, almost by definition, the proposers and the solvers are not partaking in the same discourse, at least initially. This often results in qualitative differences in metarules each cohort follows to endorse the solution-narratives. University students are not oblivious to this gap. Indeed, variations of "Can I say that on an exam?" and "I know how to solve it, but how can I write this down?" are common in many classrooms.

We propose that, in problem-solving task situations, subjecting the solution-narrative to the metarules of a conventional discourse, in which students are not yet fully versed, can become a sub-task that

students choose to pursue (cf. Koichu, 2019). We introduce the notions of *solution generation* (SG) and *solution conventionalization* (SC) to account for this phenomenon.

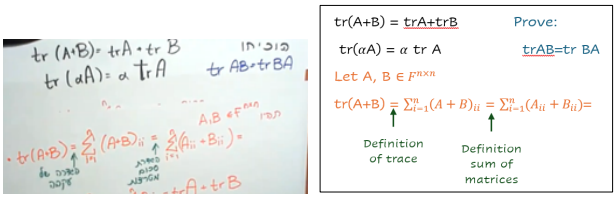
With SG, we refer to the set of routines students can implement to bring a solution-narrative into existence. This can involve reformulating the problem, making a sketch, and many other variations of what Pólya (1945) and his followers termed as heuristic strategies. Other algorithmic routines, such as equation solving, can also serve SG purposes. The overall task of SG is for students to transition from an initial task situation where the solution-narrative is conspicuous in its absence to one where the endorsability of some narrative can be considered by the solvers' community.

In some cases, the initially generated solution-narratives can be shared with a broader community as they are, or with minimal changes. In other cases, these narratives need to undergo substantial transformations to align with the metarules of conventional discourse of tertiary mathematics and be endorsed as problem solutions. We use SC to refer to the set of routines the solving students can implement to make these transformations, where the task of SC is to modify the existing solution so that it aligns with the conventions of the setting. These routines can involve switching from the oral to the written medium, which often involves formalization, symbolization, restructuring, adding explanations, and removing redundancies and extraneous steps (Morgan, 2002). These transformations are necessary to make the written solution-narrative be able to 'stand-alone' and to be shareable with a broader community. This conversion process is not necessarily linear as it can involve multiple attempts and cycles (cf. "rewriting drafts" in Vroom & Ellis, 2024).

SG and SC are differentiated by their task, output, and intended audience. At a first glance, it may appear that SG precedes SC since outcomes of the former can be expected to serve as inputs to the latter. Yet, it would be naïve to propose that the network of problem solving routines can be neatly divided into two separate regions. Indeed, the cyclical nature of problem solving has been widely acknowledged (e.g., Koichu, 2019; Selden & Selden, 2013). Then, SC can reveal issues and drawbacks in the initially endorsed solution-narrative, requiring the solvers to go back to the SG drawing board. Furthermore, some routines can have both generational and conventionalization purposes. Thus, it may be more accurate to consider SG and SC as affordances of implementing a certain routine in a specific task situation, rather than associate this routine with a particular type exclusively.

The presented conceptualization aims to provide better understanding of the complexity of students' challenges with problem solving in tertiary mathematics. This conceptualization enables us to ask how SG and SC are taught and learned. This empirical question is at the heart of our broader research agenda. We next present a vignette to make a first empirical step in this direction. It focuses on didactical heuristics that instructors implement to support their students in the development of SG and SC.

Illustrative vignette of teaching SG and SC



The vignette comes from a course in linear algebra taken by first-year students majoring in mathematics and computer science. The data corpus encompasses video recordings of interactive tutorials, held on an online platform due to Covid-19. The protagonists are six students and Ann

(pseudonym), an experienced instructor who received numerous awards for teaching excellence. We also collected Ann's informal reflections on selected tutorials and consulted with her in the analysis.

The sessions were held twice a week throughout the semester. In the sessions, all students had their cameras and microphones open. Ann used an external camera to project her writing for all students to see. Each session started with students' questions about the homework problems for that week. The students chose homework problems to discuss and shared their preliminary solution ideas.

We reviewed the recordings in a search for episodes where the discussions regarded SG and SC. In most of these episodes, the students sought Ann's help with either SG or SC. Then, our analysis was driven by the question, "*What (didactical) heuristics did Ann implement to assist her students with SG and SC?*" We chose the particular vignette due to the type of help the students sought and Ann's responses to these requests.

This vignette comes from the 8th tutorial (out of 25), whose topic was matrices. It began with proving the properties of the trace of a matrix using formal definitions (see Figures 1a and 1b).

Figures 1a (left) and its translation 1b (right): Screenshot previous to discussion below

After this, Gary asked to discuss the following problem from the homework assignment.

Problem: Given $A, B \in F^{n\times n}$, prove tr(AB)=tr(BA).

11	Gary:	I mostly got stuck with sigmas to prove it, I do not know how that will help.
12	Ann:	Let's try to write, OK? I write trace of AB [writes: "tr(AB)="]. Without justifications, OK? Start writing, OK? What's the trace of AB?
13	Zach:	sigma A B i i
14	Ann:	[writes: $\sum^{n}{}_{i=1}\,(AB)_{ii}$] And now, Gary, now what will be the next step?
15	Gary:	[Pause] I don't know. That's exactly where I got stuck.
16	Ann:	So, what is "*i i*" of AB, according to the definition? […] If I tell you that you have two matrices A B, what is *ii* of AB? [2 second pause] How do we find that element? How do you find the *ij* element of matrix multiplication?
17	Gary:	But isn't it dependent on other elements? That is exactly what I tried to see.
18	Ann:	[Writes $(AB)_{ij}$=] So, what is the *ij*-th element of AB according to the definition? Do you remember that?
19	Gary:	The product of the row times the product of the column.
20	Ann:	Correct. And how do we write that in a formal manner? [Pause]
21	Roy:	Sigma
22	Gary:	Sigma A_{ij} times B_{ji} [Ann writes $\sum_k A_{ik}B_{kj}$.]
24	Gary:	Yes. Exactly!
25	Ann:	This is the definition. This [outlining what is on board] is the definition of the *ij* element of matrix multiplication. It's a row times a column. But when we say row times column […]OK? This is the row of A [pointing] times the column of B [pointing] but this [what is written] is the formal definition. So, if we want the *ii* element, we will simply take the formula that is here. […].

The vignette opens with Gary self-reporting that he "got stuck" with the focal problem (see [11]), which we associate with an implicit request for help with SG. (Conceivably, he also needed assistance with SC, yet it seems unlikely that conventionalization concerned him while struggling to produce a solution.) The post-tutorial conversation with Ann suggested that her (didactical) heuristic for getting Gary "unstuck" (task) involved the gradual development of the formulas for $(AB)_{ii}$ and $(BA)_{ii}$ to show their equality (procedure). This is consistent with how Ann led the interaction (e.g., [12], [14]).

We note that Ann's heuristic involves the sigma notation and requires paying close attention to the multiple indexes involved in matrix multiplication. The use of formal definitions and notation is inseparable from SC. In other words, within this heuristic, the generation of a solution heavily relies on systematic implementation of routines with evident conventionalization affordances. For instance, consider [19-20], where Ann nudges Gary to "write in a formal manner" that an element of the product matrix is "the product of the row times the product of the column."

Two characteristics of how Ann implemented her routine are noteworthy. The first one pertains to its implicitness. True, on several occasions, we see Ann making explicit calls to write things down (e.g., [12]) and to use definitions (e.g., [16], [18]). Yet, we view these calls as meta-level utterances preparing the students for her next move, whereas the overall approach, suggesting that the road to SG involves routines with substantial conventionalization affordances, remains mostly unarticulated.

The second characteristic highlights Ann's recurrent attempts to build on Gary's contributions and open space for them. This is evident when Gary remarks that he "got stuck with sigmas" and Ann instantly nudges him to "start writing" them down (see [12]). We view this instructional move as a proposal of an atomic problem-solving routine that closely relates to Gary's one. The exchange also contains several instances where Ann requests Gary to perform a specific routine and then revises her request once she realizes Gary struggles to do so. For instance, in [14-16], she replaces the initial request to unpack $\sum_i (AB)_{ii}$ with the questions "what is *ii* of AB?" and "How do you find the *ij* element of matrix multiplication?" Later, when Gary refers to the *ij* element as "the product of the row times the product of the column," Ann endorses his statement before converting it into the formal $\sum_k A_{ik}B_{kj}$ (see [19-20] and [23]). Overall, these repeated connections and modifications provide opportunities for Gary to contribute to the generation of the solution-narrative that Ann led.

In another interaction, Ann both encourages students to make mathematical contributions to the interaction and explicates the value of SC. She encourages using conventional solution forms for generating different mathematical narratives that are potentially useful to solve a range of problems. In answer to Roy's question, "Do I have to do this move in order to get to the final answer?", Ann responds, "Not for a final answer…on a test or something, but for yourself it's worth it." This is consistent with her task of convincing him that the mathematics community holds on to its conventions not for sheer ritualistic reasons. This is one way in which Ann appears to bring the metarules of Roy's personal discourse closer to the more conventional ones.

Summary and concluding remarks

While learning tertiary mathematics has been studied broadly and widely, we argue that limited attention has been paid so far to students' challenges with problem solving. Coming from the

commognitive standpoint, we construed problem solving as a discursive activity, in which students find themselves in certain task situations. These require them to produce a shareable solution-narrative that will be endorsed by them as solvers and by a broader community of tertiary mathematics discourse, including instructors as the discourse experts. Consistently, we distinguished between routines students implement to bring a solution-narrative into being (SG) and those aimed at aligning the narrative with conventional metarules (SC).

Informed by Koichu (2019), our aim was to propose a conceptualization that is grounded in the discursive perspective on learning (Sfard, 2008). Operationally speaking, one key difference between Koichu's and our proposal regards the interdiscursive gap that we highlight between the community of solvers and a broader discourse community. As a result, the two communities are likely to subject solution-narratives to different metarules. One can argue that it is only natural to expect the solvers to account for the viewpoint of other people (cf. Harel & Sowder, 1998; Mason et al., 1982). Yet, let us recall that students are often newcomers to the discourse of tertiary mathematics, which makes them not yet familiar with the discourse conventions and norms. This interpretation can be viewed as a problem-solving version of the renowned learning paradox (cf. Sfard, 2008).

Research contends that systematic teaching of problem solving can be challenging (Badger et. al., 2012). This is somewhat consistent with the vignettes that we analyzed to learn about the instructor's teaching of SG and SC. In these, the students asked for assistance with either SG or SC, but the instructor did not confine herself to the requested realm. This suggests that SG and SC can be more intertwined in the problem-solving network of a versed discourse participant than newcomers imagine. The analysis also showed that, while implementing different didactical heuristics with a different degree of explicitness, the instructor mobilized both SG and SC to usher her students into the discourse of tertiary mathematics. With this modest first step, we hope to stimulate further research into how SG and SC are taught and learned in tertiary mathematics.

An inquiry-oriented approach to least squares in linear algebra

Megan Wawro[1], Michelle Zandieh[2] and Zachary Bettersworth[3]

[1]Virginia Tech, Department of Mathematics, Blacksburg, VA, USA; mwawro@vt.edu

[2]Arizona State University, Tempe, AZ, USA

[3]Western Kentucky University, Bowling Green, KY, USA

In this paper, we present a research-based task sequence for an inquiry-oriented approach to least squares for introductory linear algebra. The main goal of the task sequence is to engage students in the guided reinvention (Freudenthal, 1991) of the least squares equation and to help students understand why that equation is relevant to solving the least squares problem. The tasks can also introduce vector length, orthogonality, and projection. In this paper, we detail our approach to design research, summarize the task sequence, and share examples of student work.

Keywords: Linear algebra, least squares, inquiry, curriculum design.

Introduction

Introductory linear algebra courses frequently include the topic of least squares approximation. When $A\boldsymbol{x} = \boldsymbol{b}$ has no solution, the set of least squares solutions to $A\boldsymbol{x} = \boldsymbol{b}$ are the vector(s) $\widehat{\boldsymbol{x}}$ that are solution(s) to $A^TA\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$. One interpretation of the $\widehat{\boldsymbol{x}}$ is that they make $A\widehat{\boldsymbol{x}}$ as close as possible to $\boldsymbol{b}$, which is consistent with a subspace orientation to the problem (i.e., finding the best approximation in a subspace to a vector not in the subspace). How might instructors help students come to develop and understand the equation $A^TA\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$ and how it is relevant to solving the least squares problem?

This study is part of the Inquiry-Oriented Linear Algebra (IOLA) project (Wawro et al., 2013), which creates research-based curricular materials for the guided reinvention of core concepts within an inquiry-oriented linear algebra class. This design research is driven by making sense of student thinking and the complexity of mathematical ideas, which informs the refinement of the curricular materials. In this paper, we present a research-based task sequence for the guided reinvention of the least squares equation $A^TA\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$. The tasks can also introduce vector length, orthogonality, and projection. In the results section, we summarize the tasks and share examples of student work.

Theoretical Framing and Literature

Our instructional design work is based in Freudenthal's philosophy of mathematics as a human activity (1991) and the design principles that emerged from his work in Realistic Mathematics Education (RME) (Gravemeijer, 1999). RME design principles include didactical phenomenology, emergent models, and guided reinvention. Didactical phenomenology says "an instructional sequence meant to support the learning of a piece of mathematics should be situated in a context that can be productively organized by students using that piece of mathematics" (Larsen, 2018, p. 25), where 'organize' means to mathematize or make mathematical. The emergent models heuristic describes students' progression from an initial, intuitive understanding to a more formal and mathematized organization of the phenomena (Gravemeijer, 1999). Through engagement in a task sequence over several days, students progress from creating a model of the initial situation through activity, referring

back to this setting while extending, generalizing beyond the initial task setting, and using their new model in future activity by applying it in more formal, mathematically deductive ways towards exploring new phenomena. Finally, the guided reinvention heuristic is a mechanism for students' reinvention of mathematical ideas guided by the task sequence and instructor interactions. The result of this interconnected progression for the student is a new mathematical reality of interwoven mathematical objects and relations. More detail about our use of RME is given in Wawro et al. (2022).

Our instructional design theory also centralizes inquiry-oriented instruction (IOI) (Kuster et al., 2018) to guide student engagement in meaningful mathematics and student collaboration for sensemaking (Laursen & Rasmussen, 2019). IOI also relies on the foundational importance of instructors inquiring into students' mathematics as the instructor generates and builds on student reasoning, helps develops a shared understanding among all students, and formalizes language and notation (Kuster et al., 2018).

In our review of the literature, we found very few empirical studies related to the learning and teaching of least squares in linear algebra. Talbert (2014) presents findings that in an inverted linear algebra lesson (students watching videos outside of class that present material and working on examples in class), students performed well on the final exam solving an application problem using the normal equation $A^T A\hat{\boldsymbol{x}} = A^T \boldsymbol{b}$. Turgut (2013) presents resources designed to teach least squares using Mathematica. The lecture uses commands in Mathematica to plot dots, form matrices from points, transpose matrices, and take matrix inverses all in service of finding the line of best fit through a data set of points. Related to the teaching and learning of least squares is dot product. Donevska-Todorova (2015) identified three dot product definitions aligned with three modes of description (arithmetic, geometric, and abstract-axiomatic) and created an applet to promote students' geometric understanding of the dot product. Dray and Manogue (2006) found projection to be essential in understanding dot product, with the geometric approach benefiting physics and engineering students. In Wawro et al. (2023), we reported on students' use of literal symbols and equations when solving self-generated least squares problems based on the task sequence. We found students used unknowns and parameters in a variety of ways, and we highlighted how their use of dot product equations can be helpful towards supporting their understanding of the least squares equation.

Methods

Our methodological approach for this study was the Design Research Spiral (Wawro et al., 2022), which is composed of five phases: Design, Paired Teaching Experiment, Classroom Teaching Experiment, Online Working Group, and Web (see Figure 1), with revisions occurring between each phase as needed based on ongoing analyses of student thinking. In the Design Phase, we create a first draft of the task sequence. This is influenced by our conceptual analysis of relevant mathematics, our practice- and research-based knowledge of student reasoning in linear algebra, RME, and IOI. In the second phase, we use an adaptation of the paired teaching experiment methodology (Steffe & Thompson, 2000) to investigate pairs of students' interactions with these early task iterations. We use the students' mathematical reasoning during the interviews to inform revisions of the task sequence and instructional implementations. In phase three, we conduct a classroom teaching experiment (Cobb, 2000) to use the task sequence in a research team member's intact classroom setting. During implementation, the teacher-researcher responds to student thinking and revises the task sequence as

needed. These ad hoc preliminary analyses inform further task sequence revisions as well as the instructor implementation notes. In phase four, we work with participating instructors outside of our universities to test the task sequence in their own intact classrooms. We use online working groups (Fortune & Keene, 2021) with modified lesson study to understand instructors' implementation experiences and provide opportunities for reflection and collaboration among instructors. Our goals during this phase are to obtain feedback on tasks, formatting, and sequencing; we also learn how the task sequence played out in various classrooms with various student populations. These insights inform the development and refinement of instructor notes and the tasks themselves. During the Web phase, we add the finalized version of the task sequence and accompanying instructor support to the project website, which facilitates instructors using or adapting the materials for their own class. The task sequence shared in this paper has completed the first four phases of the design research spiral.

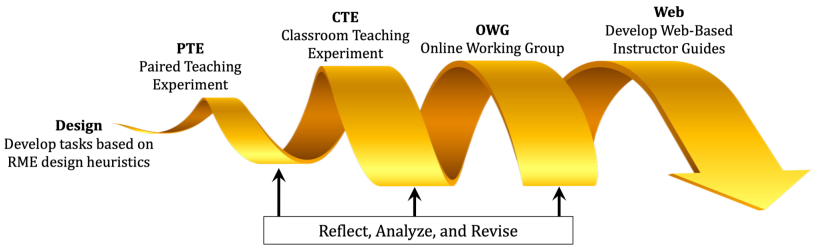

Figure 1: Model of the Design Research Spiral (Wawro et al., 2022)

The examples of student thinking shared in this paper come from a classroom teaching experiment that occurred in an in-person introductory linear algebra class at a large, public, research university in the Mid-Atlantic US in 2022. The course prerequisite was a passing grade in introductory calculus courses on differentiation, integration, sequences, and series. Most of the 27 students were second-year by credit hours and were general engineering majors. The data examples come from students' in-class work or written reflections (short after-class questions graded on effort not correctness).

The Least Squares Task Sequence

The main goals of this task sequence are to engage students in the guided reinvention of the least squares equation $A^TA\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$ and to help students understand why that equation is relevant to solving the least squares problem. In Task 1, students try to use three travel vectors in $\mathbb{R}^3$ to get to Gauss to deliver his mail but learn it is not possible. In Task 2, students find locations that they can get to with the travel vectors and determine the distances of those locations from home and from Gauss. In Task 3, students find the location that they can get to that is closest to Gauss and then use a drone to deliver his mail. They determine the location (which will be called $\boldsymbol{p}$), how to get there (called $\hat{\boldsymbol{x}}$), along what vector the drone travels (called $\boldsymbol{e}$), and the length of the drone's trip (which is $\|\boldsymbol{e}\|$). In Task 4, students combine key equations developed during Task 3 to create one general equation to determine $\hat{\boldsymbol{x}}$ no matter what A and $\boldsymbol{b}$ are, which culminates in the equation $A^TA\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$.

Task 1: Delivering Mail to Gauss

The main goal of Task 1 (see Figure 2) is for students to determine if Gauss can be reached using the given travel vectors. It is intended as a review of prior content. Through Task 1, students refresh and solidify their understanding of the equivalence of all linear combinations of a set of vectors, the span

of that set, and a geometric space of all locations that can be reached by that set. They determine that $\boldsymbol{b}$ (the vector denoting Gauss's location) is not a linear combination of $\{\boldsymbol{v}_1, \boldsymbol{v}_2, \boldsymbol{v}_3\}$ (the vectors denoting the modes of transportation), that $\{\boldsymbol{v}_1, \boldsymbol{v}_2, \boldsymbol{v}_3\}$ is linearly dependent and spans a plane in $\mathbb{R}^3$, and $\boldsymbol{b} \notin span\{\boldsymbol{v}_1, \boldsymbol{v}_2, \boldsymbol{v}_3\}$; thus, they cannot get to Gauss (see Figure 3 for examples of student work).

You've got some mail you need to give to Old Man Gauss, who now lives at $\boldsymbol{b} = \begin{bmatrix} -1 \\ 1 \\ 4 \end{bmatrix}$.

You have the same modes of transportation you had before for travel in $\mathbb{R}^3$: $\boldsymbol{v}_1 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$, $\boldsymbol{v}_2 = \begin{bmatrix} 6 \\ 3 \\ 8 \end{bmatrix}$, $\boldsymbol{v}_3 = \begin{bmatrix} 4 \\ 1 \\ 6 \end{bmatrix}$.

TASK 1: Using the modes of transportation, can you get to Gauss to hand-deliver his mail?

- If you *can* get to Gauss using these modes of transportation, say how many hours (in forward or reverse) to use each mode.
- If you *cannot* get to Gauss using these modes of transportation, explain why not.

Use your group's whiteboard space to communicate your work and your conclusion. Also try your best to include a graphical interpretation of the situation.

Figure 2: Task 1 - Delivering mail to Gauss

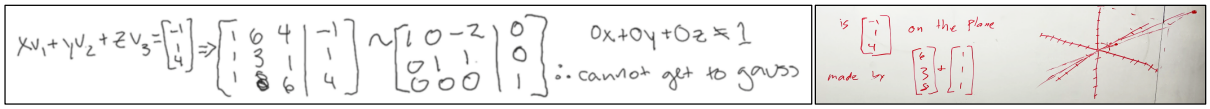

Figure 3: Examples of student work for Task 1

Our rationale for creating this task was to allow students to leverage not only understandings they developed earlier in the course, but also a familiar scenario for the situational activity, an aspect of RME design heuristics. The travel vectors $\{\boldsymbol{v}_1, \boldsymbol{v}_2, \boldsymbol{v}_3\}$ appear in the IOLA "Magic Carpet Ride" task sequence (Wawro et al., 2012), so knowing they are linearly dependent and span a plane is familiar; the new situation is reasoning about and making geometric sense of $x\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + y\begin{bmatrix} 6 \\ 3 \\ 8 \end{bmatrix} + z\begin{bmatrix} 4 \\ 1 \\ 6 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 4 \end{bmatrix}$ having no solution. Tasks 2-3 use only $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$, but starting with a linearly dependent set is useful because it sets up exploring least squares problems for linearly independent and dependent sets in Task 4.

Task 2: Getting Close to Gauss

The main goal of Task 2 (see Figure 4) is to leverage students' experience with distance between points and the distance formula as they explore the length of vectors and the distance between vectors, both in the travel scenario and in general. In Task 2, students explore that different locations on the plane (created by the span of $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$) are farther or closer to a fixed location off the plane (Gauss, denoted $\boldsymbol{b}$), so it serves as a good foundation before students are asked in Task 3 to find the closest location on the plane to Gauss. As they work on Task 2, some students may know the distance formula from other math courses. An instructor can leverage these student contributions to help formalize with the class that: the length of a vector $\boldsymbol{u}$ in $\mathbb{R}^3$ can be thought of as the distance between the origin and the point defined by the tip of the vector, namely $\|\boldsymbol{u}\| = \sqrt{(u_1 - 0)^2 + (u_2 - 0)^2 + (u_3 - 0)^2} = \sqrt{u_1^2 + u_2^2 + u_3^2}$; the free vector $\boldsymbol{w}$ in $\mathbb{R}^3$ that connects the tips of two fixed vectors $\boldsymbol{u}$ and $\boldsymbol{y}$ can be determined by creating the difference vector $\boldsymbol{w} = \boldsymbol{u} - \boldsymbol{y}$; and the length of $\boldsymbol{w}$ can be calculated as the distance between $\boldsymbol{u}$ and $\boldsymbol{y}$, i.e., $\|\boldsymbol{w}\| = \|\boldsymbol{u} - \boldsymbol{y}\| = \sqrt{(u_1 - y_1)^2 + (u_2 - \mathrm{y})^2 + (u_3 - y_3)^2}$. Students should be encouraged to also model the situation geometrically and to begin build a sense of how changing the location of a point on the plane changes the distance between this point and Gauss.

You've got some mail you need to give to Old Man Gauss, who now lives at $\boldsymbol{b} = \begin{bmatrix} -1 \\ 1 \\ 4 \end{bmatrix}$.

You have the same modes of transportation you had before for travel in $\mathbb{R}^3$: $\boldsymbol{v}_1 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$, $\boldsymbol{v}_2 = \begin{bmatrix} 6 \\ 3 \\ 8 \end{bmatrix}$, $\boldsymbol{v}_3 = \begin{bmatrix} 4 \\ 1 \\ 6 \end{bmatrix}$.

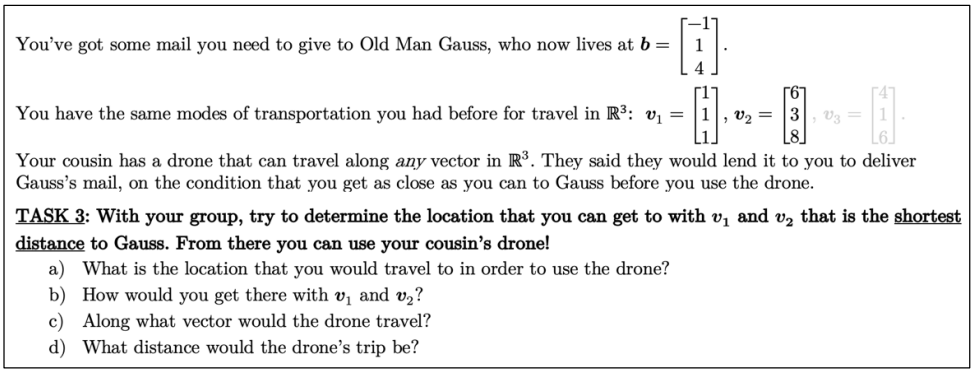
We figured out in Task 1 that you can't get to Gauss to hand-deliver his mail.
We also determined that $span\{\boldsymbol{v}_1, \boldsymbol{v}_2, \boldsymbol{v}_3\}$ is a plane in $\mathbb{R}^3$.
Thus, $\boldsymbol{v}_3$ does not help you get anywhere that you couldn't reach by using just $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$.

TASK 2: With your group, pick a location that you *can* get to with $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$.

- Say how you would get there. In other words, say how many hours in forward and reverse you need to use the modes of transformation $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ to get to your chosen location.
- Determine how far the location you chose is from where you are starting (the origin)
- Try to determine how far the location you chose is from Gauss.

Use your group's whiteboard space to communicate your work and your conclusion. Also try your best to include a graphical interpretation of the situation.

Figure 4: Task 2 - Getting close to Gauss



Task 3: Delivering Mail to Gauss with a drone

In Task 2, students determined that the locations they can get to with travel vectors $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ lie on a plane and have different distances to Gauss. In Task 3 (see Figure 5), students determine which location on that plane is *closest* to Gauss so that they can send a drone to Gauss from there. We designed the four questions in Task 3 to bring out four of the main unknown variables in the important relationships at play in least squares approximation. Question (a) asks where you should go to use the drone, the location on the plane closest to Gauss. We encourage instructors to call this location vector $\boldsymbol{p}$ so that they can later tag $\boldsymbol{p}$ as the projection of $\boldsymbol{b}$ onto the plane, if they so wish. Question (b) asks how to get to $\boldsymbol{p}$ with $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$, meaning the scalar values x_1 and x_2 in $x_1\boldsymbol{v}_1 + x_2\boldsymbol{v}_2 = \boldsymbol{p}$. Students will later recognize x_1 and x_2 as the components of $\hat{\boldsymbol{x}}$, the solution to the least squares problem. Question (c) asks for the vector along which the drone should travel. We suggest instructors call this vector $\boldsymbol{e}$ to be consistent with its conventional name, the error vector, if instructors choose to call it that after Task 4. We created the overall problem to be about travel from the plane to Gauss, so the situation matches the vector equation $\boldsymbol{p} + \boldsymbol{e} = \boldsymbol{b}$. Finally, question (d) asks for the distance of the drone's trip, which is $\|\boldsymbol{e}\|$, which could later be labeled in Task 4 as the least squares error.

We recommend students first discuss the main Task 3 prompt in small groups to share any initial thoughts they have about where the location closest to Gauss would be. The purpose is for students to have a chance to suggest that the vector that is *orthogonal* or *perpendicular* to their travel plane will be the one that is the closest to Gauss. In whole class discussion, the instructor can then leverage that intuition to establish that if $\boldsymbol{e}$ is orthogonal to the plane, then $\boldsymbol{e}$ is also orthogonal to $\boldsymbol{v}_1$, $\boldsymbol{v}_2$, and $\boldsymbol{p}$. This is a good time for the class to establish a connection with dot product, that orthogonality implies $\boldsymbol{v}_1 \cdot \boldsymbol{e} = 0$, $\boldsymbol{v}_2 \cdot \boldsymbol{e} = 0$, and $\boldsymbol{p} \cdot \boldsymbol{e} = 0$. The relationships needed to complete Task 3 are now in place for students to work in their small groups to solve for $\boldsymbol{p}$, x_1 and x_2, $\boldsymbol{e}$, and $\|\boldsymbol{e}\|$ (the answers to questions (a)-(d), respectively). These relationships appear in the equations $x_1\boldsymbol{v}_1 + x_2\boldsymbol{v}_2 = \boldsymbol{p}$ (or $A\boldsymbol{x} = \boldsymbol{p}$ for matrix A with columns $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$), $\boldsymbol{p} + \boldsymbol{e} = \boldsymbol{b}$, $\boldsymbol{v}_1 \cdot \boldsymbol{e} = 0$, $\boldsymbol{v}_2 \cdot \boldsymbol{e} = 0$, and $\boldsymbol{p} \cdot \boldsymbol{e} = 0$ and lay the foundation for the guided reinvention of the least squares equation, which occurs in Task 4.

For space, we share one example of student work on Task 3 (see Figure 6). After writing the known relationships, the student wrote $\boldsymbol{v}_1 \cdot \boldsymbol{e} = 0$ and $\boldsymbol{v}_2 \cdot \boldsymbol{e} = 0$ as a system of equations and an augmented matrix. He solved for $\boldsymbol{e}$ as a vector parameterized by t. He then used $\boldsymbol{b} - \boldsymbol{e} = \boldsymbol{p}$ and $\boldsymbol{p} \cdot \boldsymbol{e} = 0$ to

solve for $\boldsymbol{e}$ and then for $\boldsymbol{p}$. He then substituted $\boldsymbol{p}$ into $A\boldsymbol{x} = \boldsymbol{p}$ to solve for x_1 and x_2. He completed the task by finding $\|\boldsymbol{e}\|$. We note that his augmented matrix is a nice aspect for instructors to point out and symbolize as the matrix equation $A^T\boldsymbol{e} = \boldsymbol{0}$, which is central in Task 4.

You've got some mail you need to give to Old Man Gauss, who now lives at $\boldsymbol{b} = \begin{bmatrix}-1\\1\\4\end{bmatrix}$.

You have the same modes of transportation you had before for travel in $\mathbb{R}^3$: $\boldsymbol{v}_1 = \begin{bmatrix}1\\1\\1\end{bmatrix}$, $\boldsymbol{v}_2 = \begin{bmatrix}6\\3\\8\end{bmatrix}$, $\boldsymbol{v}_3 = \begin{bmatrix}4\\1\\6\end{bmatrix}$.

Your cousin has a drone that can travel along *any* vector in $\mathbb{R}^3$. They said they would lend it to you to deliver Gauss's mail, on the condition that you get as close as you can to Gauss before you use the drone.

TASK 3: With your group, try to determine the location that you can get to with $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ that is the shortest distance to Gauss. From there you can use your cousin's drone!

a) What is the location that you would travel to in order to use the drone?
b) How would you get there with $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$?
c) Along what vector would the drone travel?
d) What distance would the drone's trip be?

Figure 5: Task 3 - Delivering mail to Gauss with a drone

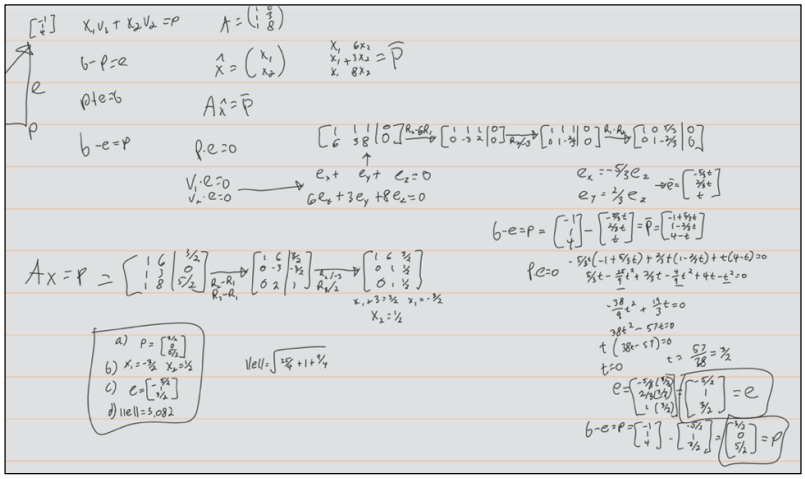


Figure 6: Example of a student's work for Task 3

Task 4: Synthesizing into a general approach

The main goal of Task 4 (Figure 7) is for students to create the least squares equation $A^TA\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$ that allows them to determine $\hat{\boldsymbol{x}}$ no matter what A and $\boldsymbol{b}$ are. As the culmination of the RME-inspired guided reinvention task sequence, this general equation grows out of students' inquiry and more specific work in Tasks 1-3. Task 4 tends to be quick for students in their small groups as they leverage their algebraic substitution skills. For instance, we have seen students substitute $\boldsymbol{e} = \boldsymbol{b} - \boldsymbol{p}$ into $A^T\boldsymbol{e} = \boldsymbol{0}$ yielding $A^T(\boldsymbol{b} - \boldsymbol{p}) = \boldsymbol{0}$, and then substitute $A\hat{\boldsymbol{x}} = \boldsymbol{p}$ in for $\boldsymbol{p}$ yielding $A^T(\boldsymbol{b} - A\hat{\boldsymbol{x}}) = \boldsymbol{0}$. Students might stop there; the instructor can discuss a further simplification to the more common $A^TA\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$**.** The instructor brings together the class's collective work on the entire task sequence by formalizing new terms and definitions; this is in line with an instructor's role in inquiry-oriented instruction to build on student reasoning and formalize language and notation (Kuster et al., 2018). In particular, the instructor can lead a discussion that emphasizes the more general and formal, namely that when no solution to $A\boldsymbol{x} = \boldsymbol{b}$ exists, we can know the best approximation $\boldsymbol{p}$ for $\boldsymbol{b}$ in the subspace spanned by the columns of A by finding what $\hat{\boldsymbol{x}}$ produces the vector $A\hat{\boldsymbol{x}} = \boldsymbol{p}$ in the subspace that is

closest to $\boldsymbol{b}$. The instructor also introduces new terms to complete the guided reinvention, namely: $\hat{\boldsymbol{x}}$ is the least squares solution for $A\boldsymbol{x} = \boldsymbol{b}$, the set of least squares solutions $\hat{\boldsymbol{x}}$ of $A\boldsymbol{x} = \boldsymbol{b}$ coincides with the nonempty set of solutions of $A^T A\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$, $\boldsymbol{p}$ is called the projection of $\boldsymbol{b}$ onto the subspace, and $\|\boldsymbol{e}\| = \|\boldsymbol{b} - A\hat{\boldsymbol{x}}\|$ is called the least squares error. As a follow-up, students can use all three modes of transportation $\{\boldsymbol{v}_1, \boldsymbol{v}_2, \boldsymbol{v}_3\}$ from Task 1 to form A and solve for the least squares solution $\hat{\boldsymbol{x}}$ of the updated $A\boldsymbol{x} = \boldsymbol{b}$, as well as $\boldsymbol{p}$ and $\boldsymbol{e}$. Students will find that $\hat{\boldsymbol{x}}$ is no longer unique but $\boldsymbol{p}$, $\boldsymbol{e}$, and $\|\boldsymbol{e}\|$ are. Instructors could then derive that $\hat{\boldsymbol{x}}$ is unique if and only if the columns of A are linearly independent.

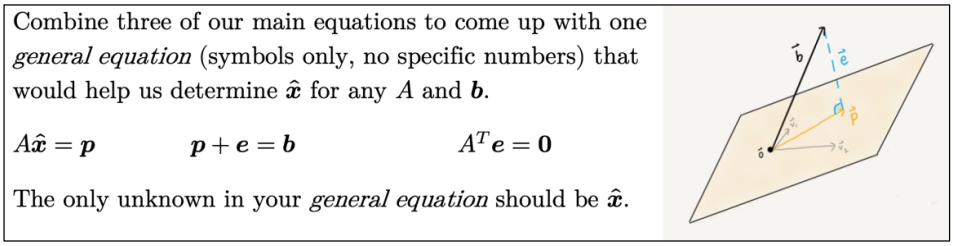

Figure 7: Task 4 - Synthesizing into a general approach

Conclusion

In this paper, we summarized a new task sequence for an inquiry-oriented approach to least squares in linear algebra. We used RME (Freudenthal, 1991), Inquiry-Oriented Instruction (Kuster et al., 2018), and design research (Wawro et al., 2022) to guide our task design and implementation. The sequence uses a subspace orientation to least squares, so that students' graphical intuition with planes and vectors can be leveraged throughout their work on the tasks and beyond. Our work contributes to the limited research on teaching innovations for least squares, as well as on how students in mathematics, engineering, and the sciences make sense of concepts involved in learning least squares in linear algebra. Our future work includes completing the Web phase of the design research spiral, as well as conducting fine-grained analyses from our data of student reasoning about least squares.

Interweaving university and school mathematics: situated learning opportunities at the transition from university to teaching at school

[3]Ruprecht-Karls-Universität Heidelberg, Germany

The perceived discontinuity between studying university mathematics and teaching mathematics at school is well-known as a challenge in teacher education. While there have been several attempts to resolve this, it remains unclear how teachers can develop the necessary subject matter knowledge for teaching and how they can learn to apply it. Our research project addresses the design and examination of situated learning opportunities for pre-service teachers called 'interweaving problems', which are currently investigated in several cycles of implementation. This paper introduces key design criteria derived from theory, including guiding questions to scaffold the process. We present data from the second cycle and a coding rubric developed to analyse how pre-service teachers draw on university mathematics to inform teaching decisions. We discuss patterns that emerge and possible consequences for the adaptation of specific scaffolding to enhance support.

Keywords: University mathematics, geometry, secondary teacher education, double discontinuity, subject matter noticing.

Introduction

The transition from studying mathematics at university to teaching it at school has been recognised as problematic for a long time, since teachers often fail to see connections between university mathematics and school practice (e.g., Klein, 2016). Our project aims to design learning opportunities that enable pre-service teachers (PSTs) to examine such connections and practice how to make use of them in typical tasks of teaching. The accompanying research is designed to provide detailed insight into how PSTs engage with these learning opportunities. After each semester of implementation, the learning opportunities are adapted based on this research.

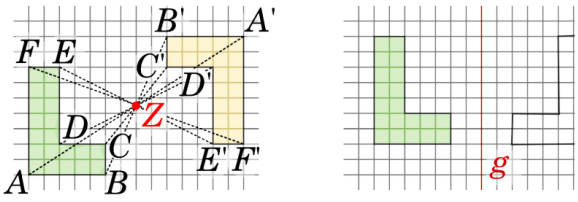
Our project works within the context of a geometry course exclusively for pre-service secondary mathematics teachers at the University of Heidelberg. The course, situated in the Master's program, is the last university mathematics class of their education. Each week, PSTs are expected to work on and hand in solutions to a number of exercise problems in groups, which are afterwards discussed in a tutorial. The exercise problems are typically focused on university mathematics, but the goal of our project is to develop problems meant to connect university mathematics and school mathematics. Eleven such problems have been developed and implemented in the course twice, with one cycle of re-design between implementations (Weith et al., 2024), and two more implementations will follow. In this paper, we will outline design criteria for the development of the problems, and present the development of a category-based coding rubric for analysing written solutions to them, which were collected during the second implementation cycle.

Theoretical background

While there is consensus that a profound knowledge of the subject matter is essential for teaching mathematics, studies show repeatedly that PSTs perceive the university mathematics taught in their university education as not particularly relevant to their profession (e.g., Gueudet, 2008; Prediger, 2013; Eichler & Isaev, 2022). There are several theoretical models aiming to characterise the subject matter knowledge teachers need in their profession. Wasserman and colleagues (2023[1]) describe the processes of connecting school mathematics to one's knowledge of university mathematics and letting this inform a teaching decision as *building up from practice* and *stepping down to practice.* Another theoretical approach is that of *school-related content knowledge* (SRCK; Dreher et al., 2018), which is conceptualised in three facets: *bottom-up, top-down,* and *curricular*. While the curricular facet is concerned with the connections within the school curriculum, the other two share similarities with what Wasserman calls *building up* and *stepping down*. SRCK, however, takes a particularly situated approach by giving a number of exemplary questions for each facet that reflect typical professional demands for teachers. Examples include: *Which mathematical ideas might be reflected by a student's remark in class?* (bottom-up perspective); *How can a certain mathematical idea be reduced for teaching purposes in the school context?* (top-down perspective) (ibid., p. 331).

Although such knowledge has been at the focus of a number of successful interventions, there is still little insight into how it is actually acquired, and how it can be made accessible when needed in typical tasks of teaching, such as selecting and adapting learning material or responding to students' questions (e.g., Prediger, 2013; Wasserman et al., 2023). One possible approach is to develop PSTs' subject matter noticing, i.e., their ability to identify and interpret relevant subject matter aspects in a teaching situation to inform teaching decisions (e.g., Sherin et al., 2011). This can be achieved by providing learning opportunities that approximate practice through realistic teaching situations, which is considered beneficial in academic mathematics classes for PSTs (e.g., Prediger, 2013). Providing PSTs with representations of practice is assumed to be especially conducive to the acquisition and restructuring of professional knowledge (Kirwan et al., 2023). It has also been observed that PSTs often perceive the relevance of university mathematics to their profession as very low, which may inhibit their knowledge acquisition and development of subject matter noticing (Sebők, 2023). Exemplifying situations where knowledge of university mathematics can directly benefit teachers may be a way of improving this perception.

Development of interweaving problems as situated learning opportunities



This research project aims to develop learning opportunities where PSTs not only examine meaningful connections between university and school mathematics, but also use this insight to inform teaching decisions. We have come to call this *interweaving* university and school mathematics, and the learning opportunities *interweaving problems.* The development process began with the choice of mathematical content; both the university course and the school curriculum were

[1] This reference provides a current and extensive literature survey, and therefore a comprehensive overview of the state of the art.

analysed for pieces of mathematical content that allow for connections that go beyond a superficial recognition of similarities. These were then embedded in text-image vignettes that represent typical situations in a teacher's job where engaging with the mathematics behind the situation can benefit the teacher's instructional decisions. The exemplary questions from the SRCK construct were used as orientation, as they reference exactly such situations. The vignettes were constructed in such a way that answering one or several of the SRCK questions would lead the teacher to a more well-informed judgment or reaction. Lastly, a number of questions was developed for each situation as guidance for the PSTs to productively work on the interweaving problems: asking them to identify and interpret particular aspects of the situation, explicitly connect and compare university and school mathematics, or use their mathematical insight to inform a teaching decision[2]. The finalised interweaving problems consisted of one text-image vignette each along with the corresponding guiding questions, and the PSTs were tasked with solving one problem per weekly exercise sheet.

Figure 1 shows the vignette used in one interweaving problem, presented as the fourth of eleven problems, on the topic of reflections. It is designed so that answering the following SRCK questions can facilitate meaningful engagement: *Which mathematical ideas might be reflected by a student's remark in class?* (bottom-up) and *How can a certain mathematical idea be reduced for teaching purposes in the school context?* (top-down) (Dreher et al., 2018, p. 331)

You are a math teacher teaching a unit on reflections with your 5th grade class. In the past couple of lessons, you have introduced reflections across an axis and reflections across a point.

Baum, M. et al. *Lambacher Schweizer 5 Baden-Württemberg.* Klett, 2014. 70/82. (nachgezeichnet)

One student comes up to you and shows you these two pictures. She says: „I dont't understand why the reflection across a point is called a reflection. When we did the reflection across an axis, it was an L in the beginning, and afterwards the L was the wrong way around. But with the reflection across a point, the green one is an L, and the yellow one is also an L. It's upside down, but it's not really the wrong way around!"

Figure 1: example situation at the basis of one interweaving problem (translated from German)

A possible way to interpret this situation from a subject matter perspective might look like this: The student has recognised that in one reflection, the L shape keeps its *orientation*, while in the other it changes. Both reflections are *motions* (i.e., isometric bijections) of the Euclidean Plane. The reflection across the axis flips orientation, while the point reflection preserves it, as it is actually a rotation by 180° around point Z, or can be seen as the composition of two reflections across perpendicular axes.

[2] In the latest (the second) iteration of the interweaving problems, these guiding questions were quite detailed, as the evaluation of the first iteration indicated that they had been too broad. (Weith et al., 2024)

In this sense, the point reflection is not strictly a reflection. It does resemble a reflection, however, in that it is its own inverse within the group of motions of the Euclidean Plane, which is a property that only reflections across axes and point reflections share. These considerations can then be used to answer the SRCK questions above and thereby inform the teacher's instructional decision in several ways: The teacher might assess that the student has made quite an astute observation, even though she cannot put the correct words to it, and encourage her for this. They might try to help specify her thoughts on orientation by visualising how in the second picture, the L shape would need to be flipped over once to get to the other side, whereas in the first picture, it would need to be flipped over twice (composition of reflections) or not at all and rotated around the centre instead (rotation).

The following guiding questions were provided. They are being grouped here into four thematic sections that we derived from the theoretical considerations outlined above and also used in the data analysis. Please note that this is not a strict separation, as the guiding questions are meant to scaffold a thought process that can in reality be quite fluid and dynamic. (The section headlines were not presented to the PSTs.)

Section 1 examines the relevance of orientation to this situation, and explicitly ties it to the course.

- What do you think the student means by "the wrong way around"? What difference between the reflections is she trying to describe?
- Which motions of the Euclidean Plane can be used to describe the reflection across an axis and the point reflection? How does the difference between the reflections that is relevant here show in their representation as motions of the plane?
- As what other type of motion can the point reflection be described?

Section 2 takes a look back at the student's statement and examines it in light of the previous mathematical considerations. This corresponds to answering the SRCK question *Which mathematical ideas might be reflected by a student's remark in class?*

- Read the student's statement again. How would you assess it after the previous considerations?

Section 3 discovers why the point reflection can still meaningfully be described as a reflection.

- Why are reflections across axes and points both considered reflections in school mathematics? For this, think about how students need to proceed when constructing the reflections.

Section 4 finally works towards a teacher's response to the student, engaging with the SRCK question *How can a certain mathematical idea be reduced for teaching purposes in the school context?*

- Which results of your considerations should be recognisable in your response to the student?
- What would your response to the student be? Choose appropriate examples, representations, etc.

Research interest and research question

As outlined above, the main research interest of the project is to develop and examine PSTs' subject matter noticing, i.e., their ability to engage with the mathematics of a teaching situation and make this directly inform an instructional decision. In this paper, we focus on written solutions to one interweaving problem, where successful subject matter noticing would be expected to appear as meaningful references to mathematical considerations in those sections that work towards a teaching

decision (here, sections 2 and 4). Accordingly, we address the following research question: To what extent and in which ways do PSTs draw on previous considerations on university mathematics when working towards a teaching decision (while engaging with an interweaving problem)?

Data collection and methods

A total of 48 PSTs, all of which gave their consent for analysis of the generated data, worked on one interweaving problem per week in 12 fixed groups of three to five people. Those groups handed in a written solution to each problem, resulting in more than 100 handed-in solutions overall. In this paper, we focus on the 12 solutions to the interweaving problem presented above (see Figure 1) to illustrate the process of analysis and development of a coding manual. The coding was done by the first author, following the guidelines of qualitative content analysis (Mayring, 2021). Coding units were generated as context units by dividing each solution into the four thematic sections outlined above. This resulted in a total of 48 coding units. Each section was then analysed from a specific perspective: Sections 1 and 3, being concerned with examining the mathematics of the situation, were deemed the only ones where the notion of correctness can be applied. The solutions were analysed as to whether the relevant questions (*What is the role of orientation?* and *Why does it still make sense to call both of these motions 'reflections'?* respectively*)* were correctly answered, and if so, how elaborately. Based on this, each coding unit was sorted into one of four categories (see Figure 2, left):

Category	Description	Category	Description
f	Entirely incorrect approach	0	no discernible reference back to mathematical considerations at all
c-	Correct approach, but elaborated to an inadequate degree	1	only superficial references
c	Correct approach and elaborated to an adequate degree	2	mathematically meaningful references are recognizable, but they are not directly used to benefit a teaching decision
c+	Correct approach and elaborated particularly well	3	meaningful references that directly inform and benefit the teaching decision

Figure 2: Coding categories for sections 1 and 3 (left) and sections 2 and 4 (right)

Sections 2 and 4 were examined for the quality of references to mathematical considerations in previous sections and for whether they were used to directly inform a teaching decision. The categories were inferred from the written solutions based on SRCK theory as outlined above and refined inductively during the coding process. Figure 2 shows the categories that resulted from this process; illustrating sample answers will be provided in the following section.

Findings

This section will focus on the coding process of sections 2 and 4, since the most meaningful insight towards answering the research question can be gained there. Sections 1 and 3 were still an integral part of this process because the coding focused on references between the different sections. We would like to provide some insight into the categories by showing and commenting on a number of illustrative excerpts from handed-in solutions. All excerpts were taken from section 4 for better comparability, and all were coded in German and then translated into English by the first author.

C**ategory 0** was only awarded once (group B, section 4), but – differently than expected – not due to a lack of mathematical substance, but to a major misalignment between sections: The mathematical

ideas referenced were entirely different from the ones mentioned in previous sections. Solutions awarded **category 1** typically referenced previous considerations mainly for superficial decisions. The PSTs in the following excerpt (group I), for instance, were only concerned with what language, definitions, and notation to use, while there was no deeper engagement with the mathematics:

> Terms to use: rotation, congruent, (orientation-preserving); Fifth-graders do not know matrix notation yet. […] The definition of motions by their set of fixed points is not useful here, either.

In contrast, **category 2** was mostly characterised by mathematically meaningful and correct references which were, however, not incorporated to directly benefit the teaching decision.

> You can reach the same result [as the point reflection] with several reflections across different axes. Looking at where the two axes intersect, you can see that it is exactly the reflection point.

There clearly is mathematical substance recognisable in this solution (group F). It is mathematically correct and directly draws on previous considerations. However, this is not being used to actually answer the student's question. The explanation neither highlights why the point reflection preserves orientation, nor why it is still called a reflection. The following excerpt from group J, with meaningful references that were beneficially tied into the teaching decision, resulted in **category 3**:

> An L remains an L, but it is upside down. The orientation stays the same. […] That is why it does not look "the wrong way around" to you. You can also picture a point reflection like this. You cut out the L and push it around, without ever lifting it from the table. […] Can you do the same for the reflection across an axis, without the L leaving the table?

The student's question is directly addressed, and the correct mathematical terminology is introduced. Furthermore, the previous mathematical considerations are clearly being used to create a visual argument that highlights the relevant mathematics while being accessible to the student. Another shared characteristic of several solutions sorted into category 3 was a systematic and reflected line of argumentation in the choice of content for the response. For instance, this excerpt from group L:

> Some [motions] preserve orientation, some do not → that is why the student recognises a difference between the reflected L shapes […] We are also leaving out differences regarding the sets of fixed points, as they distract from the essential and might confuse the student. We consider [the choice of a coordinate system, knowledge about matrices and the group of motions, and differences in the sets of fixed points] background knowledge for the teacher, […] but it is not necessary or even possible to communicate these concepts to the student. However, we consider it a good opportunity to revisit reflections in upper secondary and explain the bigger picture with the knowledge acquired in the meantime.

It is recognisable that the group engaged with their previous considerations with the clear goal of achieving an ideal response to the student. They reflected back on all the major ideas from their previous considerations and made choices based on what is best suited to the specific situation. They also incorporated curricular considerations and proposed to expand on the foundational understanding built here a few years later with more elaborate mathematical means, which the students will know by then. What else is notable in this case is that group L was awarded the code c- in section 1, indicating a significantly lacking solution there.

Discussion

This paper aims to outline the design of a new type of exercise problem for the university mathematics education of PSTs, and to present the process of analysing written solutions to such problems. While several studies have used vignettes in PSTs' university mathematics education (e.g., Prediger, 2013), the vignettes developed in our project provide PSTs with explicit scaffolding for interweaving university and school mathematics, a process that has often been identified as difficult (e.g., Sebők, 2023). The scaffolding is designed to enable the integration and restructuring of knowledge related to university and school mathematics (Kirwan et al., 2023), which is critical for mastering the typical tasks of teaching represented in our vignettes. Therefore, the project investigates PSTs' engagement with the vignettes to gain deeper insights into related learning processes. We consider this an inevitable step to improve our understanding of PSTs' learning in this context before existing approaches can be further up-scaled (cf. Wasserman et al., 2023).

Even though it remains to be examined if the developed coding rubric can be applied to the entire data set, findings are promising and the results provide first answers to the research question. Data analysis shows that the solutions vary greatly in quality, which aligns with the assumption that these types of processes are challenging and new to our PSTs. However, a number of patterns, presented here as the different categories, are already recognisable: It is promising that category 0 was only awarded once, and not for lack of mathematical substance, but of alignment to previous sections. This indicates that PSTs mostly manage to draw at least some connections to their mathematical considerations and that the provided scaffolding might support this process. The case of group L seems counterintuitive at first, since they managed to connect university mathematics to their teaching decisions very well although their previous considerations on those mathematics had not been very elaborate. One possible explanation might be that they did have some deeper mathematical understanding of the situation and were able to connect it to their teaching decision (section 4), but they did not consider it relevant when explicitly engaging with the mathematics (section 1). An in-depth analysis of solutions of this type might be warranted in the context of our research interest.

For the purpose of adapting the interweaving problems for the next semester cycle, occurrences of category 2 are of particular interest. They indicate that the PSTs are able to examine the mathematics behind a situation, but then struggle to tie this into their teaching. When more extensive findings from the coding are available, we would expect the prevalence of this category to decline throughout the semester, as applying university mathematics knowledge in a school context is a new activity for our PSTs and we expect them to become more familiar with it over time. Therefore, insight into what characterises solutions from this category is crucial to decide if and how the scaffolding can be adapted in future iterations to ideally support this activity early on in the semester.

Our research complements previous studies (e.g., Sebők, 2023) by expanding the corpus of vignette-based PSTs' university mathematics education, and showing that interweaving mathematics is a challenging endeavour. However, our vignettes are designed in a way that particularly guides interweaving processes, and accordingly, the collected data may provide insight on a more detailed level, which is needed to better understand PSTs' learning in this context and provide suitable learning opportunities. The coding rubric presented in this paper has mainly been derived from the

analysis of one interweaving problem. In a next step, it will be applied to the analysis of the other interweaving problems and adapted, if necessary, also accounting for intercoder reliability.

Exploring University Students' Mathematical Digital Competency for Communication in Computer-Supported Collaborative Learning

Wenfei Du, Eirini Geraniou, Cosette Crisan and Jeremy Hodgen

Institute of Education, UCL's Faculty of Education and Society, University College London, UK; wenfei.du.20@ucl.ac.uk

Keywords: Mathematical digital competency, computer-supported collaborative learning, mathematical communication, digital tools, university mathematics education.

Introduction

The landscape of mathematics education at UK universities has undergone significant transformation in recent decades, driven by advancements in technology. This shift has given rise to the concept of Mathematical Digital Competency (MDC), which highlights the interconnected nature of mathematical learning and digital tool proficiency (Geraniou & Jankvist, 2019). However, the incorporation of technology into mathematics education presents challenges, particularly in selecting tools that align with specific learning objectives. Students' collaboration in mathematics learning adds a layer of both challenges and opportunities, further complicating the integration. Research on Computer-Supported Collaborative Learning (CSCL) highlights the importance of collaboration in enhancing learning outcomes when using digital tools (e.g., Dobie & MacArthur, 2022). Therefore, the focus of this study is on: How do university students employ MDC when communicating mathematically within a CSCL context?

Theoretical Foundation

The present study aims to develop a framework to analyse how students communicate mathematically online, building on existing analytical constructs in both MDC and CSCL. The Theory of Knowledge-Creating Learning (TKCL) (Paavola & Hakkarainen, 2014), which emphasizes the collaborative and individual creation of knowledge through interactions with shared epistemic objects, was chosen for CSCL. The MDC framework, focusing on the interactions between tool mediation and the development of individual mathematical competency, was also considered. We utilize the networking strategy (Bikner-Ahsbahs & Prediger, 2009) that primarily focuses on "comparing & contrasting" these theoretical approaches to identify their compatibility and complementarity, followed by "combining & coordinating" them as an initial step to create a cohesive framework. To enhance complementarity with TKCL, we also consider the two foundational theoretical approaches in developing the MDC framework (Geraniou & Jankvist, 2019), namely the KOM framework (Niss & Højgaard, 2019) for defining mathematical competence through eight interwoven competencies, and the Theory of Instrumental Genesis (Drijvers et al., 2013) which highlights tool mediation in human activity through three dualities. This combination ensures a balanced analysis of both social and individual dimensions in CSCL, allowing for a deeper understanding of how students interact with digital tools in mathematical contexts.

Method and Preliminary Outcomes

This study employs a qualitative research design conducted in the UK. Students' self-organized CSCL groups focusing on mathematics learning were sampled. We select an example group consisting of two 1st-year students: one majoring in Mathematics and the other in Engineering. Data collection methods include learning analytics and observational recordings of their online interactions, in which students work on mathematical problems from the Mathematics Stack Exchange Forum, assisted by ChatGPT. We use reflexive thematic analysis (Braun & Clarke, 2022) to identify key interactions in the students' mathematical dialogues. The analysis is intended to generate themes on the interactions between MDC and CSCL to build a new framework.

In this poster (https://shorturl.at/cj6k0) we present three initial themes contributing to the new framework, focusing on interactions between tool mediation and CSCL progression in mathematical communication. The "***Illustration – Annotation and Setting the Stage***" theme highlights how students collaboratively build a shared understanding of concepts. The "***Verification – Critical Reflection and Confirmation***" theme focuses on critically assessing and confirming the correctness and relevance of their ideas. The "***Inspiration – Elaboration and Iterative Refinement***" theme captures how students seek external ideas and iteratively refine them when encountering challenges. The findings provide tentative suggestions for further improving CSCL activities while considering the concept of MDC.

Characterising internal discontinuities in mathematics in engineering education through teachers' views

Ignasi Florensa, Iria Fraga and Víctor Martínez-Junza

Escola Univ. Salesiana de Sarrià – Universitat. Autònoma de Barcelona, Spain; iflorensa@euss.cat

Keywords: Mathematics for other disciplines, discontinuity, Anthropological Theory of the Didactics

Mathematics education for non-specialists is undoubtedly one of the open fields in undergraduate mathematics education research. Specifically, the mathematical education of engineers presents particularities addressed in previous works, such as the special issue of the IJRUME devoted to this field (Pepin et al., 2021). One of the specific features of engineering education is the distinct role that mathematics plays in both mathematics and engineering courses, which has already been characterised in various engineering degrees. The transition from mathematics courses to engineering ones has been described as the "internal discontinuity" of the triple discontinuity in mathematical education within engineering education (Florensa et al., 2022). Here, we present the first stage of a study to characterise this internal discontinuity through interviews with teachers of mathematics and engineering courses in two institutions.

Study

Our work is framed in the Anthropological Theory of the Didactic (ATD), focusing on the concept of praxeology (Chevallard, 2006). This framework is employed during the interviews to guide interviewed teachers in describing mathematical activity, not in terms of the content to be taught as it is usually done but as types of tasks and their associated techniques. We consider characterising the views of mathematics and engineering teachers to partially describe the prevailing epistemology of two institutions in the ATD sense: those of the mathematical and those of the engineering courses.

Consequently, the research questions we raise in this first phase of the study are: What are the mathematics course teachers' and engineering course teachers' views of mathematical activity in the first years of mathematical training in engineering degrees? To what extent are these two groups' visions different, and how do they help describe the similarities and differences between the prevailing epistemology of these two institutions?

The first phase of this study involved interviewing university teachers from two engineering schools in Barcelona, Spain. Specifically, five teachers who teach mathematics courses (M1 to M5) and four who teach engineering-related courses (E1 to E4) were interviewed. During the interview, two activities used in mathematics courses for engineering students were presented to the teachers (see Figure 1). On the one hand, a classic exercise on function analysis was shown. On the other hand, the generative question of a Study and Research Path (SRP) on population dynamics was presented (Barquero et al., 2011). Interviewees were asked to identify the type of tasks the activities would promote and the associated techniques in their institution. In addition, they were also asked which of the two proposed activities promoted a more helpful activity for engineering education.

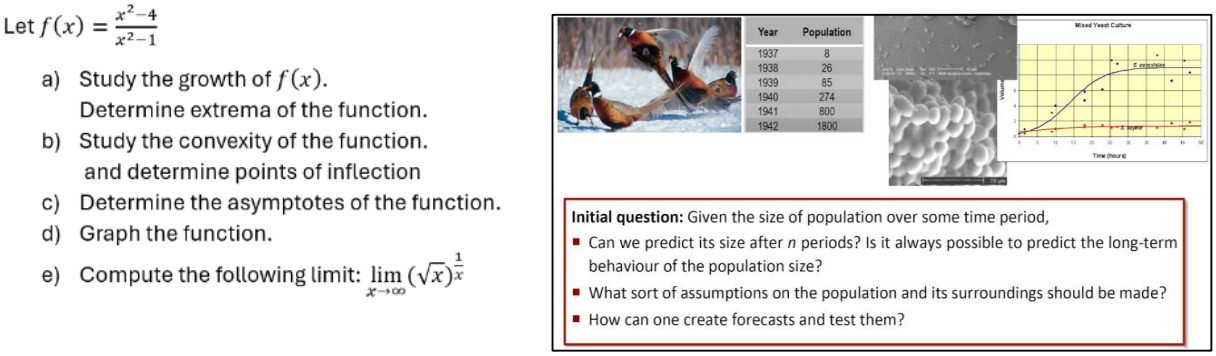

Figure 1: Activities presented in the interview

Findings

Most teachers interviewed identified the first activity as likely to promote manual techniques, as an activity intended to be solved using derivative rules and paper-and-pencil graphing. All the interviewees agreed on the types of tasks this activity would generate among first-year students. In addition, alternative methods, such as numerical calculation software and symbolic computation programs, were also noted among engineering teachers. Regarding the second activity, the diversity of types of tasks increased, including different approaches (statistical, differential equations). While most considered the second activity to be more interesting, some participants thought that the first activity was essential because of its ability to lay the foundations for a future activity.

Fostering dialogue between university researchers and upper secondary school teachers on students' mathematical preparation for university studies in STEM subjects in Iceland

Bjarnheiður Kristinsdóttir and Ingólfur Gíslason

University of Iceland, School of Education, Reykjavík, Iceland; bjarnhek@hi.is

Keywords: Secondary-tertiary transition, mathematical preparation, organization of studies, interschool communication, teacher expectations of students.

In Iceland, there is an increasing concern about the high dropout rates and low graduation numbers in STEM fields at the university level, with university instructors expressing worries about students' mathematical preparation or lack thereof. Recently, some adjustments have been made to the upper secondary (grades 11–13) curriculum in Iceland, yet teachers at this level report a lack of clear curricular guidance and adequate teaching materials. Brandell et al. (2008) highlight that the challenges students face during the transition from upper secondary school to university often stem from discrepancies between the upper secondary curriculum and the knowledge and skills expected at the university level.

As part of a broader initiative called the SamSTEM project to address these issues, we focus on facilitating collaboration between upper-secondary and university-level mathematics teachers. We explore how these two educational communities perceive the existing problems and consider the potential synergies and conflicts in their expectations.

Our research question is: What are the mutual expectations, as well as the key differences in expectations, between upper secondary and university mathematics teachers regarding students' mathematical preparation for STEM studies at the university level?

Within the SamSTEM project, 25 university instructors from the fields of mathematics, mathematics education, physics, chemistry, statistics, and computer science from three universities (University of Iceland, University of Reykjavík, and University of Akureyri) aim to increase the number of STEM subject graduates. In the school year 2023–2024, members of the SamSTEM project visited 27 out of the 31 upper secondary schools in Iceland that offer natural science strands of studies and held online meetings with the remaining four. Each visit (or online meeting) included a two-hour meeting between the STEM subject teachers at the upper secondary school and 3–6 university instructor members of the SamSTEM project, with the aim to foster a shared understanding of the preparation needed for university-level STEM studies and to map and address the challenges faced by upper secondary teachers.

In Iceland, students' selection of upper secondary school and mathematics courses offered affects their performance in undergraduate mathematics courses at university (Jónsdóttir et al., 2013) and no standardized examination is offered at the end of upper secondary school. Therefore, the SamSTEM project partners brought to the meeting school-specific data regarding how the students at the respective school fared in the university STEM programs in comparison to other schools. The upper secondary school teachers received some slides with preliminary questions to discuss at the meeting,

e.g., regarding the organisation of mathematics courses and selection of teaching materials. In many cases, the meetings also drew in principals, teachers from other subjects, and study counsellors of the schools.

In the first steps of data analysis from the meetings, there was broad agreement on what challenges upper secondary school mathematics teachers in Iceland face. Five of the project participants made a summary of the 12 main resulting challenges and drafted possible suggestions for ways to address these challenges. To check back, the preliminary results were sent to all the participating schools, and they were also presented and discussed at upper secondary school teacher gatherings. After reaching an agreement, the results were presented and discussed at two meetings with university lecturers and two seminars with a mixed group of upper-secondary and university teachers.

In this poster, we present results regarding differences and similarities in teachers' views of students' mathematical preparation for STEM studies at university. We coded and thematically analysed data from the 31 upper secondary school meetings and two university lecturer meetings. Our results indicate that university lecturers' worries align with those of university lecturers in other countries, i.e., they are widely concerned about students' increasing lack of preparation in mathematics (Brandell et al., 2008; Deeken et al., 2020; Wade et al., 2016). They also indicate that upper secondary school teachers would prefer more curricular or university guidance regarding the mathematics course content, although no general desire for standardized national assessment was expressed. Upper secondary school teachers pointed out an increased diversity in the mathematical preparation programs offered by the different upper secondary schools. In many schools, the decisions of school principals affected how teachers could assess their students' knowledge and competencies in mathematics, thus affecting their possibilities to prepare students for university. One of the main hurdles faced by upper secondary teachers was the lack of up-to-date teaching materials in mathematics, forcing them to create their own material on the go.

Learning about students' misconceptions with instructional videos and STACK tasks in university courses for teacher education

Lucia Marchionne[1], Andreas Eichler[1], Henrik Floren[2], Michael Liebendörfer[2], Mirko Schürmann[2]

[1]University Kassel, Institute for Mathematics, Kassel, Germany; lucia.marchionne@uni-kassel.de;

[2]University of Paderborn, Germany

Keywords: Instructional video, STACK, teacher education, student misconception, evaluation.

Theoretical background

The project LLV.HD ("Teaching-learning alliances in mathematics-containing degree programmes - cross-university and digital"; www.uni-kassel.de/go/llv-hd) aims to develop digital tools for teaching and learning mathematics in various study programmes (Eichler et al., 2022). This poster focuses on the teacher education programme at two universities and on the topic of upper secondary students' misconceptions in calculus. For students learning about this, we developed and evaluated two kinds of digital tools: instructional videos and STACK tasks.

Instructional videos can enhance understanding and facilitate learning of mathematics (Kay, 2012). We also use them to support the learning of mathematics education. The tool STACK (System for Teaching and Assessment using Computer algebra Kernel; Sangwin, 2013) supports designing randomised digital mathematical tasks and individualised feedback for different algebraic inputs. Although STACK is widely used to improve school students' learning, it is rarely employed in mathematics education courses for prospective teachers.

The aim of integrating these digital tools into the teacher education programme is to promote prospective teachers' professional knowledge, strengthen their beliefs and foster their motivation. This poster addresses the third aspect. In this regard, we focus on how students judge the utility value of digital tools (Eccles & Wigfield, 2002). Utility value is understood as synonymous to the construct of relevance, which fosters academic achievement (Albrecht & Karabenick, 2018). In our study, digital tools should help "students to construct or otherwise independently identify the value of engaging in academic tasks" (Albrecht & Karabenick, 2018, p. 5). Our research question asks how students estimate the relevance of digital tools for their learning.

The material in this study

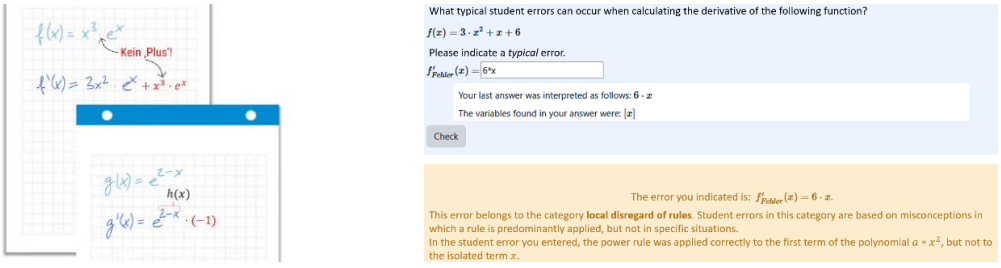

Figure 1: Scene from the instructional video concerning one kind of typical error (left side) and STACK task with the aim of giving this typical error as the solution of the task (right side)

Both the instructional video and the STACK tasks are based on a category system of students' misconceptions concerning procedural tasks when computing derivatives (Eichler et al., 2018). In the instructional video, this category system is explained using real examples of students' mistakes in computing derivatives. While the video's aim was to introduce misconceptions, the STACK tasks aimed to reflect on them and serve as an exercise.

Evaluation and results

The evaluation was conducted through questionnaires administered online immediately after the sessions in the mathematics education courses for prospective teachers, during which students' misconceptions concerning the derivative were introduced. Because this was an initial study, the questionnaires were aimed at all users and included only a few closed and open-ended items. Preliminary results indicate that the majority of students find engaging with the video's topic valuable for their future professional life and consider the instructional video helpful overall. However, while the video is highly accepted, the results regarding the STACK tasks are less positive (Figure 2). The feedback is not considered as helpful and the STACK tasks are perceived as less interesting compared to the instructional video. The video's positive reception suggests it sparks motivation, while the less favourable view of the STACK tasks indicates they may not have the same effect.

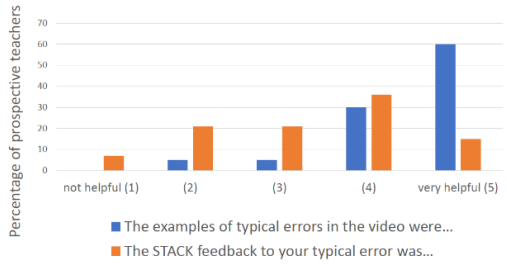

Figure 2: Two evaluation items for the instructional video (blue, $n = 24$) and STACK tasks (orange, $n = 16$)

Developing and evaluating visual supported STACK tasks for introductory courses in university mathematics

Sophie Markefka, Maxim Urich, Andreas Bley and Andreas Eichler

University of Kassel, Institute for Mathematics, Kassel, Germany;
sophie.markefka@mathematik.uni-kassel.de

Keywords: STACK, visualization, task development, evaluation.

Theoretical background

The project MAOAM Visual, funded by the foundation "Stiftung Innovation in der Hochschullehre" and integrated into the Centre for Higher Mathematics Education (https://www.khdm.de/en/), aims to combine the potential of digital tasks using STACK (System for Teaching and Assessment using Computer algebra Kernel; Sangwin, 2013) with the promoting effect of visualisation for learning mathematics in higher education. In particular, it is centred around creating visual tasks that aim to improve university students' conceptual understanding of mathematics.

The digital tool STACK can be seen as an intelligent tutoring system (Hillmayr et al., 2020) as it offers the possibility to design digital mathematical tasks, randomise them and give individualised feedback on different inputs. It is therefore considered to be a promising digital tool for mathematics education that will positively influence school students' learning processes. Visualisation can be regarded as an integral part of mathematics teaching and learning and a powerful instrument for understanding mathematical concepts or procedures (Presmeg, 2014; Arcavi, 2003)

Task Development

The task development is divided into the following four steps.

1) In cooperation with lecturers and tutors, topics where students face conceptual challenges or lack conceptual understanding are identified. Of these topics, only the concepts where another access via visualisation will likely enhance student's understanding are chosen. For example, a geometrical interpretation might shed light on new aspects of Gaussian elimination.

2) A task is then developed around the central concept defined in the previous step. This central concept is divided into sub-concepts. In particular, understanding each sub-concept could prove to be useful in enhancing students' understanding of the central concept. Duval states in (2006) that it is important that a mathematical concept is approached from two distinctly different semiotic representations. Thus, the tasks are designed in such a way that a solution requires a formal and visual approach. Moreover, the tasks aim to include a transition from one representation to the other. Thus, a coordination of two distinct semiotic systems is required. Duval (2002) considers this coordination essential to mathematical understanding.

Upon returning to the concept of Gaussian elimination for a uniquely solvable system of linear equations, one can represent equations of three variables as planes. Consequently, a sensible central concept would be the geometric interpretation of Gaussian elimination. One must first understand how a single elementary row operation changes the planes. Once this is understood, one needs to

translate the concept of a variable vanishing into its geometrical meaning. These two concepts can then be combined to conclude that Gaussian elimination rotates planes along their intersections until each plane is parallel to a different coordinate plane.

3) Task development then subsequently leads to the creation of an appropriate visualisation that can be used to answer concept-related questions. These often-interactive visualisations are usually constructed in GeoGebra (www.geogebra.org). They are designed to be user-friendly for both students and lecturers. Building on Arcavi (2003), the design of the visualisation allows students to discover mathematical properties that might have gone unnoticed when solely employing formal reasoning. Therefore, the visualisations may be implemented in the task itself, or in the feedback, to shed light on possible solutions or errors. At the same time, the visualisations should not present an immediate solution to the problem given in the task. The visualisations are integrated into the tasks as applets. However, the applets can also be used independently, for example, in lectures or tutorials.

In the case of a uniquely solvable system of linear equations of three variables, equations are represented as planes. One of these planes can then be rotated around its intersections via sliders. In matrix notation, this corresponds to the addition of a multiple of one row to a different row when carrying out Gaussian elimination.

4) In the final step, the task is refined to capitalise on STACK's function to give individual feedback as well as its randomisation feature. Latter allows us to randomise the numerically defined parameters and thus the visualisations using them. For Gaussian elimination, the equations, and thus the planes shown in the visualisation, will vary.

In the future, tasks involving visualisations will be available on Andreas Eichler's project page at the University of Kassel, which can be accessed via FB10 on the university's website.

"The goal is really to have a correct proof that you can also verify in Lean" – Exploring a lecturer's perspective of using Lean in teaching

Athina Thoma[1] and Paola Iannone[2]

[1]University of Southampton, United Kingdom, a.thoma@soton.ac.uk

[2]University of Edinburgh, United Kingdom

Keywords: Teaching with Lean, Interactive Theorem Prover, proof writing, lecturer.

Interactive Theorem Provers (ITPs) have been used in mathematics research for the development and verification processes of proofs and, more recently, they have been used in university mathematics teaching (e.g., Thoma & Iannone, 2022). Lean is an ITP with an extensive verified mathematical library. When writing a proof in Lean, the user receives feedback on the proof code and clear information regarding the context of the proof (see also Yan & Hanna, 2023).

The limited empirical studies investigating the use of Lean have mainly focused on students' use (e.g., Thoma & Iannone, 2022; Hanna et al., 2024). Thoma and Iannone (2022) discuss how students who were experienced Lean users were more precise in the use of symbols when writing proofs in pen and paper, divided the proofs in goals and subgoals and generally wrote in full sentences, unlike most students who had not engaged with Lean. However, students indicated that they found Lean difficult to learn and time consuming, mainly for its syntax (Iannone & Thoma, 2023). Further studies explore the use of Lean in task-based interviews. Thoma and Iannone (2023) investigate the interaction between students and Lean, highlighting differences between students considering "step-by-step verification", mimicking closely a pen and paper proof, or a "multi-step verification" by further utilising coding elements of Lean. Similarly, Hanna et al., (2024) discuss five different ways that students used to prove one logic task using Lean and present students' choices both in terms of the tactics and in terms of the paths they followed to prove the same statement.

However, there is a gap in the empirical studies regarding teaching with Lean. Here, we report initial findings of a study exploring lecturers' perceptions of the pedagogical affordances and constraints of using Lean in an undergraduate mathematics course.

The data come from a larger study examining the introduction of Lean in teaching mathematics at a U.S. university, where Lean has been used in mathematics undergraduate teaching for about 2 years. Previously, a lecturer had introduced Lean and created relevant teaching materials for one course during which the students engaged with both hand-written and Lean proofs. In the academic year that our study took place, two more lecturers used these teaching materials in their own courses. Here, we focus on one of these lecturers whom we call Ethan. The course Ethan taught was designed to closely follow the chapters of a textbook on "The Mechanics of Proof"[1], written by the lecturer who had introduced Lean previously. The content of the course focused on types of proofs, logic, number theory, functions, sets and relations and was designed to capture both hand-written and Lean proofs.

[1] The textbook is available through this link: https://hrmacbeth.github.io/math2001/00_Introduction.html

This was also reflected in the course's assessment. Ethan's course had 21 students from various backgrounds (either majors or minors in mathematics). The classes, 75 minutes each, were offered twice a week. One session was used by the lecturer for Lean demonstrations and the other focused on students working on the homework problems supported by the lecturer and a teaching assistant.

The data collected include course documents (assessment questions and students' responses with hand-written and Lean proofs), students' responses to surveys, task-based interviews with students and interviews with the lecturer. In this poster, we focus on the interview with the lecturer which was transcribed and analysed thematically. The analysis provided insights into Ethan's experience of integrating Lean in his teaching and changing his teaching approach to include pre-recorded materials and less "traditional" lecture time. Having marked students' work, Ethan shared that he had expected to see a difference in students' assessment compared to previous years, but he had "sort of mixed feelings as I was marking the final exams (…) I did look at a few questions on the midterm exam and compared that to previous semesters and it was maybe a little better or about the same. So at least not worse". With the results from students' assessment indicating either no change or a slight improvement he also commented on the constraints of teaching this course with Lean as there were some mathematical topics that could not be taught in this dual manner (pen-and-paper proofs and Lean proofs). Ethan also noted how he changed his own approach to teaching proof and how he would have taught differently this course with or without Lean.

Our poster offers insights into the adaptations Ethan made to his course, the constraints he faced, and the lessons learned in terms of teaching proof with Lean but also teaching proof more generally. In our next steps, we aim to explore the other lecturer's perspectives also in relation to the student data we collected.

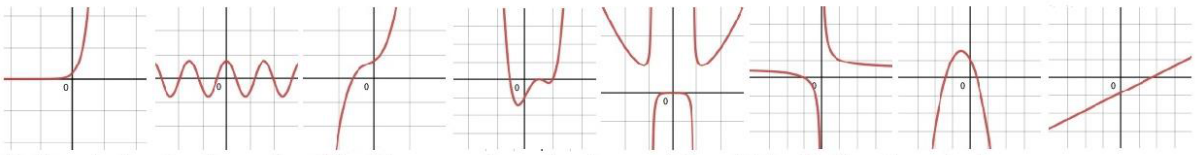
Students' conceptions of polynomial functions and their graphical representations at the secondary-tertiary transition

Juliette Veuillez--Mainard[1]

[1]IMAG, University of Montpellier, CNRS, France; juliette.veuillez-mainard@umontpellier.fr

Keywords: Polynomial functions, secondary-tertiary transition, graphical representation.



Introduction

Polynomials are ubiquitous objects in mathematics, and in most disciplines using mathematics. Consequently, polynomials hold a fundamental place in the teaching of analysis and algebra. In France, polynomials appear in grade 8 through first-degree equations, but quadratic polynomials are really studied in grade 11. Formal polynomials are introduced in tertiary education, along with their link with polynomial functions. Moreover, in secondary and tertiary education, polynomials are the first functions used in analysis, for tasks such as differentiation. In my PhD, we are interested in the teaching and learning of polynomials at the secondary-tertiary transition in France. We're currently investigating students' conceptions on polynomials; we plan to study teachers' practices around this notion; and the final aim is to develop and experiment activities that could smoothen the transition. Previous research have highlighted various challenges and ruptures happening during the secondary-tertiary transition (Gueudet, 2008). Studies have been conducted to investigate this transition in different domains: analysis (functions, tangent), algebra and linear algebra, probabilities… In the case of polynomials, there are few studies, apart from the PhD research of Pleština (2023). In this poster, we study students' conceptions of polynomial functions and their graphical representations.

Theoretical framework, research question, and methods

To analyse students' conceptions, we use the theory of conceptual fields, introduced by Vergnaud (2009). It emphasises the operational aspect of knowledge by defining operational invariants: theorems-in-action (propositions held as true by students in their activity), concepts-in-action (arguments held as pertinent by students) and action rules (implicit rules that guide the action of the student). In this work, we want to identify some of students' operational invariants, as they inform us on their conception of polynomials. Indeed, a *concept* is characterized in the theory of conceptual fields by three components: the situations which give meaning to the concept (reference); the invariants on which the operationality of the schemes is based (content); the linguistic and non-linguistic forms which allow symbolic representation of the concept, its properties, the situations and processing procedures (signifier). The *conception* of an individual can be defined similarly with these three components. We will draw on Duval's semiotic registers (2017) to describe each component of the conceptions. This leads us to investigate the following research questions: What are the students' conceptions on polynomial functions? In what way do they evolve during the secondary-tertiary transition? To answer these questions, we designed a questionnaire (extract below), focused on three main themes: definition and recognition of a polynomial, polynomial equations and roots, and polynomial functions and their graphs. It was given to 459 students (92 in grade 11, 114 in grade 12, 253 in higher education). An exploratory pre-version of the questionnaire was presented at INDRUM2024 (Veuillez--Mainard, 2024). In this poster, we mainly focus on the third theme.

7. Let P be a polynomial such that for all $x \in \mathbb{R}$, $P(e^x) = 0$. What can be said about P?
8. Plot on the graph below the shapes of the functions $x \mapsto x^n$. Differentiate the cases based on the parity of $n \in \mathbb{N}^*$.
9. Can the following graphs represent polynomial function? Provide a justification for each curve.

10. Does the function $f : x \mapsto (x+3)^2 - 1$ have an optimum (maximum, minimum)? Justify. If so, determine it.

Results

Definitions – Questions 1 and 2 of the questionnaire ask for students' definition of a polynomial. In high school, only polynomial functions are defined (and called polynomials). In higher education, polynomials and polynomial functions are distinguished. Consequently, a large proportion of students define a polynomial as a function (40% in grade 11, 52% in grade 12, 24% in university).

Recognition of graphs – Question 9 (above) was designed to identify operational invariants used by students in the recognition of polynomial graphs. It is an unusual task for students, hence half of them didn't justify their answer for at least one graph. We were able to identify several operational invariants, such as: *a graph of a polynomial is a parabola (or several parabolas)*; *a polynomial function is increasing; a continuous and increasing graph is a polynomial graph*. We also observed that some students use properties of monomial graphs (such as symmetry) to identify polynomial graphs. Moreover, when students provide an algebraic expression of the represented function, they often give the expression of a translated and dilated monomial: $ax^n + b$.

Links with polynomial expressions – In (Veuillez--Mainard, 2024), we presented first results about the recognition of polynomial expressions. We observed disconnections between the recognition of polynomial expressions (e.g. identifying whether e^x is a polynomial expression) and the recognition of polynomial graphs (e.g. identifying the graph of e^x as so, and then identify whether it is a polynomial expression), even in university. This is a manifestation of difficulties in articulating the graphical and algebraic registers. In the poster, we presented more data and illustrated our results with examples of students' answers.

The challenges we face as a society require well-educated citizens, and in particular more students going into STEM fields. Since mathematics underpins all STEM disciplines, this requires exceptional secondary mathematics teachers (SMTs). Thus, it is not surprising that the preparation of SMTs has seen an increased research interest in recent years. In this area, one of the main challenges that teacher educators face is connecting SMTs' academic mathematical studies with their teaching in schools (Wasserman et al., 2023). This is an old problem – it has concerned mathematics educators for more than a century – but it remains pertinent and unresolved. In many countries, prospective SMTs are required to complete extensive coursework in mathematics or in some cases attain a bachelor's degree in mathematics, yet many SMTs experience academic mathematics as irrelevant to their future practice (Wasserman et al., 2023). Given that mathematicians are de-facto in charge of the academic mathematics education of SMTs, surprisingly little is known about their views on, and involvement in, SMT education (Wasserman et al., 2023). The literature that does exist addresses issues such as the views of mathematicians on their role in SMT education (Hodge et al., 2010); on what they wish prospective SMTs to take away from their mathematics coursework (e.g., Leikin et al., 2018); on what it is important for prospective SMTs to know about the discipline of mathematics (e.g., Hoffman & Even, 2024); and on how they would design a hypothetical course targeted solely at prospective SMTs (Lai & Ahrens, 2024; Leikin et al., 2018). While the growing body of literature in this area provides many valuable insights, much of the research conducted so far in this area has been small-scale, with few participants ($n \approx 10$) in one country or even at one university. As such, the insights developed so far may be seen as local, and there is a need for research that could support consolidation of these insights and their translation across institutions and countries. To this end, there is a need for a framework for describing similarities and differences between different educational contexts in relation to mathematicians' involvement in the education of SMTs.

In light of this need, the Mathematics Education Committee of the European Mathematics Society (EMS), of which the authors are members, has commissioned a large-scale survey of mathematicians' views on their role, and on the role of academic mathematics, in SMT education, and of local initiatives that different universities have taken to strengthen the mathematics education of prospective SMTs, apart from those already reported in the literature. This survey will take the form of an online questionnaire followed by interviews with selected respondents. The survey will target mathematicians working in mathematics departments across Europe that are involved in SMT education or in efforts to improve it. In designing the questionnaire, we draw on previous large-scale surveys of mathematicians' views (e.g., Pinto & Koichu, 2023), on findings from previous studies,

and also on the literature survey by Wasserman et al. (2023), who identified "three different aspects within the literature in terms of the problems, challenges, and solutions emphasised with respect to university mathematics and teacher preparation" (Wasserman et al., 2023, p. 724): bridging school and university mathematics; distinguishing mathematical concepts from mathematical practices; and recognising the didactical realm and connecting to teaching. Wasserman et al. present a theoretical framework built around these aspects which we will use to frame the survey.

Access and response rates are well-known problems when conducting surveys of this sort, yet past experience suggests that the EMS can provide invaluable help in gaining access to and good will from mathematics departments and mathematicians. Questions will, for instance, concern what kinds of goals the mathematicians have for the learning of prospective SMTs in their courses, whether there are any goals that are specific to prospective SMTs, and what kinds of activities or tasks they use to help the SMTs fulfil these goals. The questionnaire will also include open questions asking for detail on any specific initiatives relating to the mathematical education of SMTs, and we aim to conduct follow-up interviews with mathematicians involved in such initiatives, to elaborate and refine our findings. However, a major obstacle in designing the questionnaire is the great diversity in the organisation of SMT education across Europe, and we made use of the poster as a means of soliciting further information about this diversity, to support us in the design of the questionnaire.

Acknowledgment

This study is undertaken with the support of the European Mathematical Society.

Research-informed and collaborative reform in university mathematics teaching: The case of secondary to tertiary transition

George Witty, Owen Hooper, Elena Nardi and Irene Biza

University of East Anglia, Norwich, United Kingdom; g.witty@uea.ac.uk

Keywords: Secondary-tertiary transition, teaching design, teacher-researcher partnerships.

Mathematics students are known to face many difficulties during their transition from secondary to tertiary education (Gueudet, 2008). During the teaching of an introductory course for first-year mathematics students, the first author (Witty) encountered numerous issues which he associated with this transition, particularly related to students' attempts at mathematical communication, as well as their low engagement levels. For example, it was common to encounter students who would produce solutions that used new mathematical words and symbols, but lacked the rigour he would expect from something 'mathematical'. Gueudet (2008) states that, when students begin university, they notice the new language used by their teachers and imitate it: this "leads them to produce texts looking like mathematics, focusing sometimes more on the form – many symbols, usual language brought to a minimum – than on the mathematical meaning" (p. 244). Similarly, Sfard (2008) notes that "there are important differences between construction and substantiation routines practiced in colloquial and literary mathematical discourses, and these routines change again in the transition from school discourse to the scholarly discourse of mathematicians" (p. 225). As Witty believed it is important to consider how to assist students in overcoming these differences and difficulties in their first year, he became interested in learning more about changes he could make to help. There have been calls for the design and evaluation of interventions that support students during the secondary-tertiary transition. For example, Biehler et al. (2022) state that "there is a growing interest in teaching practices fostering students' active engagement" (p. 10) and that research in mathematics education can support teachers at university-level in this aim. With this in mind, Witty embarked on the design, implementation and evaluation of a new set of teaching sessions created for a course on 'Mathematical Skills' he leads with the aim of alleviating some of the difficulties of the secondary-tertiary transition. Although this intervention was produced in a partnership between him and mathematics education researchers (Hooper, Nardi, Biza), here he reflects on his own experience, mainly of the design part, through a reflexive autoethnographic approach (Ellis et al., 2010).

In this Year 1 course, students are introduced to core definitions and concepts of pure mathematics, such as properties of sets, numbers, and functions, as well as to mathematical proof. When Witty took on this course, he was given materials used previously which lend themselves to a typical 'chalk-and-talk' lecture format. He saw problems in students' engagement and use of mathematical words and symbols whilst teaching this course, and there were additional issues he encountered with his delivery such as an inability to fully convey passion for the new way of mathematical thinking when consigned to a blackboard. He attempted to fix some of these problems in his second year of teaching the course by introducing quizzes into lectures and moving problem solving activity into lecture time. This improved things, but the lack of a systematic approach and understanding of whether he was changing things in a pedagogically sound way meant he did not feel he was reaching the full potential of moving

to a new lecture format. When he was made aware of an opportunity to work with the university's Mathematics Education research group on a project that would involve redesigning a course to include more interactive elements and use of different methods of teaching, this seemed like a good opportunity to improve and expand on his approach to easing the transition to university mathematics.

The approach to planning and designing the new structure for the course was done through regular meetings with Mathematics Education researchers (mostly Hooper) where Witty provided updates on the content and the aims of the sessions, whilst researchers provided research-informed insight on innovative teaching practices, such as inquiry-based group work with flipped classroom elements and use of online tools, such as Padlet, as means for increasing student engagement and contributions during lectures (Hooper & Nardi, 2024). We created a lesson plan template (Figure 1) to detail timings and use of interactivity during a session, along with an explanation by Witty of why he wanted to deliver each part of the session in this way.

Time	Activity	Interactivity	Why
00:00-00:10	Quick recap of statements from pre-lecture video with true/false quiz with some statements.	Wooclap (https://www.wooclap.com)	Need to refresh the idea of the definition from the video as it will be important throughout the lecture. Quick quiz allows immediate interaction and works well for true and false statements!
00:10-00:20	Introduction to truth tables, giving example of not(A) and not(not(A)). Discuss 'and' and then set them the task of completing the truth table.		Good to see an example first of new notation etc. before some doing!
00:20-00:25	Students complete truth tables for 'A and B' and 'A and not(B)'	Working in groups	Students actually work with the truth tables.

Figure 1: Template excerpt for the plan of the beginning of a lecture

The creation of a plan for each session – and its collaborative production with the Mathematics Education research team – is a novelty that we see as of potential pedagogical value to other university mathematics teachers. We see its value in being asked to reflect explicitly on why Witty was choosing a certain method or activity or tool. The poster (https://tinyurl.com/CERME14-Poster-Witty-et-al) presents this design process, highlights of the course implementation and reflections thereof.

TWG 15: Teaching Mathematics with Technology and Other Resources

Thematic Working Group 15

Teaching mathematics with technology and other resources

Bärbel Barzel[1], Gülay Bozkurt[2], Nicola Bretscher[3], Eirini Geraniou[3], Ornella Robutti[4] and Andreas Tamborg[5]

[1]University of Duisburg-Essen, Germany; baerbel.barzel@uni-due.de

[2]Izmir Demokrasi University, Turkey; [3]IOE, UCL's Faculty of Education and Society, University College London, UK; [4]University of Turin, Italy; [5]University of Copenhagen, Denmark

Teaching mathematics with technology embrace both innovative and traditional tools to adopt a broad view of using technology resources in mathematics education such as mathematics-specific learning environments and general digital tools. Technology use is relevant both to teach mathematics in the class and to manage the professional issues from designing curricula to designing learning activities and classrooms in different didactic scenarios, and assessment.

Keywords: Technology, teacher practices, AI, computational thinking, teacher competences

Introduction

TWG15 accepted 19 papers and six posters for presentation at the conference, which reported research from 17 countries (Austria, Canada, Denmark, France, Germany, Greece, Ireland, Israel, Italy, Norway, Portugal, Spain, Sweden, Turkey, UK & United States). In total, 31 participants took part on the group, comprising 15 academics and 16 young researchers. The papers and posters were presented across seven sessions with an additional session dedicated to summarizing the discussions and preparing the final report. The contributions drew upon a wide range of theories – both general educational theories and those specific to mathematics education, both addressing overarching issues as well as those related to teaching with technology. The papers and posters dealt with a wide range of technologies and related issues - from traditional digital learning environments to computational thinking and, most notably, emerging technologies such as artificial intelligence (AI). The contributions touched different *roles of teachers*– teachers as designers, learners, working alone or and as participants in communities. Pre-conference, all papers and posters were organised and grouped into four sub-themes: *New Theories - Future directions* (six papers/posters), *Generative AI* (six), *Computational thinking* (six), and *Technological learning environments* (seven). Each thematic session began with a brief introduction and concluded with a synthesizing summary.

Sub-theme 1: New Theories – Future Directions

In the sub-theme, developed by five papers and one poster, discussions focused on the role of theory in understanding teaching mathematics with technology and other resources. The contributions considered how to adapt theories to encompass emerging technologies (Geraniou et al.; Lyublinskaya & Du) or refine or extend them to address situations involving new configurations of users and/or artefacts (Nøhr et al.; Bretscher et al.; Sayadi & Abboud). Each paper made connections between existing theories in some way. However, in Rocha, comparing theories, to elicit similarities and

differences between them, was the central focus. Drawing on Artigue's (2007) CERME5 plenary, the papers in this session recognise the continuing theoretical diversity inherent in our field, resulting from the need to adapt frameworks in ways that fit the particular needs of the social, cultural and educational contexts that the TWG15 community are living and working in, and at the same time, working on theoretical commonalities, provide a basis for the important work of networking theories.

The instrumental approach provides the theoretical foundation for three papers in this sub-theme. For example, Sayadi and Abboud use instrumental genesis, supplemented by instrumental Approach (Abboud, 2024) and semiotic bundles (Arzarello, 2006), introducing the concept of resonance to account for interactions between different subjects' instruments in the context of geometric constructions. Likewise, Nøhr et al. propose an extension of instrumental genesis to accommodate group cognition, moving away from a theoretical focus on individuals' use of technology to contexts involving multiple users. Geraniou et al. reflect on the strengths and limitations of the Double Instrumental Genesis (Haspekian, 2014) when applied to teachers' use of generative AI, concluding that teachers must continually update their competencies to 'keep up' with the pace of technological change.

The other three papers draw on theories beyond those associated closely with research on digital technologies in mathematics education. From a resource perspective, Bretscher et al. explore how the notion of transparency (Lave & Wenger, 1991) may be used for analysing pre-service teachers' interpretation of other resources, beyond digital technology. Founded in theories beyond mathematics education, Lyublinskaya and Du illustrate how a pedagogical framework for integrating AI literacy can be applied in teaching mathematics. Finally, Rocha presents a 'global model' of teachers' knowledge for teaching mathematics with technology informed by a comparison of the similarities and differences of diverse theoretical frames essentially based on the pedagogical and content knowledge for teaching, with the specific reference to the use of technology by teachers, basing on TPACK (Misha & Koehler, 2006), PTK (Thomas & Hong, 2013) and KTMT (Rocha, 2020).

In summary, the instrumental approach continues to evolve, yet remains central to much of the research on teaching with technology and other resources. In future, networking theories may provide an inclusive approach to managing theoretical diversity, while encouraging continued theoretical growth, adaptation and refinement inspired by new technologies, contexts and concepts from within and beyond mathematics education. These theoretical reflections echo and resonate in subsequent sessions, notably those focusing on generative AI and computational thinking, where emerging technologies exert a disruptive, yet productive, influence on theories in mathematics education.

Sub-theme 2: Generative AI

This session addressed the implications of emerging technologies and AI for mathematics teaching, featuring four papers and two posters. The contributions collectively explored various questions related to teaching mathematics in diverse technological contexts, each with distinct yet overlapping emphases. Notably, generative AI (GenAI) was central to four of the six contributions. The two papers not focused on GenAI were authored by Ovadiya and Marabash. Ovadiya examined challenges

faced by teachers when integrating digital technology into the process of posing mathematical problems. Marabash presented a self-study investigating how mathematical digital competencies manifested in their own experimental approach to posing and solving problems using digital tools.

The remaining contributions addressed different aspects of the intersection between GenAI and mathematics teaching. Yavuz and Dede explored how pre-service teachers utilized ChatGPT as a scaffolding tool to solve a geometry problem within GeoGebra. Segal and Biton investigated whether pre-service teachers' use of ChatGPT for generating mathematically defined problems with specific educational goals could enhance their technological, pedagogical, and content knowledge (TPACK, Misha & Koehler, 2006). Byrne et al.'s poster reported on an intervention in which in-service teachers participated in professional development designed to foster dialogue among teachers, their colleagues, and AI systems. Embid and Perdomo-Díaz's poster examined the ability of various GenAI chatbots—GPT-4, Claude 3.5, Sonnet, Copilot, and Gemini—to generate plausible mathematical problems involving fractions at varying difficulty levels.

Beyond their varied empirical foci, these contributions employed a range of theoretical frameworks and research methodologies, including the zone of proximal development, TPACK, design-based research, and theories of mathematical problem solving. This diversity underscores that GenAI's influence on mathematics education is multifaceted and that our field possesses robust theoretical tools to study and understand these implications.

Mathematics education has a long tradition of adopting and critically engaging with new technologies, continually developing theoretical frameworks to analyse their affordances, applications, and limitations. A key point arising from the discussions was that while existing theories remain valuable for understanding new technologies, there may be a need to network these theories in novel configurations. Despite this point, a central theme of discussion at this session was whether GenAI represents a fundamentally different kind of technology compared to those traditionally used and studied in mathematics education, in relation to different theoriesetical frameworks. The discussions converged to use Double Instrumental Genesis as a foundation for GenAI with a revision to integrate the distinctive characteristics of Gen AI. It is agentic, allowing interactive engagement from both students and teachers; it is dynamic, with unpredictable frequent updates and constantly feature enhancements; and it is probabilistic, often producing varied outputs to identical prompts. Rather than rushing to definitive conclusions about the implications of these features for our field, the discussion focused on critical questions that warrant further inquiry: Should we consider GenAI as agent or artifact, and what are the implications of this choice, in relation to interactions with it, and possible schemes of use? Should they be considered in a traditional way or a completely new way? For what educational purposes might we best leverage GenAI's unique capabilities? How do we balance potential gains in efficiency with the risk of diminishing students' opportunities for deep mathematical thinking? And what new risks and challenges do GenAI introduce to mathematics education? We are confident that research on this type of technology will remain important. The contributions and discussion in this sub-theme illustrated that TWG15 is up for this task.

Sub-theme 3: Computational Thinking

Within the Computational Thinking (CT) theme, we had six contributions, five of them looked into empirical data from small studies with mathematics teachers, whereas one offered a theoretical perspective by exploring how three frameworks offer different perspectives on using computational technology. All the studies highlight the growing interest in integrating computer programming and CT into mathematics education, while also exposing significant challenges.

In more detail, Nordby and Gadanidis focused on the potential role of programming in enhancing teaching and learning of mathematical ideas and relationships in primary school classrooms (grades 1–7). Drawing on diSessa's (2018) framework of computational literacy, they analysed 32 classroom activities using Scratch and found they align with the core principles of computational literacy. Therefore, by highlighting this particular example, they demonstrated how programming can reshape discussions and engagement in primary mathematics, but argued that there is a lack of resources and PD to support teachers in this field. So, they called for more research into how best to support teachers in using computer programming in mathematics classrooms.

Rama et al. presented the case of a grade 8 mathematics teacher, who participated in a lesson study involving four mathematics teachers in total, discussing how the collaboration of these teachers led to the one teacher's "mobilization" of their CT, as they designed a lesson plan involving the use of Scratch. The authors discussed how the teacher's designed lesson encouraged student participation and CT practices, claiming that Scratch played a crucial role in this development. Collaboration with the other teachers was also key as it helped in mobilizing the teacher's knowledge in action, improving the lesson plan and the tasks used and in the effective use of CT practices. As authors concluded, further research could provide insights into how to enhance teachers' abilities at different educational levels to effectively incorporate CT into their teaching and how to more efficiently utilize existing resources (Ponte, 2012).

Borg presented a case study of how a Swedish teacher integrated programming into his mathematics teaching, using the *Structuring features of classroom practice framewor*k (SFCP) (Ruthven, 2009) as an analytical lens for the design decisions and justifications for his teaching approach. The findings highlight how the teacher's background and "craft knowledge" (as a qualified programming teacher) influences the integration of programming in their mathematics classroom. The study shows that the way programming was added to the Swedish curriculum—without removing existing content or clarifying programming goals—has significantly influenced how teachers plan and deliver lessons. This places a heavy burden on teachers, who must teach both programming skills and their application in mathematics, contributing to their criticism of the current approach. Comparatively, countries like England treat programming as a separate subject, and its integration into mathematics depends more on individual schools, highlighting the need for further research into how various curriculum models impact teachers' ability to incorporate programming into mathematics education.

The study by Jemai et al. seeks to offer teacher educators meaningful insights into how preservice teachers (PTs) perceive CT. By examining the notes and reflections of three PTs as they used programming to solve mathematics problems, the authors aimed to uncover PTs' CT perspectives. Using Brennan and Resnick's (2012) CT framework—specifically its focus on perspectives, they

explored what the PTs identified as challenges and how they perceived their value. The results indicate that the PTs viewed themselves as beginners in programming, concentrating on learning to code and creating tools to enhance student learning. They selected familiar math problems and considered programming to be the primary difficulty. Ultimately, they saw their struggles with programming as a valuable part of their learning journey. In summary, the PTs focused mainly on programming, engaged in productive struggle, and aimed to create educational tools for their students—highlighting the need for further research on how teacher educators can help them better connect mathematics and programming.

Kallo also focused on the interaction between CT and problem solving. He emphasizes that introducing CT through problem solving, rather than an extension of 'mathematical thinking' can better harness its potential to develop abilities to engage with complex problems in a digital context.

Last, but not least, Tamborg et al. investigated how three frameworks—the KOM framework (Niss & Højgaard, 2019), CT (Weintrop et al., 2016), and computational literacy (CL) (diSessa, 2018)—offer different perspectives on teaching mathematics using computational technology. KOM sees mathematics as a discipline where technology serves as a supportive tool, relying on teachers' existing mathematical knowledge. CT introduces additional, computer science-related practices that need to be integrated into the curriculum, posing challenges for teachers lacking expertise in this area. CL takes the most transformative stance, suggesting that technology can reshape both the discipline of mathematics and its teaching, requiring teachers to critically evaluate the evolving relationship between tools and mathematics. The paper concludes by emphasizing the need for thoughtful consideration when incorporating computational technology into mathematics education and encourages further research to build on these initial insights.

In the conclusion we highlight that teachers both pre-service and in-service – across different institutional and cultural contexts, struggle with limited resources, lack of clarity in curricula, and insufficient professional development, particularly when programming is introduced without adjusting existing content. Collaboration among educators and supportive frameworks can play a key role in helping teachers meaningfully connect programming with mathematical learning. The perspectives on integration vary—from viewing programming as a supportive tool (KOM), to additional disciplinary knowledge (CT), to a transformative force reshaping mathematics itself (CL). Overall, the research emphasizes the need for clearer guidance, targeted support, and continued investigation into how programming can be effectively and sustainably embedded in mathematics education to support mathematical thinking.

Sub-theme 4: Technological Learning Environments

Within the broader scope of TWG15, this section focuses on the theme of Technological Learning Environments particularly drawn on perspectives pointed out in the seven submissions including five papers by Alan and Akkoç; Cheung and Lyublinskaya; Diamantidis and Kynigos; Läufer and Ludwig; Yiğit Koyunkaya and Bozkurt, and two posters by Lindenbauer and Infanger; Liu et al. All these submissions collectively explore how teachers engage with, design, and integrate digital

technologies in mathematics education. These contributions shed light on the complex interactions between teachers' professional knowledge, technology tools, and classroom practices, revealing critical insights into fostering effective technology-mediated learning environments.

Three contributions focus on pre-service teacher education, highlighting how digital tool use can be developed through structured university-based training. Lindenbauer and Infanger emphasize design challenges in creating GeoGebra-based digital materials (dMs) and propose using an adapted Dynamic Geometry Task Analysis (DGTA) framework to guide future training. Läufer and Ludwig, through the TPACK lens, explore the integration of 3D printing into a mathematics seminar, showing how different phases of 3D modelling correspond to varied knowledge domains. Similarly, Yiğit Koyunkaya and Bozkurt analyze a pre-service teacher's development of Digital Resource Design Capacity (DRDC) during practicum, demonstrating how real teaching experiences support strategic use and critical reflection on technology-use.

In contrast, Liu et al. and Cheung and Lyublinskaya examine in-service teacher practices in different cultural and educational contexts. Liu et al. shed light on Chinese teachers' limited familiarity with tools like GeoGebra and underscore the need for design tasks aligned with teachers' existing practices and available technologies. Cheung and Lyublinskaya trace the evolution of two elementary teachers' orchestration strategies when using the Finch robot, showing how sustained, targeted professional development can foster a shift from teacher-centred to student-centred practices.

Alan and Akkoç as well as Diamantidis and Kynigos contribute a deeper theoretical and conceptual engagement with teacher orchestration and digital resource design. Alan and Akkoç introduce the idea of "linking models" to differentiate didactic goals within orchestration chains, illustrating how identical orchestration types can serve distinct pedagogical purposes. Diamantidis and Kynigos adopt Cultural-Historical Activity Theory perspective to examine tensions in collaborative digital artefact design among teacher educators, offering insights into how institutional and historical factors shape design processes and learning.

Collectively, these contributions highlight not only the complexities of integrating technology into mathematics instruction but also the necessity of context-sensitive, theory-informed, and practice-driven approaches to teacher education. The studies demonstrate a shift from viewing teachers as mere users of digital tools toward recognizing them as designers, facilitators, and reflective practitioners. This evolving perspective underscores the importance of professional development that fosters not only technical proficiency but also pedagogical reasoning and adaptive expertise. As mathematics education continues to evolve in the digital age, supporting teachers' dynamic engagement with technology remains a critical focus for research and practice.

Conclusion: Topics and future issues relevant to the TWG15 community

In addition to the presentations in our group, we created many opportunities for exchange in small groups. After the sessions according to the sub-themes, we reflected on the key points within the topic. At the end of the conference, we discussed and summarised these key points regarding our overall topic of teaching with technology and to explicate the challenges and questions for the future.

We perceived in the contributions and discussions a natural use of theories relevant to our topic as a basis for convergence of different theoretical approaches and networking theoretical frames (Artigue, 2007) to serve as a adequate framing for specific research interests. For example, the synergy of upcoming theories about teacher competences (TPACK, Mishra & Koehler, 2006) and consolidated traditional theories about epistemic processes (such as Instrumental Approach) is convincingly described. The adaptation and expansion of traditional theories was also described very eloquently. Analogous to the adaption of Haspekian (2014) who used Double Instrumental Genesis to describe the epistemic processes using technology on the two levels of students and teachers, Nøhr et al. came up with Group Instrumental Genesis to support understanding and analyzing processes of instrumental genesis within the work of small groups.

The rapid development of emerging technologies was overwhelming – an experience we share with TWG16 about "Learning with technology". Traditional mathematical tools like geometry software or computer algebra were taken into account through contributions to learning environments with GeoGebra in our group, which gave us a good impression of current research in this field. Computational thinking as programming and algorithmic thinking within mathematics teaching is solved in very different ways in the countries and will be an important topic for us in the future. This is also particularly true for generative AI, where we are just at the beginning to understand the challenges popping up with this new unpredictable technology. "Hurry up slowly" (quotation by August emperor) succinctly expresses what the motto for our research must be from now on. These emerging technologies as part of mathematics curricula have to be used as tools in which students' and teachers' creativity, imagination, critical abilities, mathematical and interdisciplinary competencies can be used, supported, and enhanced in education, both individually and in communities of practice. Math education research on teaching with technology is not only evolving with the technological developments, but must foster all fields which are relevant for teachers to design and manage their classrooms with integration technology beneficially. Future issues which were not addressed in our TWG at this time at CERME are still needed for the future. Tools can only be game changers if teachers are prepared for the shift. Therefore, we still need intense research on *professional development* as teachers need ongoing support to learn, adapt and experiment with especially the recent trends. We need research on the *influence of educational policies* on teaching with technology like relieving bureaucratic stress, assessment, curriculum changes, special cultural factors and ethical issues.

Regarding all these diverse challenges in our research field we would highlight the necessity to discuss more about our research interests and research methods which will allow us also further to coordinate our efforts, deepen our collaborations and learn even more from each other.

Formation of orchestration chains: linking models

Seyfettin Alan[1] and Hatice Akkoç[2]

[1]Mus Alparslan University, Faculty of Education, Muş, Turkiye; s.alan@alparslan.edu.tr

[2]Marmara University, Turkiye

This study elaborates on the notion of orchestration chain (OC), which we previously defined in CERME13 as the orchestrations sequenced to serve a specific didactical goal. For this aim, we designed a case study. The microteaching lesson of a prospective mathematics teacher, together with the lesson preparation process, were examined. Based on the data analysis, two OCs formed by connecting the same types of orchestrations in the same order were selected. We found that two identical OCs may have different didactic goals that link the orchestrations and may be linked to form different models. We called these models as linking models. We believe that the notion of linking models presented in this study will improve the theory of instrumental orchestration and contribute to our understanding of teachers' activities in the classroom.

Keywords: Instrumental orchestrations, orchestration chains, technology integration

Introduction

The emergence of new technological tools offers new potential for mathematics teaching (Lavicza, 2010). However, reaching these potentials is more challenging than it seems (Drijvers & Trouche, 2008). Mathematics teaching practices incorporating technological tools are more complex than initially expected (Drijvers et al., 2009). Recognizing this complexity, researchers have argued that there is a need for a theoretical approach to technology integration that would address technological tools and other resources of the classroom environment together (Monaghan, 2004). The instrumental approach to tool use emerged as a result (Drijvers, 2015).

The instrumental approach focuses primarily on the relationship between an artifact and its user. As long as the user does not know what kind of tasks the artifact can be used for and in what ways, the artifact is meaningless to him. When the user develops mental tools to use the artifact, it becomes meaningful for him (Drijvers & Trouche, 2008). The person should establish an instrumental relationship with the artifact and become able to use it for his purposes. Then, the artifact becomes an instrument for the person (Verillon & Rabardel, 1995). This process is called *instrumental genesis* (Guin & Trouche, 2002). However, teachers must mentor students for instrumental genesis (Drijvers et al., 2010). To describe how a teacher arranges students' use of instruments in the classroom and how they can construct coherent instrument clusters, Trouche (2004) established the theoretical framework known as *instrumental orchestration* (IO).

Theoretical Framework

Instrumental orchestration theory was developed to explain how teachers organize instruments and create coherent instrument clusters (Trouche, 2004). According to this theory, types of orchestrations express teachers' actions. Drijvers et al. (2013) classify orchestrations as individual or whole-class. During whole-class orchestrations, the entire class participates in instructional activities. Some

examples of these types are *technical-demo*, *guide-and-explain*, *link-screen-board*, *discuss-the-screen*, *explain-the-screen*, *spot-and-show*, *sherpa-at-work*, and *board-instruction* orchestrations. The *technical-demo* orchestration involves showing students the instrumented techniques that the teacher will use in the classroom. The teacher guides the procedures during the *guide-and-explain* orchestration by posing questions to the students as they work on their instrumental tasks. The *link-screen-board* orchestration integrates digital technologies with conventional media, including books, paper, and board. The teacher engages the class in discussing what is displayed on the screen during the *discuss-the-screen* orchestration. Explaining to students what is on the screen is part of the *explain-the-screen* orchestration. The teacher examines each student's work individually during the *spot-and-show* orchestration and presents it to the class. The teacher requests students to share their work utilizing individual tools during the sherpa-at-work orchestration with the class. The conventional teaching method, in which the teacher stands on the board, is called the *board-instruction* orchestration. Conversely, individual orchestrations occur when students use their equipment to work alone or in small groups as the instructor moves around the classroom, providing guidance. Individual *technical-demo,* individual *guide-and-explain,* individual *discuss-the-screen, link-screen-paper,* and individual *technical-support* orchestrations are individual types of orchestration described in the literature (Drijvers et al., 2013).

Drijvers at al. (2019) states that in instrumental orchestration theory, orchestration types are treated in isolation, and no attention is paid to how they are integrated into teaching. Considering this gap in the literature, two studies focusing on OCs were conducted in the last two years. Ratnayake et al. (2024) showed how orchestration types are linked together through teacher decision-making and defined an OC as "a sequence of IOs together with teacher decision-making links" (p.11). On the other hand, Alan and Akkoç (2023) focused on specific OCs performed at different moments of study and defined OCs as "the orchestrations sequenced to serve a specific goal" (p. 2584). In this paper, we will expand on the concept of an OC and demonstrate how different orchestration types interact to construct OCs that are put together with specific didactic goals of teachers.

In this study, we divided the lesson into moments of study in parallel with Besnier's (2016) research to identify OCs. These moments are *moments of introduction and discovery*, *moments of learning and training*, *synthesis moments*, and *evaluation moments*. Introduction and discovery moments are when a teacher engages students in a task or introduces a topic. Students perform exercises during learning and training moments, work through challenges, and participate in tasks. The practices used in the previous moments of study are combined in synthesis moments. The teacher evaluates students' learning during evaluation moments. We divided the teaching practice into the moments of study in line with these definitions. We identified the types of orchestration used at each moment of the study and analyzed how they were sequenced to align with specific didactic goals.

Methods

We designed a case study with a single case: a prospective mathematics teacher's (Esin) lesson. We considered three criteria in selecting Esin as a participant: Being in the fourth year of the teacher preparation program, using GeoGebra at a sufficient level, and having a positive opinion about technology-enhanced mathematics teaching. She attended a four-year teacher preparation degree at a

state university in Istanbul, Turkiye. She prepared a lesson using the GeoGebra software. Following a three-week preparatory period, Esin taught a forty-five-minute microteaching lesson. Microteaching is a technique used in pre-service training to improve prospective teachers' teaching skills and was part of the course requirement. Esin taught their peers a microteaching lesson on maximum and minimum problems that could be solved using derivatives. Data collection methods were interviews, direct observation, and documentation. PC screens and videos of the microteaching environment were recorded. Other data sources were the lesson plan and teaching materials.

The qualitative data analysis program ATLAS.ti was used to analyze the data. The definitions of orchestration types provided by Drijvers et al. (2013) were used. To determine how the orchestrations were lined up, the microteaching lesson video was divided into sections based on the moments of study (les moments de l'étude) defined by Besnier (2016) based on Chevallard (2002). We identified the OCs in each moment of study in line with the definition of OC (the orchestrations sequenced to serve a specific didactic goal of the prospective teacher) given by Alan and Akkoç (2023). We then analyzed how orchestration types are linked to form certain chains by identifying the instruments used during these orchestration chains and analyzing the didactic goals for which they are employed.

Findings

Our analysis revealed that identical orchestration chains (the same types of orchestrations arranged in the same order) can take on different structures to serve different didactic goals. This section will discuss two moments of study from Esin's micro-teaching lesson—the "learning and training moments II" and the "evaluation moments" indicated as shaded in Figure 1. We identified two distinct OCs for these moments of study, with identical orchestration types but for different goals. After giving a brief overview of Esin's teaching approach, we will present the two linking models emerging from our analysis.

Esin's micro-teaching practice

Esin mainly focused on using the derivative concept to solve maximum and minimum problems and developing an understanding of its geometric meaning. To achieve this goal, she first explained the concept of instantaneous velocity by approximating the number pairs (learning and training moment I). Then, she explained the instantaneous velocity-limit-derivative relationship geometrically (learning and training moment II). Next, she provided a geometric explanation of the relationship between the derivative and the maximum and minimum points (Synthesis-moments II). Lastly, Esin gave the students a real-world problem that involved applying derivatives to find the maximum and minimum points. The students (Esin’s peers) then used the board and GeoGebra to solve the problem (Evaluation moments). Figure 1 illustrates the various orchestrations and OCs that Esin used throughout this process.

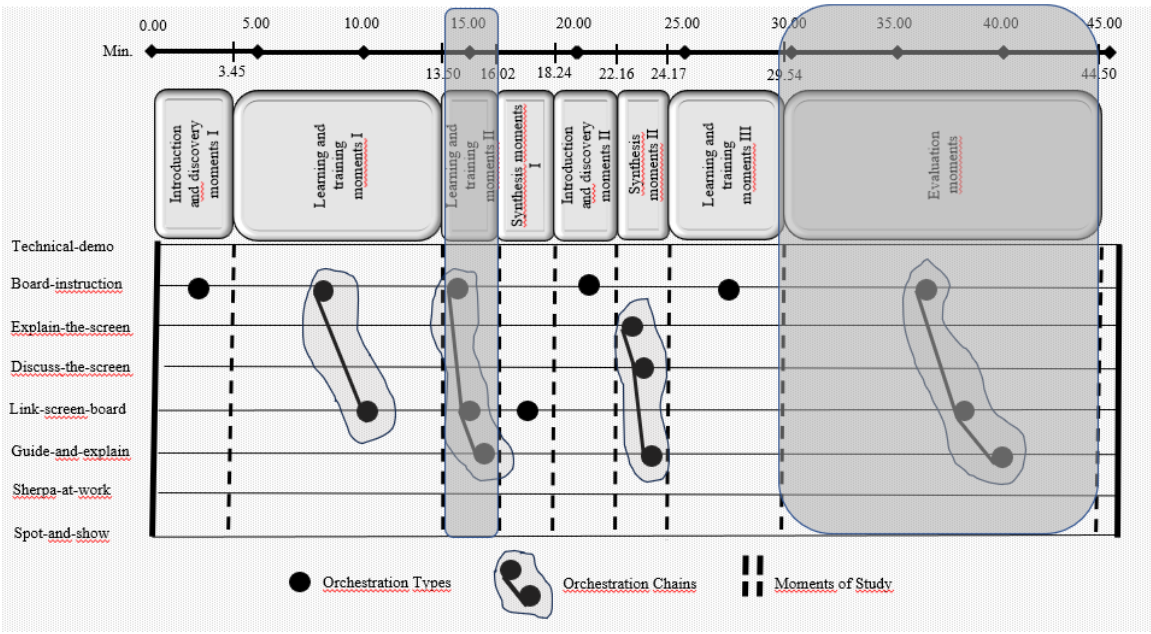

Figure 1: Analysis of Esin's micro-teaching lesson

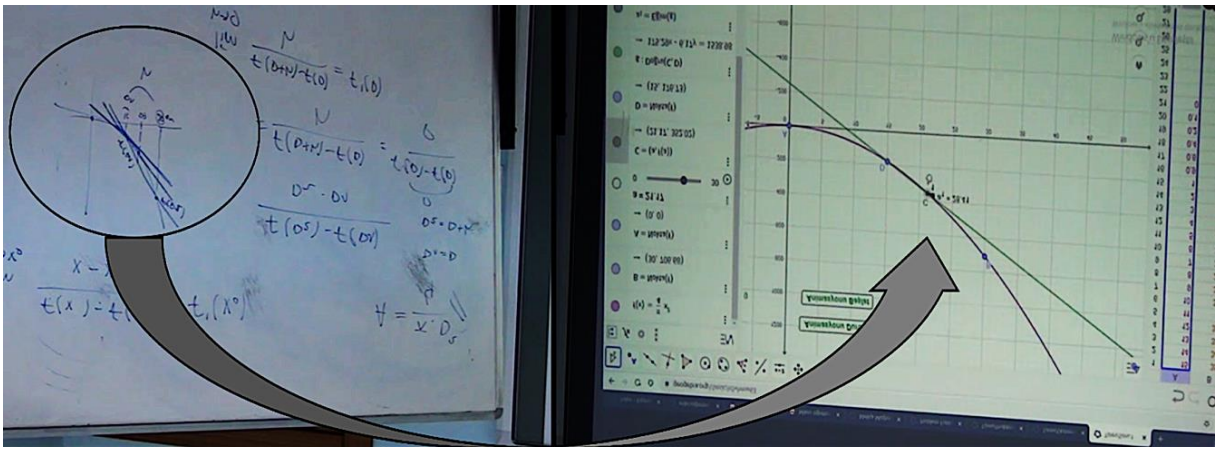
Linking Model A

During this lesson section, Esin gave a worksheet that included five questions regarding the relationships among instantaneous velocity, limit, and derivative. After completing the first three questions on the board, she verified her answers on the screen using GeoGebra (the learning-and-training-moments I).



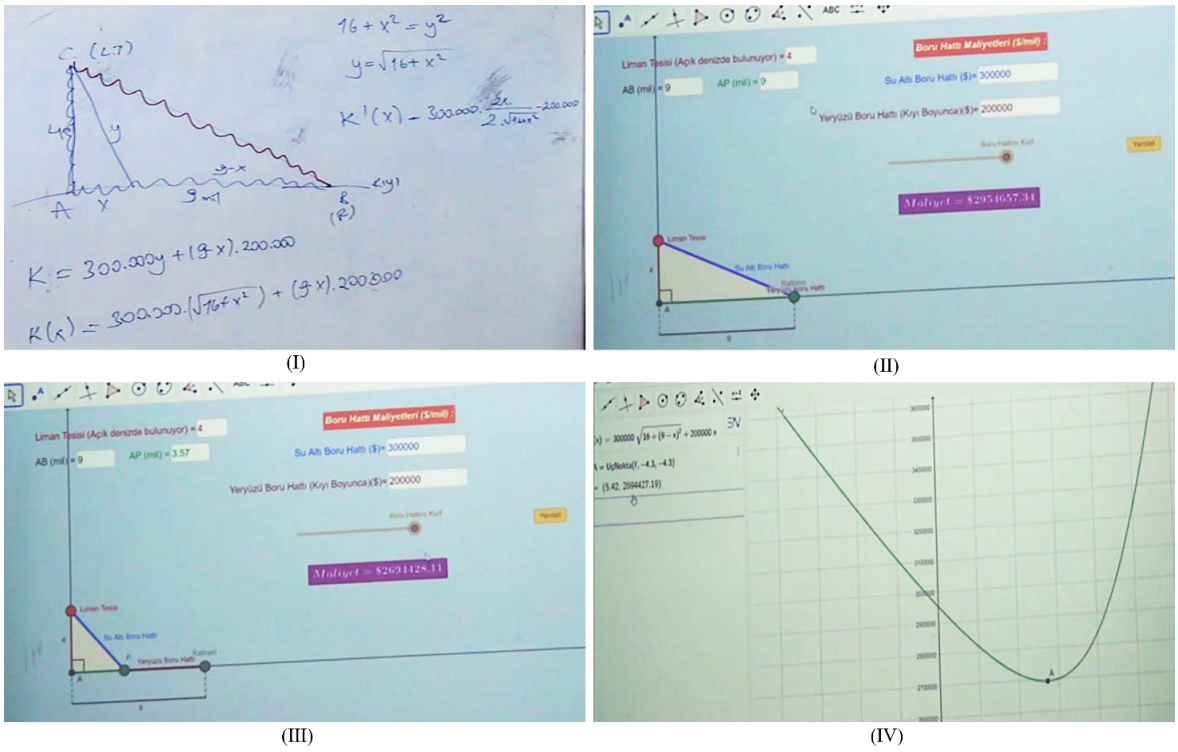


Figure 2. Screenshots from Esin's lesson (derivatives-limit-slope relationships)

For the other questions, Esin began to illustrate on the board how the secant lines approach the tangent or how the average rates of change approach the instantaneous rate of change. Using a step-by-step method, she explained why the result was undefined when h is zero on the board (Board-instruction orchestration). However, when the board was insufficient, she turned to GeoGebra (see Figure 2) and entered $h = 0.001$ to demonstrate that the secant line became the tangent. The result was 23.6, and she said, "So this is the slope of the secant line, the tangent, in that very, very small range" (link-

screen-board orchestration). Using the GeoGebra slide, Esin guided the students with explanations such as "Look, the slope is decreasing, right?". Esin said, "Look, when I get to that point, our secant line is now our tangent line. Our instantaneous rate of change is the slope of our tangent" and ended her explanations on GeoGebra (Guide-and-explain orchestration).

We identified Esin's implementation as a chain that consists of board-instruction, link-screen-board, and guide-and-explain orchestrations. In this process, she utilized GeoGebra because of the board's constraints. Esin overcame the board's constraints with GeoGebra's potential and created an OC with this characteristic feature. She drew attention to the limitation of one instrument and then tried to overcome this limitation with the potential of another instrument (we detailed the formation of this chain in CERME13).

(I) (II)

(III) (IV)

Figure 3. Screenshots from Esin's lesson (a maximum-minimum problem)

Linking Model B

Esin presented the students with a real-world problem to solve in the final section of the microteaching session, requiring them to apply what they had learned. The problem was a maximum-minimum problem about laying a pipeline from an oil facility some distance from the coast to an onshore refinery at the least cost. She told the students that they could work in groups and use calculators. After the students had found their answers, Esin went to the board and constructed the algebraic function to minimize the cost (Board-instruction orchestration). Then, she launched GeoGebra to test the accuracy of the values. The applet Esin prepared was the simulation of the real-world problem (See Figure 3). The model produced and plotted the findings as the variables in the simulation took on various values. Esin looked at cases where the pipeline crosses the simulation's

right triangle's hypotenuse and sides. Esin entered the 3.57 value obtained on the board and the very close 3.56 value into the simulation and showed that the least cost was 3.57 (Link-screen-board orchestration). Finally, Esin moved on to another GeoGebra activity to explain what this means graphically. Esin ended her explanation by showing on the graph that the value of 3.57 she found by experimenting in the simulation was indeed the extremum point of the function graph (Guide-and-explain orchestration).

Esin's practice uses the same types of orchestrations as in the previous section: a chain of board-instruction, link-screen-board, and guide-and-explain orchestrations. However, embracing a different approach, Esin used GeoGebra to show the possibilities of the real-world problem she presented and that the mathematically obtained value is indeed the minimum value. Unlike the other OC, GeoGebra was not strictly necessary here. However, the simulation allowed her to enrich the problem. Esin used simulation to engage with the problem and got results that could not have been obtained by using only the board. In summary, Esin carried out a teaching practice in which the problem's solution started on the board, was enriched with GeoGebra, and then focused on the intended result in GeoGebra. The data indicated that Esin used technology as an enrichment tool. The data showed that Esin used technology as an enrichment tool, prioritizing understanding with GeoGebra over lengthy blackboard procedures.

Discussion

This study aimed to expand upon OCs and explain the different linking models of orchestration types that form these chains. In this regard, we focused on two OCs that consist of the same types of orchestrations arranged in the same order. Our study revealed two linking models in the formation of OCs. We named the first linking model the "Linking Model A," in which the potential of one instrument and the constraint of the other instrument complements each other to form an OC. The second linking model is the "Linking Model B," where the teacher starts on the board, then uses the instrument to enrich the initial problem, and then focuses on the problem's original goal. These two linking models were identified based on the purpose of activating GeoGebra in teaching, aligned with specific didactic goals. Our findings show that the reason for activation shapes the orchestration's structure, making instrument activation and deactivation key determinants of linking models.

Drijvers et al. (2019) suggest elaborating on the relationship between orchestration types and instrumentation schemas. Ratnayake et al. (2024) describe how teacher decisions link orchestration types. In this study, we considered a specific OC as a whole and tried to identify the didactic goals behind it. The linking models we have put forward may have paved the way for us to comment on how orchestration types form chains and why the teacher forms specific chains. In future studies, we expect to increase the explanatory power of IO theory by identifying new OCs and linking models.

The findings of this study suggest that the concept of OCs, taken together with linking models, can help us better understand the patterns teachers use. According to Ruthven (2014), instrumental orchestration theory aims to identify patterns in technology-enhanced teaching practices. However, the patterns constructed by the participants in this study occur in the classroom. Teachers can design broader patterns related to schooling procedures beyond the classroom, which warrants further exploration in future studies. Additionally, GeoGebra (along with AR and 3D) was the only

technological tool used in this study. The orchestration structures (OCs) could become more complex when multiple technological tools are involved. A deeper understanding of OC dynamics requires further case studies. Finally, we suggest integrating them into the professional development of both prospective and in-service teachers.

Acknowledgment

This study is part of the first author's Ph.D. thesis, "Analysis of instrumented activities in mathematics teaching within the framework of instrumental orchestration theory," submitted to the Institute of Education at Marmara University, İstanbul, Türkiye.

Problem-posing based on digitally enhanced experimental mathematics: What does it demand of teachers?

Marita Barabash[1]

[1] Achva Academic College, Israel; mrtbrbsh@gmail.com

This is an excerpt from an experienced mathematics-teacher educator's self-study that aims to delineate the expectations of mathematics teachers if the linkage between experimental mathematics, enhanced by digital tools, and theoretical, formal mathematics becomes a part of the school reality. The problems appearing in the paper are authentic and are posed through experimentation in a dynamic digital environment that reveals phenomena otherwise probably undiscoverable. They also present and question situations that necessitate the acceptance of the solution only as a plausible one that is not ascertained from the mathematical-epistemological point of view. The educational implications of the study are discussed from the perspective of teachers, their knowledge, and their competences.

Keywords: Catenary and parabola, computational triangulation, experimental mathematics using digital tools, critical thinking, mathematics teachers' digital competences.

Introduction: Theoretical frameworks of the study

Experimental mathematics in school in the era of advanced digital platforms

Experiment-based conjecture has always been integral to mathematical investigation as an inductive basis for further formal deductive investigation and has been growing with the digital upsurge in mathematics research. In reference to the role of computers, Devlin considers the epistemological implications as follows:

> [E]xperimentation is (...) a significant part of the mathematical enterprise (...). In particular, this (...) gives an epistemological status to assertions that, while supported by (...) experimental results, have not yet been formally proved, and in some cases may never be proved. (Devlin, 2019, p. 65)

Experimental mathematics (EM) characteristics relevant for this paper include gaining insight and intuition, discovering new relationships, visualizing math principles, testing, and, especially, refuting conjectures (Borwein, 2012, pp. 73–74). The intertwining of EM and formal mathematics (FM) as described by Arzarello et al. (2012, p. 132) *inter alia,* enhanced by the "heavy use of new technology", touches upon both epistemological and didactical dimensions. Digital tools, however sophisticated and advanced they may be, do not absolve a user of the need to be alert, critical (Engelbrecht & Borba, 2023), and appropriately skilled and educated in working with them, as the examples in this paper suggest. One source of questionable results of digital experiments is imprecision in the resolution of graphical output. The following configurations, accessible at https://www.geogebra.org/m/ym5vskrc and https://www.geogebra.org/m/qqvrtwzd, provide lucid examples of the need to adopt a critical attitude toward visual computer outputs, even if provided by advanced platforms, and to test them by means of FM. Indeed, Borwein and Delvin (2009) dedicate a special chapter to the need to test computer-generated experimental mathematical results by FM. This is sometimes easier said than done, however, because mathematical problems are not always

explicitly solvable. Thus, special methodologies are needed to interlink EM and FM as a complement to straightforward mathematical testing of experimentally observed results. Denzin (1970, p. 301) worked out the so-called "method of triangulation" in social-sciences research in order to amplify the credibility and validity of research findings by deriving mutual support from various methods. Abramovich (2023) "imports" this methodology from the social sciences to substantiate solutions to mathematical problems that are attained by combining various methods and tools. It is one of the methods that I will apply in this paper to experiment-based problems and attempts to solve them. When an agent as powerful as a digital dynamic platform is added to the classroom reality, mathematics teachers are urged to acquire additional qualifications that pertain to it.

Mathematical knowledge for teaching that involves EM

Mathematical experiments are a rich source of context-based problems that are not always easily solved or even solvable by methods available within the school curriculum, pose a challenge to teachers and impose special demands on them insofar as the teachers adopt mathematical experimentation as part of their classroom mathematical culture. They may face, for example, students' experimentation that yields unexpected results; therefore, they must be equipped with professional pedagogic approaches to the handling of such an occurrence. Kortenkamp (2004, p. 62) is one of a number of mathematics-education scholars who see the requirement of teachers' specific EM–FM-oriented (mathematical) knowledge as "an opportunity to change the focus of teaching from the arithmetic to mathematics in a more global fashion". Therefore, this study proposes a deeper look at this specific strand of mathematical knowledge that is essential for intertwining EM with FM, an expression that I denote below by MK–EM.

Self-study: The choice of a theoretical approach

This study focuses on mathematics teachers' perspectives in coping with EM practices. Therefore, I chose self-study as an appropriate framework for the tracking and analysis of my own actual experience, the challenges I faced at each stage, and the decisions I made. In Hauge's (2021) comprehensive review on self-study by teachers' educators, the interplay between research and practice is emphasized.

> Self-study tends to be methodologically framed through questions, challenges, problems and desires related to areas in practice (...), and where the method most appropriate for examining and collecting data is used according to the study's intent. (...) The researcher must show who he / she is (...) by illuminating thoughts, opinions, interpretations, actions, development, and it (*self-study*) must involve the construction of meaning and knowledge. (Hauge, 2021, ch. 4)

In this spirit, being a mathematician, a mathematics teacher, a teachers' educator, and a researcher, I chose the approach linked to these areas, striving "[to] formalize the work and make it available to the professional community" (Hauge, 2021, ch.4). The study was performed from the teacher's perspective; accordingly, I monitored step-by-step my own experience with digitally empowered EM along a sequence of experiments with reflection properties of the catenary inspired by those of the parabola, performed on the GeoGebra platform. The questions I posed were inspired by the ostensible similarity of the two curves, in the spirit of mathematical problem posing summarized by the "what

if not?" approach, and I tried to answer them. These experiments, I suggest, are illustrative of problems that stem from mathematical experiments, albeit obviously not exhaustively. The experiments, outputs, conjectures, and problems that emerged in the search for formal corroboration or refutation of the conjectures are original and authentic. My methods of solution and my considerations in appraising them emerged "on the fly" and I consider them no less valuable for the purposes of this study than the results obtained. In formulating the research questions, I found it important to refer explicitly to teachers' mathematical knowledge specific to EM (MK–EM) as a basis for the critical thinking needed to appraise the results of the experiments. I adopted some of the components characterized by Geraniou et al. (2024), modifying them to EM, namely:

MDCT2-EM: an awareness of which digital tools to apply in different mathematical situations and contexts and of the capabilities and limitations of the various tools in relation to EM.

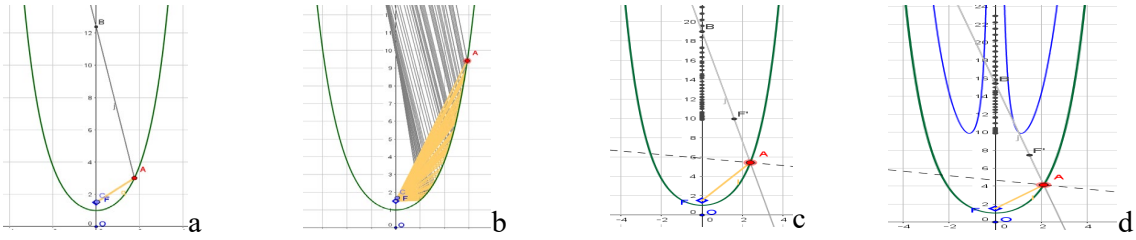
MDCT3-EM: "doing mathematics" (problem-solving as defined in MDCT3) within its specific EM adjustment.

Accordingly, the research questions are:

RQ1: How do the characteristics of MDCT2-EM, MDCT3-EM manifest in problem-posing and -solving on the basis of mathematical experiments that make use of digital tools?

RQ2: What occurrences in mathematics teachers' mathematics knowledge (MK-EM) and critical thinking (CT) specific to EM-based problem-posing manifest in *posing problems* based on mathematical experiments and appraising their solutions?

Methods



Data collection and analysis

I adopted the approach outlined in LaBoskey (2004) (cited in Hauge, 2021) that self-study uses primarily qualitative methods that are often invoked in educational research. Working out all stages illustrated in the example below, I carefully transcribed all the self-questions and self-answers that arose in the course of this work in real time and a posteriori in a quest for the answers to the research questions. Being an experienced educator of mathematics teachers, I made notes of all occurrences that might have a direct or indirect impact on teachers' competences. Having completed the whole series of problem-posing and -solving, I sorted out my notes in accordance with the characteristics I sought in order to answer the research questions as comprehensively as possible. In the following section, I present an excerpt from this data and its analysis.

The experiment and one of the problems appearing in it

It is hardly surprising that Galileo mistook the catenary ("the chain curve") given by y=cosh(x) (= $0.5(e^{x} + e^{-x})$) for a parabola; they do look similar, for good reason. The approximation of the catenary by first two terms in the Taylor series is $y = 0.5x^2+1$. The next term is $x^4/24$, which means that the difference between the catenary and the parabola is $0.5x^2+1$ is O((x^4)), which yields "pretty close" graphs for small values of x, i.e., around x=0. What does "pretty close" mean for two objects that are not only purely mathematical but also have certain physical properties? A parabola is known to have an important focal property: Any ray emanating from a source located in its focus F, when

mirrored from its inner surface, becomes parallel to its axis. So how do the rays emanating from F behave after being mirrored by the catenary? See Figure 1a for the configuration; the tangent and the normal are not visible. For clarity and due to symmetry, it suffices to consider the reflection only to the right of the y-axis. By applying the Trace On command to the emanating (yellow) and reflected (grey) rays, I follow their behavior as Point A glides along the catenary, see Figure 1b. It suggests, in particular, that there exists a lowest location of Point B where the rays intersect with the y-axis; it is located slightly higher than (0,10), see Figures 1b and Figure 1c.

Figures 1 a, b, c, d: Rays, reflection, intersection point B, its lowest location, graph of $y_B(x_A)$

These conjectures require formal validation or rejection. Therefore, the following problems are formulated and need to be solved**:** Problem (a): Prove or refute the existence of a minimum of $y_B \equiv y(B)$, as a function of x_A. Problem (b): If the minimum exists—what is its value? The solutions by two different methods and applying two different tools are outlined here. In both problems, I express y_B as a function of x_A and look for its minimum. The ray emanating from Focus F(0,1.5) is determined by Points F, $A(x_A, y_A) = A(x_A, \cosh x_A)$. The reflected ray passes through Points A and $F'(x_{F'}, y_{F'})$, the reflection of F with respect to the normal at A: $y = m_{AF'}(x - x_A) + y_A$, or $y = m_{AF'}(x - x_A) + \cosh x_A$; $m_{AF'} = \frac{y_{F'} - y_A}{x_{F'} - x_A}$. One possible way of finding the values of $x_{F'}, y_{F'}$ as a function of x_A is applying equidistance of F and F' from p, the normal to the catenary at A, which yields the location of B: $y_B = y_{F'} - \frac{y_A - y_{F'}}{x_A - x_{F'}} x_{F'}$; $x_{F'} = \frac{-3\sinh x_A + 2x_A + 2\sinh x_A \cosh x_A}{\cosh^2 x_A}$, $y_{F'} = 1.5 + \sinh x_A \frac{-3\sinh x_A + 2x_A + 2\sinh x_A \cosh x_A}{\cosh^2 x_A}$.

An alternative way of constructing Function $y_B(x_A)$ is to consider ΔFAB, in which the normal to the tangent to the catenary at Point A serves as an angle bisector of ∠A. The standard mathematical ways of finding the minimum of y_B as a function of x_A are by differentiating it with respect to x_A, finding the point(s) where the derivative vanishes, and making sure that it is the minimum. In view of the lengthy and intricate expression for y_B, I used the CAS module of GeoGebra for symbolic computations. The expressions for $y_B(x)$ obtained by different approaches did not look equal; an additional computerized procedure ensured their identical equality. In neither approach was CAS able to solve the equation $y'_B = 0$; hence, I turned to Wolfram Mathematica (WM) and obtained a similar result. Unable to complete the formal mathematical procedure of verifying the existence and finding the minimal location of y_B, I turned to "looking under the lamppost," namely, plotting the graph of $y_B(x)$. Figure 1d represents the GeoGebra graph of y(B) as function of x (i.e., of (x_A), side-by-side with tracked locations of B. Computation of the minimal value of y_B by WM yields the result y(B)= 9.85727330600264, compatible with the location of B as shown in the graphs in Figures 1b–d.

Findings

On the one hand, I cannot claim that Problems (a, b) are explicitly and completely mathematically solved. On the other hand, following two mathematical paths and using two different platforms, I arrived at the numerical value that seems to answer the question of the lowest position of Point B to a precision of 14 decimal digits, although precision alone is not a guarantee of correctness. The plausibility of the positive answer to Problem (a) and the numerical value of the answer to Problem (b) are supported (not verified!) by concurrences of various numeric and graphic results. In Table 1, I present some examples of characteristics appearances discerned on the basis of data.

Table 1: Examples of appearances in the data of characteristics defined in research questions

Characteristics	Examples of appearances and explanations
MDCT2-EM: awareness of which digital tools one should apply	a. The phenomena observed in the experiment were detectable due to special properties of the GeoGebra platform, including construction of dynamic applets subject to the ray-reflection laws, tracing graphic objects and thus discerning phenomena related to their behavior *en masse* (see Figure 1b) across a range of parameter values. The possibility of tracing the location of B on the y-axis (see Figure 1c) provided additional support for the existence of its lowest location and its approximate value. b. Application of CAS and WM for extremum value computation, computing the actual minimum of y(B) by WM, indicates awareness of affordances of these tools specific to EM.
MDCT3-EM: problem-solving based on EM	Discerning the existence of the lowest location of B on the y-axis (Figure 1b–c) led to mathematical problems to be posed and solved. By "doing mathematics" following experiment observations, EM and FM are intertwined as a matter of fact.
CT + MK-EM Critical thinking based on mathematical knowledge	The variable range can be neither exhaustive nor precise in digital representation. Therefore, the observed phenomenon induced a conjecture that had to be cross-checked for validity and evaluated by formal mathematical methods and was dealt with by FM involving MK–EM. FM did not provide an explicit answer; therefore, the "triangulation" was applied to the results. Recognizing that the more diverse indications supportive of the results are accumulated, the more plausible (though not mathematically certain) the results are, is a manifestation of CT.
CT + MDCT2-EM Application of digital tools to resolve the issue originating in critical appraisal of results	Encountering two different expressions for y(B) obtained by two different formal tool-aided solutions (CT), and making sure that they are identical, abate doubt on the way to the solution; this was performed by appropriate use of the digital tools (CAS)— awareness of which digital tools one should apply.

Discussion

This study focused on a specific form of mathematizing—problem-posing based on digitally empowered mathematical experiments that exemplify the EM–FM linkage—from a teacher-centric perspective. The answers to the research questions emerge from my self-study based on a specific set of experiments:

RQ1: By invoking constructs defined by Geraniou et al. (2024) and extending them to EM, I was able to focus on EM-oriented tool affordances and "doing mathematics." The appearance of both characteristics throughout the findings (see Table 1 for examples) suggests their relevance and efficiency for experiment-based problem-posing and -solving. The findings indicate the explicit and essential appearance of MDCT2 extended to EM. As for MDCT3-EM, which refers originally to problem-solving and doing mathematics, in the EM context it extends to problem-posing, which I consider an essential addition to its characteristics.

RQ2: The specific MK required in the EM context, denoted by MK-EM and manifested in different instances in the findings, is on the one hand essential for successful EM-based mathematical activity and, on the other hand, not necessarily included in teachers' MK related to FM. Some examples of occurrences of such knowledge appearing in Table 1 are awareness of the finite variable range in an experiment as against the infinite actual range in FM, the possibility of different analytic attestations of the same result, and the need to search for an *en masse* graphic representation of dynamically obtained behavior of a variating object, such as the one of emanating and reflected rays. The findings also indicate that CT is indispensable in appreciating the outputs of mathematical experiments, more so because some of the outputs are not mathematically dispositive and require critical appraisal of each result separately and of several results as a mutually supportive composite (Engelbrecht & Borba, 2023).

I suggest that self-study was an appropriate method for this type of research. The research aimed to reveal and meticulously record mathematical, computational, and tool-related deliberations of a teacher during encounters with phenomena emerging from an authentic mathematical experiment. The results of the experiment and the types of problems posed, along with their mathematical challenges, were unclear a priori, and the solutions were neither obvious nor premeditated. Thus, notwithstanding my previous experience, the deliberations that comprise the data genuinely reflect, albeit not exhaustively, those that may emerge in similar situations of coping with the unexpected, and do not seem to bias the researcher's opinions.

Data analysis was performed using qualitative research methods. Clearly, with different focuses on EM-FM-in-school-related research, other methods should be considered, depending on research aims, populations, and questions.

Practical and pedagogical implications and future research

The answers to both research questions indicate the important and distinctive modifications of all the characteristics on which they focused for digital–tools-based EM. In reference to the appearance of digital tools in school mathematics, the EM-FM linkage indicates lucid awareness of a distinction between the affordances of tools for EM purposes versus limitations as a source of formal conclusions. The basic understanding that *no output of a mathematical experiment, however*

advanced the tools applied in it may be, is acceptable unless it accords with mathematical theory, leading to a problem that either affirms this accordance or refutes it, is the essence of the twining of EM with FM.

In reference to the expectations of teachers' professional competence, as an educator of teachers, I suggest that further actions are needed in both theoretical and practical- pedagogical respects. In respect to theory, further research seems to be welcome in search of a deeper insight into the adoption of such a mode of teaching school mathematics from the perspectives of teachers, educators, and education systems. A step in this direction is taken by Naftaliev and Barabash (2024). Another important theoretical, pedagogical, and practical-systemic aspect, in my view, is the scope and spirit of school mathematics, as Kortenkamp (2004, p. 62) put it (cited above): "an opportunity to change the focus of teaching from the arithmetic to mathematics in a more global fashion".

Acknowledgments

This study was supported by the Israel Science Foundation (grant no. 780/19).

I am grateful to my friend and colleague Elena Naftaliev for her helpful comments after reading a draft version of this paper.

I greatly appreciate the constructive and fruitful feedback from my TSG colleague Andreas Borg, as well as the ensuing group discussion. His remarks prompted me to clarify my standpoint regarding the self-study method, and the attitudes of my colleagues will undoubtedly encourage me in my future research.

Incorporating programming into mathematics education: The adaptation of a teacher's craft knowledge

Andreas Borg

Karlstad University, Faculty of Arts and Social Sciences, Karlstad, Sweden; andreas.borg@kau.se

In recent years, programming has gained a more prominent role in mathematics education in various European countries. However, the incorporation of digital tools, such as programming, is not always a straightforward process as it may require, among other things, an adaptation of teachers' craft knowledge. This paper reports on a case study analysing a Swedish teacher's incorporation of programming into his mathematics teaching and the rationales behind such design, using the Structuring Features of Classroom Practice framework as a conceptual lens. The results reveal how the teacher's background shapes the use of programming in his classroom. It also illustrates that the way programming is intended to be incorporated into Swedish school mathematics places high demands on teachers when it comes to teaching students both how to program and how programming can serve as a tool for learning mathematics.

Keywords: Mathematics Education, Programming, Mathematics teaching, Craft knowledge, Structuring features of classroom practice.

Introduction

Programming has long served as an everyday tool for mathematicians. During the 2010s, it was also incorporated into school mathematics in several European countries. Since 2018, students in Swedish compulsory schools are expected to use programming as a tool starting from grade four (age 10), with the objective of creating and utilizing mathematical algorithms. In the non-mandatory upper secondary school (ages 16–19), the extent to which programming is incorporated into mathematics courses varies among different study programmes. When included, programming is intended to be used as a tool for problem-solving, for solving tasks numerically, and/or for data processing. Thus, the Swedish curricula do not associate the use of programming with any specific mathematical content but rather with different practices (Tamborg et al., 2024). Nor do the curricula specify which programming concepts students are expected to master or which specific programming language they should use. In Sweden, where there is no dedicated computing subject, unlike in England (Tamborg et al., 2024), students are expected to learn programming within their mathematics lessons.

In his study of Swedish mathematics teachers' use and perception of how to implement programming in school mathematics, Humble (2022) highlights that many teachers are critical of the way programming is expected to be incorporated into school mathematics. Teachers express how limited time and vague instructions from both school leaders and other stakeholders have negatively affected the incorporation. Kilhamn et al. (2021) illustrate how the arguments for incorporating programming in school mathematics differed among 20 Swedish mathematics teachers. The first category of arguments relates to the view that programming could be a powerful tool on a more general level once the teachers and the students master it. However, learning to master the tool is regarded by many of these teachers as a time-consuming endeavour. The second category of arguments is related to the view that programming in itself is engaging and that it connects to reality. These teachers do not argue

that the use of programming will increase students' understanding of mathematics but rather increase their engagement during mathematical activities. A third category of arguments is related to the view that the use of programming may develop students' computational thinking. The fourth category of arguments relates to the viewpoint that using programming could enhance students' learning of mathematics. These teachers contend that programming can aid students in comprehending mathematical concepts and that programming itself can be regarded as a mathematical activity.

The studies of Humble (2022) and Kilhamn et al. (2021) indicate that mathematics teachers find it challenging to incorporate programming in their mathematics classrooms and hold varying perspectives on the rationale for using programming in school mathematics. It could be presumed that this, in turn, influences how these teachers incorporate the tool into their classrooms.

In this paper, *the Structuring features of classroom practice* (SFCP) framework (Ruthven, 2009) will be operationalised to analyse how structuring features shape a Swedish upper secondary school teacher's incorporation of programming into a mathematics course. Such analysis is of extra interest in the Swedish context where the curricula offers mathematics teachers limited guidance on how to operationalise such incorporation (Tamborg et al., 2024), a situation that appears to frustrate teachers (Humble, 2022). Ruthven (2009) argues that the rationales for how to incorporate digital technology rest on teachers' *craft knowledge*, which encompasses the professional knowledge and thinking used in their classroom teaching. He claims that part of this knowledge has been developed through "(often unconscious, sometimes reflective) adaptation in response to experience" (p. 132). Simsek and Clark-Wilson (2024) argue that the use of the SFCP framework has the potential to make teachers' craft knowledge "more observable and accessible, making it not only apparent to researchers but also accessible to practitioners and thus bridging the gap between research and practice in mathematics education" (p. 22). Given the Swedish context, this paper thus aims to investigate the adaptation and/or development of a teacher's craft knowledge in relation to structuring features of classroom practice when incorporating programming in upper secondary mathematics education.

The structuring features of classroom practice framework

The technological development of the last few decades has meant that for today's mathematics teachers there is a plethora of digital tools available. Teachers are therefore faced with the task of creating a "coherent use of a relatively small selection of [such tools] to form an effective resource system" (Ruthven, 2009, p. 145). The incorporation of new technologies in classrooms is dependent on what Ruthven (2009) refers to as a professional adaptation, and he identifies five structuring features of classroom practice which shape such adaptation. *The curriculum script* is a structuring feature which stems from the teacher's professional knowledge and concerns goals and actions related to the specific mathematical topic, guiding the way the teacher teaches the topic (Ruthven, 2014). A script is in this framework viewed as a psychological construct which relates to an "event-structured organisation of knowledge, forming a loosely ordered model of goals, resources and actions for teaching the topic, incorporating potential emergent issues and alternative courses of action" (p. 386). It thus affects the teacher's lesson design as it interweaves the mathematical ideas to be learned, the tasks to be undertaken, the relevant activity format to be used, and the potential student difficulties to be expected (Ruthven, 2014). A second structuring feature involves the choice of mathematical tools

and the associated curriculum material and how these build a coherent *resource system*. Ruthven's (2009) meaning of the term resource involves "some (physical or virtual) artefact which has either been designed specifically for curricular purposes, or been the subject of educational appropriation for such purposes" (p. 146). The classroom incorporation of new technologies also implies an adaptation of existing activity formats which set the scene for actions and interactions between participants during classroom activities (Ruthven, 2014). Such adaptation of activity formats results in a revised *activity structure* for lessons incorporating new digital technologies. Orchestration types, identified by Drijvers et al. (2010) and originally associated with the Instrumental Orchestration theory, have recently been utilized alongside the SFCP framework (e.g., Simsek & Clark-Wilson, 2024) to describe activity formats. *Time economy* is a structuring feature related to the return (in the form of the pace of the lessons as well as the students' advanced understanding) of the time invested when incorporating a digital tool in mathematics classrooms (Ruthven, 2009). The last structuring feature is the *working environment* which relates to changes in the physical environment as well as to the classroom routines. This implies that the classroom may be organized differently when utilizing digital tools compared to more traditional mathematics lessons.

Method

The findings presented in this paper are part of a case study where the author studied a teacher and his class of Swedish upper secondary school students in the science program, utilizing programming throughout a course in mathematics (Mathematics 3c). In the autumn of 2022, data was collected during five lesson activities where the students were expected to utilize programming to solve mathematical tasks numerically. The first three activities concerned a numerical method for calculating function limits (related to the limit concept, the definition of the derivative, and the derivative of exponential functions), the fourth activity concerned a numerical method for calculating local minimums of functions, and the last activity concerned how to calculate integrals numerically. Since it was expected that students had varying extents of experience using programming in primary and lower secondary school, the school assigned about ten extra hours associated with the previous course to teach students how to use basic programming in mathematics. This is rare in a Swedish context since students are expected to be trained in how to program during regular mathematics lessons. The mathematics teacher in this study had worked as a teacher for 14 years and was also a teacher in physics and programming (specialised in algorithms and computation). He could thus be regarded as a proficient programmer, and he had played an important role at the school in designing the incorporation of programming into the different mathematics courses.

Data collection and data analysis

An audio-recorded and transcribed interview with the teacher, together with field notes taken during all five lesson activities, served as the main data sources when using the SFCP framework to analyse the adaptation of the teacher's craft knowledge. During the semi-structured interview, conducted after the course, the teacher was asked questions concerning his views on programming as a tool in school mathematics and the design of each learning activity. Field notes were taken to portray how the teacher introduced the mathematical content to the students. The researcher also had access to the online programming environment Google Colab used by the students, in which the mathematical

tasks as well as solutions to the tasks (including code) were integrated. After listening to the interview and reading the transcription several times, extracts were classified based on the five components of the SFCP framework, as described and exemplified in the literature presented in the previous section. Parts of the field notes related to the teacher's craft knowledge were also classified according to the components of the framework. Triangulation of data was then conducted, allowing the author to gain a more comprehensive understanding of the teacher's craft knowledge and how his described intentions (related to the components of the SFCP framework) were manifested in the classroom.

Results and analysis

Guided by the structuring features of the SFCP framework, the analysis focuses on the teacher's incorporation of programming in his mathematics classroom and how such incorporation has brought about an adaptation of the teacher's craft knowledge.

Curriculum script

As a foundation for his curriculum script, the teacher in this study expresses a positive attitude towards the incorporation of programming in mathematics education, although he had hoped for more guidance in the curricula on how and when to use programming in the mathematics courses.

> Teacher: My attitude is basically quite positive, although I think it is clear that there has to be a balance between traditional math and programming. But I think, in this digitized society, it is good to have knowledge of computations using programming.

The teacher's design of the learning activities is mainly based on the view that programming offers students opportunities to conduct repeated calculations, which are too time-consuming to conduct using pen and paper, and which could be used to solve mathematical tasks numerically. Based on this view, the primary goals of the learning activities, classified as central parts of the curriculum script, were for students to enhance both their understanding of numerical methods for solving mathematical tasks and their understanding of mathematical concepts through the use of step-by-step instructions.

> Teacher: If you take numerical integration where you sum a bunch of rectangles. Then it may be that you understand what integration or the integral represents more through programming. […] I also think that sometimes the programming can be closer to the definition. If we again take integrals as an example, the definition of an integral strictly mathematically is via this limit value and not via a primitive function.

As part of the curriculum script, the teacher also describes the rationales for the designed activities and how the limited amount of time available to teach students fundamental programming has affected the tasks chosen for the learning activities. These actions are classified as part of the teacher's curriculum script since they are closely associated with the choice and teaching of the mathematical topics. This part of the script is affected by the way programming has been included in the Swedish mathematics curricula. First, the fact that programming was added to the course without any other content being removed forced the teacher to find ways to incorporate the use of the tool and still have time to handle the pre-existing mathematical content in the syllabus. Therefore, the teacher and his colleagues initially identified a number of mathematical tasks related to the mathematical content of the course that were considered well-suited for solving using programming. Some of these tasks were later excluded so that the remaining tasks could be solved using a similar code structure (involving a single loop) together with a limited number of programming concepts (primarily related to variables,

iterations, selection statements, and print statements). Second, since the curriculum for primary and lower secondary school does not explicitly specify which specific programming concepts students are expected to learn, the teacher does not expect new students to master all of the abovementioned concepts. Thus, to prepare the students for the course, the teacher and the school identified the need for additional time associated with the previous course in mathematics to teach students about fundamental programming concepts and the code structure.

With the intention of keeping a clear focus on the mathematical algorithms and not spending an extensive amount of time debugging, the designed task sequences of the learning activities contained examples of code which the students could reuse and modify. This part of the script has evolved from the teacher's prior experiences of using programming solely as a mathematical problem-solving tool.

> Teacher: When [the curriculum] stated that you should use [programming] for problem solving, my interpretation was that then you must be a good enough programmer so that you can write the code from scratch. But then I noticed that quite a few students got stuck in like just… yes but like print [statements] or wrong brackets or something like that. Then they didn't get over that step so they didn't learn anything. And I guess I also think that it's not really a programming course that we're doing, but the focus is on understanding the math behind the algorithms.

In summary, it could be claimed that the teacher's craft knowledge related to the curriculum script has been developed and adapted through the interplay between his own view of programming as a tool in school mathematics, the conditions given by the syllabus, and his own prior experiences.

Resource system

The teacher's resource system comprises digital tools and curriculum material. Classified as central parts of the resource system are the programming language Python and the programming environment Google Colab. The teacher also used the dynamic mathematics software GeoGebra, with which the students were familiar, to make graphical representations of functions (e.g., when introducing the limit concept and the definition of the derivative). This is an example of double instrumentation (Ruthven, 2014) where the teacher manages to handle an existing tool alongside the new one.

The teacher provides specific rationales for the choice of using the programming language Python.

> Teacher: So, I have no formal training in Python, but it felt like a simple programming language for math. There are a lot of built-in math functions from the beginning and relatively little code is required to access the algorithmic thinking compared to like Java or C++ which is a bit more software-related. I also think that Python has a lot of support for making quick visualizations, for example, of processes and so on. It's not something that I work with together with the students, but I demonstrate and it's easy to do. And I have the impression that Python is one of the big languages when it comes to, for example, machine learning, which is something we're aiming for in some way here at the school [in the course Mathematics – specialization].

The teacher's rationale for using Google Colab is that it offers the opportunity to design curriculum materials such as digital worksheets containing task descriptions and windows where students can write and execute their code as well as write their own text. Also classified as part of the resource system is the code structure (mentioned in relation to the curriculum script) which the students had been trained to use and which was applicable to all tasks presented to the students. The code structure included a specific WHILE-loop and an IF-statement used to control when the loop should terminate.

Activity structure

The field notes served as the main data source when analysing the teacher's activity structure during the learning activities, which in many ways resembles traditional teaching in mathematics. As an introduction, the teacher often introduced the mathematical content and methods for solving given tasks using programming in front of the class. Using the typology of orchestration types related to the use of technology in mathematics education, presented by Drijvers et al. (2010), as an analytical construct, this is classified as *technical-demo* orchestration. In this type of orchestration, the teacher demonstrates different techniques required to use the programming environment (e.g., how to construct a given loop). However, the teacher also connected his use of programming to the specific mathematical content, such as relating the generation of function values to the limit value, which is classified as *explain-the-screen* orchestration. There were also examples of *link-screen-board* orchestration, where the teacher stressed how the actions taken when programming could be represented in different media (e.g., algebraically using the whiteboard and graphically using GeoGebra). During the introductions, the teacher asked the students to reflect on new mathematical content as well as on code presented on his screen. The outcome of these reflections, classified as *discuss-the-screen* orchestration, was often a collective discussion about how the use of technology related to mathematics. After the introductions, the students started to solve the tasks presented to them in Google Colab while the teacher moved around the classroom and supported students' work when needed.

Time economy

Several aspects related to the teacher's curriculum script are also classified as time economy features. The additional time associated with the prior course, the choice of tasks to limit the number of programming concepts that the students should master, and the use of a given code structure could all be seen as examples where the teacher tries to change "the 'rate' at which the physical time available for classroom activity can be converted into a 'didactic time' measured in terms of the advance of knowledge" (Ruthven, 2014, p. 386). But the teacher also reflects on such 'rate' in relation to the national exam in mathematics, which do not include tasks involving programming aspects:

> Teacher: In a way, you can say that [the students] would probably have managed the Mathematics 3 course with better results if they hadn't spent so much time on programming and algorithms, if you just look at a national exam. There is no programming there, or at least very seldom. But I try to plant a seed of thought for the future which is probably quite good if you are going to continue with math since you won't get like integrals that can always be solved [algebraically] and so on.

The verbatim extract illustrates how the design of the national exams is associated with the time economy feature since the conversion rate into 'didactic time' is measured not only in relation to the intentions and goals of the syllabus but also in relation to the success rate at the national exams.

Working environment

The analysis of the field notes reveals small adjustments to the working environment in the classroom during the learning activities involving programming. Since the students' textbook did not contain any sections specifically related to the use of programming, the teacher integrated his designed tasks within the programming environment Google Colab (as described earlier). This implies a shift from

solving mathematical tasks in the textbook using pen and paper to a new routine where all students documentation (i.e., the code and the task solutions) is performed within the programming environment using the Chromebook computers provided by the school to each student at the start of their upper secondary school studies.

Discussion

In this paper, the SFCP framework (Ruthven, 2009) has served as a valuable lens to portray and analyse how various features of classroom practices were linked to the adaptation and development of the teacher's craft knowledge during the incorporation of programming in his classroom. In accordance with Simsek and Clark-Wilson (2024), I argue that the results reveal how different structuring features are more prominent than others and to a greater extent connect mathematical and technical aspects. The results particularly highlight how the craft knowledge associated with the curriculum script was adapted in various ways and how such adaptations in turn affected many of the other structuring features. For example, the aim to keep a clear focus on the mathematical algorithms and not spend an extensive amount of time debugging (associated with the curriculum script) led to the development of a code structure related to the resource system. The findings also reveal that the teacher's status as a licensed programming teacher shaped many of his decisions (e.g., focusing on students' use and design of algorithms in order to solve mathematical tasks numerically). The teacher's existing craft knowledge relating to teaching programming thus affected and eased the incorporation of programming in his mathematics classroom. The teacher belongs to the category of teachers who, according to Kilhamn et al. (2021), view programming as a tool that could help promote students' understanding of mathematical concepts (e.g., integrals), and he regards the use of programming as a mathematical activity in itself. The teacher also looks beyond the course and grades on the national exam when he argues that the use of programming may widen students' view of mathematics, provide them with overarching ideas concerning different ways of solving mathematical tasks, and increase their digital competence. For teachers with no or little prior experience of using programming, the rationale and motivation for using programming in school mathematics may differ significantly and be less holistic. Further research is thus needed to explore how mathematics teachers with diverse views on programming and varied backgrounds adapt their craft knowledge when using the tool, and how these adaptations affect students' learning of mathematics.

The results also demonstrate how the adaptation of the teacher's craft knowledge was influenced by the way programming has been introduced into the Swedish curricula. The inclusion of programming in the mathematics curriculum, without removing any existing content and without specifying which programming concepts students should master, affected the teacher's task design in several ways. This was also the reason for the additional time allocated to the prior course. I argue that great demands are placed on Swedish teachers when trying to teach students about programming alongside using the tool for mathematical purposes. This challenge is also one of the reasons why Swedish teachers express their criticism towards how programming is expected to be incorporated into school mathematics (Humble, 2022). Unlike Sweden, England has chosen to introduce a computing subject where students are taught how to program. However, since programming is not mentioned in the English mathematics curriculum, the incorporation of programming into school mathematics rests on the interest of individual schools and teachers (Tamborg et al., 2024). Findings from the ScratchMath

project (Noss et al., 2020) reveal that such incorporation could also be impeded by the high-stakes testing in English school mathematics. The introduction of programming into school curricula varies between countries such as Sweden and England. Therefore, further research is also needed to better understand how various approaches to introducing programming into school curricula set the stage for teachers' incorporation of programming into school mathematics.

Beyond digital technology: Exploring transparency as a tool for analysing pre-service teachers' interpretation of an ideational resource

Nicola Bretscher[1], Jill Adler[1,2], Tim Clark[1], Suman Ghosh[1] and Piers Saunders[1]

[1]IOE, UCL's Faculty of Education and Society, London, United Kingdom; n.bretscher@ucl.ac.uk

[2]University of Witwatersrand, South Africa

Previous research has used the notion of transparency to understand teachers' use of GeoGebra as a resource for teaching circle theorems. In this paper, we move beyond digital technologies to explore using the notion of transparency to analyse pre-service teachers' interpretation of other resources, specifically an ideational resource called the Mathematics Teaching Framework. We illustrate our theoretical framework using data from two pre-service teachers' written descriptions of their mathematics teaching. We use the findings from this analysis to reflect upon extending theoretical frameworks to other resources, beyond digital technologies, and identify implications and next steps.

Keywords: Transparency, situated abstraction, ideational resource, Mathematics Teaching Framework, pre-service teachers.

Introduction

Developing theoretical frameworks for analysing teachers' use of digital technologies has been a long-term focus of TWG15 (Barzel et al., 2023). A central issue in developing such frameworks is their range of application, that is, to what extent are they particularised for analysing teachers' use of digital technologies and to what extent these frameworks are applicable to 'other resources'. For example, the *instrumental approach* was classically applied in mathematics education to understand teachers' integration of a specific digital artefact, such as a graphic calculator (Guin et al., 2005). Building on the instrumental approach, the *documentational approach to didactics* shifted to analyse teachers' interactions with a *set of resources*, both digital, such as dynamic geometry software, and non-digital, such as textbooks (Trouche et al., 2020). More recently, the definition of resources to which the documentational approach applies has been extended to *meta-resources* (Gueudet et al., 2023), including *ideational resources* (Adler, 2021), which have been "explicitly designed for supporting mathematics teachers' planning of teaching and learning activities" (Gueudet et al., 2023, p. 27). Exploring the range of application of theoretical frameworks for analysing teachers' use of digital technologies can lead to refinement of the theoretical framework itself and/or reflection upon how digital technologies and resources are conceptualised. Such exploration and reflection seem especially important given the rapid evolution and blending of digital technologies with more 'traditional' resources.

Bretscher (2022) used the notion of *transparency* (Lave & Wenger, 1991; Wenger, 1998) to understand teachers' use of GeoGebra as a resource for teaching circle theorems. We build upon this work by exploring transparency as a theoretical tool for analysing pre-service teachers' interpretation of an ideational resource. Specifically, we investigate how a framework for teaching mathematics serves as an ideational resource for developing a shared language about mathematics teaching between pre-service teachers and teacher educators. We introduced the Mathematics Teaching

Framework (MTF), developed by Jill Adler and colleagues at the University of Witwatersrand (Adler, 2021), into university-based sessions of the Post-Graduate Certificate of Education (PGCE) Secondary mathematics programme at our institution with the purpose of making more explicit or *transparent* (Lave & Wenger, 1991) aspects of mathematics teaching. Our aim was to support pre-service teachers focus on mathematical aspects of planning and evaluating lessons by developing a shared language around the aspects of mathematics teaching highlighted by the MTF and valued by the PGCE team of teacher educators. We chose the MTF because the framework was developed for use in professional development with secondary school teachers in a context where mathematics teaching needed significant development starting with explicit attention to core mathematics teaching practices, and their coherence. Hence the framework seemed appropriate in our context of working with pre-service teachers with varied mathematical backgrounds and with little or no experience of teaching mathematics in secondary schools. Central to the MTF is the identification of a *learning goal*, an articulation of the object of learning that is the focus of the planned lesson, i.e. what learners must know and be able to do by the end of the lesson. The MTF highlights three main categories of mathematics teaching practice that serve to mediate this goal in the classroom: *Exemplification* being the teacher's choice of mathematical examples, representations and tasks; *Explanatory communication* being what the teacher says and writes, including how their explanation is justified; and *Learner participation* being how the learners are invited to participate in doing and talking mathematics. Finally, the MTF emphasises that each of the three categories should be *coherent* in focusing learners' attention on the learning goal.

Working with colleagues, we have embedded the MTF into sessions taught at university and into the lesson planning template used by pre-service teachers to support their planning of lessons during their practicum placement in school. From a pragmatic viewpoint, we are interested in whether this innovation has supported our pre-service teachers to develop teaching practices valued by our teacher education team. From a theoretical point of view, we aim to contribute towards understanding how resource use can support the development of a shared language between pre-service teachers and teacher educators. In this paper, we use our investigation as a context for addressing the question: *How does a theoretical framework for analysing teachers' use of digital technologies apply to their interpretation and use of other resources, particularly ideational resources?* In the next section, we explain our theoretical framework, combining the related notions of *transparency* and *situated abstraction* as a means of understanding how pre-service teachers interpret the MTF. We then proceed to operationalise these notions in relation to our research and present the initial findings of our analysis and next steps.

Theoretical background

Adler (2021, p. 1212) refers to the MTF as an *ideational resource* "to foreground it as a reified set of ideas about mathematics and mathematics teaching in general, and ideas in a mathematics lesson in particular". As noted in the introduction, Gueudet et al. (2023) extend their definition of *meta-resources* to include ideational resources, such as the MTF. We draw on two related notions to conceptualise how pre-service teachers use the MTF as an ideational resource to negotiate meaning about mathematics teaching. Firstly, we draw on the notion of *transparency* (Lave & Wenger, 1991; Wenger, 1998) to describe the relationship (Adler, 2021) between a user and a resource in practice.

Transparency describes the extent to which users have access to the communal knowledge and practices embedded in a resource and can interpret and mobilise these in their own practice. Transparency was elaborated by Lave and Wenger (pp. 101-102) through two inter-related notions: *visibility* "in the form of extended access to information" and thus whether the user can "see" or access the ideas embedded in a resource, and *invisibility* "in the form of unproblematic interpretation and integration into activity", and thus whether the user can "see through" these ideas to interpret and embed them into their practice. For the purposes of our study, we are interested in whether pre-service teachers "see" the practices highlighted by the MTF categories, and so can name and talk about them, and whether they can "see through" these ideas, interpreting and embedding them meaningfully into their mathematics teaching.

Secondly, we draw on the notion of *situated abstraction* (Noss & Hoyles, 1996) to provide an over-arching perspective on mathematical knowledge in use in teaching, viewing such knowledge as embedded within situations that occur in the context of teaching and yet simultaneously 'abstract' or generalised, e.g. across lessons or teaching episodes. In the context of digital technologies, combining the two notions of transparency and situated abstraction provided a means of analysing teachers' recognition and interpretation of the constraints and affordances of the software in their mathematics teaching (Bretscher, 2023). Identifying the intertwined processes of recognition and interpretation appears to provide a theoretical means to analyse the non-linear progression of teachers' technology integration. For the purposes of this paper then, combining the two notions of situated abstraction and transparency enables us to conceptualise teachers' progression in a non-linear way in terms of their recognition and interpretation of the MTF as an ideational resource in their mathematics teaching. Building on Bretscher (2023), we use situated abstraction to define a developing user-resource relationship through a continuum of visibility and invisibility in terms of the following four broad categories: (1) *visible-abstract*: a user can access ideas embedded in a resource but their interpretation shows little or no meaning in practice. In our study, this means a pre-service teacher recognises MTF categories but misinterprets or makes little or no connection between them and their teaching; (2) *visible-situated*: a user can access ideas embedded in a resource and their interpretation shows meaning in specific, localised contexts. In our study, this means a pre-service teacher recognises MTF categories, interpreting them coherently in localised ways, e.g. in a specific lesson sequence but not consistently across lesson sequences; (3) *invisible-situated*: a user does not appear to "see through" ideas embedded in a resource, although elements may be used tacitly in specific, localised contexts, e.g. although elements may be tacitly embedded in their teaching, a pre-service teacher shows implicit or no recognition of MTF categories; (4) *invisible-abstract*: a user accesses and "sees through" ideas embedded in a resource and their interpretation consistently shows meaning across contexts. In our study, this means a pre-service teacher interprets MTF categories consistently and coherently across lesson sequences.

Methods

Our overall sample selection for the project aimed to represent all categories of our theoretical framework. We invited pre-service teachers to participate in the project based on teacher educators' perceptions of their mathematics teaching, derived through ongoing interaction with them during the PGCE programme. Of those invited, eight pre-service teachers agreed to participate. For this paper,

our analytic aim was to illustrate the *visible-situated* and *visible-abstract* theoretical categories as well as confirming their descriptive validity for the wider study. For this reason, we selected a subset of our overall sample to ensure that we would be able to distinguish the *visible-situated* and *visible-abstract* theoretical categories and therefore provide an initial insight into how pre-service teachers interpret the MTF. We selected two pre-service teachers, Oliver and Sarah, who represented telling cases (Miles et al., 2020) in terms of their understanding of mathematics pedagogy as perceived by teacher educators involved in the PGCE programme. Oliver was perceived as having good mathematical knowledge, but his understanding of pedagogy was underdeveloped. For example, whilst he was a confident mathematician, lesson observations indicated that he needed to plan his teaching to connect more closely to needs of his students. Sarah was perceived as having a good understanding of mathematics-specific pedagogy in general, but this was not consistent in her teaching. As such, we expected Oliver to exemplify the *visible-abstract* category and Sarah to exemplify the *visible-situated* category. Hence, our sample selection aimed to enable us to take first steps in operationalising the theoretical framework and identify initial findings by comparing these two pre-service teachers. We collected course artefacts that pre-service teachers produce during the PGCE programme as data for this qualitative study. In this report, we focus on analysing a written assignment in which pre-service teachers plan, teach and evaluate a sequence of 3-4 lessons in a specified mathematical domain, drawing on recent and relevant theory and research. The pre-service teachers were recommended to use the MTF as a guide to focus their written presentation of the plan for their lesson sequence, but not required to reference the framework explicitly. Thus, we focussed our analysis on the planning section of the written assignment in which they present a detailed description of the lesson sequence. The written assignment was completed in the first term of the PGCE programme. In this term, teacher educator input had focussed primarily on the Exemplification category of the MTF. Hence, for this report, our analysis focused on how the pre-service teachers interpreted the Exemplification category only.

In our first step of analysis, we broke down the text of the plan for each lesson into *planned teaching episodes*, indicated by a break in the text, such as a new paragraph or a textual indicator such as "this will be followed by…" or "After that, …". We then coded each episode as *visible* if at least one aspect of MTF terminology related to the Exemplification category, i.e. the words *example*, *representation* or *variation*, was used explicitly in the text. We coded the episode as *invisible* if there was no explicit use of MTF terminology. Finally, we coded each episode as either *fully situated*, *partially situated* or *incoherent*. Episodes were coded as *fully situated* if (a) specific examples or representations were named in the text, (b) a rationale for the specific examples or representations was given and (c) the specific examples or representations named in the text were coherent in supporting the learning goal within the context of the lesson. Episodes were coded as *incoherent* where specific examples were named but these appear to distract from the learning goal. Otherwise, episodes were coded as *partially situated*. Each assignment was coded by the first two authors separately and then the results compared to ensure reliability across coders. We illustrate this analytic process with examples of coding in the next section.

Results

We first present examples of planned teaching episodes from Oliver's written assignment to illustrate the application of our coding scheme. In these examples, we use pink-highlighted text to identify explicit use of MTF terminology; red-highlighted text to identify specific, named examples or representations; and green-highlighted text to identify a rationale for the specific examples or representations. We then present the overall results of analysing Oliver's and Sarah's planned lesson sequences.

The learning goal for Oliver's first lesson was that his students should be able to identify and simplify equivalent fractions. His first planned teaching episode was coded *visible* since he made explicit use of MTF terminology including "examples", "exemplification", see Figure 1. In this episode, he named a specific triad of equivalent fractions and illustrated these using a specific representation, which he named as a "bar model". He explains his rationale for introducing the bar model and this seems coherent with the learning goal. Hence Oliver's first planned teaching episode was coded as both *visible* and *fully situated*.

> When considering the actual examples and questions, I was interested in seeing whether the bar model or other exemplifications would be successful in mitigating some of the difficulties of students applying the concept of partitioning to equivalency mentioned in Nunes & Bryant (2009), as was the case in Boylan et al. […]
>
> The exemplification I provided started with simple bar models showing 4/5, 8/10, and 12/15 on top of each other, lined up to show that the shaded parts were the same size (without the numbers), and specifically had the lines that were common in bold. My aim was to cut each part of the 4/5 bar into two to produce the 8/10, and again cut each part into 3 to produce 12/15, asking the question of what fraction each bar represented to students. Then underneath, I would make sure to write explicitly that 4/5 = 8/10 = 12/15" in order to not introduce the same misconception discussed in Muzheve and Capraro.

Figure 1: Oliver, Lesson 1, Planned teaching episode 1 – Coded: Visible, Fully Situated

His third planned teaching episode was coded as *visible* since Oliver again made explicit use of MTF terminology "representation", see Figure 2. He specified introducing a "circle" representation but without providing a clear rationale. This episode was coded as *incoherent* since the introduction of new representations without a clear rationale seemed to distract attention from the learning goal. The incoherence of episode 3 was reinforced by Oliver returning in episode 4 to the original examples of equivalent fractions, see Figure 2. In episode 4, Oliver again names the specific pairs of equivalent fractions and explains his rationale for the choice of numerical example. However, he does not make explicit use of MTF terminology, hence episode 4 was coded *invisible* and *fully situated*.

> Before exploring this formally, I wanted to give the students a chance to practice independently, using again similar representations that involve the same area being partitioned into different denominators, but with different areas [*shapes? Typo?*], such as a circle. While this has issues on traditional freehand drawing as described before, when planned digitally I did not think it would be an issue. I made sure that I would go on to explain how these different representations related to each other, and how we could visualise one as another, using animations. [*Planned teaching episode 3*]

After that, my aim was to allow the students to think about the relationships between the numerators and denominators in the original pairs of fractions, 4/5 = 8/10 and 4/5 = 12/15. My choice of numbers were those that were common multiples but weren't overly simple in order to make sure the students could be convinced that the pattern would be applicable in general. [*Planned teaching episode 4*]

Figure 2: Oliver, Lesson 1, Planned teaching episode 3 – Coded: Visible, Incoherent; and Planned teaching episode 4 – Coded: Invisible, Fully Situated

The sixth and eighth of planned teaching episodes in Oliver's first lesson were both coded as visible, partially-situated, see Figure 3. There is very little detail in the eighth episode, although a form of general pedagogic rationale is provided in relation to tailoring examples to match the "pace of the class". However, the sixth episode provides more detail by naming a specific example and providing a rationale based in general mathematics pedagogy around using open-ended questions to test conceptual knowledge. Currently, the greater mathematics-specific detail in episode 6 is not indicated in our coding. We return to reflect on this later in the discussion section.

For the independent student practice questions, I wanted to provide worksheets that gave some more varied problems that tested their conceptual knowledge and understanding between the numbers in the fractions. Some of these involved discussing with partners questions that were open ended, such as "how many equivalent fractions are equivalent to 2/5" which I planned to discuss as a whole class. [*Planned teaching episode 6*]

I chose to do a matching equivalent activity, where I would write down a lot of fractions on the board and instruct the students to group them into different fractions for after the worksheet, as I would be able to tailor the examples to make them more difficult or more simple matching with the pace of the class. [*Planned teaching episode 8*]

Figure 3: Oliver, Lesson 1, Planned teaching episode 6 – Coded: Visible, Partially-situated; and Planned teaching episode 8 – Coded: Visible, Partially-situated

The results from our coding of Oliver's and Sarah's planned lesson sequence are presented in Tables 1 and 2. Both pre-service teachers have a similar proportion of planned teaching episodes coded as visible and fully situated (for Sarah, 3/11 = 27%; for Oliver 6/18 = 33%). In addition, the majority of their planned teaching episodes were coded as visible in each case, in line with the expectations upon which our sample selection was based. Partially-situated episodes were the modal category for both pre-service teachers. What separates these two cases is that five of Oliver's planned teaching episodes were coded incoherent because he introduced examples or representations that appeared to distract from the learning goal.

Table 1: Summary of the analysis of Oliver's planned teaching episodes

All lessons	Fully situated	Partially Situated	Incoherent	Total
Visible	4	3	5	12
Invisible	2	4	0	6
Total	6	7	5	18

Table 2: Summary of the analysis of Sarah's planned teaching episodes

All lessons	Fully situated	Partially Situated	Incoherent	Total
Visible	1	5	0	6
Invisible	2	3	0	5
Total	3	8	0	11

Discussion and conclusion

Our initial findings indicate that our theoretical framing can be extended productively beyond digital technologies, in terms of identifying and distinguishing pre-service teachers' interpretations of an ideational resource, the Mathematics Teaching Framework, in relation to their teaching. The two pre-service teachers, Oliver and Sarah, were selected with the expectation that they would represent the categories visible-abstract and visible-situated respectively. Our analysis provides support that the teachers can be categorised in this way and that this categorisation is meaningful in terms of describing their interpretation of the MTF. We discuss these findings before indicating implications and next steps for our research.

Our findings show that the MTF Exemplification category was visible to both pre-service teachers in that they both used MTF terminology in describing their teaching in the majority of the episodes analysed. In addition, a similar proportion of the planned teaching episodes for each teacher was visible and fully situated indicating their interpretation of the MTF terminology in the context of these episodes was meaningful, i.e. that their selection of examples was justified and coherent with their learning goal. Incoherent episodes enabled different interpretations of the MTF to be distinguished. In all her planned teaching episodes, Sarah's use of MTF terminology was at least partially situated in her teaching in meaningful ways that were coherent with her learning goal. This is consistent with a categorisation of her interpretation of the MTF as visible-situated. By contrast, in five of Oliver's episodes, his choice of examples or representations seemed to (mis)interpret MTF terminology as meaning that using a greater number of examples and representations improves teaching and learning. In this sense, the MTF seemed too visible for Oliver: he seemed to attribute such importance to using MTF terminology that he overlooked whether its use was coherent with his learning goal. This is consistent with a categorisation of his interpretation of the MTF as visible-abstract, i.e. incoherent with his learning goal and thus lacking in meaning connected to his teaching. Reflecting on our coding of partially-situated episodes leads us to question whether the coding of this category needs further refinement based on the degree of mathematics-specificity in the episode. This finding indicates the significant empirical work required to operationalise and validate a theoretical framework in the context of other resources, beyond digital technology. Nevertheless, our study indicates the productive potential for extending theoretical frameworks to analyse teachers' use of resources beyond digital technologies (Gueudet et al., 2023), encouraging reflection upon how digital technologies are conceptualised in the context of rapidly evolving resources available to teachers. Such theoretical extension could also encourage collaboration with other groups, such as TWG22, in keeping with the CERME spirit. Our next steps are to extend this analysis to the rest of our sample and to apply our coding scheme to the other categories of the MTF. In this way, we aim to identify and distinguish the other categories of the framework and test the reliability of our coding.

Acknowledgement

We gratefully acknowledge the support of pre-service teachers and tutors on the PGCE Secondary Mathematics programme at the Institute of Education, UCL's Faculty of Education and Society in carrying out this research.

Evolution of Finch robot orchestrations in teaching primary school mathematics

Marcus Yuen-Yiu Cheung[1] and Irina Lyublinskaya[1]

[1]Teachers College, Columbia University, New York, USA; myc2131@tc.columbia.edu

This study utilised the theoretical framework of instrumental orchestrations to analyse changes in types, frequencies, and sequences of orchestrations of two co-teachers in a 3rd grade Integrated Collaborative Teaching (ICT) classroom in New York City public school. The teachers implemented mathematics activities that used Finch robot and native block-based coding App to address topics in the standards-based curriculum while also attending monthly professional development (PD) sessions to support their implementation of these activities. Analysis of six videos collected over a period of one year indicated that as time progressed, the teachers felt more confident in using Finch to support mathematics instruction. They shifted from mostly teacher-centred orchestrations towards more student-centred ones. At the same time, they started using more types of orchestrations which also led on average to a larger orchestration frequency.

Keywords: Instrumental orchestration, primary mathematics, classroom teaching practice, robot coding integration, technology.

Introduction

The incorporation of robotics and coding into primary school mathematics has attracted considerable interest. Introducing young learners to robot coding as early as kindergarten is increasingly viewed as an effective strategy for developing computational thinking and digital fluency (Angeli & Valanides, 2019). Integrating robot coding into mathematics lessons can make the subject more engaging and relevant, thereby potentially improving students' attitudes towards mathematics (Zhang et al., 2021) and enhancing their content knowledge (Sáez-López et al., 2019; Souza et al., 2019).

We examined how a year-long professional development (PD) program influenced the types, frequencies, and sequences of orchestrations used by two co-teachers in a 3rd-grade Integrated Collaborative Teaching (ICT) classroom in a New York City public school. In ICT classrooms, general and special education teachers jointly instruct classes comprising students with and without disabilities. Initially addressing teachers' needs related to technology skills, PD subsequently refocused to discussions of cognitive demand in mathematics tasks within culturally relevant activities and facilitated the sharing and development of strategies to enhance instruction.

The Finch Robot, with built-in sensors and precise movement capabilities for measuring distances, determining orientation, and performing drawing tasks (https://www.birdbraintechnologies.com/), was used in the study. These features support teaching core mathematical concepts, such as counting, simple addition and subtraction, patterns, measurements, identifying basic 2D shapes, representation of numbers on a number line, fractions, etc., while providing immediate feedback through sound, light, and movement, enhancing student engagement and self-assessment (Kentros et al., 2019). Finch supported culturally relevant mathematics tasks co-designed by teachers and researchers by representing the story in each task, e.g., being a subway train that stops at different stations or a

shopping cart pushed through the store aisle. These tasks made mathematics meaningful to all students, including those with learning disabilities, by linking learning to their cultural and everyday experiences (Lyublinskaya et al., 2024). For example, using forward and backward movement blocks, students were able to link the movement of a robot representing a subway train to addition and subtraction on a number line. They also used sound or light blocks to indicate subway stops, connecting these stops to numbers on the number line.

Theoretical framework

This study applies the Instrumental Orchestration (IO) framework (Trouche, 2004), which examines how teachers intentionally organize and manage instructional environments to foster students' instrumental genesis. Instrumental genesis involves the process by which a digital artefact becomes an instrument through its use in learning activities, shaped by both the tool's design and the users' intentions and practices (Drijvers et al., 2019). Central to this framework are three key components: the didactical configuration, arranging artifacts and participants in the learning environment; the exploitation mode, detailing how these configurations are intended to support specific learning objectives; and the didactical performance, capturing the teacher's adaptive decisions during implementation. These components enable systematic guidance in technology-rich environments.

Initially developed for analysis of Computer Algebra Systems (CAS) integration into mathematics education, the framework applications have since expanded to include diverse digital tools and contexts (Drijvers et al., 2020). This study adds to this body of knowledge by applying this framework to examine robot coding orchestrations in the elementary mathematics classroom.

Instrumental orchestration involves teachers systematically guiding learning processes in technology-rich environments (Drijvers et al., 2020). Teachers' choices of orchestration types depend on their perspectives on teaching, mathematics learning, and practical constraints such as time and technology. Drijvers et al. (2020) identified eight whole-class orchestration types and five individual/group orchestrations. The modified version of this framework, as applied in this study, is detailed in the methods section.

Methods

This year-long study followed mixed methods research design and addressed the following research questions: 1) What are sequences and frequencies of the whole class and individual orchestrations with Finch in teaching mathematics in primary school? 2) In what ways do Finch orchestrations evolve over time?

The two teacher-participants were Maria and Yulia (pseudonyms). Maria, a general education teacher with nine years of experience, holds a bachelor's degree in childhood education. Yulia, a special education teacher with 11 years of experience, holds a master's degree in special education. Their class consisted of 14 students, evenly split by gender, with 43% being students with disabilities.

The teachers implemented 10 activities between October 2023 and May 2024, each lasting around 20-30 minutes, while also participating in grade-based monthly online PD sessions that focused on various aspects of implementation. Data included video recordings of six 35-minute lessons that integrated robot coding activities, e.g., moving Finch along a number line to develop addition and

subtraction strategies, drawing shapes with Finch to understand the difference between squares and rectangles, etc. Qualitative analysis involved using the codebook (Table 1) to identify Finch orchestration types and frequencies of whole-class and individual/group orchestrations with Finch. The study replicated video data analysis procedure suggested by Drijvers et al. (2009). Specifically, each "unit of analysis was an episode, which concerns the whole-class treatment of one task" or individual student/small group treatment of one task. “If this treatment consisted of different orchestration types, the episode was cut into sub-episodes” (Drijvers et al., 2009, p. 3). In addition to the orchestration types identified by Drijvers et al. (2019), the codebook also includes whole-class and individual Link-screen-embodiment orchestrations we identified during the analysis. We also examined the sequence of orchestrations in each lesson.

Table 1: Finch orchestrations codebook

Whole-class orchestration (code)	Colour	Brief explanation	Individual/small groups orchestration (code)	Colour	Brief explanation
Board-instruction (WBI)		A teacher in a whole-class teaching in front of the board. No connections are made to the use of digital technology.	Technical-support (ITS)		The teacher supports the student in technical problems, such as login difficulties, connection issues, or hardware issues.
Technical-demo (WTD)		The demonstration of tool techniques by the teacher.	Technical-demo (ITD)		Individual/small group demonstration of techniques for using the digital content by the teacher.
Explain-the-screen (WES)		Whole-class explanation by the teacher, guided by what happens in the technological environment. The explanation involves mathematical content.			
Guide-and-explain (WGE)		An explanation based on what is in the technological environment provided by the teacher with some,	Guide-and-explain (IGE)		Individual exchange between teacher and (a pair of) student(s) in which the teacher provides guidance and instruction to the student, explains mathematical concepts or methods based on

		often closed, questions for students.			what happens in the technological environment, or raises questions to make the student reflect on his actions and results.
Link-screen-board (WLSB)		The teacher stresses the relationship between what happens in the technological environment and how this is represented in the conventional mathematics of paper, book and board.	Link-screen-paper (ILSP)		The teacher stresses the relationship between what happens in the technological environment and conventional paper-and-pencil and textbook counterparts.
Link-screen-embodiment (WLSE)		The teacher stresses the relationship between what happens in the technological environment and how this is represented through body movements	Link-screen-embodiment (ILSE)		The teacher stresses the relationship between what happens in the technological environment and how this is represented through body movements
Discuss-the-screen (WDS)		A whole-class open discussion about what happens in the technological environment.	Discuss-the-screen (IDS)		The phenomena in the technological environment lead to a discussion between teacher and student(s). The student has considerable impact on the direction and the content of the talk, for example by expressing his difficulties.
Spot-and-show (WSS)		Identification of interesting student work during the lesson, and its deliberate use in a whole-class classroom discussion			
Sherpa-at-work (WSW)		Sherpa student uses the technology to present his or her work, with all students able to follow the actions of both the Sherpa			

		student and the teacher easily.			

Colour codes were assigned to each orchestration type and used in the process of annotated timelining (Lyublinskaya & Du, 2023) to look for changes in types, frequencies and sequences of orchestrations over time. The four shades of green represent student-centred (SC) orchestrations and other colours represent teacher-centred (TC) orchestrations.

Findings and discussion

We present here an analysis of changes in patterns of frequencies and sequences of orchestrations observed over time.

Patterns in frequencies of Finch orchestrations

The frequencies of orchestrations identified in the six videos of lessons are shown in Table 2.

Table 2: Frequencies of orchestrations identified in observed lessons

Week	ITS	WBI	WTD	WLSB	WES	WGE	IGE	WDS	WLSE	WSS	WSW	ILSE	ILSP	IDS
1	4	2	3	1	4	0	1	0	0	0	0	0	0	0
7	2	4	4	4	2	2	0	1	1	0	0	0	0	0
14	2	3	1	2	1	0	1	1	0	0	0	0	1	0
19	3	2	3	0	2	2	1	0	0	0	0	0	0	0
Sub.	11	11	11	7	9	4	3	2	1	0	0	0	1	0
30	5	4	1	3	1	3	1	1	1	3	0	0	0	1
32	2	1	2	2	1	1	3	2	2	1	3	2	0	0
Total	18	16	14	12	11	8	7	5	4	4	3	2	1	1
T/SC	TC	TC	TC	TC	TC	TC	TC	SC	TC	SC	SC	TC	TC	SC

Initially, teacher-centred orchestrations dominated, with frequent whole-class presentations without Finch (WBI = 16), demonstrations of Finch's technical features (WTD = 14), and individual technical support (ITS = 18), reflecting teachers' focus on direct instruction and building technical skills. This aligns with the initial focus of PD on developing teachers' technical skills (coding with Finch). Whole-class discussions (WDS = 5) occurred throughout, but student-centred orchestrations emerged later. The gradual increase in student-centred orchestrations, such as demonstrations of problem solutions (WSS = 4, WSW = 3) and teacher-facilitated individual or group discussions of Finch codes in mathematics (IDS = 1), likely reflects both teachers' growing confidence with Finch and the shift

in PD focus from technical skills to pedagogy, emphasising student coding and connecting that to their mathematical understanding. This changes in PD focus influenced teachers' move towards student-centred approaches.

The findings also indicate a non-linear trend in orchestration frequencies suggesting the influence of factors like lesson topic, student needs, and time constraints on teachers' instructional choices. Nevertheless, the overall trajectory towards increased student-centeredness and diverse orchestrations reflects a positive influence of PD on evolution in confidence in using the Finch for mathematical learning, which is consistent with other studies (Drijvers et al., 2019).

Patterns in sequences of Finch orchestrations

The sequences of Finch orchestrations in each lesson were plotted on a vertical timeline (Figure 1). The evolution of Finch orchestration sequences across the lessons reveals a clear shift towards student-centeredness, as indicated by the ascending green line plot and the increase of green blocks, reflecting more effective integration of the Finch into mathematical practices.

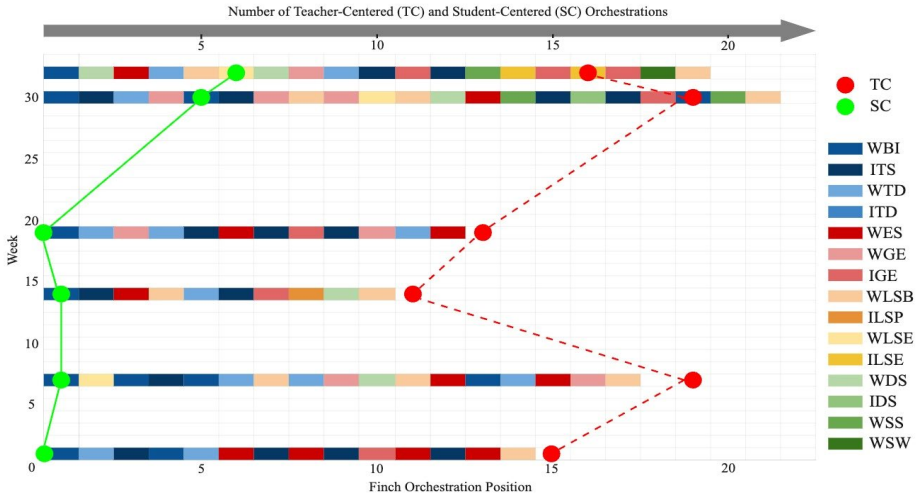

Figure 1: Timeline of Finch orchestration sequences

Analysis indicated that all lessons began with Whole-class board instruction (WBI) without using the Finch to outline the lesson flow and introduce problem scenarios. This was typically followed by technical support (ITS) and technical demonstration (WTD) to introduce Finch, often leading to individual guidance and explanation (IGE). Lessons usually concluded by linking Finch's actions (e.g., movement, lights) with traditional mathematical representations (WLSB), although Week 19 ended prematurely due to time constraints.

In early lessons (Weeks 1 and 7), Finch activities were mainly teacher-led, with a focus on technical demonstrations and explanations (shown in blue or red blocks). Mathematical content was gradually introduced, primarily through whole-class teaching. For instance, in Week 1, Yulia guided the class in counting robot lights to solve an addition problem. By Week 14, explanations and linking activities appeared earlier, reflecting a deliberate effort to connect Finch's functions to mathematics topics. For example, Maria linked robot movements to grid-based subtraction tasks. This phase also introduced

individual student interaction with Finch, enhancing hands-on learning. However, Week 19 highlighted challenges, such as rushed pacing and unfinished tasks, indicating the need to balance teacher guidance with student exploration.

In Week 30, green blocks, signifying student-centred orchestrations, became prominent. Student demonstrations and individual discussions fostered an interactive environment, encouraging students to take ownership of their learning. Examples include Yulia's whole-class presentation of a Finch-drawn shape coded by a student and Maria's individual discussions about shape properties based on student codes. By Week 32, the approach had evolved into a fully student-led model, with open discussions initiated immediately after problem introduction. Combining whole-class and individual activities with embodied demonstrations enriched the learning experience. For instance, Yulia, acting as Finch, used gestures to prompt a discussion on rectangle properties, and guided a student, acting as Finch, to draw a square by physically walking alongside them. Embodied teaching, central to instrumental orchestration, is a crucial role in learning. Drijvers et al. (2019) highlighted embodiment as key in their perspectives on instrumental orchestration, linking to instrumental genesis.

Conclusions

This study adds to the literature by examining the evolution of elementary school teachers' decisions in using robot coding in mathematics instruction. Findings reveal that as teachers engaged in targeted PD, their choices shifted from teacher-centred orchestrations to greater student involvement, reflecting the recognition of robot coding as a tool for supporting mathematical understanding. Embodied teaching provided students with tangible links to abstract concepts. Instructional practices are likely influenced by the ongoing intervention, which included monthly PD sessions that encouraged teachers to reflect on their teaching, build their confidence, and become more willing to let students take initiative and relinquish control over learning. In-class coaching provided support when teachers encountered challenges, reinforcing their growing confidence and suggesting that these changes were facilitated by targeted efforts rather than occurring independently.

Methodologically, this research advances prior studies by combining sequence and frequency analysis with annotated digital timelining, offering deeper insights into the dynamic integration of classroom technology. The study is limited to six lessons from one co-teaching team. Future research should include additional teams and teachers' perspectives to better understand the changes.

The design of artefacts by mathematics teachers' educators as a window to tension between their actions

Dimitris Diamantidis and Chronis Kynigos

National and Kapodistrian University of Athens, School of Philosophy, Department of Educational Studies, Athens, Greece; dimitrd@eds.uoa.gr

In this research we present the results of two cases' analysis where two pairs of teacher educators on the use of digital tools for Mathematics designed digital artefacts during the preparation of a large-scale training, in Greece. We aim to identify points of disagreements and tensions, whether they were resolved or not. Drawing on activity theory (CHAT), we connect the tensions with the rules of training, the position and obligations of trainees and educators, as well as with the educators' approaches to the broader training framework.

Keywords: Design of digital artefacts, CHAT, tension.

Introduction

The study of mathematics teachers as designers of teaching interventions, with the use of digital or non-digital media has a significant contribution to the understanding of their teaching actions (Remillard, 2018). Furthermore, studies of teachers as designers of digital learning objects for their teaching make clearer the kind of knowledge they draw on as professionals (Laurillard et al., 2018). However, mathematics teachers working in the school can adopt other, hybrid roles, apart from the role of teacher, interacting with the school environment in many ways: as colleagues, as collaborators, as employees, as educators, as trainees, etc. Therefore, we suggest that it is necessary to study their designs considering all these roles and the relevant context. In this research, we will focus on teachers' designs that arise from their roles, as educators of their colleagues.

To conduct the research, we took as our motivation the context of the training of mathematics in-service teachers in the use of digital technologies in teaching, organized by the Greek Ministry of Education, and the large numbers of mathematics' teachers who have been trained in the last fifteen years. This training requires a lot of effort by the trainees and the educators who also are mathematics' teachers, who have been certified as educators for the specific program. The educators' training includes over 400 hours of blended learning courses, at the University, which include courses in Mathematics Education and design with digital media (Zagouras et al., 2022). The study of teachers' designs in the context of this training, with the aim of understanding the type of knowledge they use, the practices they participate in, as professionals and finally to look for and analyse elements of their professional development, should be the subject of an extended research design, likely utilizing a range of methods. As a starting point of our attempt to build this plan we will present the study of two pairs of educators who designed digital artefacts for mathematics to be exploited during the training courses. Through the present study we aim to identify and analyse elements of designers' actions that will help us understand in depth aspects of their practice and to identify contradictions which sometimes may create problems, but on the other hand often led to the development of these practices (Sannino, 2016).

Theoretical Framework

Research around the practices of mathematics teachers in relation to the use of digital media for teaching offers researchers a range of theoretical approaches (Clark-Wilson et al., 2022), while others focus on the knowledge they use (Mishra & Koehler, 2006), how it evolves, in the description of their teaching actions, etc. However, in the present research we wanted to understand holistically and in-depth aspects of teachers' actions who designed digital artefacts for Mathematics in the context of training, having the role of teachers' educator. Beyond the schemes of use of the digital artefacts that led their designers to create them, or capturing the knowledge that they employed in order to design them, we wanted to study other elements, such as time constraints of the training, rules of the training framework, limitations arising from the training curriculum, or design principles followed by designers for other reasons, e.g., due to personal perceptions. In previous research, to holistically understand aspects of the actions of teachers who designed digital artefacts for teaching and to detect evidence of potential changes in these actions (Diamantidis & Kynigos, 2023), we leveraged third-generation cultural-historical activity theory (CHAT) (Engeström, 2001), seeing from the outset the change in teachers' practices as the result of dialectic-type tensions that can appear in any aspect of teacher activity. We did something similar in this research by studying, analysing and interpreting the actions and statements of the teachers, who as educators this time, designed digital artefacts, within the general context in which they acted.

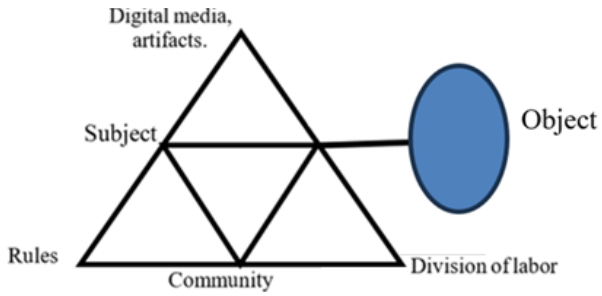

Figure 1: The CHAT 3rd generation activity system (AS)

In our case the "activity" was the design of digital artefacts for training in the use of digital tools in the teaching of Mathematics (design/training) and is described by the "activity system" (AS) and its elements in figure 1 (Engeström, 2001): Subjects are educators/designers (more generally, not just research participants), while rules refer to the context of training and community refers to everyone involved (including schools, mathematics' teachers, trainees and educators of such training, etc). The rationale of employing CHAT is to study the activity by analysing the interactions between the AS's elements. Moreover, it detects possible changes of the activity, where tensions in these interactions occur. The object is described by the objective, the outcome and the motive of the activity (e.g., the digital tool designed for such training and the training activity performed with it). Since different designers/educators were engaged in a similar activity (i.e. design/training), then AS and object can be determined by studying different subjects. Each subject may have different motivations (e.g. different educational goals and design principles) that lead to different outcomes. Thus, the activity is finally described with completeness and with more and more accuracy by the study of more and more subjects and its results (Engeström, 2001). For this specific research, the description of the

activity included elements from the study of the two subjects, while in the future it can be enriched by the study of even more.

Moreover, in the context of CHAT, a possible change in the activity described is favored when tensions are detected, i.e. when inconsistencies are indicated between the elements of the AS (Engeström & Sannino, 2010). For example, in the design/teaching research (Diamantidis & Kynigos, 2023) we identified tensions in the teachers' actions related to their diverse approaches to teaching guidelines for the specific concept that they designed digital artefacts, as formulated by the Ministry of Education. In the present research, we focused on the question: Were there any tensions located at the action of the designers/educators, in these cases we studied and in which interactions between AS's elements were detected? Which were the structural features of these tensions?

Method

For our research, as mentioned we studied the activity of two pairs of designers/educators (DT1 and DT2 was the first, while DT3 and DT4 was the second) who designed digital artefacts for the specific training. These two cases of design took place during the same training, around the same period (2021 and 2022) and were related to a blended model of training (face-to-face and online synchronous and asynchronous activities). The educators aimed to design artefacts which could be exploited during a hands-on session near the end of the training, without having decided in advance what the trainees should do during this session. They also seemed to have at least three common elements, in terms of the AS: the common object "to design a digital artefact for mathematics, to be used at the end of the training", the same digital medium which was "GeoGebra, as an authoring tool", and the same community (consisted of the educators and the participants). All these were reasons for us to present these two cases in the same study. However, all these assumptions had to be confirmed by analysis. Moreover, two more reasons for the selection of these two cases were the centrality of artifact design and the contrasts that emerged, and the long period that each pair worked densely together (more than a year).

The research data consisted of the notes from the face-to-face group conversations, the texts of the remote electronic conversations, the generated digital materials and the transcripts of the semi-structured interviews of those participants who were willing to give. As a result of their long period of collaboration, the pairs of educators developed common codes of communication and thus our methodological approach had elements of ethnography. So, we adopted an approach closer to thematic analysis, focusing more on the meanings and less on detecting patterns in the content; we analysed the data defining the unit of analysis as the "units of meaning" (Veldhuis-Diermanse, 2002). We analysed the units of meaning into two stages. In the first stage we categorized them with a more grounded approach (Kelle, 2005) and in the second we classified each unit of meaning into the elements of AS and thus attempted to match the categories of the first stage to AS's elements.

Results

During the first stage of our analysis six categories emerged, of which we will present those needed for discussion of the results. In our coding, we use the same letter(s) for codes that belong to the same theme, and a different number to indicate a diverse dimension of this theme which often conceals

contradiction, and the possibility of a tension emergence. For example, Codes T3 and T4 correspond to diverse (and somehow contradictory) units of meaning about the same theme; the tradition that the training has created all these years (almost two decades). We use the term "tradition", meaning all those that educators are accustomed to exploit and that attribute some value to their use, whether one thinks it should be continued (T3), or implies that it is not needed at this point (T4). F2 and F3 correspond to descriptions about the functionalities of a tool, i.e.: F2 fits with the approach that there is no point in trying to duplicate the functionalities of a tool, with a different one, because the activity with the new one will have much difference, while F3 stands for an approach like "it's worth designing what is closest to the functionalities of one tool with another and thus simulate them as good as we can". E3 and E4 encode units of meaning about the effort that needed to be put into designing actions and about the person who will perform those actions; the educators who design the training (E4) or those who will participate in it (E3)? D1 and D2 refer to risks designers need to be aware of during the selection of artefacts from other resources, such as training materials, in terms of sustainability; D1 is related to legislation, while D2 is related to variables of the artifact selected that they cannot control, e.g., to prevent it from being inactive. Ph1 and Ph2 refer to issues related to the philosophy of the training, one aspect of which is "the teacher as designer"; Ph1 approach is that the "teacher as designer perspective" does not presuppose technical fluency in mathematics digital environments, while a meaning categorized as Ph2 argues that technical fluency and the designer's perspective strongly correlated. We should say that we faced dilemmas during the coding, since there was no absolute identification of the category and each unit of meaning corresponded, so we made the decision to assign some units of meaning to more than one category. This was not a weak point of our analysis since, we exploited it during the second stage, identifying connections between AS's elements.

Our first case was two educators who discussed and proceeded, based on GeoGebra, in the design of an artefact that aimed to simulate the functionalities of Function Probe (FP), which are no longer available. One of them was to horizontally distort the graph of a function by manipulating a tool. Instead of that tool, they connected the parameters of each available function to a slider, which if someone manipulates, it results in distortion of the graph. Figure 2 shows the specific tool in the case of FP, but also the designers' artefact in GeoGebra. We present two excerpts of their dialogs. The first one took place before designing the specific functionality:

56	DT1:	We should make a medium with GeoGebra, that could be utilized like Function Probe (FP). FP is not available nowadays, but it was a central to training in previous years.
57	DT2:	But is it better to show them how to do with GeoGebra tools, what can be done in FP? Why put effort to build a new tool based on GeoGebra? Let's not mention the following: we won't exactly achieve to "copy" its functions.
58	DT1:	Let's make it look like FP's tool as best we can. So that we can also use the material we have for FP, with modifications, but also for them to see what was there before their training.

The following excerpt was drawn from the data after the functionality's design:

81	DT2:	Do you see? It's not the same! It doesn't feel the same when you move the slider, one is on the plot [FP], the other is a variable off the plot.
82	DT1:	Okay, we'll just show the educators anyway. I think they will understand what we want to tell them. And maybe we'll tell them what you're saying!

83	DT2:	Okay, maybe if we could have touch screen capability and students, or educators could distort the plot with their fingers by touching it we'd be closer to FP's functionality. And maybe a step further!
84	DT1:	This could be a topic of discussion during training. Make a note of it!

From our analysis we categorized lines 56 and 58 to T3, and line 57 to T4, which indicated a tension between DT1 and DT2 around the exploitation of the "training tradition". Moreover, lines 57 and 58 revealed another tension between DT1 and DT2, because we coded them in the categories F2, E3 and F3, E4 respectively.
