M2: I see that many of them may figure out how to do but may still have difficulties to **really understand** what is happening. (…) There are probably many students who struggle to **really, deeply understand the essence of this relationship**. (…) Well, you can learn all kinds of knowledge very routinely by heart, and then you can learn things... well, **learn it deeply**. And that's really what we want.

M6: It doesn't happen automatically that you understand the concept of ratio, that you can apply it to other tasks later (…) it is, somehow contextually learned in some way. (…) **If you truly understand the concept** of ratios (…) you can **solve many different problems** (…) To become a problem solver, you have to understand the concept theoretically (…) to know mathematics, not only understand the concept in a context you need a more theoretical approach.

In contrast to former categories, there is thus a focus on mathematical concepts, generalized across different situations. However, in contrast to both category 2, and the next coming categories, the relation to, and understanding of, the vocational context, is not focused in this category of description. Furthermore, in contrast to category 4, the ability to apply geometric concepts in a vocational context is unproblematized and taken for granted.

Category 4: Conceptual connection between vocational and mathematical contexts

This category focuses on the connection between mathematics used in the classroom, and mathematics used in vocational practice. The application of geometric concepts in a vocational context, is in the foreground and referred to as a non-trivial part of vocational mathematics understanding. Teachers, who voice this perception, typically focus on students' difficulties to understand that mathematics in the classroom and mathematics used in vocational practice is "the same mathematics", and suggest that, seeing this connection, provides an enhanced way of handling vocational tasks, as well as an increased understanding of mathematics.

V4: You have to help them **to see that connection**. And then sometimes, suddenly: 'Oh well! That's right! It's, kind of, the same thing as in the maths textbook, even though we're now in the construction hall, on the floor. (…) When they get this: 'Aha!', as I said, the connection to the maths textbook, like: 'Oh well! Okay! This is how we can use it! Now! Oh! Now I will calculate!'...and that they, **in this way, really understand** what they are doing.

V5: We use percentages, for example concerning humidity in concrete. And then suddenly a student was saying: 'What! **It's the same percentage** as in maths!' So, it is such a difference. It's something that you do in math over there. But **this is for real**. (…) We got rid of this: math over there and the math here (…) it is **the same mathematics** it is actually **not anything new**.

Emphasising these aspects indicates that the transfer of knowledge between mathematics classroom and vocational settings, is seen as an essential, non-trivial part of vocational mathematics knowing.

Category 5: Fusion of vocational and mathematical knowing

In this category, educationally significant vocational mathematics knowing is perceived as an integrative process, where mathematical concepts, vocational understanding, and workplace experiences are combined to address complex vocational challenges. Geometry is referred to as an essential, but insufficient part, which indicates that vocational mathematics knowing is seen as a field of knowledge beyond general mathematics. At the same time geometric aspects are discerned and highlighted. Teachers convey this view by giving examples of complex vocational problems, in which both mathematical and vocational aspect have to be considered, and by emphasising all of these aspects as essential components. That is, various aspects are simultaneously in the foreground, vocational as well as mathematical, theoretical as well as practical. Moreover, the integration of those aspects is also perceived as an essential aspect of vocational mathematics knowing.

V4: When you calculate wallpaper consumption, for example, you can't, simply, use area calculations, because **there are so many other things to take into account** (…) vocational skills, or vocational experiences, things you cannot learn by reading.

V9: I think the context might be the most difficult part. (...) it **adds another dimension**, like. It's really about problem-solving, like in all practical professions (...) [During mathematics lessons] they probably go more in-depth (…) and we focus more on **the matter at hand**. Of course, **the depth is really important** for them to grasp (…) [in the construction site] we have the **theoretical and practical parts at the same time**.

These quotations indicate a focus on vocational knowledge and experience, as well as mathematics understanding, together with the ability to grasp how all of these aspects are related, in order to form a coherent understanding of complex authentic vocational mathematics problems as a whole.

Category 6: A significant part of vocational *bildung*

In the final category, *educationally significant vocational knowing in geometry* is seen as a part of an individual's vocational *bildung* involving, not only factual knowledge and vocational skills, but also reflection, creativity, adaptability, and development. This perception is voiced in the quotes by referring to an increased level of mathematical knowing, as "another way of seeing" (V5). Moreover, a more in-depth mathematical understanding is suggested to entail an ability to handle a variety of situations in creative ways, and to become confident in the vocational role. Compared to previous categories, the focus thus extends beyond immediate demands to a more holistic view of education.

V5: You get another eye (…) It is a matter of **confidence and security** as well. 'I have made the calculations, and it will be all right'. It's like a certificate, **it is about knowledge**. (…) There are various possible ways to go, but the more mathematics you understand… well, **you can see things in a different way** (…) Basically, that is what knowledge really is about.

M2: I would find it valuable to understand the mathematics behind (…) I believe it can help them to **think more broadly**, when everything is not straight (...) If you really understand what you're doing, it's easier to **adapt to various situations**.

M8: …I really think it makes a huge difference, when you get out into the working life. (…) It gives you a **capacity for action** (…) You become more **independent**. (…) As a result of this kind of problem-solving mindset (…) they have a **different way of thinking.** (…) There's an understanding that there are multiple ways into a problem (…) they get **more tools** to handle a task.

The focus on these aspects indicates that the phenomenon is seen as a part of an extended vocational *bildung*, which in turn provides an opportunity to understand, evaluate and solve a variety of vocational mathematics challenges in creative and adaptive ways.

Discussion

This study aimed to explore vocational and mathematics teachers' various perceptions of *educationally significant vocational mathematics knowing*. The result presents six categories of description which illustrate diverse perceptions of this phenomenon. These various perspectives provide insights into the potential role of geometry in vocational activities and may thus inform decisions about mathematical learning objectives. In an interview study, by Christidis et al., (2024) students' experience of mathematics as an aspect of vocational knowing, is explored. The study confirms that while students often recognize mathematics as a part of vocational knowing, they may still lack awareness of its role for future development of the vocation. The authors highlight the significance of curriculum and teaching for preparing students to identify mathematics in vocational activities. How vocational and mathematics teachers identify, understand and articulate vocational mathematics knowing, is thus a critical factor in the enactment and development of vocational education. Previous studies exploring vocational mathematics knowing describe it as a complex competence, frequently embedded in vocational practices (Christidis et al. 2024; Hoyles et al. 2010). Moreover, the importance of considering both mathematical aspects and the vocational context, along with the ability to integrate mathematics into the workplace setting, has been emphasised (FitzSimons & Boistrup, 2017). The result of this study shows that teachers to various extent and in various ways acknowledge both mathematical and vocational aspects of vocational mathematics knowing, and the relation between them. The richness of perspectives in the outcome space shows that vocational mathematics knowing is not merely perceived as basic arithmetic, but that several other aspects are also appreciated, such as relational understanding of geometric concepts, and practice-based perceptions of geometric aspects in vocational tasks. Moreover, the result highlights problems of transfer between the mathematics classroom and the vocational setting and illustrates the complexity of integrating mathematical and vocational knowledge in vocational problem solving. Additionally, it suggests a view of vocational mathematics knowing as an essential component part of students' holistic vocational *bildung*, a means to improve the ability to engage in vocational activities, by developing the eye through which the world is seen. A view, which illuminates aspects of vocational mathematics knowing such as creativity, confidence and adaptability, aspects which in the prolongation might enhance further development of workplaces and vocational competencies.

Not just threats and weaknesses: Seeking opportunities for the teaching/learning of mathematics in prison schools

Federica Mennuni, Andrea Maffia, Luca Decembrotto and Veronica Manzoni

Alma Mater Studiorum University of Bologna, Italy; federica.mennuni@unibo.it

Scientific literature about teaching/learning mathematics within the context of schools in prison is very scarce. Framed by Educational Design Research, the Learning Math in Prison project started with an exploration phase of the context, realised together with Italian mathematics teachers in prison schools. The analysis conducted till now pointed out several categories of characteristics of the process of teaching/learning mathematics in Italian prisons. With the desire to better understand the nature of this process, more than listing and defining these categories is required. In this contribution, we wonder what the relationships between these characteristics are, focusing on some of them in particular. Alongside several weaknesses relating to the specific context, mathematics teachers identify particular opportunities that may prove helpful to support design principles for mathematical tasks within the prison context.

Keywords: Prison education, theory-driven categories, data-driven categories, SWOT analysis, mathematics teachers.

Introduction

The literature on teaching and learning mathematics in prison is very scarce. There is a notable gap in research on mathematics teaching and learning in prison contexts (Gagnon & Barber, 2014), despite mathematics occupying a unique position among the subjects taught, acting as a source of personal satisfaction and a gateway to future educational or employment opportunities (Ahl & Helenius, 2021). In this type of context, many of the usual peculiarities of teaching to adults (Gal et al., 2020) intersect with other issues related to managing the process of learning mathematics for vulnerable adults in a non-native language, dealing with non-homogeneous class groups, and sustaining very different motivations for learning (Gagnon & Barber, 2014; Byrne & Carr, 2015; Gal et al., 2020; Ruhil & Gut, 2019). The literature on teaching/learning mathematics in prison is characterised by discontinuity in class attendance because students come from backgrounds marked by previous failures, low levels of self-efficacy and a negative view of mathematics (e.g., Gagnon & Barber, 2014; Byrne & Carr, 2015) or provides only general data about students' attainment (e.g., Ruhil & Gut, 2019) and does not provide recommendations for educational practice. Consequently, in order to address this gap, two years ago the Italian national research project "Learning Math in Prison" (LeMP) was launched. The LeMP project is an interventionist Educational Design Research project (EDR, McKenney & Reeves, 2018) which involves five universities and teachers from three different prison schools. As usually happens for EDR, our LeMP project is organised into three main phases: analysis and exploration, design and construction, evaluation and reflection (e.g., van den Akker et al., 2006; McKenney & Reeves, 2018). Each phase involves interaction with practitioners and contributes to an intervention's theoretical understanding and progressive development (McKenney & Reeves, 2018). Therefore, the general aim of LeMP is to fill this gap by developing a set of design principles for creating teaching materials for Italian prison schools based on close and

intensive collaboration between researchers and practitioners (teachers involved). Within the LeMP project, the prison context is framed as a context of multi-complexity. This term is used in medical research to refer to patients with multiple (often chronic) diagnoses, whose cure cannot be the simple sum of the therapies for each pathology. In our view, this term only emphasises the high degree of complexity in the prison context, resulting from the complex interaction between personal, relational and structural factors, not necessarily attributable to persons in prison. We are convinced that juxtaposing already available design principles developed in other contexts could not be sufficient.

Starting from these considerations, in this paper, we present the analysis of the initial exploration phase of our research framework, which was based on a systematic literature review and teachers' interviews. Specifically, this article reports on the first phases of a broader work stream that aims to describe practitioners' perspectives on their work context (Maffia et al., submitted). McKenney and Reeves (2018, pp. 78-79) pointed out that "collaboration with practitioners is sought to shape a better understanding of the educational problem to be addressed, the target context, and stakeholder needs". For this reason, we want to fine-grain describe the context, as no such description exists in the literature. In this contribution, we delve, from a theoretical point of view, into some of the categories identified in (Maffia et al., submitted) and ask whether they are disjoint or, if not, what are their mutual relationships. A more precise Research Question is presented after the next section.

Theoretical Framework

Based on the analysis of available literature and the data collected in the first exploration phase of our EDR, we have categorised characteristics of the teaching/learning mathematics process in the prison context (Maffia et al., submitted). Below, we present those categories. Then, to understand the relationship between the presented categories, we use SWOT analysis as a framework for our research.

Theory-driven and data-driven categories

To highlight the aspects that characterise the process of teaching mathematics in prisons, we identified and, at the same time, validated categories linked to the most discussed topics among mathematics teachers; we distinguish between *theory-driven categories* and *data-driven categories*. The *theory-driven categories* are the themes that have been considered a-priori based on the existing literature on teaching in prisons and previous research experiences in prisons (e.g. Maffia & Decembrotto, 2022). In the Methodology section, we will see that the *theory-driven categories* have been used as thought-provoking hints for the teachers' contributions on a Padlet. An example of a *theory-driven category* is the *Motivation to study*, which Maffia et al. (submitted) defined as "students' relationship with study, in general, and with educational institutions, including the purpose of the study".

On the other hand, the *data-driven categories* are the themes necessary to codify the posts in the Padlet, which are characterised by the teachers' observations and are not covered by the *theory-driven categories*. In this paper, we will refer to the following examples of *data-driven categories* defined by Maffia et al. (submitted) as: "*Class group composition*: characteristics of students, […], high turnover, specific needs and any difficulties encountered (of social, cognitive, relational...)";

"*Personalisation*: individualisation and/or personalisation of teaching and/or training paths for students, including their flexibility".

There are more *theory-driven* and *data-driven categories* than those we have listed as examples. Due to space limitations, we have restricted the presentation to those addressed in this contribution.

SWOT analysis

SWOT is the acronym for Strengths, Weaknesses, Opportunities, and Threats (Helms & Nixon, 2010). SWOT analysis provides a clear frame for gathering information from various sources, bringing out an overview of internal factors (i.e., Strengths and Weaknesses) and external factors (i.e., Opportunities and Threats) that could be useful in describing the characteristics of the teaching/learning mathematics process. In this contribution, we will refer to how the reciprocal relationships between the categories identified above (Maffia et al., submitted) could highlight Strengths, Weaknesses, Opportunities, or Threats characterising the teaching/learning of mathematics in prison. In our study, Strengths (S) are seen as the positive characteristics of the school where teachers work and supporting their work. Weaknesses (W) refer to the characteristics that make teachers' work more difficult and hinder their aims. Opportunities (O) refer to the internal or external characteristics offered by the environment in which teachers work that could be exploited to benefit their work. Finally, Threats (T) can be seen as external difficulties independent of the teachers. Still, they undermine the successful functioning of their work in the classroom, thus limiting the achievement of their aims.

Using this theoretical framework, we intend to investigate the characteristics of teaching and learning mathematics in prison. To this end, we analyse teachers' comments on a Padlet (see the next section), addressing the following research question: Which relations between categories (if any) can describe the characteristics (concerning SWOT) of the teaching/learning of mathematics in the prison context?

Methodology

The present study is part of the larger research project LeMP. LeMP is an Italian national project that arose from the collaboration between researchers in Mathematics Education and Special Pedagogy, and three prison schools. Participation is voluntary in the LeMP project, and the research presented in this paper has been proposed to all mathematics and science teachers in the schools involved, all of whom have a master's degree in a scientific discipline but have not received specific training in teaching mathematics and science with adults, foreigners and/or in the prison context. However, our sample is characterised by various work experiences in prison, ranging from a single year to over 20 years. For this study, nine teachers have volunteered to represent all three school contexts involved in the LeMP project. The teachers involved have been asked to fill out a Padlet (described in more detail below) and then to participate in an online meeting to discuss some of the issues that emerged from the Padlet analysis. Due to the space limits, we focus our attention only on the content of the Padlet and its analysis.

To collect the teachers' perspectives, we have created a Padlet by adding some thinking-provoking hints such as *Motivation to study, Classrooms, Equipment, Role and purpose of education in prison, School-prison relationship, Absence of INVALSI tests, Other*, chosen by the researchers as relevant

topics based on the existing literature, their previous research experiences in prison, and the analysis of the institutional documents from the schools. This tool helped us to point out the aspects considered relevant by the teachers to describe the characteristics of teaching/learning mathematics in prison. Beyond this, the choice of using Padlet to bring out aspects relevant to teachers for describing their context is motivated by the desire to collect data remotely from teachers working in dispersed prisons in Italy.

Initially, teachers were asked to access the Padlet individually and post their reflections about internal factors (S and W) and external factors (i.e., O and T). Only then were the posts on the Padlet made visible to all teachers. They were then asked to comment on other colleagues' posts. This phase of work ended with an online meeting to further explore some of the issues that emerged from the Padlet and refine the categories identified in the content analysis of the Padlet (Maffia et al., submitted). Collecting data through a focus group discussion is motivated by the desire to triangulate individual thinking and reflection at the group level (Cohen et al., 2007).

The analysis of the data from the Padlet was divided into several stages in which data-driven categories were identified using the principles of qualitative content analysis (Cho & Lee, 2014). More precisely, the analysis process followed several steps based on an initial parallel analysis of the data collected in the Padlet using the a-priori categories and an initial identification of possible new data-driven categories and then on the comparison and discussion of the parallel analyses of all researchers involved to reach an agreement on the coding of each post and finally, the shared identification of the data-driven categories. The results of this analysis have been presented in detail in another work (Maffia et al., submitted), and we are not introducing that analysis in this paper. In this study, with reference to the chosen theoretical framework, the data analysis aims to describe the relationships between some categories by emphasising the aspects linked to the internal and external factors that the teachers have considered relevant according to their different experiences. In the next section, we describe only the relationships between the following categories: *Motivation to study* (with a focus on the attitude towards mathematics), *Group class composition*, and *Personalisation*.

Results and Discussion

Teachers have described the three categories considered in this study as having positive and negative aspects. The category relating to the *Group class composition* is described by the teachers with critical aspects (5 posts for W and 3 posts for T) and positive aspects (3 posts for S and 4 for O). On the other hand, the category relating to *Personalization* is described mainly by focusing on positive aspects (4 posts for S and 7 posts refer to O) with only 1 post pointing out W. Finally, the category related to "*Motivation to study*" is described by teachers with both positive aspects (3 posts for S and 5 posts for O) and negative aspects (3 posts for W). To answer our research question, in this section, we analyse the data collected with the Padlet by highlighting the relationships between the categories of *Group class Composition*, *Personalization*, and *Motivation to study*, which allow us to describe S, W, O, and T, characterising the process of teaching/learning mathematics in prison also by highlighting the number of posts in which they appear.

Group class composition and Personalisation

A relationship between the categories *Group class composition* and *Personalisation* is highlighted in 2 posts for S, in one post for W, and in 4 posts for O, which could be helpful for us in describing the process of teaching/learning mathematics in the prison context. More specifically, an aspect considered relevant by teachers within the category of *Group class composition* is related to the high turnover of students entering and leaving prison throughout the school year. This aspect presents itself as a challenge that, in most cases, negatively affects teachers' work in the classroom (*High turnover of entries, transfers, and releases: partial or missing information on the educational path. The number of students in each class is constantly changing throughout the year [...]*). However, at the same time, it emerges that this aspect is seen as an opportunity to be stimulated (as teachers) to personalise their teaching practices by students' competencies (The high turnover of inmates, on the one hand, slows down the development of a full curriculum, but on the other hand allows the development of lessons focused on the actual deficiencies/needs of the students in the limited time available). This opportunity stems from the fact that, because of the high turnover of students in the classes, there is also a wide heterogeneity among the students as they have different age levels, different cultural backgrounds, different literacy levels, and different mathematical skills and competencies derived from their different educational and professional experiences. Although the high turnover and the vast heterogeneity of the group of students are considered negatively by teachers, it also emerges from the posts on the Padlet that working in these contexts requires teachers to pay more attention to personalising the educational program that considers the individual student's educational needs. Thus, the need to personalise students' educational programs offers teachers the opportunity to develop teaching strategies aiming at enhancing the mathematical competencies and skills of detained students based on their real and different learning needs (The opportunity to work effectively with multi-class groups of varying levels of proficiency in Italian, ages, and diverse cultures is undoubtedly complex but constitutes a great wealth). However, despite the difficulty linked to the need for teachers to pay specific attention to the needs of individual inmates, it is possible to see that the ability to personalise the education of students by taking into account both their skills and their real learning needs becomes a Strength of the process of teaching mathematics in prison context (The didactical activities are based on the personalisation of the re-educational path of each student [...]and take into account expressed and unexpressed interests and needs).

Group class composition and Motivation to study

It is important to highlight a relationship between the categories of *Group class composition* and *Motivation to study* with the internal and external factors that characterise the process of teaching/learning mathematics in prison. A relationship is highlighted in 2 posts for S, 1 for W, and 3 for O. More specifically, the first negative aspect concerning the category of *Motivation to study* is related to the fact that, in many cases, students have a low motivation towards mathematics. This depends on previous negative school experiences, or in the case of foreign students, it depends on a poor level of schooling (Many students have had negative experiences with school and in particular with mathematics, and also Difficulties with mathematics are more significant in those who have little schooling even in their country of origin). These situations could also provoke feelings of frustration and rejection towards mathematics. From this, it can be seen that different levels of schooling or

different school experiences result from the vast heterogeneity of the class group. Thus, the wide heterogeneity of the class group generally influences motivation towards study and, more specifically, towards the study of mathematics, making it different among students. In particular, in these cases, the students' motivation to study emerges as being associated with other purposes, such as the desire to have better job opportunities after prison (Some students are motivated to obtain a degree to be able to work once they are out of prison); the desire to have opportunities for socialisation (The school in prison is a fundamental element of the rehabilitation pathway for the future reintegration of the imprisoned person into society. It is a place for socialisation, confrontation, acceptance and reflection, as well as learning); the desire to have opportunities for redemption from a previous unsuccessful course of study; the desire to have a new chance in being able to study a subject one has always been fascinated by; the desire to have personal growth with positive effects on the students' self-confidence as they are encouraged by the gratification of studying mathematics and the wish to be distinguished from others; the desire to obtain a school certificate or a certificate recognising their exemplary conduct at school to get a possible reduction in their penalty. From the description of this relationship between the two categories under consideration, it also emerges that this relationship helps describe the S and O of teaching mathematics in the prison context. In particular, in many situations, the psychological and affective aspects of the students emerge as a decisive motivating factor, often having a positive attitude towards the study of mathematics. In these cases, teachers emphasise that this depends on the fact that school, and especially the study of mathematics, offers the students a chance to escape from the reality they are obliged to live by allowing them at that time to forget other negative thoughts (The prisoners are not just students, they must live with guilt, nostalgia, anger, anxiety... a mathematical question can momentarily distract them and keep this burden away for a while, respond to the need to take their head elsewhere).

Motivation to study and Personalisation

Among the Padlet posts, some tried to clarify this relationship by describing internal and external factors characterising the teaching/learning of mathematics in prison. In particular, 3 posts aimed to describe the S and O offered by the context in which the involved teachers work, and that could help improve their work in prison. In these posts, teachers highlighted that motivation towards studying mathematics could be positive when teachers design lessons encouraging students to discover mathematics collaboratively. In these cases, it could be observed that it helps bring out the creative aspect and the students' desire for manual skills and concreteness in an intense way, so that students' motivation might be continually stimulated. To have a greater involvement of the students, the teachers once again highlighted the need to personalise their teaching practices by using more experiential techniques rather than transmissive ones, by designing manual, concrete, and creative activities that – thanks to possible collaborations with experts from outside the institution – could be appropriate for each student, taking into account the real learning needs of individuals (The educational offer could be expanded by allowing and encouraging the entry of external experts who offer their availability also free of charge. [...] or also The didactical activities are carried out with the use of techniques that are mostly experiential as opposed to transmissive and are based on the personalisation of the re-educational path of each student [...] and take into account their expressed and unexpressed interests and needs, to reinforce their motivation to learn). Thus, teachers are given

an additional opportunity to design teaching programs that leverage these kinds of dynamics and are oriented towards personalising the educational pathway of each detained student. Through this classroom activity, the teacher could help students improve their self-confidence and push them to understand that, once the prison experience is over, they could go on in their lives outside with new awareness and tools (The classroom activity aims to recover self-esteem and a sense of self-efficacy, in the direction of a redefinition of oneself, to, once the detention experience is over, resume one's life "outside" the prison with new awareness and new tools). During this type of activity, teachers also pointed out that, to stimulate motivation towards mathematics in the students, they could support them by constantly showing the usefulness of studying mathematics within their educational paths.

Conclusion

The analysis of the individual teachers' posts on the Padlet reveals many weaknesses and threats linked to the difficulties of their work context. However, in this contribution, we have shown that the relationships between the three considered categories also highlight strengths and opportunities as closely connected to some of the characteristics of the teaching/learning mathematics process in the prison context and not always available in other educational contexts. From our analysis, it is possible to note that not only weaknesses and threats emerged as a first preliminary analysis of the categories, but they also seemed to point out mainly (Maffia et al., submitted).

Thus, with the analysis presented in this paper, we enriched the context description (still scarce in literature), also providing positive aspects that may provide a base for designing innovative teaching practices and, consequently, for improving the process of learning mathematics. Such a more detailed exploration and analysis of the context is the necessary first step in any EDR project (McKenney & Reeves, 2018). The results of this first phase of research inform a process of evaluation aimed at refining the problem definition (namely, evaluating the discrepancy between the existing situation and the aim of our project, decomposing the problem into its constitutive parts). As exemplified in this contribution, pointing out opportunities (and not only threats) allows determining the so-called "jurisdiction of change", but that is also, distinguishing what is possible to change from the unchangeable (McKenney & Reeves, 2018). Starting from this awareness, the next phase of our project consists of determining the "design requirements". According to van den Akker et al. (2006), such requirements will become design principles only when based on theoretical arguments (as those developed in this contribution) and empirical ones, which will be based on data to be collected in the future phase of the project.

Subject integrated team teaching vs. textbook learning: A comparative study on students' experiences in vocational mathematics education

Karolina Muhrman and Peter Frejd

[1]Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden; karolina.muhrman@liu.se

This study investigates the effects of subject integrated team teaching (SITT) versus textbook-based learning (TBL) on students' experiences of vocational mathematics education. Data from a post-questionnaire of 234 students from two schools revealed significant differences in the effectiveness of vocational preparation between the groups. The SITT group reported positive experiences, high motivation to learn mathematics and identified vocational relevance as a key factor. Conversely, the TBL group had negative experiences and felt that the mathematics they were learning was impractical. The study also explored various motivators and barriers to the implementation of these approaches, highlighting the crucial role of teachers and the impact of grades on student motivation.

Keywords: Subject integrated team teaching, vocational education, vocational mathematics, questionnaire.

Introduction

There is a broad agreement, both at the national and international level, among scholars in the field of mathematics education that it is crucial to implement exploratory teaching and learning methods that link the mathematical concepts students acquire to their prospective professions (Frejd & Muhrman, 2022). Vocational mathematics education serves as a platform where learning occurs, with a clear objective of equipping individuals for their future careers (FitzSimons, 2014). Despite this, it is often observed that students enrolled in vocational education exhibit a lack of enthusiasm towards learning mathematics and fail to understand its relevance (Muhrman, 2016). This disconnect can be destructive to their learning process. However, Dalby and Noyes (2016) propose a solution to this issue. They suggest that incorporating realistic scenarios from the workplace can serve as a motivating factor for students to learn mathematics. This approach can help students understand the practical applications of mathematical concepts, thereby enhancing their interest and engagement in learning.

The idea of incorporating authentic situations into vocational education is not new and there are several ways how to make the teaching realistic (Frejd & Muhrman, 2022). For instance, a student could interview workers on what mathematics they use, or follow a worker a week and identify some mathematics on their own, read about workplace situations in books, work with authentic problems in the classroom and so forth.

In this paper, we introduce and share preliminary findings of our ongoing research project. This project is designed with the objective of exploring how different teaching interventions of mathematics in vocational education can prepare students for their future professional endeavours. Our primary objective is to examine the impact of these interventions on two key areas: the mathematical proficiency of the students and their motivation to learn mathematics. Our project

draws on Ryan and Deci's (2000) theory of motivation, which distinguishes between intrinsic and extrinsic motivation. Intrinsic motivation involves an internal drive to engage in tasks because they are interesting or meaningful, while extrinsic motivation is driven by the desire to avoid penalties or achieve high grades (Ryan & Deci, 2000). Extrinsic motivation is linked to surface learning, whereas intrinsic motivation is associated with deep learning and predicts overall school performance and long-term academic success (Taylor et al., 2014). According to Ryan and Deci's (2000) Self-Determination Theory (SDT), the three aspects of *autonomy*, *competence*, and *relatedness* are considered essential for promoting motivation. Briefly, autonomy refers to the need to feel in control of one's actions and decisions, competence refers to feeling effective and capable in one's activities, and relatedness refers to feeling connected and having meaningful relationships with others.

The project is longitudinal and involves nine upper secondary vocational schools, more than 1000 students and 20 teachers across Sweden. We use a combination of pre- and post-tests, questionnaires, and interviews as our data collection methods. This allows us to gather comprehensive data before and after the implementation of the interventions. Furthermore, we conduct follow-up data collection sessions at 18 months post-intervention. The objective of this paper is to offer preliminary results on students' experiences of a subject integrated team-teaching approach for mathematics learning compared to traditional textbook-based learning. The following questions, connecting to students' feeling of competence and intrinsic and extrinsic motivation, will guide our research:

RQ1: *What are students' experiences regarding the effectiveness of the teaching approaches in preparing them for their future professional roles?*

RQ2: *What experiences do students describe about how the teaching approaches they have encountered motivated them to learn mathematics?*

Subject integrated team-teaching approach in vocational education

Drawing on the work by Cook and Friend (1995) as well as by Frejd and Muhrman (2022), we define a subjected integrated team-teaching (SITT) approach for mathematics in vocational education as a co-teaching approach where two teachers (one mathematics teacher and one vocational and training teacher) jointly organize and deliver a teaching practice in connection to students' training halls.

SITT includes many aspects for qualitative teaching as found in the research literature on vocational mathematics education. Collaboration across disciplines encourages mathematics teachers to collaborate with other professionals and it is essential for developing a teaching practice that consider challenges and requirements of different workplaces (Frejd & Muhrman, 2022), as well as highlights the social and cultural workplace practices (FitzSimons & Björklund Boistrup, 2017). Since the mathematics in the workplace is deeply rooted in traditions and use of artifacts they should also be an integral part of the classroom activities in order for providing authentic learning opportunities (Mouwitz, 2013). A collaboration between the mathematics and the VET-teacher is therefore fundamental in both the design of learning opportunities and in the process of developing students' workplace identity and self-esteem according to Mouwitz (2013). In addition, our definition of SITT includes the learning of mathematics in relation to students' training halls. According to Frejd and Muhrman (2022) learning of mathematics in students' training halls significantly enhanced student

motivation and engagement compared to traditional mathematics classrooms. Vocational tasks in the mathematics classroom alone tend to maintain conventional classroom dynamics, making it difficult for students to apply these tasks to real workplace situations (Sundtjønn, 2021). However, integrating realistic problems linked to vocational contexts in both the mathematics classroom and vocational training hall can redefine classroom roles and alter perceptions of expertise. In training halls, students often view themselves as more knowledgeable compared to their mathematics teachers (Frejd & Muhrman, 2022; Sundtjønn, 2021).

The intervention and data collection

This paper presents initial results from the first year of a four-year study. We compare the responses of students in school A, which uses a Subject Integrated Team Teaching method (SITT, n=106), with the responses of students in school B, which uses a Textbook-Based Learning method (TBL, n=128). The participating students in both schools are enrolled in Mathematics 1a, a compulsory course covering the topics of arithmetic, algebra, linear and exponential functions, probability and statistics. In addition to a focus on academic mathematics it should also include mathematics for the student's future occupation.

School A, applying SITT, has six vocational education programmes and their teaching practice comprise three hours per week. One of these hours is called “vocational mathematics” and is located in the vocational classroom. During this lesson, both the mathematics teacher and the vocational teacher teach together following the dress code for the particular workplace and provide students with mathematics activities related to the workplace. The teaching activities is an outcome of a collaboration between the mathematics teacher and the vocational teacher, with a focus on what students are actually working on in the vocational subject. Examples of activities are connected to, recipe conversion and establishing prices for products (Restaurant management and food programme), driving time and engine displacement (Vehicle and transport programme), the costs of paint and materials for construction (Building and construction programme), etc. The other two lessons are textbook based and take place in the mathematics classrooms. School B, applying TBL, has two vocational programmes (the vehicle and transport programme as well as the natural resource use programme) with different profiles, such as agriculture, forestry, horse breeding, construction machine operator and transportation. In addition, about 20 of the 128 students have chosen a course that includes more mathematics, physics and chemistry, which qualifies them for further education at colleges and universities. School B has allocated four hours per week for Mathematics 1A and the main source of their lesson design is the use of the textbook. The mathematics teachers and the vocational teachers do not collaborate either on content or on teaching activities.

This paper focuses on the students’ post-questionnaire, which were distributed and filled out individually directly after students had completed a post-test in spring 2023. The questionnaire was developed using Microsoft forms for online surveys. It included 23 statements about motivation adapted evaluation forms of PISA (OECD, n.d.) and connected to Self-Determination Theory’s (SDT) aspects of autonomy, competence, and relatedness (Ryan & Deci, 2000), to be ranked on a 10-point Likert scale (1- strongly disagree and 10-strongly agree), and these 23 statements were the same in the pre- and post-questionnaire. In addition, did the post-questionnaire include a question on:

(Q24) what type of teaching approaches the students had met during the year; two statements to be ranked about (Q25) if the mathematics they had learnt had prepared them for their occupation and (Q27) if the organising of the teaching had motivated the students to learn mathematics; as well as two open questions (Q26 and Q28) where the students were asked to explain their reasoning regarding (Q25) and (Q27). The questionnaire question Q25 to Q28 are analysed in this paper.

Analysis and results

The students' responses to the questions in the post-questionnaire, 106 (SITT) and 128 (TBL), were exported into a spreadsheet (Excel). Answers on the Likert items (Q25) and (Q27) were analysed and compared using descriptive statistics and two independent sample t-tests. The students' answers to open questions (Q26) and (Q27) were short in length and most answers were just a few words and even fewer a few sentences. A line-by-line analysis (cf. Chenail, 2012) was used, with a focus on what reasons the students expressed based on their experiences. Briefly, each line in the students' responses was examined to identify units (words, phrases or sentences that convey significant information). These identified units of meaning were then coded with labels describing the essence of the content. These codes were finally grouped into different themes, which are discussed in the next sections.

Students' experiences of the effectiveness of the teaching approaches in preparing them for their future professional roles

In (Q25) the participants in the study ranked the statement*: The math we have learnt has made me prepared for my occupation*. The mean score for the SITT group was 5.92 with a standard deviation of 2.21 and for the TBL group the mean score was 3.98, with a standard deviation of 2.21. The t-statistic was 6.72, with df=224 ($p < .05$) show a significant difference of scores between the two groups. Figure 1 below illustrates the bar charts of frequency of students' rankings in both groups.

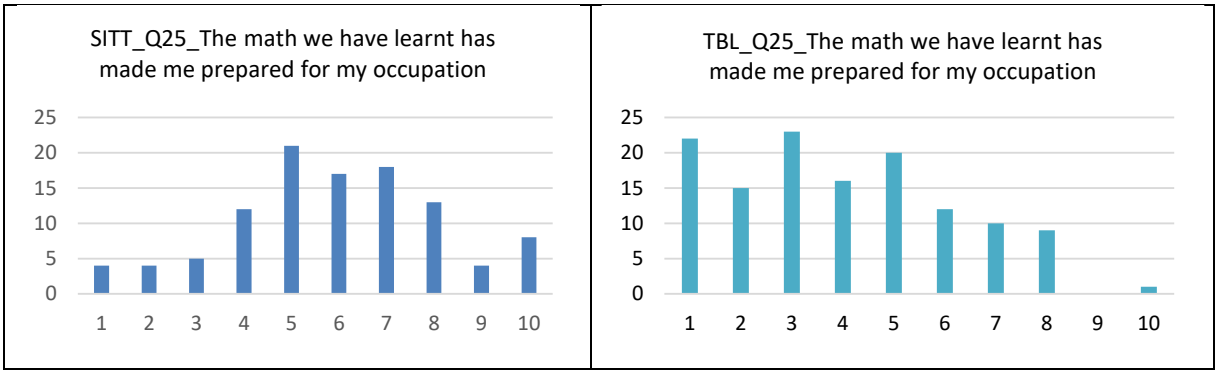

Figure 1: Bar charts of students ranking of Q25, left the SITT- group and right the TBL-group

From figure 1 to the right (the TBL group) it is possible to observe that only one student strongly agreed (ranking 9 or 10) with the statement that the mathematics taught has prepared that student for his or her future occupation, whereas in the TISS-group (in the left bar chart) there are 12 students that strongly agree to the same statement.

Table 1: Examples of students' expressed reasons in Q26 for their ranking of Q25

SITT-Frequent students 'expression with codes in italic	TBL- Frequent students 'expression with codes in italic
We have *vocational math* once a week and we learn about when and how to use math at work. In regular math, we don't really have math that will prepare me for my profession, but we have *vocational math* which is better preparation for the profession itself. However, I don't think we work with it enough to actually be able to remember all the formulas etc. So more vocational math to make it more preparatory. We get to learn *vocational math* that helps with things regular math doesn't and it's more fun.	I am going to drive a truck and do not need to know x*4^5=1 [Code: *unusable math*] I will not need so much mathematics in my occupation. [Code: *not needed*] I think we can work with more things that we can use in our future profession and not a lot of other things that we won't need. [Code: *unusable math*] We use a regular math book with regular math questions, nothing related to the profession. [Code: *unusable math*]

The line-by-line analysis of the students' answers on the open questions (Q26) generated 7 themes. The examples of students' expressions of their experiences in table 1 show the most frequent identified themes, namely *vocational math* (SITT-group) and *unusable math* (TBL-group). About 35% of the students' answers in the SITT-group described the weekly hour when the mathematics teacher and the VET-teacher worked together as a reason for making them prepared for their future occupation. Thereafter, the themes *Yes* (students' expressions that argued for usefulness by only writing yes or yes together with examples of mathematics in the workplace) and the theme *I don't know/no response* were identified 25% respectively. The last 15% of students' answers in the SITT group were distributed between the themes *No* (expressions that argued not being prepared with no argument) [10%] and *Not needed* (expressions connected to that mathematics was not needed for their occupations) [2%], and *other* (single arguments not connected to other themes) [3%]. In the TBL-group almost 40% of the answer describes that students had learn mathematics they express as *unusable* for their profession and a call for learning of workplace related mathematics rather than academic mathematics as well as these answers include expressions that their future occupation does not include any mathematics belonging to the theme *Not needed*. The theme *No* included 5% of students answers, *I don't know/no response* 25%, *Yes* 15%, *General mathematics ability* (expressions that mathematics can be useful in the future life) 10% and *Other* 5%.

Students' described experiences about how the teaching approaches they have encountered motivated them to learn mathematics

How the different teaching approaches have motivated students to learn mathematics was analysed through Q27. The results show that the mean score for the SITT group was 4.93 with a standard deviation of 2.13 and for the TBL group the mean score was 3.87, with a standard deviation of 2.37. The t-statistic was 3.62, with df=230 ($p < .05$) illustrates a significant difference of scores between the SITT-group and the TBL-group. The frequency of students' answer is displayed in Figure 2 in the next page. Notable, the mode for the SITT-group (figure 2 left) is 5, but for the TBL-group (figure 2 right) the mode is 1. The tendency for the TBL-group's answers were compiled on the disagree side of the spectrum (ranking 1-4), whereas the SITT-groups answers are equally distributed on both side of the centre pile.

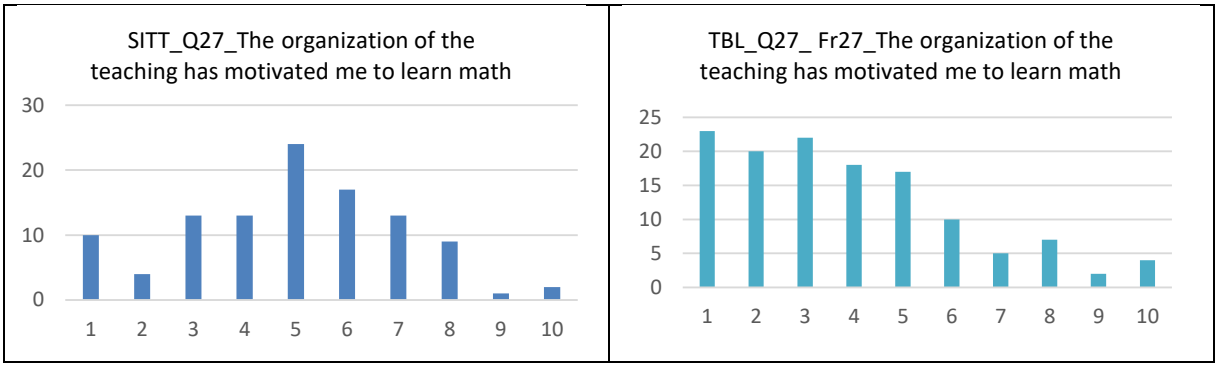

Figure 2: Bar charts of students ranking of Q27, left the SITT- group and right the TBL-group

For the analysis of the open question Q28 the line-by-line analysis resulted in 18 themes. The SITT-group addressed *vocational math* as positive motivator for their learning also in relation to the organisation of the teaching approach, see examples of students' reasons in Table 2 below.

Table 2: Examples of students' expressed reasons in Q28 for their ranking of Q27

SITT-Frequent students 'expression with codes in italic	TBL- Frequent students 'expression with codes in italic
Vocational math [Code: *vocational math*] I had a good teacher who could explain in a good way so you I understood, and I didn't learn anything unnecessary only things I will need. [Code: *teacher*] The arrangement itself does not motivate me. [Code: *other*] It has not been as stressful as in 7-9 grade [Code: *time*]	I would have preferred agricultural related tasks, etc. [Code: *unusable math*] Good teacher [Code: *teacher*] It hasn't been that different from 7-9 grade [Code: *similar to before*] The book is boring grade [Code: *boring*] I just want to get a grade [Code: *other*]

For both groups a good *teacher* was another motivator expressed for learning. Also, were the motivators *small groups*, *small test*, *well defined lesson structure*, and *easy* identified themes in the TBL-group and *time*, *fun and interesting lessons*, v*ariation between workspaces*, and *useful tasks* were found in the SITT-group. However, the analysis also showed that where *other* motivators not really connected to the organisation the seemed to impact on students' motivations, such as grades. In addition, negative motivators were also identified such as *boring* books, *no interest* to mathematics, *lack of variation*, *similar to before*, and *difficult*. Overall, were more negative motivators identified in TBL-group (40%) compared to the SITT-group (20%).

Conclusion and discussion

Our analysis indicates significant differences in the perceived effectiveness of the teaching approaches between the SITT-group and the TBL-group. The SITT-group had a higher mean score of 5.92 on the post-questionnaire and attributed their positive experience to *vocational math*. In contrast, the TBL-group had a mean score of 3.98 and felt they had learned *unusable math*. There was also a significant difference in how the students felt the teaching approach motivated them to learn mathematics. The SITT-group was more positive (4.93) compared to the TBL-group (3.87). However, both groups explained positive motivators related to each approach such as *small groups*,

easy, and *well-defined lesson structure* (TBL-group) and *fun and interesting lessons*, v*ariation between workspaces*, and *useful tasks* (SITT-group). In addition, the *teacher* was an important motivator, but so were *other* aspects not related to the teaching approach, such as grades.

Following recommendations from previous research on teaching approaches where teachers collaborate across disciplines (Frejd & Muhrman, 2022), emphasise social and cultural workplace practices (FitzSimons & Björklund Boistrup, 2017), and provide students with authentic learning opportunities (Mouwitz, 2013; Sundtjønn, 2021), our findings show that students encounter this type of teaching are more engaged and motivated to learn in learning vocational mathematics compared to traditional textbook-based learning. The extent to which the responses to the questionnaire measure effectiveness is of course open to debate, but it does provide an insight into the current situation, although the extent to which these approaches also affect students' academic performance requires further research. The results are the outcome of our design and we only examine two vocational schools in this study, where both participating schools have a fairly long tradition of using the approaches. We cannot generalize our findings, as teaching approaches depend on social and cultural contexts. Further research on the SITT approach is needed to better predict pupils' experiences. Therefore, we will continue and analyse students' experiences in our larger study of 9 schools.

Of the motivators we have identified, it is not only the teaching approach itself that effects students' motivation to learn mathematics, but also how well *teachers* are able to support and communicate with students, and how well students get the *grades* they want. The need for autonomy, competence and relatedness (Ryan & Deci, 2000) such as enough *time* for students to complete tasks on their own, *easy* (and difficult) tasks in terms of feeling competent and *useful tasks* related to the workplace were reported. Our results also show that the students in SITT-group described more intrinsic motivation compared to students in TBL-group who described more motivators connected to external motivation. However, several of the students in the TBL group mentioned *boring* books and *lack of variation* as negative motivators. One possible solution to overcome the lack of variation is to vary not only the content and the teaching method, but also the *workspace*. Previous research (Frejd & Muhrman, 2022; Muhrman, 2016) shows that it is very important for the teacher to consider the didactic questions of *how*, *what* and *when*, as well as *where*, when designing vocational mathematics lessons, as students do not necessarily learn mathematics best in the mathematics classroom. The aspect of relatedness (Ryan & Deci, 2000) is a key need in SDT, and perhaps this need comes to the fore in the teaching of mathematics in the vocational classroom compared to the teaching in the traditional mathematics classroom, but such an assumption needs further research.

Learning Math in Prison: Preliminary outputs of an Educational Design Research

Silvia Regola[1], Luca Decembrotto[2], Federica Mennuni[2] and Veronica Manzoni[2]

[1]University of Bergamo, Department of Human and Social Science, Italy; silvia.regola@unibg.it

[2]Alma Mater Studiorum University of Bologna, Italy

"Learning Math in Prison" is an Educational Design Research project that aims to provide practical guidelines for developing structured interventions in mathematics education within Italian prisons and to contribute to the theoretical understanding of this issue. This article presents the results of the initial exploration phase, which outlines partial design requirements and initial design propositions for the specific context. These results are essential for guiding the subsequent phase, in which pilot studies will be conducted to develop design principles and field-test teaching activities.

Keywords: Educational design research, prison education, design requirements, design propositions.

Introduction and theoretical framework

Education is a significant challenge in prison, and mathematics holds a unique position among the subjects taught, serving as a source of personal satisfaction and a gateway to future educational or employment opportunities (Ahl & Helenius, 2021). Despite its importance, there is a notable gap in research on the teaching and learning of mathematics in prison contexts (Gagnon & Barber, 2014). The existing literature highlights that prison context is characterised by discontinuity in class attendance; moreover, students' backgrounds are characterised by previous failures, low self-efficacy levels and a negative view of mathematics (Gagnon & Barber, 2014; Byrne & Carr, 2015). Despite this, active and participatory methodologies can potentially improve mathematical learning in prison (Ferrarello & Mammana, 2022). These single case studies have limited insight into teaching methodologies, and we observed a lack of discussion on the effectiveness and replicability of the approaches used. A significant contribution to this panorama is that of Maffia and Decembrotto (2024), who proposed a set of preliminary design principles for mathematical teaching in Italian prisons: *(I) it is essential to consider a problem-based situation that is accessible to all students, presented through tasks with several levels of difficulty and possibilities for generalisation; (II) it is necessary to refer to fields of experience for students in order to propose problem-based situations that are both contextualized and relevant to their background; (III) it is necessary to set up a didactic contract incorporating various strategies and acknowledging errors as an integral part of the learning process, thus impacting beliefs about mathematics; (IV) it is necessary to build a climate of mutual trust in order to achieve effective interactions between students and among students and teach*ers. Maffia and Decembrotto (2022) also highlighted the extreme need for further research on this issue, making their study the foundation for the "Learning Math in Prison" (LeMP) project. LeMP is an interventionist Educational Design Research (EDR, McKenney & Reeves, 2018) project involving five universities and teachers from three different prison schools to co-construct mathematical teaching units. The project aims to build a theoretical framework for mathematics education in prison embedded with the design and development of educational interventions, which will be disseminated to teachers in Italian prisons. The LeMP project consists of three main phases,

each involving interaction with practitioners (teachers) and contributing to theoretical understanding and gradual development of an intervention (McKenney & Reeves, 2018). The first iteration of the analysis and exploration phase involved identifying and diagnosing the problem. Analysis was done by consulting experienced practitioners and conducting a systematic literature review to obtain theoretical insights related to the issue. A more open-ended exploration was conducted in collaboration with practitioners to examine potential solutions, with the aim of identifying partial design requirements "determined by exploring the opportunities and boundary conditions present; and initial design propositions [which] are generated based on contextual insights" (McKenney & Reeves, 2018, p. 79). The exploration process in design research often remains in the background compared to more formal research activities (such as the literature review). It is often scarcely documented despite its importance for insightful research (McKenney & Reeves, 2018). This contribution aims to document this initial phase of the LeMP research project, presenting partial design requirements and initial design propositions to address the question: What are feasible and appropriate design choices for teaching mathematics in prison?

Data and Methods

The exploratory process in the first phase of EDR aims to identify design requirements and propositions to guide the initial experiments. Subsequent cycles of reflection and evaluation may confirm, refute, or modify these preliminary outputs. The exploration process is an open-ended activity that requires collaboration with practitioners—in this case, nine middle school mathematics teachers working in three prison schools across different Italian regions. The outputs are drawn from diversified sources (see Table 1), offering a multifaceted view of the issue under analysis.

Table 1: Type of sources considered in the analysis and their description.

Source	***Data Description***
Padlet	Written observations on a shared digital platform: practitioners had to share their perspectives on teaching mathematics in prison identifying the related Strengths, Weaknesses, Opportunities, and Threats (SWOT). All teachers were involved.
Focus-group	Notes taken during an online meeting involving 7 practitioners and all the researchers. The meeting aimed to explore the themes that emerged in the Padlet.
Meetings with teachers	Notes taken during face-to-face meetings with practitioners in each school, focused on school practices.
Teaching units	Collection of 4 teaching units made by teachers for teaching mathematics in prison.
Semi-structured Interviews	Videorecording, full transcription and notes of interviews to 4 practitioners (referred to by fictional names) from 2 schools, conducted online by 2 researchers at a time, focused on teachers' identity and professional development needs.

Six researchers qualitatively analysed the comments on Padlet identifying recurring themes. Using the SWOT framework and addressing the questions proposed by McKenney and Reeves (2018, p. 107), we outlined freedoms (aspects of the system that can be changed and offer chances for

improvement) and constraints (aspects of the system that cannot be changed and constitute boundaries for interventions) that form the partial design requirements. Additional insights and practices were gathered from all data collected to refine design requirements and inform the development of initial design propositions. These are based on a sound understanding of the problem and context, and, as McKenney and Reeves (2018) note, they can be heuristic statements that reveal positions on key issues arising from researchers' reflective hypotheses and aim to guide initial design attempts. Design propositions will be evaluated by studying the interventions based on them and revisited after the project's second phase. They are stated here in a simplified conditional schema: "If the goal _, then _. Argument (empirical and/or theoretical)," similar to the one proposed by van den Akker (2010).

Results

Partial design requirements: Constraints and freedoms

Data analysis highlighted several constraints related to teaching mathematics in the prison context. In the Padlet, most teachers stated that the relationship between the prison institution and the school is complex and often conflictual. Teachers complain about a lack of shared goals with prison officers, which makes collaboration difficult. In subsequent meetings, we explored its negative impact on teachers' work. Time dedicated to school, and thus to mathematics, is less than in standard school courses. It can be further reduced by organisational or logistical issues, resulting in students arriving late in the classroom or leaving early and several disruptions during lessons. Classroom spaces are often inadequate, and basic equipment commonly found in ordinary schools is lacking in the prison context. Technological equipment is often absent or inoperative, and access to the internet is not allowed. On security grounds, the prison administration prohibits many everyday objects, including teaching tools (e.g., rulers, squares, calculators). Even fewer objects can be brought by students into their cells to practise individually after the lessons.

The Padlet also offers several freedoms related to mathematics in prison. Since mathematics, as an abstract subject, often requires no specific equipment to be practised—a simple pen and paper, or even just imagination, may suffice—the lack of materials is consequently less critical than in other disciplines. This creates opportunities to devise new ways to teach mathematics with the few materials available in prison. Currently mathematics textbooks used in prison schools are inadequate, but they can be updated and improved to better suit the context; this is an addressable issue.

In both Padlet and meetings, teachers expressed the challenge of constraints related to class-group heterogeneity. In prison, student ages might range between 14 and 25 years old in juvenile detention centres or between 18 and 70 years old in adult prison, while students may have enormously different socio-economic backgrounds (most of them have a poor and/or migratory background). In the same class, teachers work with students with various levels of Italian language proficiency, and those who have received some schooling may have received it in very different cultural contexts. School classes are formed according to logistic issues, meaning they may not share education-related characteristics or needs. Classes are composed of a variable, but generally low, number of students.

This last characteristic also allows for a high degree of personalisation in teaching interventions, compared to what is typically possible. Indeed, teachers often emphasise that they have more freedom

regarding curriculum choices and assessment practices in this context, as they are not subject to much external pressure (as often occurs in ordinary schools). As emerged in Padlet, teachers are *"freer to choose which core topics to cover and which activities to carry out"* and feel less pressure about grading, as they are not subject to external expectations related to student performance.

All the teachers involved in the project agree that one significant constraint is the high turnover of students who continually enter or leave the school. This issue is especially prevalent in "casa circondariale" institutions, dedicated to people awaiting trial or serving short sentences. This characteristic disrupts educational continuity, resulting in fragmented learning paths that are difficult to certify and/or reconstruct. Other factors, such as students' psychological conditions and personal needs (e.g., family visits), further hinder regular attendance.

Also, practitioners voiced other freedoms related to teaching mathematics in prison. Interesting points emerged about motivation to study, which, in this context, is often influenced by external factors; indeed, attending school can bring advantages throughout imprisonment (in terms of good conduct) and a useful qualification for future work purposes; this kind of motivation is fragile and clashes with the fact that students have often had negative school experiences in the past. Motivation to study mathematics seems to be lacking, as it is often perceived as a discipline for "smart ones". Teachers are aware of this, and during the focus group, they stated that it is important to work on students' motivation and change the relationship that many of their students have with mathematics, adopting appropriate teaching methodologies and proposing mathematics contents that students can see as close to their reality and useful for their future. Data from Padlet and interviews highlighted that school has a positive connotation in prison: teachers pointed out that education consists of exercising a right by prisoners, in contrast to the restrictions and deprivations that characterise this context.

Initial design propositions

Based on the design requirements identified in terms of freedoms and constraints and capitalising on practitioners' experience, we go one step further to identify initial design propositions.

a) *If the goal is to actively involve students in learning mathematics, then intrinsic/inner motivation must be aroused by affecting their view of mathematics and sense of self-efficacy.*

Argument: Motivation to study in the prison context is particularly fragile, as highlighted in the design requirements. On the one hand, participation in classes is not compulsory, so it presupposes a good level of motivation; on the other hand, motivation is often extrinsic so the objective is set by others and depends on factors outside the control of both student and teacher. This type of motivation is not strong enough to support continuing studies outside prison (Ahl & Helenius, 2021). Intrinsic motivation, rooted in personal satisfaction, might be more solid and lasting. However, prison classes mainly include students who come from unsuccessful and negative school experiences, especially in mathematics, so intrinsic motivation is scarce and must be encouraged. Several references can be found in the data collected, particularly from the interviews. For instance, Caterina said: "*It has often happened [that students] say 'teacher, I'm not doing anything today!' and, by putting these small problems, questions, even just small logic quizzes […] on the table, the student already starts working without being aware of it."*

Thus, our data confirms that it is important to work on self-motivation and metacognition (Maffia & Decembrotto, 2022). Since these aspects are also related to the purpose of teaching mathematics in prison, a new design proposition emerges:

b) If the goal is to offer opportunities for redemption, emancipation, and life planning, then educational design must include non-academic objectives.

Argument: The educative and rehabilitative role of the school in prison emerges strongly from all our data sources; for instance, in the Padlet Arianna wrote: *"The classroom activity aims to recover self-esteem and a sense of self-efficacy, towards a redefinition of oneself, in order to, once the prison experience is over, resume one's life 'outside' with new awareness and new tools."* Some teachers highlighted the central role played by mathematics teaching in the students' educational path precisely because it is often experienced as an obstacle, more so than other subjects. *"Teaching Maths in prison produces a lot; above all, it leads to overcoming these obstacles and, through this, finding oneself. The very fact of getting up and coming to the blackboard to do something (because they have found a stimulus to do so) makes it different from other subjects"* (Salvo). At the same time, there is concern that their work may be mistaken for that of psychologists and social workers, both because teachers are not trained for such roles and because they believe that schooling in prison serves a distinct and essential function. Thus, it is important that these extra-curricular objectives, which are felt to be important to teachers involved in the research, are integrated into the teaching activity. They should not be the focus of separate moments, in apparent suspension of the teacher's work, but should be part of the school practice. The Mathem-Ethics Project (Ferrarello & Mammana, 2022) can be an example of a teaching activity in which mathematical disciplinary objectives were integrated with other objectives, such as ethics.

c) If the goal is that each student learns mathematics, with their competencies acquired in formal and non-formal contexts, then personalised teaching interventions must be provided.

Argument: As emphasised in the design requirements, the differences between students in prison are not limited to personal characteristics nor different "levels of schooling". The same class may include students with various life experiences and knowledge acquired in the most diverse contexts. Several aspects of these diversities emerge from the interviews related to mathematics learning; as Salvo says: *"Meanwhile, these people acquired other skills and competencies, they have acquired them necessarily! So, to go back from what […] has become their way of reasoning, and thus, of using mathematical tools (also unconsciously) is very difficult."* Learning mathematics must be integrated with the skills they already possess, which must not be underestimated but enhanced. To do this, it is necessary to personalise the teaching activity as much as possible. This already seems to be part of the practices of the teachers, as Caterina stated in the Padlet: *"Teaching activities are geared towards personalising the re-educational pathway of each student, starting from an individual education pact, which certifies the skills already possessed at entry level and outlines the skills to be acquired for the validation of the pathway."* Prison teaching aims to enhance and consolidate students' previous experiences, adapting the selection of contents and topics according to their interests and needs, both explicit and implicit. Flexible teaching tools, techniques, and methodologies are used to stimulate learning motivation, thus offering solutions best suited to the needs of each student. This is also

possible due to the small number of students in each class, as Anna said: *"Since there are only a few of them, you can really follow them individually; I stand alongside them; I mean, it is easier [to include students with difficulties in maths]."*

Also, a reflection on assessment practices is needed regarding personalised teaching in prison context:

d) If the goal is to adopt personalised teaching approaches suitable for the prison school context, then a formative assessment approach is preferable to a summative assessment.

Argument: We refer to Black and William's (2009) distinction between summative assessment (SA, assessment of learning) and formative assessment (FA, assessment for learning). Through the analysis of the data collected in this research project, it is evident that within the prison context, FA plays a crucial role both as a choice guided by the context of fragility and as a practice shared by most of the teachers interviewed who consider it fundamental to observe the students' entire learning trajectory. Within the focus group, teachers mentioned the possibility of not grading, given that particular context conditions allow informal assessment to occur in a relaxed atmosphere, without pressure about grades as judgment. Naturally, the effects of this type of approach on students also emerge. Although teachers do not explicitly use the term "formative assessment", their descriptions align with this concept, reflecting its practical application in their teaching approach. "*[Here education] does not involve big tests or exercises to be carried out rigidly; it is a continuous exchange that allows us to understand competence levels"* (Caterina). It turns out that FA takes on a personalised and helpful role in the school within a prison, whereas SA risks being perceived as *"another form of judgement that falls upon them,"* as Camilla stated.

Important reflections on time management emerged when the teacher planned a mathematics learning activity; in this case, the specific type of prison where the schooling occurs seems relevant.

e) If the goal is to involve all students who have not consistently attended, then, in a context with higher turnover, it is recommended to plan short activities.

Argument: In some prisons, it is common for students to have fragmented paths due to recurrent releases and incarcerations during the school year or other systemic reasons (e.g. transfers to another prison). In this context, the inclusion of new students in a class, or their abandonment, occurs frequently throughout the school year. The teachers operating in these contexts made explicit the need for the activity to occur in extremely limited time. During the interview, Anna told us: *"There the difficulty is that they run away from you, [...] and you have to make little packets so that at the end of a [teaching activity], they take something home"*. The intention, therefore, is to prevent interruptions in the lessons and to ensure that the student can grasp the objective of the teaching activity, integrating it with personal knowledge and thus benefiting from the learning. Teachers suggest that initially, it is better to introduce and partially formalise the mathematical content to involve all students and provide core information. Deepening and reinforcing the topic can be postponed for those who continue to attend classes.

f) If the goal is to involve all students who have not consistently attended, then, in a long-term detention context, scheduling with a flexible timeframe should be provided.

Argument: Class composition is more stable over time in institutions dedicated to prisoners with long sentences. This difference was referenced by Anna: "*At Monza, that was the class; from start to finish, it was always them. [...] so, I remember there wasn't this problem, of this, let's say, dispersion, loss."* Despite this, the context contributes to a lack of consistency in students' attendance due to personal and systemic needs (e.g. medical visits, family and lawyer interviews, and other activities planned by the prison management). Moreover, school activities often last less than the established timetable due to issues related to the prison organisation (e.g., non-punctuality in moving students between classrooms and cells, interruption of lessons, and inspections). In this case, it is common for a student absent from some lessons to attend the following, necessitating brief review sessions of key concepts to ensure everyone can effectively participate in the teaching activity. It is challenging to predict this type of occurrence in advance. Therefore, a flexible approach to timeframes is advisable, with the expectation that the duration of planned teaching activities may need to be extended or shortened. This is made clear, for instance, in the teaching units collected in the initial phase: "*Note on timeframe: the planned timeframe took into account the various criticalities of the prison […] but, even so, I was not able to respect it and took 4-5 hours longer than planned"* (Camilla).

Finally, the last design proposition emerges with the specificities of the LeMP project:

g) If the goal is to disseminate the design of a teaching activity among colleagues from other prison schools, then adaptations or alternatives must be provided, as the availability of specific facilities (classrooms and/or equipment) varies across contexts.

Argument: The scarcity of accessible materials and technologies in prison schools constitutes a significant challenge for teachers. As mentioned in the design requirements, many resources that are standard in every Italian classroom are often either forbidden or inadequate in prison. Consequently, teachers seek guidance on how to adapt teaching interventions when working with limited materials. "*[I would like to develop maths topics] in a more engaging way, one that does not involve the use of technology. Because we at school now are used to doing everything with the Internet, the presentation, the documentary on the Internet... and there nothing, you can't, so you always have to reinvent everything"* (Camilla). In addition, the classroom equipment and tools are highly dependent on the specific institute in which one operates; therefore, in order to make a design replicable and generalisable, one must pay attention to the description of materials and tools used, how to obtain them, where possible, hypothesising different scenarios and envisaging some possible ways in which one could compensate for the lack of a didactic tool without distorting the teaching activity.

Conclusions and further steps

In this paper, we reported the results of the LeMP project exploration phase, aimed at understanding the multifaceted complexity of teaching mathematics in prison contexts, starting from teachers' experiences and perspectives. Data analysis allowed us to identify several design requirements in terms of freedoms and constraints, and thus to reflect on the aspects that teachers and researchers can influence in this context. Starting from the design requirements, seven design propositions were formulated. These expanded upon the design principles proposed by Maffia and Decembrotto (2024), particularly concerning students' intrinsic motivation and the personalisation of teaching interventions. Additionally, new considerations were introduced, including the role of assessment,

the timing of activities, the inclusion of broader objectives, and attention to the availability of materials for replication and generalisation. These results will allow us to design feasible and appropriate teaching activities for mathematics in prison that will be experimented with in the further steps of the project. Furthermore, from a theoretical point of view, design requirements and propositions will be refined and integrated to develop new design principles.

Complexities when students authenticate aspects of a task in vocational mathematics education

Trude Sundtjønn[1]

[1]OsloMet – Oslo Metropolitan University, Oslo, Norway; trude.sundtjonn@oslomet.no

In this paper I study how students in vocational mathematics education can interact with paper-based mathematics tasks with a vocational context. I used the verb "to authenticate" when students (1) recognized that an aspect in a task really existed out-of-school and (2) gave a convincing argument for this. The data is from a mathematics class for Technical and Industrial Production students that worked on a task related to the volume of engine cylinders. I found that students could authenticate several vocational aspects in the task, such as the real-world context, the question/assignment, the illustration, the data, and the purpose. The authentication process consisted of referring to a vocational origin and showing expertise by describing details not given in the task. The results indicate that when students in vocational mathematics education are given space to use their out-of-school expertise, their vocational identities can raise their motivation to engage with mathematics.

Keywords: Vocational education, authentic aspects, mathematics tasks, communities of practice, students' identity.

Introduction

Mathematics as encountered in schools differs in many ways from mathematics encountered in workplaces. For instance, mathematical workplace problems are not stated clearly on paper but arise practically and messily. Also, solutions in workplaces may not need the working methods, symbols and precision as often required in school mathematics (FitzSimons, 2014; Saló i Nevado & Pehkonen, 2018). These differences pose challenges for mathematics in vocational education for adolescents. In many countries, the mathematical content in vocational education aims to be practical and connected to workplace settings (FitzSimons, 2014; FitzSimons & Boistrup, 2017). These aims can be implemented, for example, through team-teaching by a mathematics and a vocational teacher (Frejd & Muhrman, 2020), through transforming a classroom into a simulated workplace (e.g., a skin care saloon) and ask students to act professionally towards fictive clients (Dalby & Noyes, 2015) or using artifacts from workplaces as starting point for mathematical calculations (Sundtjønn, 2022).

In this paper, I indicate the compulsory mathematics taught within vocational education for adolescents as *vocational mathematics education*. An important constricting factor of this type of mathematics education is that the teaching of mathematics often happens within regular mathematics classroom settings. Frejd and Muhrman (2020) found that students' ways of working on mathematics tasks depended on whether the teaching happened in a mathematics classroom or in a workshop setting. Research, for instance Carotenuto et al. (2021) and Fitzpatrick et al. (2019), shows that students do not use realistic considerations when working on word problems in a school setting. In a regular mathematics classroom with rows of tables and a blackboard in the front, students can interpret tasks with a workplace context as standard word problems they have encountered many times before in their schooling. This suggests that *only* describing a vocational context in a paper-based task does not sufficiently simulate students' future work life.

To better understand how students in vocational mathematics education can interact with paper-based mathematics tasks with a vocational context, I aimed to study the role of *authenticity* in these settings. I follow Vos (2011) in saying that a task created for schooling cannot be fully authentic, since school environments allow for errors to learn from, unlike workplaces, where errors can have serious consequences. However, as Schlüter and Besser (2024) argue, separate aspects within a task can be authentic. Vos (2018) defined that for an aspect within a task to be authentic, it needs to have (1) an out-of-school origin and (2) a certification of originality. The certification can, for example, be a photograph (see Figure 1) or a testimony from an out-of-school expert explaining that the artefact really exists.

The aim of this paper is to study the processes of judging aspects in tasks as authentic by students in vocational mathematics education. I indicate this judgemental process as *authenticating*. So far, the research literature has focused on how authentication can be provided by out-of-school experts, or teachers from the vocational courses. For this paper, I explore how students in vocational mathematics education can showcase their perceptions of authenticity in vocation-related mathematics tasks. The research question is: *how do students in vocational mathematics education authenticate vocation-related mathematics tasks in a classroom setting?*

Theoretical framework

To analyse processes within vocational mathematics education, I use the notion of *communities of practice*. Within a community of practice, members have a common enterprise, they have a shared repertoire of actions and ways of interacting (Wenger, 1998). Newcomers will not immediately fit in and need to be enculturated into the rules and routines of the community of practice. Students in a mathematics class can be perceived as a community of practice. In this particular community, students have many years of experience of how to behave and what is regarded as the "normal" ways of working with mathematics tasks, with learning mathematics and how to deal with teachers. Simultaneously, they will be members of communities of practices in out-of-school domains, such as being a player in a sports team, or working part-time in a shop.

A special feature of vocational education is the aim to prepare students to find their way into workplaces. Through vocational internships, students become what Wenger (1998) describes as *legitimate peripheral participants,* in the community of practice of their future vocation. By receiving increasingly more responsibility on the work floor, they become enculturated into the rules, routines and requirements in workplaces. Through the lens of Wenger's (1998) concept of communities of practice, students in vocational mathematics education are members of a mathematics class with a growing vocational identity. In Frejd and Årlebeck's (2024) literature review, the contribution of mathematics education to this process of vocational enculturation can pertain to learning about 1) tools or artifacts used at the workplace, 2) how workers cooperate, 3) taking a clients' perspective, and 4) developing a worker's identity and professional pride.

As said before, paper-based vocation-related mathematics tasks can never be fully authentic, but they can contain authentic aspects from workplaces. For instance, authentic tools and artefacts used for making calculations or measurements at the workplace can be a start for mathematical activities. Schlüter and Besser (2024) give further explanations and backgrounds of the term *authenticity*. They

created a *Model for Authenticity in Modelling Test Items* (MAMTI), which is a framework for analysing authentic aspects within paper-based mathematical modelling tasks. The MAMTI-framework offers categories for aspects of mathematical modelling tasks that can be judged as authentic or not, such as the real-world situation described in the task, or the tools used in the task. Schlüter and Besser (2024) describe for each aspect, how these can be authenticated. For a *real-world context* to be authentic, the context needs to clearly exist in real life. For an *event* to be authentic, all activities described in the task can potentially occur. For *objects* to be authentic, these must be objects derived from reality, just like authentic *data* are data that are real. The category *question/assignment* is about whether the posed question in the task would be asked in the same way by people in the situation. The category *figures* is about whether illustrations originate from the real world. The category *use of mathematics* is about whether the mathematics is used in the same way as a person in the real-world context would. The category *purpose* is about whether the work done would fulfil a need in the real-world. For further explanations of the categories, see Schlüter and Besser (2024).

The MAMTI-framework can be used to analyse mathematical modelling task before their implementation in a classroom. However, an important tension arises whether and how students judge the authenticity of these aspects in tasks. For an in-depth analysis of this authentication process, I draw on Wenger's (1998) description of communities of practice, in particular on students' identity as a member of a mathematics class and their growing vocational identity.

Methods

In Norway there are many different vocational strands (e.g., building and construction; restaurant and food processing; healthcare, child and youth development; crafts, design and product development, etc.) and all programmes has a compulsory mathematics course in the first year. The data were gathered in vocational mathematics education for Technical and Industrial Production. The class consisted of 16 students, around 16 years of age. Although I do not have the students' mathematics achievement history, many students in vocational education in Norway often have a strained relationship with mathematics.

The data consisted of transcripts from video recordings of students working on the task Engine Cylinders, explained below. These data were transcribed and anonymized (Student A, Student B, Student C, etc., Teacher, Trude). At an earlier stage, these data have been used for Sundtjønn (2021); for the present study they were re-analysed. The task was about calculating volume of engine cylinders, first for moped engines and then for car engines. The start of the task is given in Figure 1. The lesson started with an introduction by the teacher, then the students worked individually, before a discussion in the whole class. During their individual work they talked together, and with the teacher and with the researcher, which yielded episodes to analyse.

The task first offered students two *illustrations*: a table snipped from a brochure on moped engines, and a picture of a moped cylinder block, see left side of Figure 1. On the righthand side, there is a stylized illustration and a series of mathematical questions that the students were asked to solve. These pertain to calculating volumes of cylinders when diameters are given; they aim for students to practice using volume formulae. In terms of the MAMTI-framework (Schlüter & Besser, 2024), a number of aspects in the task can be recognized as authentic. For instance, the type of moped cylinder

and its dimensions are authentic as certified by the given photograph and the photocopied technical specifications. This means the object given in the task and the data are authentic. Likely, the legal regulations regarding a maximum stroke volume for mopeds are also authentic, since they can be looked up. On the other hand, the posed questions seem inauthentic, since there is no evidence that such calculations are carried out by vocational workers repairing or installing moped cylinders.

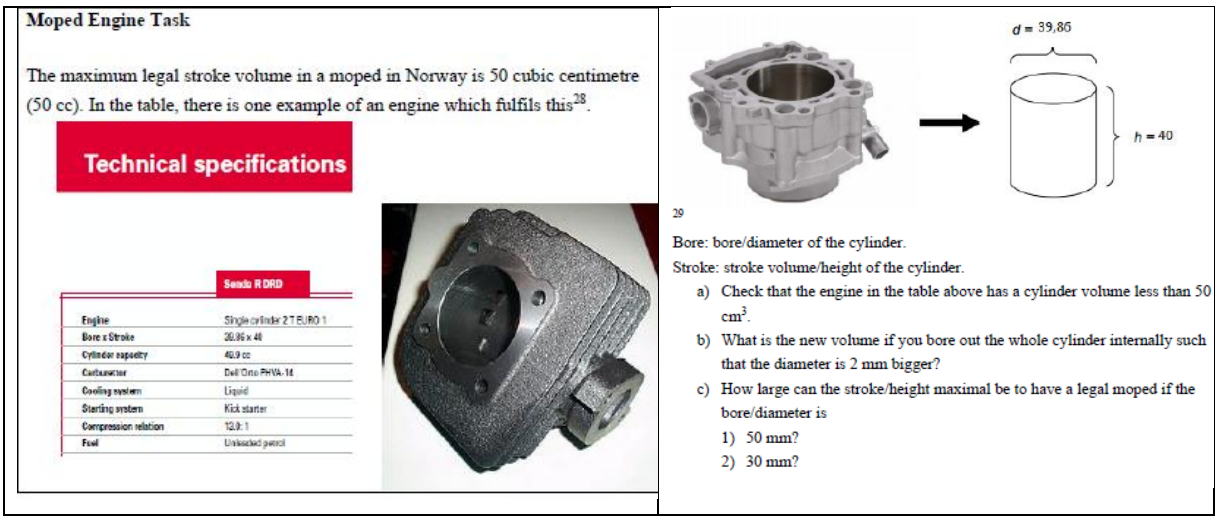

Figure 1: The start of the task *Engine Cylinders*

For the analysis of the students' utterances, I used the MAMTI-framework (Schlüter & Besser, 2024) to categorise the aspects in the task that the students authenticated. However, I did not aim to find that all aspects would be authenticated. I used Wenger's (1998) communities of practice concept to analyse how the identity of students as member of the mathematics class and/or as future vocational worker played a role in the process of authentication.

Findings

In the presentation of findings below, I exemplify how the students authenticated different aspects in the Engine Cylinders task or refuted the authenticity. The aspects from the MAMTI-framework that students discussed were: real-world context, events, objects, question/assignment, figures, and purpose. A potential authentication of the aspect *use of mathematics* did not show in the data. With regards to the *real-world context* in the task, several students owned mopeds. They started talking with each other about their out-of-school experiences with modified moped engines. For instance, during the work on the task in Figure 1, Student A explicitly said: "I'm trying to figure out my own cylinder", and then started calculating the cylinder volume of his own moped. Later, when Student A shared with the class how he had calculated the volume of his own moped cylinder, another student asked "which pistons? How do the pistons go around?". Another student asked which kind of brand the cylinder was. In these utterances, the students collectively judged that the context of the task had an out-of-school origin. Moreover, they showed their knowledge as moped owners, knowing different brands, and understanding that the volume relates to the moped's performance. In this way, their identity as "moped experts" drove the authentication of the task context. Later in the lesson the students worked on calculating volume of car engines cylinders, different sized V4, V6 and V8

engines. Student B said when he explained how he had found his answer that he "thought of another [known] engine and compared them". He had been helping part-time in a car repair shop, and here showed his knowledge and authenticated the *real-world context* in this part of the task.

Student A's knowledge of the context also showcased how another task aspect, namely the *question/assignment* was authenticated by the students as experts who brought out-of-school knowledge into the classroom. When Student A talked about "figuring out my own cylinder", another student asked if he had drilled it to become bigger (a larger volume enhances the motor's performance). Student A replied "it does not help that much", and later confirmed that he had his cylinder block replaced instead. Hence, the students authenticated the questions regarding the volume of the cylinder because this volume question matters to moped owners who want to improve a moped's performance. Simultaneously, the students attested that the calculation of volumes was not an aim in itself but mattered for getting more moped speed through an adjustment of the cylinder (increasing its volume or replacing it). For the students as participants in a community of owners of (illegal) mopeds, the authenticity of a *question* on finding volumes was directly related to the underlying *purpose* of finding more speed.

The task aspect *illustration* was authenticated in the following way. After the class, the teacher told in an interview, that Student A had been shown the printed sheet with the task (see Figure 1) and told "today we are calculating car engines". Student A had immediately said "eh, that is not a car engine, it is a moped engine", with just a short look at the illustration in the task. The student thereby showed to be an expert able to authenticate *the illustration*. When Student A was later asked whether he knew the volume of a regular car engine cylinder, he clearly stated "no". So, he obviously was a moped engine expert but knew his limitations. During the work, the students were critical of the *data* in the task. For instance, when calculating volume of car engines, Student C pointed out that the given volume, 3.5 litres, was not much in a V8 engine. Student D said that in a V4 engine the given number was "yes, I think it is too large. It's 2.8 in my [known engine]". In this way, students showed their expertise regarding engine cylinder volumes of cars without a need to look these up. If real data had been used in the task, the students could have authenticated these.

With regards to the *use of mathematics*, there turned out to be several aspects. In the first place, there was the issue of mathematical *precision*. For instance, Student A did not use his identity as a moped owner but asked the researcher what would be considered as "right". To solve the task in figure 1, he had used the diameter 39.86 from the technical specifications (see Figure 1, on the left), and divided it by 2 to obtain the radius needed for the volume calculations. Then, he rounded off the answer from his calculator to 20.

Student A:	Should it be very precise?
Trude:	What is precise? What should I say?
Student A:	Can I just take 20?
Trude:	You can try it with 20 and be very near, yes.

In this episode, Student A asked for the expertise of the researcher. It means that he could not relate the use of mathematics to his out-of-school moped knowledge. Instead, he considered the researcher as an expert on the use of mathematics, and she did not relate it to out-of-school use either. With no out-of-school origin, the precision of the calculations remained inauthentic. Another aspect in the

category *use of mathematics* was the *tool use* by students for performing calculations. Rather than using a school calculator, the students preferred to use their mobile phones. It had sufficient precision, and they had it readily in their pockets. Using their mobile phones looked like a routine, as if they were not in a mathematics classroom. Being a tool from out-of-the-classroom, and being habitually used by the students, it can be analysed as a non-verbal authentication of the use of this tool for making calculations within vocational contexts.

With regard to this same aspect, *use of mathematics*, another observation was also relevant. The students often tried different numbers. Student A had worked diligently on his calculations to figure out the size of the diameter of a cylinder with height 65.6 mm in a 3.5 l V8 engine. I asked him if he saw approximately how the size of the numbers should be. He then confirmed that he knew moped cylinder sizes. Thus, he again used his expert knowledge on moped engines, also for his calculations. Here is how he explained how he solved the problems.

Student A:	I tried my way to do it.
Teacher:	You tried your way again. You're good at trying; it seems like you mostly get the answer, so that's good. Yes, and how do you do that when you try your way forward then?
Student A:	Take different numbers.
Teacher:	3.14 times some radius times some radius times 65.6 times 8?
Student A:	Yes.
Teacher:	Is there anyone who has calculated differently, or have you [also] done trial and error? (...) Are there any others who have tried and got the same? (Silence 4 seconds). No, but [Student A] has at least figured it out. Okay, there are some who has tried an equation then?
Student E:	I tried, but it didn't go well.

In this exchange between the teacher and the class, Student A explained that he tried numbers. According to his earlier exchange with me, these came from his knowledge on moped cylinder sizes. So, he did not try random numbers, but made *intelligent guesses* to approximate the solution, and thereafter refine the numbers to find the answer. Student A's approach parallels the numerical methods in advanced mathematics for solving ordinary differential equations (e.g., Euler's method, Runge-Kutta method). This is a well-functioning mathematical method often used in vocational communities of practice. Unfortunately, this typical use of mathematics was not explained to the whole class. The teacher named this method "trial-and-error" and judged it as "good" because the correct answers were reached. Yet, by asking for an equation, the teacher showed what solution method which was really valued in this classroom community. We see here two processes that hinder potential authenticating of out-of-school solution methods. First, Student A does not clearly explain his use of pre-knowledge to the teacher and the full class as he explained it to me. Second, the authority of the mathematics teacher closed down opportunities to value a well-functioning method.

Discussion and concluding remarks

My research question was: *how do students in vocational mathematics education* authenticate *vocation-related mathematics tasks in a classroom setting?* Regarding the aspects in the MAMTI-framework (Schlüter & Besser, 2024), I found that students could authenticate several of the aspects in the task, such as the *real-world context*, the *question/assignment*, the *illustration*, the *question*, the *data*, and the *purpose*. The authentication process, as discussed by Vos (2018), consisted of pointing

at a vocational origin and showing expertise in how it was used there. The authentication process was supported by students' obvious, and sometimes extensive experiences and knowledge from their participation in vocational, out-of-school communities of practice. By expressing their knowledge of the vocational context through details not given in the task, they established their expertise. Contradicting Vos (2018), there was no need for an out-of-school expert to convince the students of the authentic aspects. Because of their participation in multiple communities of practice, the students could act as out-of-school experts.

Authentication of the task aspect *event* was not observed because the task did not describe humans undertaking an action, and hence, the tasks did not contain an event. Schlüter & Besser (2024) point out that that there may be differences between if aspects of a task are authentic. In this case, *the questio*n to find a volume from a given moped cylinder diameter is authentic, but the *solution method*, calculating it with a formula and calculator, is not authentic. In the workshop the students would probably look it up from the technical specifications in a catalogue. The authentication of the task aspect *use of mathematics* turned out to embrace several aspects, such as *precision, tool use* and *solution methods*. The analysis shows that all three aspects could have had out-of-school origins, with *precise numbers* being pragmatically rounded off, with *tools* being those that are habitually used out-of-class (mobile phones), and *solution methods* allowing for educated guesses and stepwise approximations. However, there seemed to be too little space in the classroom community for authenticating students' ways of dealing with *precision* and *solution methods.*

The study shows that students' expertise from their participation in out-of-school communities can support the use of paper-based vocation-related mathematics tasks within vocational mathematics education. Students in vocational education can bring highly relevant knowledge that a mathematics teacher may not have (Sundtjønn, 2021). Such expert students can authenticate task aspects to other students and to the teacher, indicate what might be relevant for future learning and hence raise motivation within the classroom community. Important factors that can facilitate such authentication processes are the "space" that students in vocational mathematics education have for judging, for using their experiences, and for working autonomously on what is relevant in future vocations.

The study also shows that task designers and teacher may perceive certain aspects in a task as authentic, whereas the task turns out to also contain inauthentic aspects that work demotivating. For instance, an emphasis on precision and the use of equations in the Engine Cylinders task could demotivate exactly those students who have expertise about the absence of such mathematics in these vocational communities of practice. Further work is needed on tension between the use of authentic real-world context and other aspects, like the questions, that may not be authentic. The results indicate that when students in vocational mathematics education are given space to use their out-of-school expertise, their vocational identities can raise their motivation to engage with mathematics.

Measuring adults' numeracy: Which instruments are used and what do they measure?

Marieke Bor-de Vries[1,2], Lonneke Boels[1], Tamara Madern[1], Kees Hoogland[1] and Paul Drijvers[2]

[1]HU University of Applied Sciences Utrecht, The Netherlands; marieke.bor-devries@hu.nl

[2]Utrecht University, The Netherlands

Keywords: Numeracy, instruments, adults, Common European Numeracy Framework.

Introduction and theoretical background

In our review of research on numeracy and financial difficulties (Bor-de Vries et al., 2025), we identified a variety of instruments used to measure numeracy. Some studies, such as the Berlin Numeracy Test (Cokely et al., 2012), make use of well-tested and validated instruments, while others rely on single questions specifically designed for their own research. These instruments—mostly questionnaires—all aim to measure numeracy, but they approach it in different ways. By examining these instruments more closely, we can better understand and compare findings across studies. This poster is based on the instruments found in the literature review by Bor-de Vries et al. (2025) and addresses two questions: What instruments are used to measure numeracy? What aspects of numeracy do these instruments focus on?

The numeracy aspects of the instruments can be described in terms of the Common European Numeracy Framework (CENF) (Hoogland, 2023) as theoretical framework. The CENF emphasises four aspects that contribute to improving the quality of numerate behaviour: Context, Knowledge and Skills, Higher Order Skills, and Dispositions. Each of these aspects has different sub-aspects, for example, the aspect Context contains: Everyday Life, Work-related, Citizenship, Further Learning, Finances, Health and Care, and Recreation. For more detailed information on the CENF, see: www.cenf.eu/framework.

Method

In our systematic literature review (Bor-de Vries et al., 2025), we identified 24 numeracy instruments and their variations. Certain instruments, such as the PIAAC numeracy assessment or subtests of IQ tests, were unavailable for public access and thus excluded from our analysis. For the remaining instruments, we compiled a list of all items—questions—included and checked for duplicates, resulting in 155 remaining items.

Example item: *Do you think that 10% is bigger than 1 out of 10, smaller than 1 out of 10, or the same as 1 out of 10?*

Each item was coded using a codebook to determine which aspects and sub-aspects of CENF were addressed. To gain deeper insight into the different numeracy instruments, we then aggregated the codes for each specific instrument. To enhance the clarity of the findings, we utilized an iceberg model to visually illustrate the results for each instrument; see Figure 1 for an example. The model illustrates the four aspects of numeracy, with the numbers representing the sub-aspects. The iceberg

model highlights that although certain aspects of numeracy are explicitly captured in numeracy instruments, others are less visible but nonetheless contribute to variations in test scores.

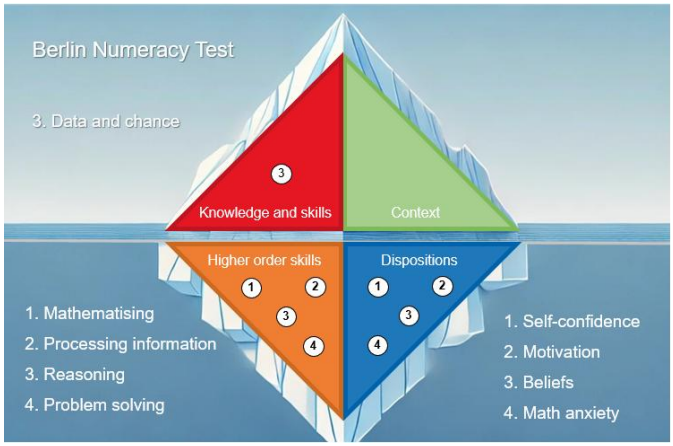

Figure 1: Iceberg model representing numeracy aspect and sub-aspects of Berlin Numeracy Test

Preliminary results and discussion

The instruments vary in length and range from one single item to 23 items, with an average of 6.2 items per instrument. Most questionnaires are short; 19 out of 24 contain five or fewer items. A substantial number of instruments focus on the CENF aspect of *Knowledge and Skills*, particularly the areas of *Quantity and Number*, as well as *Data and Chance*. Many of the items do not include real-world contexts, but when *Context* is provided, it typically relates to *Health and Care* or *Finance*. Some instruments assess *Higher Order Skills*, particularly in the areas of *Mathematising* and *Processing Information*. Instruments not measuring skills do measure *Dispositions*, especially *Self-confidence* and *Math Anxiety*.

Our findings indicate that the instruments used to measure numeracy differ both in their quality and in the particular aspects of numeracy they assess. Since most instruments focus on a limited part of numeracy and include only a small number of items, they are insufficient for assessing the full scope of numeracy. Moreover, comparing results is difficult because the various instruments emphasise different aspects of numeracy. We advise researchers to specify which aspect of numeracy they are evaluating to help other researchers, policymakers, and educators better interpret the results.

How is Europe doing on numeracy in the 2nd cycle of PIAAC?

Kees Hoogland[1] and Javier Díez-Palomar[2]

[1]HU University of Applied Sciences Utrecht, the Netherlands; kees.hoogland@hu.nl

[2]University of Barcelona, Faculty of Education, Barcelona, Spain

Keywords: *PIAAC second cycle, numeracy, numeracy assessment, adult skills.*

Introduction

Since the significant 'mathematisation' of our society, driven by rapid technological developments and digitalisation, educators and policymakers have increasingly expressed concern. They argue that large segments of the working population must develop and maintain their numeracy skills to participate autonomously and effectively in today's technology-driven, data-saturated world (Hoogland & Díez-Palomar, 2022). A lack of numeracy competence can lead to difficulties in managing everyday tasks and navigating the modern workplace. To gain a better understanding of the current state of adult skills, the first international comparative assessment, the International Adult Literacy Survey (IALS), was conducted in the 1990s, followed by the Adult Literacy and Lifeskills Survey (ALL). These efforts culminated in the global OECD initiative known as the Programme for the International Assessment of Adult Competencies (PIAAC), which assessed skills in literacy, numeracy, and adaptive problem-solving through two cycles conducted in the 2010s and 2020s (Tout & Gal, 2015).

The definition of numeracy has evolved over the last decades (Kaye, 2018; Hoogland, 2023; Hoogland & Díez-Palomar, 2022), culminating in the definition used in the second cycle of PIAAC.

> Numeracy is accessing, using and reasoning critically with mathematical content, information and ideas represented in multiple ways in order to engage in and manage the mathematical demands of a range of situations in adult life. (OECD, 2021, p. 93)

This reflects the broad, social, and holistic perspective now commonly applied to functional mathematical skills. Examples of this approach can be found in the materials developed in the project Common European Numeracy Framework (Hoogland, 2023).

Method

Our research question for this poster is: 'How is Europe doing on numeracy in the 2nd cycle of PIAAC?' The data we use to answer this question is collected through the assessment within PIAAC, known as the Survey of Adult Skills (OECD, 2021). This is a tablet-based household survey of adults in the age range 16 to 65 years. The survey assesses proficiency levels in literacy, numeracy and (adaptive) problem solving. We will use for our study the country scores on numeracy as reported in the OECD overall report and database (OECD, 2024). The 2nd cycle of the Survey of Adults Skills has been conducted in 31 countries and economies so far. A first round of data collection took place in 2022-2023.

Main results

Compared to Cycle I of PIAAC (2012–2018), numeracy scores in the 2nd cycle have increased in 8 of the 31 participating countries, remained stable in 12, and declined in 7. Notably, most of the countries showing a decline are located in Eastern Europe. Alongside these overall trends, the data reveal a growing disparity in numeracy performance within countries—an increase in inequality that mirrors patterns observed in other recent large-scale assessments such as PISA and TIMSS. While the gender gap in numeracy performance—historically favouring men—has narrowed slightly, it remains significant, with men scoring approximately 10% higher on average (OECD, 2024, p. 52).

One particularly relevant indicator for policymakers is the proportion of adults performing at Level 1 or below. In PIAAC terms, individuals at this level are likely to face regular challenges when confronted with everyday numeracy tasks. On average, 25% of adults across participating OECD countries and economies fall into this category, with national figures ranging widely from 10% to 56% (OECD, 2024, p. 63).

Conclusion

Alongside the cognitive scores, a wide range of data was collected from participants through a basic questionnaire. This enables a more in-depth analysis of the skill scores by correlating them with socio-economic factors and the actual behaviours of participants. For example, participants self-report the frequency with which they perform calculations, such as calculating prices, costs, or quantities. These can range from daily to less than once a month or never. The results of such analyses will be disseminated to the scientific community in the coming years and can inform the development of policies around adult education and lifelong learning in various countries.

Numeracy in social work education

Hugo Mulder[1], Monica Wijers[2], Sabine de Vries[1] and Lonneke Boels[1]

[1]HU University of Applied Sciences Utrecht, The Netherlands; hugo.mulder@hu.nl

[2]Utrecht University, The Netherlands

Keywords: Numeracy, social work education, lifelong learning, mathematical literacy, Common European Numeracy Framework (CENF).

Introduction and theoretical background

Data from the Programme for the International Assessment of Adult Competencies (PIAAC) show that a substantial number of citizens are lacking essential numeracy skills (OECD, 2013). Recent studies (e.g., Gal et al., 2020) have shown that insufficient numeracy skills are a significant risk factor for increased vulnerability in social functioning, manifesting in health and financial problems, and having an even greater impact than insufficient literacy skills. Social workers often encounter clients facing daily challenges linked to inadequate numeracy skills, positioning the social workers to identify such issues early. With sufficient numeracy skills, social workers can better detect and address these problems, ultimately helping clients mitigate or prevent life difficulties. This support enhances social participation, boosts self-confidence, and fosters self-reliance (Gal et al., 2020).

In response to these challenges, this study contributes to the broader discourse on numeracy in professional and societal contexts by focusing on how numeracy is embedded in social work education. We investigated: (1) to what extent Dutch social work education programs focus on developing students' numeracy skills, and (2) how these programs address students' understanding of clients' numeracy skills and needs.

Method

An educational program operates on three levels: the intended curriculum (educational documents and competency profiles), the implemented curriculum (actual lessons), and the enacted curriculum (what students ultimately learn and apply). By combining a document analysis of the intended curriculum in Dutch social work programs with a survey (approximately 160 students) and interviews (10 graduate social workers), we aimed to assess the extent to which numeracy is sufficiently developed within the program. Using a matrix derived from national and international frameworks (e.g., Hoogland et al., 2019) and publications on numeracy (Drijvers et al., 2021), we analysed the intended curriculum for evidence of numeracy integration across four key aspects: context, knowledge and skills, higher-order skills, and dispositions. This approach provided a structured framework to evaluate whether numeracy was explicitly or implicitly integrated into the intended curriculum. The questionnaires explored students' understanding of numeracy, their experiences working with low-numerate clients, and their educational needs related to numeracy. Semi-structured interviews with students offered additional insights. The aim is to verify our findings in the intended curriculum by assessing their alignment with the enacted curriculum, with the results reviewed by a feedback group of students, educators, and numeracy experts to ensure accuracy and consistency.

Preliminary results and outlook

The results of this research provide insights into the extent to which numeracy is embedded in social work programs and how students perceive these skills in relation to their professional practice. Typically, education programs teach aspects of numeracy through generic courses in arithmetic, mathematics or statistics. These courses primarily focus on mathematical content, placing less emphasis on the broader concept of numeracy, as defined in the Common European Numeracy Framework (Hoogland et al., 2019). This indicates that while students are exposed to numeracy, the curriculum may not fully integrate numeracy in ways directly relevant to social work practice. Consequently, recommendations will be made to strengthen the focus on numeracy within the curriculum, specifically tailored to the practical needs of social workers.

In addition, based on preliminary results from the survey, students seem to recognize the importance of numeracy, as reflected in responses to questions such as "I need numeracy in my internship" and "I find it important that my education addresses numeracy in my future profession." However, responses to questions like "Topics in numeracy lessons relate to social work" suggest that many students perceive a lack of connection between numeracy education and practical social work applications. These early findings indicate that current programs may not be fully preparing students to understand and address the numeracy skills and needs of their clients effectively. This highlights the need for curriculum adjustments to better equip students with the skills necessary to recognize and support numeracy-related challenges among their clients. These findings can be incorporated into existing social work education curricula and professional training programs, as recommended by Drijvers et al. (2021). Moreover, this study may contribute to refining or expanding the professional competence profile of social workers, thereby enhancing the effectiveness of interventions addressing sufficient numeracy skills in social work practice.

Adults studying for a general certificate in secondary education (GCSE) in mathematics in England: self-efficacy, anxiety and examination grades

Jennifer M. Stacey

Sheffield Hallam University, Faculty of Education, Sheffield, England; stillknitting@gmail.com

Keywords: Adult learning, self-efficacy, anxiety, examinations.

Introduction and Methods

GCSE mathematics is a high-stakes examination necessary for many university courses in England, such as nursing or teaching degrees. In 2020 there were over 30,650 adults enrolled for the examination, approximately 10% of the total. This research was conducted with 21 adults in Further Education (FE) colleges, an under-researched group of learners (Gal, 2024). The research questions were: What are the perceptions of adults enrolling for GCSE mathematics courses, in terms of their self-efficacy and anxiety about the course content, aspects of the classroom environment, and assessments? Are participants' perceptions correlated with their examination results, i.e., are participants with low anxiety and high self-efficacy more likely to pass the examinations? Finally, do participants' perceptions of examinations vary between mathematics and others?

This was a small-scale, mixed methods study and whilst no generalisations can be made from the findings, the research revealed several findings which made an original contribution to understanding the importance of the perceptions of adult learners, which indicates that a larger study is needed. There were 21 participants in total from at least two colleges in England and two academic years.

Findings from other research can lead to beliefs that can be described as stereotypes, which can be detrimental to progress in adults' classrooms. For instance, in other research, older learners were found to be more anxious than younger ones (Watts, 2011), females were more anxious than males according to Szucs et al. (2017), and English speakers can have an advantage over those whose first language is not English in mathematics classrooms (Woolley, 2013).

This research used a questionnaire with two attitude scales on 15 statements: one on self-efficacy (Bandura, 1997; Swan, 2006) and one on anxiety. The statements were mainly taken from the existing Abbreviated Math Anxiety Scale (AMAS) by Hopko et al. (2003), with six additional statements, namely a word problem, a percentage , a fraction , a statement on drawing charts and graphs, one on asking a question in class and another on perceptions of non-mathematics examinations. Each statement required self-efficacy and anxiety rankings, and space for (optional) comments was given.

The data analysis used thematic analysis to cluster both the ranked responses and the comments made on each scale, using main themes, sub-themes, emergent themes, and learner characteristics, to both enhance understanding and protect the identity of participants (Braun & Clarke, 2013).

Findings

For the main themes of self-efficacy and anxiety, it was a mixed picture, but self-efficacy was a better marker for passes in the examinations than anxiety, because most of those with high self-efficacy, as

judged by the median values, passed the examination (8 out of 10). However, some did not (n=2). Some with low self-efficacy and high anxiety also passed (3 out of 9) but both of the learners who withdrew had low self-efficacy and high anxiety (n=2). Tests and examinations were considered the most challenging for all, with lower self-efficacy and higher anxiety rankings than course content or classroom issues.

For the sub-themes, based on statements in the questionnaire, the word problem of 'if it takes three people 5 days to fit a kitchen, how long will it take two people?' had the least self-efficacy and the highest anxiety expressed; algebra statements came second to the word problem. Some participants (4/21) were unable to ask a question in class, even the most able as judged by examination results.

Half of the participants made comments, which allowed for an analysis of emergent themes from the data. The themes showed a belief in innate ability, with comments such as "Maths has always been a failing point for me, I just can't do it", and "I don't have a mind that can learn maths easily". A fatalistic approach to examinations also emerged with "It will be what it will be". There was an awareness of the negative impact of time pressure on thinking and performance, as a participant said, "I read too much into it and panic". The importance of a sense of community was identified by some participants with "We are all in this together", and "I enjoyed being with my peers". A meta-cognitive benefit of participation was also described: "I think that it has been quite a cathartic process for me".

In terms of learners' characteristics, males (n=3) were just as anxious as females (n=18). In addition, older learners (25+) were less anxious, had greater self-efficacy, and were more likely to pass (11 out of 17) than younger ones (one out of four participants passed). Those whose first language was not English were more likely to pass (three out of four) than the native English speakers (10 out of 17).

Bridging the gap: Facilitating female adult learners in the East Midlands region of England to re-engage with mathematics

Farhat Syyeda[1], Fay Baldry[1] and Ben Harvey-Ashenhurst[1]

[1]University of Leicester, School of Education, Leicester, UK; fs230@le.ac.uk

Keywords: Adult education, disadvantaged communities, transformative learning, action research.

Introduction

Mathematical knowledge and skills are considered essential tools for further and higher education, employment, future earnings, health and well being. However, the numeracy proficiency level of adults in England is quite low, and nearly half of the adult working population have numeracy skills expected of an 11-year-old (National Numeracy, 2017). Over the years, successive governments have initiated many programmes to provide free mathematics education for adult learners, emphasising that good numeracy skills not only unlock job opportunities and lead to higher wages, these are also useful in day to day life such as for budgeting money and helping children with homework. Yet, returning to formal education is a daunting task and potential learners are reluctant to re-engage due to unpleasant prior experiences of maths, stereotype threat related to age, race or gender and other barriers (Syyeda, 2021).

Benefits of re-engaging in mathematics learning

Studying on adult maths courses can be a transformative experience for women, especially among BAME (Black, Asian & Minority Ethnic), migrant and disadvantaged communities. It empowers them to become confident and agentic, and can have a significant impact on their families (Syyeda, 2021). Migrant mothers often use participation in adult learning courses as a crucial tool to integrate their families in the host society (Kelly, 2018). Many women are motivated to enrol on maths courses to equip themselves with the knowledge and skills needed to help their children with homework and enable them to progress in school. Moreover, working on mathematical problems together creates opportunities to spend quality time with children and bond (Syyeda, 2021).

Context and aim of this research

This study is based in a multicultral city in the Midlands region of England and is run in collaboration with a local adult education college. The college has its main campus in the city but also offers maths courses in satellite centres in adjoining areas. There is significant variation in the rate of student enrolment in different areas, with some centres having no intake, which is a cause of concern. The purpose of this research is to understand the reasons for this variation and facilitate potential learners in disadvantaged areas to enrol. The study will be guided by the following research questions:

RQ1: What are the key enabling and disabling factors that impact the participation of women in maths learning, especially in low income, disadvantaged and minority ethnic communities?

RQ2: How does engaging with mothers in primary schools to raise awareness about the provision of maths courses and to facilitate them to enrol influence their participation in these courses?

Methods

This study adopts an Action Research design with data collected through focus group interviews with current and potential female adult learners. Action Research focusses on a problem rooted in a specific context, plans and implements an intervention and evaluates the change; a "process based on a continuous interaction between researcher, action, reflection and evaluation" (Hart, 1996, p. 454). Action research is appropriate because the aim is to address educational inequality and emancipate the voices of disadvantaged women. This study has three phases: in phase 1, we analysed secondary data to map the rate of student enrolment in different parts of the city and conducted three focus groups with current students in areas of high enrolment. In phase 2, we will run workshops in three primary schools and invite mothers/grandmothers and children to participate in fun maths activities. The selected schools are located in disadvantaged areas near adult education centres where enrolment on maths courses is very low. During the workshops we will provide information on courses offered and share success stories of mothers who have previously enrolled and reaped benefits for themselves and their families. The workshops will create opportunities to engage with potential learners and invite them to participate in focus groups to understand their perspective and make the courses more accessible for them. In phase 3, we will look at data on student enrolment for the next iteration of courses to capture any change in student numbers as a result of our intervention in selected areas.

Results

Preliminary findings from phase 1 show that women in these communities have insufficient access to information about the availability of maths courses. Therefore, engaging potential learners in disadvantaged areas through primary schools could be a positive way forward, particularly as this hooks into a key motivation of being able to help with their children's education. The findings of this research could provide useful insights for regional providers of mathematics courses and may also be beneficial for other countries in similar contexts.

Introduction

The Thematic Working Group 8 (TWG08) "Affect and the teaching and learning of mathematics" has been in CERME since 2003 (CERME 3) and the contributions have led us towards understanding the field better as well as developing new questions that should be answered in the past 22 years. Our call for papers for CERME 14 listed a diverse example of topics and we had contributions with different but related topics. In this section, we would like to introduce the work that has been presented and discussed in TWG8 in CERME 14.

A total of 20 papers and 2 posters had been submitted to TWG8 and 13 papers and 2 posters were accepted, another 2 papers were proposed to become posters, for presentation at the conference after a rigorous revision process. The contributors were from institutions based in a variety of countries, from Europe and from outside Europe. We had several contributors who participated in our group for the first time.

We started with introducing our group and how we planned to work in the sessions, followed by an ice-breaking activity. Considering that there were several new comers, a review of previous work done in TWG8 was presented and contributors were given tasks to discuss the recent directions pointed in the presentation. We planned the next five sessions to have other ice-breaking activities, all of them conducted brilliantly by Hanna Viitala, and the contributions have been briefly presented (10 minutes) followed by a short discussion (5 minutes) for each individual paper, plus a session of 30 minutes dedicated to raise general and overarching themes that emerged from each session of presentations. The 30-minutes discussions have been prepared by Janina Kravitz, Robin Goeller and Chiara Andrà, while Domenico Brunetto prepared and led the final session dedicated to a discussion about the work of the entire WG. The organisation of the sessions allowed us to create a friendly and welcoming atmosphere, together with in-depth discussions about our researches, seeking for links and connections among our research interests.

Reflection on prior research in affect

The focus on affect has gained attention since McLeod (1992)'s review paper on the affect constructs. He addressed the major affect constructs as beliefs, attitudes and emotions and characterized them based on their stability and affective-cognitive properties. Beliefs were considered the most stable over time, the least affective and the most cognitive. Emotions were considered as the least stable, the most affective and the least cognitive, with attitudes in between beliefs and emotions. This categorization was followed by numerous research and elaboration within the affect researchers. CERME5 discussions in this group focused on clarifying definitions of the concepts, enhancing the field by new concepts and specifying the relationships between these concepts (Hannula et al., 2007). Hannula and colleagues (2007) identified motivation, rather than attitudes, as one of the major affect categories. In the following years, based on Hannula (2011)'s analysis of affect research in mathematics education in CERME7, affect constructs beliefs, motivation, and emotions have integrated both state and trait dimensions and social, psychological, and physiological dimensions in the presented contributions (Schukajlow et al., 2019).

Affect can also be viewed by focusing on (a) the object of the affect (such as mathematics or task performance), (b) the subject of the affect (such as teachers, students, or preservice teachers), and (c) valence (such as positive or negative) (Schukajlow et al., 2017). These characteristics can be addressed with acquisitionist or participationist theoretical approaches. Affect constructs are closely related to each other (Goldin et al., 2009; Gómez-Chacón et. al., 2023; Hannula, 2011) in systems and change in one construct results in change in the others.

Contributions in the TWG8

We had the opportunity to learn and discuss interesting studies this year. There were five studies that focused on motivation. Schukajlow and his colleagues, through a quantitative study conducted with lower-secondary school students, examined the motivation behind using the questioning strategy while solving modelling problems (i.e., the strategy to generate questions about the situation described in the task), focusing specifically on the relationships among three components of strategy-based motivation: self-efficacy, values, and costs. Attention has been paid to gender differences in these three components. Interestingly, findings revealed a positive relationship between self-efficacy and values, and lower self-efficacy in the questioning strategy in female students. Viitala's research addresses the descending trend of secondary pupils' mathematics performance (between cohorts) and pupils' mathematics-related affect that develops negatively throughout the school years (within cohorts) by implementing and monitoring a collaborative problem-solving intervention. The results show that while pupils value learning mathematics, they do not think they need to show competence or avoid showing incompetence in mathematics lessons. Krawitz and Wiehe examined the impact of problem-posing prompts on students' motivation and they showed that reformulating easy problems, compared to difficult ones, led to higher expectancies for success, greater utility and attainment value, and lower perceived costs. More broadly, the findings highlight the distinct nature of task-value components and suggest that incorporating prompts for easier problems in problem-posing tasks can positively impact students' motivation. Wang and Zhu investigated the effect of a growth mindset on mathematical performance, considering also mathematics anxiety and mathematics learning

motivation, comparing advantaged and disadvantaged students across six East Asian countries/economies and OECD countries. In East Asia, a growth mindset negatively affects math achievement directly among disadvantaged students but improves it indirectly by reducing anxiety and boosting motivation. In OECD countries, the positive direct effect of a growth mindset is more pronounced, highlighting cultural and socioeconomic differences in its impact. Dell'Anna and Brunetto introduced a theoretical framework that integrates cognitive, motivational, and affective dimensions to analyse how students interact and evolve over time in collaborative settings. The model specifically addresses the role of motivation by examining how students' engagement, goals, and values influence their participation and learning outcomes in group settings.

Identity was the focus for two papers presented this year. Heyd-Metzuyanim explored the unification of the commognitive framework with complexity theory to theorize how students' mathematical identities stabilize to form ritual patterns of participation in mathematical learning. The results suggest that a student's subjectifications cohered with her mathematizing, which was mostly ritual and focused on procedures that she attempted to recall from memory. These subjectifications in turn cohered with her role-identity narratives that revolve around "succeeding" in mathematics for instrumental goals, all forming an attractor state in the complex dynamic system of her role identity. Gildehaus observed that many preservice primary teachers seem to struggle with their compulsory mathematics education at university. Besides cognitive struggle, they report low interest, negative emotions, and an overall rejection towards mathematics. Identity-based approaches shed light on these connections, identifying contrasting relationships and clusters of "either-or" participation for preservice primary teachers in mathematics.

Emotions and values were the focus in another four studies. Turconi and her colleagues consider the students' narrative about the secondary-tertiary transition in mathematics education and aim at evaluating the extent to which artificial intelligence can support the researcher in narrative analysis by identifying relevant themes to categorise keywords and highlight emerging themes from student texts. The model has proven to be a promising tool for automating part of the analytical process for qualitative data, especially in its preliminary stages, without sacrificing the depth of the research. Gómez-Chacón and Bacelo explored the relationship between epistemic emotions and control actions in undergraduate mathematics and computer engineering students in a task requiring the use of computational thinking and linear algebra concepts. The findings reveal that mathematics students give more importance to control elements associated with formalization of mathematical concepts, while computer engineering students give more importance to emotions associated with the instrumental and technological control dimension. Goeller explored the formation of emotions and values situated in university mathematics education and grounded in students' personal epistemology, finding useful hints for theorising the formation of emotions and values grounded in mathematics-specific personal epistemology (PE) with practical implications to overcome alienation and exclusion in university mathematics education. Satyam explores the use of the tool emotion graphing for studying participants' emotions and fostering a larger theorized structure of meta-affect. Emotion graphing, within the range of pictorial methods, can capture shifts in affect through drawing maps or pictures and serves as a vehicle for more effective communication during interviews as well as a form of experience-based sampling, with pedagogical use as exit tickets.

Two studies reported findings related to mathematics teacher affect, with an eye also on their students. Hagenkötter considered the mathematics teacher's conceptions and intention to teach mathematics within an exploratory interview study. The results indicate that the teacher's intention to convey to her students that mathematics is a coherent system and that doing mathematics is a sense-making process does not get through to most of her students, who associate mathematics and doing mathematics primarily with arithmetic and finding results. Hamidy and colleagues examined the impact of mathematics teacher support and mathematical self-concept on the students' perceived value of mathematics. The results show that the indirect effect of instrumental mathematics teacher support on Value via mathematical self-concept is significant, while the indirect effect of emotional mathematics teacher support does not exist. Furthermore, they confirm the framework suggested by the expectancy-value theory and provide a better picture of the relationship between internal and external factors of mathematical resilience.

Lastly but not leastly, four studies investigated feedback and assessment in mathematics. In his systematic review of literature, Daniel focused on teacher feedback practices as a primary mechanism influencing students' appraisal of self-efficacy information, with a particular focus on students' attributions as a potential mediating factor. Spagnolo and Andrà investigated how pre-service and in-service teachers perceive the difficulty of mathematical tasks and examined the factors that shape their evaluations. The findings reveal significant differences between pre-service and in-service teachers, particularly in their handling of open-ended versus structured tasks, shedding light on the influence of teacher experience on perceived difficulty and underscoring the importance of addressing both cognitive and affective factors in teacher professional development. Nicchiotti and colleagues, in a related study, explored the emotional factors influencing primary school students' perceived difficulty when solving mathematical tasks. The results indicate that while emotional factors, both positive and negative, emerged, students often struggled to articulate their emotions. The findings suggest that emotions are meaningful and independent contributors to perceived difficulty. Street and colleagues studied the impact of classroom quality on students' mastery experiences, especially in the context of tasks of different levels of difficulty. The research investigated how quality of student-teacher interactions predicted students' mastery experiences across a sequence of four lessons. The importance of instructional support for students' mastery experiences stood out.

Evolution of the TWG

We had a smaller number of contributions this year but several contributors who visited TWG08 report session indicated that their current studies have an affect dimension, which they plan to present in the next CERME. The number of contributions, on the other hand, enabled us to discuss the ideas presented in the studies in depth. Most of the studies were about students but there were also those about teachers and on the relationship between teachers' and students' affect. Gender continued to be a part of our discussions in some studies. Several studies utilized sophisticated quantitative methods but we also had mixed methods studies with several instruments, as well as emerging and valuable qualitative studies.

Our discussions focused on different aspects of the studies in terms of both content and method. We are still dealing with the definitions of newer terminology, such as engagement, which is enriching

the field with fruitful discussions. We are still bounded by our data collection tools; however, this brings a positive trigger and leads us to think about other possibilities as well as contextual issues that result in such limitations. Identifying limitations helps us to develop improved tools to address affect in our studies. We still call for more research on the relationship between affect and cognition, theorising, deepening new concepts, longitudinal and comparative perspectives, and research focusing on different groups of students such as students with special needs.

The COIF model: Modelling the evolution of student states during collaborative sessions

Helena Dell'Anna[1] and Domenico Brunetto[1]

[1]Politecnico di Milano, Department of Mathematics, Milan, Italy; helena.dellanna@polimi.it

This article introduces the COIF Model, a theoretical framework developed to contribute to the understanding of student working group. The model builds on cognitive and motivational aspects, perceived competence, and emotional disposition to analyse how students' states evolve over time. The model specifically addresses the role of motivation by examining how students' engagement, goals, and values influence their participation and learning outcomes in group settings. After presenting the theoretical background, the paper outlines the model's central components, introduces the representative schema used, and demonstrates how the model can characterize the evolution of student states, including their motivational aspects.

Keywords: Group dynamics, student participation, student motivation.

Introduction

In recent decades, research in mathematics education has recognized the crucial role of social interactions in student learning (e.g., Sfard, 2001) as well as the interplay of cognitive, motivational, and emotional dimensions as key factors influencing behavior (Hannula, 2012). Affective factors shape the educational experience by influencing students to form meaningful connections with both the mathematical content and the social context of the classroom. Andrà and Liljedahl (2014) highlights how affective moves influence group dynamics in classroom interactions.

Liljedahl (2020) proposes pedagogical practices to transform the classroom into a space of active engagement, based on participation and collaboration, where teachers have the discretion to intervene in small group activities, with their interventions being either cognitive or affective in nature. This perspective aligns with the work of Andrà et al. (2015, 2020), who identified four fundamental modes of participation during group activities based on the levels of "I Can" and "You Can". Additionally, motivation plays a pivotal role in this context, influencing student engagement, goals, and values, which in turn affect their participation and learning outcomes (Eccles & Wigfield, 2002).

Despite the importance of group work in mathematics education, research often examines it in fragmented ways, focusing on individual factors, yet students are influenced by cognitive, motivational, emotional, and social elements simultaneously. As Hannula (2012) observes, many studies in mathematics education foreground one dimension—cognition, motivation, or emotion—while relegating the others to subordinate roles, thus neglecting their interconnected nature. This fragmented approach presents challenges for understanding the complexity of group dynamics.

The COIF Model aims to address this gap by integrating these dimensions within a unified analytical framework. We use the term "model" in the scientific sense, as defined by Schoenfeld (1999, p. 248), who states that "a representation of a particular phenomenon, in which objects and relationships characterized in the model correspond to selected objects and relations in the phenomenon being represented". Specifically, a model is defined as a triple (D, M, f) consisting of a domain D of the

real world, a subset M of the mathematical world and a mapping from D to M (Blum, 2015). Following Blum's (2015) framework of mathematical modelling, which outlines seven key steps, this study focuses primarily on step 2 (structuring), step 3 (mathematizing) and step 4 (working mathematically), thus we started from the situation, proposing a real model, which is transformed into mathematical-model, and provide some mathematical results. The COIF Model is tailored to secondary school contexts, with future research aimed at validating (step 6) its practical applicability within this setting.

This paper begins with a detailed *Theoretical framework*, reviewing key literature that provides the foundation for the COIF Model. This is followed by the *Key hypotheses for mathematical model construction* section, followed by which outlines the theoretical assumptions of the model. The next section, *Results - COIF model*, explains how the model was structured and provides two examples of a simulation to demonstrate how student state transitions are analysed. Finally, the *Discussion and conclusion* reflect on the interpretation, such as the educational implications of the model, its limitations, and potential directions for future research.

Theoretical framework

The focus on affect in educational research has grown significantly since McLeod's (1992) review, which introduced a taxonomy that organizes affective constructs along a spectrum from beliefs (most stable and cognitively oriented) to attitudes (intermediate stability and involving both affective and cognitive components) to emotions (least stable and primarily affective). Building on this, Hannula (2012) emphasizes the interconnected nature of cognition, motivation, and emotions. Cognition involves processing information, while motivation directs behaviour through goals and choices, and emotions provide feedback for both. Hannula (2012) also suggests distinguishing between the stable, trait-like nature of affective variables, and their more variable, state-like nature. Di Martino and Zan (2011) highlight the complex relationship between beliefs, emotions, and attitudes in mathematics learning, showing how perceived competence (e.g., 'I can/can't') and emotional disposition (e.g., 'I like/dislike mathematics') influences students' engagement and group interactions. This framework provides valuable insights into how attitudes influence behaviour, particularly in group settings, where belief states significantly influence the development of the activity (Roth & Radford, 2011).

Likewise, student emotions fluctuate during problem-solving, shaping the mathematical activity itself (Roth & Radford, 2011). Research shows that students' motivations, emotions, and perceived competence can change not only throughout the academic year (Andrà & Scalvini, 2023) but also within the same collaborative session (Liljedahl, 2020). These findings underscore the variability of motivation, emotions, and perceived competence, highlighting their critical role in shaping student engagement and collaborative interactions. Di Martino and Zan (2011) highlight how perceived competence influences participation, with "I can" fostering engagement and "I can't" leading to passivity (Andrà & Liljedahl, 2014). Recognizing peers' abilities ("You can") also shapes group dynamics (Andrà et al., 2015). In their study, Andrà et al. (2020) identified four fundamental modes of participation during group activities, each characterized by different levels of "I Can" and "You Can" (Andrà et al., 2015; 2020). These modes include *cooperative* participation (high levels of both "I Can" and "You Can"), *obstinate* participation (high "I Can" but low "You Can"), *isolated*

participation (low levels of both "I Can" and "You Can"), and *follower* participation (high "You Can" but low "I Can"). Building on Hannula's (2012) concept of states as variable and momentary expressions of affective variables, and acknowledging the documented fluctuations in perceived competence, we define student states in our model as characterized by three key dimensions: "I Can", "You Can" and motivation. This framework allows us to examine the dynamic interplay of these factors during collaborative activities. By focusing on the variability of "I Can" and "You Can", we aim to study the evolution of participation modes (Andrà et al., 2020) in group settings. Additionally, the model integrates a motivational component to reflect the interdependence between perceived competence and engagement, modeling transitions between states based on the success or failure of collaborative efforts.

Given the importance of group work, as well as the impact of emotional states and motivation on educational outcomes, this study seeks to address the following research question: How can we model the evolution of student states and their reciprocal relationship with motivation during collaborative group work?

Key hypotheses for model construction

The model is based on key hypotheses regarding student transitions between different states during collaboration. Specifically, when a student solves a task independently, their "I Can" confidence increases, reflecting a sense of self-efficacy, while reliance on peers ("You Can") decreases. This dynamic can lead to obstinate behavior, as the student perceives less need for group input. Conversely, when a student struggles to solve a task independently but observes peers succeeding, their "I Can" confidence may decrease, while their reliance on peers ("You Can") increases. This adjustment fosters follower behaviors, where the student values and depends more on the contributions of others. Success in group activities is hypothesized to increase both "I Can" and "You Can", encouraging cooperative behaviors and enhancing group cohesion. On the other hand, failure may result in frustration, disengagement, and a decline in both "I Can" and "You Can" perceptions, which can manifest as withdrawal or isolated behaviors. These changes highlight the interplay between confidence, motivation, and group participation during collaborative tasks. In addition to these dynamic elements, the model incorporates the level of preparation as a stable cognitive trait that shapes the baseline conditions for group interactions. This trait influences the group's capacity to succeed and the dynamics of collaboration. Building on these key hypotheses, we formulated further theoretical hypotheses regarding the outcomes of collaborations among students, taking into account their initial states, including their initial modes of participation and levels of preparation.

For clarity, Table 1 illustrates the hypotheses regarding the outcomes of collaborations involving a cooperative student paired with others (cooperative (C), obstinate (O), isolated (I), or follower (F)) at different levels of preparation (high or low). When both participants are well-prepared, group success (1,1) is achieved, leading to an increase in both "I Can" and "You Can", which foster self-efficacy and group cohesion. Conversely, when neither is well-prepared, group failure (-1,-1) occurs, decreasing both metrics and potentially reducing motivation and engagement. The dynamics vary when one participant is well-prepared while the other is not. In collaboration between two

cooperatives (or one cooperative and one follower), success (1,1) is likely even if only one participant is prepared, as mutual trust and perceived competence foster effective collaboration. In pairings between cooperative and obstinate students, success (1,1) is achieved if the obstinate student has high preparation, as their competence, combined with the cooperative student's encouragement, facilitates collaboration and can lead to group success. In contrast, if the obstinate student is unprepared, group failure (-1,-1) is likely, as low recognition of peer ability and obstinance hinder progress. Collaboration between cooperative and isolated students presents more complex outcomes. When only one has studied, the prepared student achieves individual success (1,-1 or -1,1), while the unprepared student does not, reflecting individual success but group imbalance. In these cases, the prepared student increases their "I Can" and decreases their "You Can" for their partner, while the unprepared student experiences the opposite.

Table 1: Collaboration outcomes with cooperative student

C|C	High	Low
High	$(1,1)$	$(1,1)$
Low	$(1,1)$	$(-1,-1)$

C|O	High	Low
High	$(1,1)$	$(-1,-1)$
Low	$(1,1)$	$(-1,-1)$

C|I	High	Low
High	$(1,1)$	$(1,-1)$
Low	$(-1,1)$	$(-1,-1)$

C|F	High	Low
High	$(1,1)$	$(1,1)$
Low	$(1,1)$	$(-1,-1)$

These assumptions ensure the model captures the dynamics of different participatory states and their impact on group work success or failure. Furthermore, successful outcomes (1,1) and (1,−1) increase motivation by boosting confidence, while unsuccessful outcomes (−1,1) and (−1,−1) decrease motivation, as frustration reduces effort and engagement.

Results - COIF model

Initially, the COIF model was structured by focusing exclusively on the evolutionary states of students, represented by the four primary states: Cooperative (C), Obstinate (O), Isolated (I), and Follower (F). This initial phase of the model aimed to describe transitions between states based on group interactions and task outcomes, utilizing a Markov chain (Norris, 1997) to map the transition probabilities. As illustrated in Figure 1, the links between nodes represent the probabilities of transitioning from one state to another (e.g., from Cooperative to Obstinate), while self-loops represent the probability of remaining in the same state (e.g., a Cooperative student staying Cooperative). The transition probabilities for each state j = C, O, I, F, are defined as follows:

- p_j: Probability that a student in state j solves the task independently, leading to an increase in their "I Can" and a decrease in "You Can", making them obstinate.
- q_j: Probability that a student in state j does not solve the task, while another student does so independently, leading to a decrease in their "I Can" and "You Can", making them a follower.
- r_j: Probability of a student in state j achieving a solution collaboratively within the group, leading to an increase in both "I Can" and "You Can", making them cooperative.
- s_j: Probability that neither a student in state j nor their group collectively solves the task, leading to a decrease in both "I Can" and "You Can", making them isolated.

We stress that these probabilities are based on theoretical assumptions about the possible outcomes of collaborations and are not intended to represent objective quantitative measurements but are instead meant as trends in the evolution of student states.

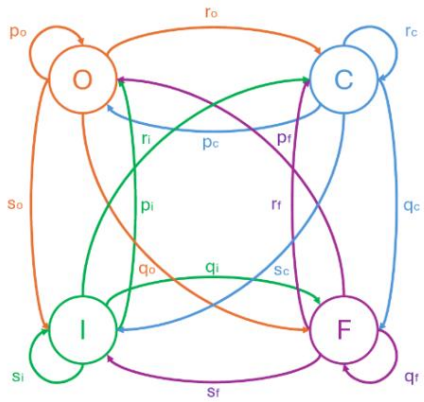

Figure 1: Representation of student state transitions

The evolution of the number of students in each state is modelled using a system of differential equations. The rate of change for a state j is calculated as the algebraic sum of the inflow (students transitioning into state j, weighted by the corresponding transition probabilities) and the outflow (students leaving state j, weighted by the probabilities of transitioning out of that state). For example, if C represents the number of cooperative students, the rate of change in cooperative students is given by: $dC/dt = r_O \times O + r_I \times I + r_F \times F - (p_C + s_C + q_C) \times C$, where I, F, and O represent the number of isolated, follower, and obstinate students, respectively.

To incorporate motivation into the model, we introduce the new variable M, representing the level of student motivation, ranging from 0 to 1. In this framework, motivated students who achieve the correct solution remain motivated, while students who fail to find the solution may decrease their motivation and potentially experiencing frustration. Conversely, initially unmotivated students who succeed can increase their level of motivation. The rate of change in motivation (dM/dt) is calculated by considering the transitions between high level of motivation ($M \geq 0.5$) and low level of motivation ($M < 0.5$), weighted by their respective probabilities. This formulation dynamically captures the interplay between student motivation and task outcomes in collaborative settings.

This system of differential equations provides insights into the evolution of the number of students transitioning from one state to another, representing the group's overall dynamics. However, our primary focus is on understanding how the individual student's state evolves in terms of “I Can”, "You Can” and motivation variables. To that end, we define three global quantities: the average levels of “I Can”, “You Can” and motivation across the group. The average of I can at the time t (EI(t)) is the mean number of cooperative (C(t)) and obstinate (O(t)) students at that time t: $EI(t)=[C(t)+O(t)]/N$, where N is the total number of students. Similarly, the average of You can (EY) and motivation (EM) are: $EY(t)=[C(t)+F(t)]/N$, and $EM(t)=[M(t)]/N$, where M(t) is the number of students in Layer 1 at time t (students with high motivation). We then compute the global variation (Δ) for each of these quantities over a time interval Δt: $\Delta I=EI(t+\Delta t)-EI(t)$, $\Delta Y=EY(t+\Delta t)-EY(t)$, $\Delta M=EM(t+\Delta t)-EM(t)$. This allows us to model level of the states of each student at time $t+\Delta t$ by

summing their state variables at time t with the corresponding global variation. For example, the level of I can of student *i* at time t+Δt is: $I\ can_i(t+\Delta t) = I\ can_i(t) + \Delta I$.

To clarify the behaviour of the model, we provide two examples. Figure 2 (left) shows the dynamics of the first group of four students the cooperative (C) and obstinate (O) students start with high motivation, while the isolated (I) and follower (F) students have lower motivation. As we can see in the figure, both "I Can" and "You Can" levels steadily increase, indicating growing confidence and enhanced student cooperation. However, the zig-zag pattern indicates fluctuations in motivation. According to the model's hypothesis, which links motivation closely to task success, this dynamic suggests that the group faces obstacles, delaying progress and making it challenging to reach the correct solution quickly. These challenges manifest as alternating periods of high motivation during progress and low motivation when frustration arises from setbacks. Despite these fluctuations, the overall increase in "I Can" and "You Can" suggests the enhance of group's cohesion and cooperative efforts. In the Figure 2 (right), the isolated and follower students now exhibit higher motivation than the cooperative and obstinate students. As observed in the figure, the trajectories of all variables, "I Can," "You Can," and motivation, increase monotonically. In particular, the greater overall increase in motivation and the more significant rise in "I Can" levels suggest that fostering individual confidence through achievable tasks can enhance engagement. However, the smaller increase in "You Can," compared to the first scenario, could be attributed to the presence of a motivated isolated student, which may slow down cooperation. This aligns with findings by Andrà et al. (2020), which emphasize that isolated participation can act as a barrier to group cohesion, even in scenarios of high individual motivation.

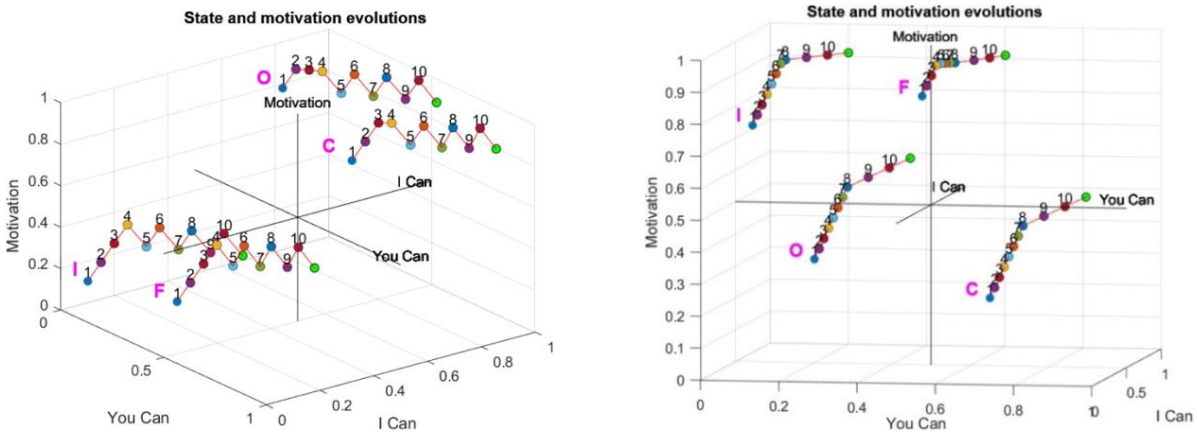

Figure 2: State and motivation evolution of two work groups

Discussion and conclusion

The two reported examples and their relative analysis drive attention towards the outcomes of the group work, wondering what a positive outcome means. We claim that positive outcomes occur when students become cooperative (i.e., increase both "I Can" and "You Can") with high motivation. As consequence, the success of the task is left on background as variable which is influenced by high motivation. Namely, the priority of the positive outcome is not the success of the task itself, but the

high motivation and cooperation which can bring students towards the correct solution. The results confirm that this model aligns with the literature and fulfills our objective of mathematical modeling.

In the first example, students with high "I Can" levels also exhibited high motivation, demonstrating that, even after setbacks that could decrease their motivation, they were able to improve their collaboration and self-confidence. This supports the idea that collaborative group work, even during fluctuating periods of motivation, fosters both individual and collective confidence (Liljedahl, 2020). In the second example, favourable dynamics emerged when students with lower confidence levels exhibit higher motivation. Increased motivation helps balance their lower 'I Can' levels, enabling them to contribute more positively and boosting their confidence. This aligns with the expectancy-value theory, which posits that students' expectations for success and the value they assign to tasks significantly influence their motivation (Eccles & Wigfield, 2002). These two scenarios reinforce the concept that the variables under analysis are strongly interconnected, with each influencing the others (Hannula, 2012).

In this theoretical work, we aim at providing a model for the evolution of the students' states during collaborative work. Contributing to the need for a more integrated analysis of classroom interactions and the research question, the development of the COIF model aims at bridging the gap identified in the literature by offering a framework to analyse the evolution of student states within a collaborative classroom setting. The presented examples indicate that the model is on the right track as a descriptive tool for scenarios already explored in the literature. Our ambition is for this model to evolve into an analytical and informative instrument for researchers, guiding the investigation of yet uncharted scenarios, and a valuable tool for advancing insights into classroom dynamics.

To that end, we will refine the parameters within the COIF model to better mirror real-world classroom scenarios. The other that requires further reflection is the role of motivation, which should be integrated in more holistically way, considering it not only as a consequence of interactional outcomes but also as a driving force that shapes student engagement and participation from the outset. Finally, empirical validation could prove challenging, as motivation could be more difficult to capture compared to the "I Can" and "You Can" dimensions.

While empirical validation, comparing the model's predicted state transitions with observed classroom data, is a longer-term goal, the current model provides a solid foundation for representing the evolution of student states in collaborative contexts. Despite its limitations, the COIF model serves as a promising starting point for further research and development.

You are what you feel? – How primary teacher students' identification as mathematicians and teachers relates to other affective variables

Lara Gildehaus[1]

[1]Alpen-Adria-Universität Klagenfurt, Austria; lara.gildehaus@aau.at

Many preservice primary teachers seem to struggle with their compulsory mathematics education at university. Besides cognitive struggle, they report low interest, negative emotions, and an overall rejection towards mathematics. Identity-based approaches shed light on these connections in recent years from a qualitative perspective. In this paper, I aim to investigate the relation between one's identification with mathematics (and teaching) and other affective variables from a quantitative perspective. A correlation, as well as cluster analysis for n = 99 preservice primary teachers, was conducted, identifying rather contrasting relationships and clusters of "either-or" participation for preservice primary teachers in mathematics. Theoretical implications about relations of affective variables, as well as practical implications for teacher education, are being discussed.

Keywords: Preservice primary teachers, affect, identification, relations in affective variables.

Affect and identity in preservice primary mathematics teacher education

While mathematics is compulsory for most preservice primary teachers worldwide, many seem to struggle with studying and learning mathematics during their teacher education (Chen, 2017; Ingram et al., 2018), which may also hinder their later teaching and influence their future students' mathematical learning (Beilock et al., 2010). Recent studies also point towards affective struggles next to cognitive challenges (Coppola et al., 2012; Ingram et al., 2018). For example, Fray and Gore (2018) found in their meta-study on study choice motivation that preservice primary teachers are more motivated for teaching per se and less motivated for the subjects to teach, such as mathematics. Regarding subject-specific content, many preservice primary teachers question the relevance of their obligatory mathematics courses at university and show low motivation for them (Gildehaus, 2024). However, many preservice primary teachers also report high negative emotions, such as anxiety or frustration when learning mathematics at university, as well as rather low self-efficacy about their mathematical abilities (Jenßen, 2023). Thus, their struggle seems not only indicated by less motivation for the subject but also by deeper underlying social structures that cause negative feelings and low self-esteem in mathematics.

In recent years, identity-based approaches to preservice primary teachers' relation with mathematics investigated these underlying structures. They showed a broader yet worrying picture of preservice primary teachers' mathematical identities: Many students reported very negative experiences with mathematics during their school experiences (Hodgen & Askew, 2007). Stories of failure and exclusion were being narrated, told about not knowing or understanding mathematics (directly) and therefore being pointed out (Lutovac, 2020). Such failure experiences play a significant role in becoming a teacher during university education (Lutovac, 2020). They may thus be related to or even be part of possibly underlying reasons for low self-esteem, motivation, and negative emotions of preservice primary teachers during their university education – specifically when also during university education experiences of not understanding are quite common (Gildehaus et al., 2024; Ingram et al., 2018).

However, while such a relationship between identity and affective variables seems likely from a theoretical perspective, its empirical evidence is rare. Moreover, there is evidence that also preservice primary teachers who do not develop a positive relationship towards mathematics but their overall pedagogical competence and teaching can show a highly functional teacher's identity (Alderton, 2020). On the opposite, Lutovac and Kaasila (2014), for example, investigated how specifically preservice primary students with negative experiences from their school education were able to overcome these negative experiences and build up a more positive mathematics learner identity. Coppola et al. (2012) also stated that besides the dominance of negative emotions in their study about how preservice primary teachers feel about mathematics, positive emotions, such as enjoyment and satisfaction, had been mentioned simultaneously. Thus, the overall situation of different affective variables may be more complex than theoretically anticipated.

In the following, I aim to bridge the social context of identity with preservice primary teachers' overall affect from a quantitative perspective. I will first investigate possible relations between one's "identity" (operationalized as identification with a certain community) and different affective variables (operationalized as self-efficacy, emotion, and motivation). Secondly, different clusters of students' affective profiles at the end of their mathematics university education are being identified to investigate possibly different states of relations between these variables.

Theoretical background

Following this aim, I first clarify how to operationalize identity towards a quantitative framework and further investigate relevant affective variables and their relatedness to each other as well as to the social context. Hereby, different objects of preservice primary teachers' affect are also considered.

Operationalizing identity as identification

The cited identity works above stem from a qualitative and mostly discursive paradigm. While this reconstructs the rich complexity of underlying structures, it cannot be operationalized in a quantitative study design without immense reduction. Yet, given that identity has been intensively researched during the past years in mathematics education, we do have a great overview of *how* students see themselves as belonging and identifying with a mathematics community (c.f. Wenger, 1998 on how building one's identity is becoming a member of a certain community). Instead of further investigating this *how*, I will in the following focus on the *if*, in terms of *if* students do identify themselves with a mathematics community and *if* they feel a sense of belonging towards this community. In this sense, I am stepping away from the relevant process given rise to the *if* but may still observe a situated positioning of identification directly related to the social context.

Moreover, preservice teachers are also known to be torn between different communities, for example, that of theory and practice (Solomon et al., 2017) or that of mathematics and mathematics teaching (Gildehaus et al., 2024). In addition to identifying with the mathematics community, I am also operationalizing one's identification with the teaching community.

Self-efficacy and shame as affective variables related to the social context

Following this aim of staying related to the social context, Hannula (2012) argued that affective variables can also be seen from a social (additional to a psychological) perspective. While a psychological perspective perceives affective variables as individual mental processes, a social

perspective may see them as aspects of social interaction and structure (Hannula, 2012). I will, at least to some extent, bridge those two perspectives by investigating affective variables from a psychological perspective but still interpret them in relation to the findings of students' identification with mathematics. For example, self-efficacy, an affective variable closely related to cognition and performance, may also be related to one's identification with the community in which one perceives oneself as efficient.

Furthermore, emotions play a crucial role in mathematics, and Hannula (2012) states them as the most social and situated affective variable. Hereby shame can also bridge our psychological and social perspective since it is known to be a social emotion. In contrast to anxiety or frustration, it only concerns a given social context – one feels ashamed of something in front of someone. Yet, shame is often related to general beliefs about one's capability, for example "I am just too stupid to ever learn mathematics" (Jenßen, 2023), making it individually accessible and measurable. Therefore, I would anticipate a (possibly negative) relation towards one's identification with the mathematics community.

Different objects in preservice primary teachers' motivation

Taking our relatedness to the social context further, Schukajlow et al. (2023) stress the importance of explicating possible different objects towards which affective constructs can be directed. This, again, seems of specific importance in the context of teacher education. For example, as I discussed earlier, preservice primary teachers' motivation in teaching is often higher than in the subjects. Thus, the objects of teaching and the subject can be differentiated in their motivation (Fray & Gore, 2018).

Taking a closer look at preservice *mathematics* teachers, they often seem to differentiate between the objects of mathematics as they know from school and mathematics at university (cf. Ufer et al., 2017), where the first is more related to the general object of teaching and the second to the subject. Furthermore, preservice teachers report different objects they value in relation to how they identify (e.g., as stated earlier, mathematicians and future teachers) – at least in some qualitative studies (cf. Gildehaus et al., 2024). While "understanding mathematics deeply" seems to be relevant for students who see themselves as part of a mathematics community, "nicely explaining mathematics to children" seems of great importance for students identifying as future mathematics teachers (Gildehaus, 2024). Operationalizing such different objects in preservice teachers' motivation may again enable us to investigate such possible social relations from a more quantitative perspective.

Research Questions

Given this overall setting, I pose the following research questions. While RQ1 focuses on the concrete relations between different variables, RQ2 aims to further investigate different patterns of relatedness in these variables for different students, following the earlier discussed aim of getting insights into students' different clusters of affective profiles at the end of their mathematics university education.

RQ1: How do identification with mathematics and teaching relate to the affective variables self-efficacy, shame, motivation for school and university mathematics, and motivation for understanding and teaching mathematics?

RQ2: What different clusters of students can be found throughout these variables, and what characterizes them?

Methods

Sample

The sample consisted of a total of $n = 99$ students from a medium-sized German university. The surveyed course, "Elements of Mathematics", focused on basic ideas of formal mathematics, such as logic and (generic) proofs. It is the last mathematical course the students attend during their studies before they finish their university education. The course was obligatory for preservice primary teachers in this context; however, they could voluntarily intensify courses in mathematics (8.2 % reported to have chosen this option). Furthermore, the course could be visited by preservice teachers for special education as well, who would have also chosen the course voluntarily (14.1 % reported to have chosen this option). Of all students, 88.7 % reported identifying as female, 11.2 % as male, and 0 % as non-binary. Most surveyed students (66.3 %) were in the last year of their master's program, 21.4 % had just started their master's, and 14.3 % were in the last year of their bachelor's degree.

Data collection

The data was collected with an online questionnaire during lecture time in the third week of the semester. Students were guaranteed anonymity and participated voluntarily. As discussed earlier, students' "identity" was operationalized as identification with a mathematics community (Math I.) and identification with a teaching community (Teaching I.). The former scale had recently shown great reliability (Kempen & Liebendörfer, 2021), while the latter was adapted for this study for the first time.

Adapted scales from PISA were used to measure self-efficacy, which had often been used in university mathematics contexts before (c.f. Gildehaus, 2024; Kempen & Liebendörfer, 2021). The well-established SHAME-Q was used to measure shame (Jenßen, 2023).

To measure motivation for different objects, I used the scales recently evaluated by Gildehaus (2024). Motivation is understood in terms of expectancy and value (Eccles & Wigfield, 2020) and different objects for the values are addressed: school and university mathematics (in line with Ufer et al., 2017) as well as understanding and explaining mathematics (in line with Gildehaus et al., 2024). This resulted in four scales in total for intrinsic value for school mathematics (IValue school) and university mathematics (IValue Uni), as well as attainment value for understanding mathematics (AValue Understand) or explaining mathematics (AValue explain).

The original 5-point Likert scale from 1 (= strongly disagree) to 5 (= strongly agree) of the SHAME-Q was kept, while the other variables were measured on a 6-point Likert scale accordingly. Example items are displayed in Table 1. All the scales showed great internal consistency (Cronbach's $\alpha > .83$ for all scales) as well as discriminatory power between the different items (item-rest-correlation $> .55$ in all cases). However, a potential ceiling effect for the scale "attainment value explaining" was identified (*mean*: 5.6), which I keep in mind for the following analysis.

Data analysis

To answer RQ1, a correlation analysis (PCC) of all variables was performed. For RQ2, a *k*-means cluster analysis was performed. The analysis was conducted for $k = 1, \ldots, 10$ clusters with different starting points, to avoid dependences of those, as well as with *z*-standardized variables to take care of the different scales. To identify the optimal number of clusters, the gap statistic approach was used.

It compares the total intra-cluster variation for different values of *k* with their expected values under null reference distribution of the data. The estimate of the optimal *k* will be the value that maximizes the gap statistic (Tibshirani et al., 2001). All analyses were performed using Jamovi 2.3.2.1.

Table 1: Overview of the Scales (number of items in parentheses), example items and their Cronbach's α

Scale (number of items)	Example Item	α
Math I. (5)	I would describe myself as a mathematician.	.87
Teaching I. (5)	I would describe myself as a primary/special needs teacher.	.83
Self-Efficacy (4)	I am convinced that I can perform well in homework and exams.	.91
Shame (6)	I am ashamed that I am not as good in math as I would like to be.	.93
IValue School (4)	I enjoyed mathematics in school.	.95
IValue Uni (4)	I like the mathematics at university.	.89
AValue Understand(4)	I want to deeply understand mathematics.	.89
AValue Explain (4)	I want to be someone who can explain mathematics really good	.87

Results

Research Question 1

Table 2 provides all correlations between the variables. Math Identification is highly correlated with Self-Efficacy, Intrinsic Value for School and University, and Attainment Value for Understanding. It is also negatively correlated with Shame, as well as with Teaching Identification. The latter, in contrast, shows negative correlations with Self-Efficacy, Intrinsic Value for University, and Attainment Value for Understanding, but no correlation with Attainment Value Explaining. Moreover, Self-Efficacy is highly correlated with all Values except Attainment Value Explaining and is negatively correlated with Shame. Shame, in line with that, is negatively correlated with these Values. Both Intrinsic and Attainment Values are positively correlated.

Table 2: Correlations of the different variables $^{*}p < .05$, $^{**}p < .01$, $^{***}p < .001$

Variable	1	2	3	4	5	6	7
Math I. (1)							
Teaching I. (2)	$-.37^{***}$						
Self-Efficacy (3)	$.54^{***}$	$-.30^{**}$					
Shame (4)	$-.28^{**}$	.12	$-.51^{***}$				
IValue School (5)	$.40^{***}$	-.20	$.47^{***}$	$-.45^{***}$			
IValue Uni (6)	$.46^{***}$	$-.26^{*}$	$.55^{***}$	$-.33^{***}$	$.49^{***}$		
AValue Understand (7)	$.38^{***}$	$-.26^{*}$	$.50^{***}$	$-.18^{*}$	$.24^{**}$	$.65^{***}$	
AValue Explain (8)	.17	.10	.05	-.14	.17	$.18^{*}$	$.30^{***}$

Research Question 2

The gap statistic revealed two different clusters as the optimal number *k*. This provided two rather dichotomous clusters that highly contrast each other in all variables. Cluster 1 (44.9 % of all students) shows, in comparison to Cluster 2 (55.1 % of all students), low Math Identification (*z-standardized mean*: -.66) but high Teaching Identification (.30). In line with that, students in Cluster 1 report low Self-Efficacy (-.76), high Shame (.64), low Intrinsic Value for School (-.69) and University (-.64) as well as low Attainment Value for Understanding (-.50). In contrast Cluster 2 shows higher Math Identification (.51), but lower Teaching Identification (-.23). Students report higher Self-Efficacy (.59), less Shame (-.49), higher Intrinsic Value for School (.53) und University (.49), and slightly higher Attainment Value for Understanding (.38). They also report slightly higher Attainment Value for Understanding (.31) compared to Cluster 1 (-.41). However, given the ceiling effect in this scale, I would not necessarily interpret this as an actual difference.

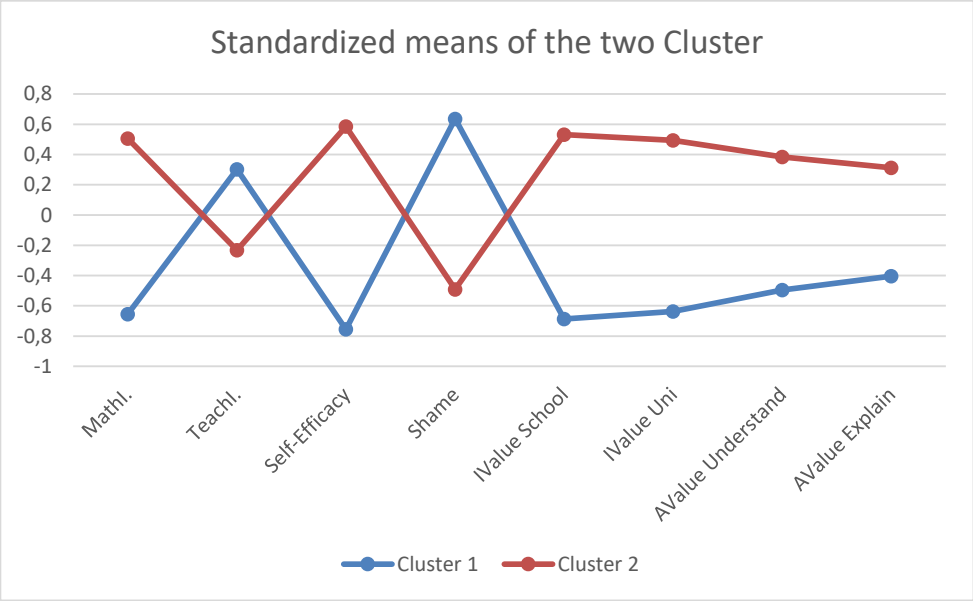

Figure 1: Display of the standardized means of the two Cluster

Preservice primary and special needs teachers were almost equally distributed through the clusters, as well as female and male students. However, all preservice primary teachers who opted to intensify mathematics had been distributed to Cluster 2.

Discussion

My aim in this paper was to bridge the social context of identity (operationalized as identification) with preservice primary teachers' overall affect from a quantitative perspective. In line with that, RQ1 investigated correlations between one's identification as a mathematician and as a teacher, where rather contrasting pictures could be found: While the latter was negatively correlated with Self-Efficacy and Motivation but positively with Shame, Identification as a mathematician was positively correlated with Self-Efficacy and Motivation, but negatively with Shame. Furthermore, Math and Teaching Identification were negatively correlated, indicating a dichotomous rather than an inclusive picture. In RQ2, this dichotomy was further established, given the cluster analysis revealed two contrasting clusters of students reporting either high Math and low Teaching Identification or vice

versa, accompanied by high Self-Efficacy and Motivation but low Shame or vice versa. At first, this confirms the theoretical understanding and sporadic evidence that low identification with mathematics seems to be related to overall low positive affect (cf. Gildehaus, 2024; Ingram et al., 2018). In contrast, higher identification indicates higher means in positive affective variables.

Surprising, if not yet striking, in these findings, is the clear dichotomy of the clusters, as well as the negative correlation between math and teaching identification. This suggests that preservice primary teachers in mathematics at the end of their university education have developed an "either-or" identification. They either see themselves as somewhat part of the mathematics community or they do not – which goes hand in hand with an overall problematic affective relationship to mathematics that may make it challenging to teach mathematics. It remains unclear if these "either-or" identifications are directly related to the earlier discussed often negative mathematics experiences in school (cf. Hodgen & Askew, 2007). However, the significant difference in the motivation for school mathematics between the clusters at least indicates that. Furthermore, these findings underline the importance of identity work in preservice teacher education and the relatedness of affect with the social context. Practical implications for teaching preservice primary teachers may point towards pedagogical practices that could help preservice teachers overcome their negative experiences (Lutovac & Kaasila, 2014) and build a ground for identification with the mathematics community.

Even though it is a strength of this analysis to provide empirical evidence for often theoretically assumed relations, our data sample was still small and from a specific national context. Its representative power is thus very limited, and further investigations towards the relation of affective variables and one's identification seem desirable – not only from an empirical perspective.

Emotions grounded in mathematics-specific personal epistemology

Robin Göller

University of Klagenfurt, Austria; robin.goeller@aau.at

This paper explores the formation of emotions and values situated in university mathematics education and grounded in students' personal epistemology. To do so, a case study based on four interviews with Alex, a high-achieving mathematics preservice teacher reporting predominately negative emotions towards her mathematics study, was analysed, revealing how her negative emotions emerge from discrepancies between her beliefs and her experiences at university regarding mathematics, the learning and teaching of mathematics, as well as the learning environment and the herein incorporated roles of students and lecturers. The findings give hints for theorising the formation of emotions and values grounded in mathematics-specific personal epistemology (PE) with practical implications to overcome alienation and exclusion in university mathematics education.

Keywords: Emotions, values, beliefs, personal epistemology, secondary-tertiary transition.

Introduction

The secondary-tertiary transition is accompanied by several difficulties (e.g., Gueudet, 2008), which are often linked to strong negative emotions (Di Martino & Gregorio, 2019; Göller & Gildehaus, 2021). Consequently, affect, and especially students' emotions, has emerged as a crucial topic that, however, is still rarely researched (Di Martino & Gregorio, 2019; Göller & Rück, 2022; Gueudet, 2008). The differences between school and university mathematics (cf. Gueudet, 2008) entail epistemic challenges regarding, for example, the nature of mathematics and mathematics learning, which has been described as "beliefs overhang" (Daskalogianni & Simpson, 2001), leading some students to disengage from mathematics portrayed as alienation, missing sense of belonging, or positioning as outsiders (Gildehaus et al., 2024; Lahdenperä & Nieminen, 2020; Solomon & Croft, 2016). Additionally, affective variables, such as mathematics-specific beliefs, values, and self-concepts, are associated with exam achievements, study satisfaction, and study dropout (Benden & Lauermann, 2023; Geisler, 2023; Göller & Gildehaus, 2024) and are closely related to emotions students experience when studying mathematics at university (Göller & Gildehaus, 2021).

This interplay of control and value appraisals with emotions is theorized and empirically proven by control-value theory in great detail (Pekrun, 2024). However, although social environments, sociocultural contexts, and personal beliefs are considered in control-value theory as influencing factors for students' control and value appraisals, the processes of assigning value to a specific situation are described and empirically analysed in far less detail. Therefore, the present paper aims to investigate the formation of students' mathematics-related values in light of their personal beliefs situated in the social environment and the sociocultural context of university mathematics education.

Theory

The theoretical perspective on mathematics emotions presented in this paper is vastly influenced by considerations of Op't Eynde et al. (2004; 2006a, 2006b). Learning is considered a form of engagement that enables students to actualise their identity by participating in activities in a specific

context (Op't Eynde et al., 2006a). This means that students are continuously challenged to integrate their past experiences with the way they experience themselves in the given context (here, the university mathematics learning environment) and its practices to discover meaning and to renegotiate or construct new meanings through their way of participating (Op't Eynde, 2004). These past experiences are thought of as being condensed in students' beliefs, which are defined as their implicitly or explicitly held subjective conceptions that are considered true (Op't Eynde et al., 2006b). Mathematics-related beliefs can refer to different objects, for example, to *mathematics*, to *mathematics teaching*, to the *self as a mathematician*, or to the *environmental context*, such as socio-mathematical norms or the role of the self and others in learning mathematics (Op't Eynde et al., 2006b). Through the personal relationship towards such beliefs, beliefs can be valued in the sense that they, for example, do not only refer to what mathematics, mathematics teaching, or the role of a mathematics teacher is but also to which aspects of mathematics or mathematics teaching are preferred by students or what they think the role of the teacher should be. Indeed, some students seem to value *instrumental/static* aspects of mathematics, such as knowing the rules and applying them correctly by performing the (schematic) calculations, while others rather value *relational/dynamic* aspects, such as figuring out why the rules work or puzzling over mathematics problems (Di Martino & Zan, 2010; Gildehaus et al., 2024; Göller, 2023). This system of mathematics-related valued beliefs is subsumed as *personal epistemology* (PE, cf. Hofer & Bendixen, 2012) in the following.

Students' *emotions* are theorised to arise from their evaluative interpretations – their appraisals – of the specific situation, which are grounded in their personal epistemology (Op't Eynde, 2004). This importance of appraisals for students' emotions aligns with psychological emotion theories (Pekrun, 2024; Scherer, 2019). Control-value theory, for example, elaborates in detail on the effects of control and value appraisals on different emotions (Pekrun, 2024). However, their personal epistemology is not always transparent to individuals. Often, they do not know a priori what they will find worthwhile acting upon; it emerges in the situation (Op't Eynde, 2004). Herein, it is the emotions students experience that reveal to them who they are and what they value in this specific situation (Op't Eynde et al., 2006a). Emotions are perceived as an act of participating in certain practices and grounded in the way students experience themselves in that context (Op't Eynde et al., 2006a), which in turn is theorised to build on past experiences and is manifested in values and beliefs that mirror students' personal epistemology. This means that studying, for example, joy or frustration implies analysing joyful or frustrating situations in the respective context (Op't Eynde, 2004) and to study students' personal epistemology, it appears fruitful to analyse joyful, frustrating, positively or negatively appraised situations for underlying values and beliefs that become apparent in this situation.

Research aims and research question

This paper aims to situate students' emotions in the specific context of university mathematics education by analysing the case of Alex for the interconnectedness of students' emotions, values, and beliefs and, building on that, exploring the formation of emotions and values situated in university mathematics education grounded in students' personal epistemology.

Research question: How are the emotions Alex experiences in her university mathematics study grounded in her mathematics-specific personal epistemology?

Methods

The case of Alex is theoretically chosen due to her rare combination of high mathematics achievement and negative emotions found in previous analyses of the data (e.g., Göller & Rück, 2022). According to control-value theory (Pekrun, 2024), this holds the potential to analyse the formation of emotions and their corresponding values and beliefs while mitigating the (often dominant) effects of achievement issues and control appraisals. Alex, a mathematics preservice teacher, was interviewed four times during her first year of study on her self-regulated learning processes and attitudes towards university mathematics. The first time, she was interviewed two weeks before the start of the lectures of her first semester while attending a preparatory mathematics course; the second time in the middle of her first semester, the third time at the end of her first semester, and the fourth time in the middle of the second semester of her university study. In her first semester, Alex attended two theorem-proof-focused pure mathematics lectures on linear algebra and mathematical foundations (logic, proof types, sets, finitary relation, functions, …) together with mathematics major students; in her second semester, a follow-up course on linear algebra together with mathematics major students and an elementary geometry lecture for preservice mathematics teachers. To pass these courses, students had to achieve 50 % of the points given for weekly exercises and pass a written exam determining the grade for the respective course at the end of the semester. Alex achieved the most points of all students in the weekly exercises of her first semester in the lecture on mathematics foundations, the third most in linear algebra (out of more than 200 students), and passed all her mathematics examinations with good grades. Nevertheless, Alex reported predominately negative emotions towards her mathematics study in the interviews.

All interviews were audio recorded, transcribed verbatim, and analysed using MAXQDA24. Following the considerations in the theory (cf. Op't Eynde, 2004), as a first step, all interview data of Alex were screened for words indicating positive (e.g., good, like, great) or negative (e.g., bad, annoying, stupid) appraisals as well as positive (fun, happy, (en)joy) or negative (e.g., frustrating, depressing, no fun) emotions. In the second step, the passages identified in this way were analysed regarding their underlying values and beliefs presented in the theory. These were then analysed in terms of the interconnectedness of emotions, values, and beliefs in the third step.

Findings

In the following, we first look at Alex's personal epistemology at the beginning of her study to set the ground for analysing the interconnectedness of emotions, values, and beliefs, which will be presented in the second part of the findings.

Two weeks before the lectures started: Alex's personal epistemology at the start of the study

Regarding the choice of mathematics as a study subject, for Alex, it had been clear "since the fifth grade that I had to continue (maths) somehow because I can't do without it," indicating a high personal value of mathematics (which here appears to be relatively general and independent of other persons). Regarding the choice of her second subject (physics), the prominent role of the respective teachers becomes apparent, especially regarding her emotions towards the respective subjects.

> I had actually planned to study biology, but I had a horrible biology teacher in secondary school. She literally took the joy out of it. And I had a great physics teacher, and since then, it's been fun.

As important skills for herself as a mathematics teacher, she mentioned "that I can explain well and have my class under control […] and that I master the content." Alex's personal epistemology regarding *mathematics teaching* here identifies good teaching through a prominent role of the teacher, who is competent, able to explain well, and controls the class.

More details about Alex's *valued beliefs about mathematics* can be found in the following excerpt:

Interviewer:	Can you describe what you find interesting about maths, what you enjoy about it?
Alex:	Hm, the numbers and calculating, that I somehow find the solution or get there in a roundabout way. [...] Hm, the graphs, I actually quite liked that. We used to draw things, that was kind of fun. And in analysis, with the functions, with the curve sketching [Kurvendiskussion], it was always the same. You had your scheme and could work according to it.
Interviewer:	And you found it important to have a scheme?
Alex:	Yes.
Interviewer:	Why?
Alex:	Otherwise, I wouldn't have known what to do with the function.

This excerpt indicates that Alex values *instrumental/static* aspects of mathematics, especially specified here by valuing calculating and working according to a predefined scheme. This suits with valuing a prominent role of the teacher, who explains what to do (here "with the function").

However, in this first interview, it seems that Alex could also develop positive emotions towards *relational/dynamic* aspects of mathematics, as is indicated here by her appraisal of proofs in the preparatory course: "They [the proofs] were actually fun here in the preparatory course." These positive appraisals can be traced back to her experiencing herself as being able to perform (possibly referring to *instrumental/static* aspects of mathematics), that "it worked out" when "something was given, and then you came to the same result as you wanted to prove." As we will see later, these positive experiences rely on a way of teaching in the preparatory course that fits her valued beliefs.

During the first year of study: A clash of valued beliefs and experienced learning situations

Noteworthy, Alex's personal epistemology hardly changed during her first year of study. On this basis, Alex experienced most learning situations with negative emotions, which can be traced back to discrepancies between her experiences and her valued beliefs, as will be illustrated in the following. Regarding the *environmental context* of learning mathematics at university, such discrepancies could be found in her personal relationship with the professor who gave the lectures, the style of the professor, his teaching style with the herein incorporated roles of students and lecturers, the style of the tutorials, as well as her perception of goals, valued beliefs, and strategies of her peers. As an example, we look at the very beginning of the interview in the sixth week of Alex's first semester:

Interviewer:	How are your studies going so far?
Alex:	It's quite exhausting and too much. [...] Actually, if mathematics weren't so bad, then it would be better because the new lectures are kind of stupid.
Interviewer:	Can you elaborate a little on that?
Alex:	I don't know; maybe if another professor were doing it, it would be better. [...] you sit there with the exercises: Yes, what does he actually want from me now? And we have to find our way through somehow. And in the lecture, he tells you what he wants, but you're not really allowed to ask questions, apparently. Or at least, if you ask questions, you make a complete fool of yourself. And I don't really need that.
Interviewer:	Why do you think asking questions makes you a fool? Do you have an example?

Alex: He always makes a mockery of it. Or: "Yes, that's trivial", or some weird stuff. And he also writes far too little on the blackboard. He says something but doesn't write it down. And somehow, you only have half notes. And in the end, you can't do much with them.

Firstly, the mathematics study is experienced as too "exhausting and too much", indicating high cost (negative value); it is appraised as "bad" and the lectures as "stupid". These appraisals are first directly referred to (the personal relationship with) the professor, which aligns with the prominent role of the teacher in Alex's personal epistemology (PE). In this personal relationship, Alex feels excluded and not valued, as becomes apparent later in the interview: "He said that he isn't interested in teacher training. He mainly refers to math majors and everything else. You notice that: 'Oh, you're just a preservice teacher.' That's somehow a bit annoying."

The teaching style Alex experienced contradicts her PE regarding the ability to explain well. Here, she experienced that the professor "writes far too little on the blackboard" so that "you can't do much with" the notes, indicating bad explaining (i.e., bad teaching in her PE). So, she experiences that in this university mathematics setting, students "have to find [their own] way through" and that there are no clear instructions on what "he actually wants from me", which contradicts her PE of teaching and also her *instrumental/static* valued beliefs regarding mathematics (see below).

All this, as well as the importance of asking questions in her PE, can be found in the following excerpt, especially in comparison to the preparatory course:

Alex: Maths is no longer fun here. It was fun in the preparatory course, but now, when you get a professor like him, and then in both maths lectures, you're really fed up. I hope to get a better one in the third semester because otherwise, I don't know if it still makes sense.

Interviewer: Can you tell me why that is? [...] That it's no fun, or what was better or different in the preparatory course?

Alex: We could ask questions to [the teacher of the preparatory course], and she explained things to us in such a way that we could do it. And she also wrote it down in such detail when you looked at it again at home that it was all okay. But here, you kind of miss the connections, and then, at some point, you get frustrated because it's just stuff you no longer understand.

Asking questions is emphasized here as an important part of Alex's PE, while the learning environment is experienced as obstructing these. In the lecture, the feared "mockery" of the professor and the risk to "make a complete fool of yourself", but also in tutorials and peer learning situations, she experiences others as "annoyed because I hold up everything, I hold up the business, and they're not so enthusiastic about that". Overall, Alex experiences the social environment at the university as not conducive to learning:

Alex: In the tutorials, I somehow always have one-to-one conversations with the tutor because the others don't give a shit or leave after half the time or right at the beginning. And when I ask a question, there's moaning at the back the whole time.

Interviewer: Really?

Alex: It's really annoying when you ask a question, and they start moaning. If they're not interested, then they can leave. I thought the tutorials were there to ask questions.

Interviewer: Yes, but why do you think the others don't ask questions in Linear Algebra? Why do you believe that is?

Alex: Because they're just trying to get above 50 per cent, and after that, they don't care. They just want to get through somehow. And they don't want to understand everything so precisely. They just want to pass somehow.
Interviewer: And how is that with you?
Alex: I want to understand it because if a teaching degree doesn't turn out to be my choice after all, then perhaps I would still have the option of a Bachelor's degree or, in general, I would need it for the final examination.

Because of these different goals, peer learning appears "useless" to her because there she experienced that "one person solves it and the rest copies it", while in her PE "it's better to discuss it".

Regarding her valued beliefs about mathematics, Alex enjoyed doing calculations – "Gauss [algorithm], it's fun if you can do a bit of calculating for once" – and disliked proofs, which is in line with her PE in favour of *instrumental/static* aspects of mathematics but also refers to the way she experiences herself in the given learning environment (cf. her experiences in the preparatory course).

Alex: Right now, with the stupid proofs. We now have an exercise sheet with proofs. And nobody knows how to do the proofs. I asked someone in the third semester, and he couldn't help me either. And that's quite depressing. I know a lot of people who are quitting because they can't cope with it. […]
Interviewer: Were there any tasks that you enjoyed that you liked?
Alex: Yes, when I had a matrix and had to do some calculations, a bit of calculating and not just proofs.

The frustration about this excluding learning environment and being confronted with "stuff you no longer understand" seems to crystallise in her opposition to proofs that "nobody knows how to do", which are identified as an essential feature of this university mathematics learning environment. All this leads to a situation in which Alex experiences that studying mathematics is "no fun anymore" and especially a devaluation of proofs, which are appraised as being "pointless" and something "you never need at school". We conclude with an excerpt exemplifying this argumentation:

Interviewer: Has your attitude towards mathematics changed during your studies so far?
Alex: It's shittier.
Interviewer: Yes?
Alex: I liked it at first, but now/ Every time I go to [linear algebra], I think to myself: Oh my God, I hope it's over quickly. [...] It's no fun anymore. […] There were mainly proofs, for me that's something, I can't stand that, I don't need that somehow, it's pointless for me. Because moving letters back and forth, that's not really my thing.
Interviewer: Well, is proving only moving letters back and forth? Is that so?
Alex: Yes, I see it that way. […] I think it's pointless; you can't do anything with it.

Discussion

The presented case study of Alex, a high-achieving mathematics preservice teacher who reported many negative emotions toward her mathematics study, focussed on the formation of mathematics-specific values grounded in personal epistemology (Hofer & Bendixen, 2012; Op't Eynde, 2004) to better understand students' emotions in the secondary-tertiary transition. Thereby, our theoretical considerations regarding the analysis of emotions alongside students' valued beliefs about mathematics, mathematics learning, the self as a mathematician, and the mathematics learning environment (Op't Eynde, 2004; Op't Eynde et al., 2006a) have proven fruitful for further theorising the formation of values and emotions. Indeed, the findings reveal that Alex experienced the university mathematics learning environment as opposing her personal epistemology in all these aspects.

Regarding her valued beliefs about mathematics, Alex's negative emotions can be traced back to a mismatch of her positive appraisal of instrumental/static aspects of mathematics that did not change during her first year of study and conflicted with the experienced focus on proofs and the way they were taught and learned in this specific university mathematics learning environment. The findings indicate that this "beliefs overhang" (Daskalogianni & Simpson, 2001) that was also found in other studies is not only a cognitive issue that can be solved by acquiring knowledge but additionally requires an adaption of values attached to such beliefs for positive appraisals towards university mathematics (cf. Göller, 2023). The results on Alex's experience of proofs in the preparatory course indicate that with a teaching environment aligned to Alex's other valued beliefs, this adaption could have been possible but did not materialise, for example, due to her experiences of exclusion in the mathematics university learning environment. Indeed, the way she experienced teaching and the herein-incorporated roles of students and lecturers at the university that obstructed a realisation of her valued beliefs about teaching and learning mathematics (e.g., asking questions, discussing exercises) highly contributed to a missing sense of belonging and a positioning as an outsider (Gildehaus et al., 2024; Lahdenperä & Nieminen, 2020) and even seemed to play a bigger part in her emotional alienation (Solomon & Croft, 2016) from university mathematics than the mathematics difficulties and challenges of her valued beliefs about mathematics. This gives hints on how changes towards more inclusive teaching practices have the potential to ease transition difficulties without changing mathematics contents (Lahdenperä & Nieminen, 2020).

In line with our theoretical considerations, Alex's emotions and appraisals of the mathematics learning environment are highly individual and based on her personal experiences and epistemology. Such results should not be generalised without further similar studies. Nevertheless, the findings call for a fundamental reflection and reconsideration of university mathematics teaching practices, which create such toxic-experienced learning environments even for the highest-achieving students.

Connections between epistemic emotions and control actions in linear algebra

Inés M. Gómez-Chacón[1,2] and Adrián Bacelo[1]

[1]Universidad Complutense de Madrid (UCM) and [2]IMI, Spain; igomezchacon@mat.ucm.es

Emotions related to knowledge acquisition (epistemic emotions) play a key role in epistemic processes in linear algebra. In this study we explored the relationship between epistemic emotions and control actions in 99 undergraduate mathematics and computer engineering students in a task requiring the use of computational thinking and linear algebra concepts. Control (theoretical, semiotic and technological) and appraisals as antecedents of epistemic emotions are analyzed. It is shown that mathematics students give more importance to control elements associated with formalization of mathematic concept while computer engineering students give more importance to emotions associated with the instrumental and technological control dimension.

Keywords: Epistemic emotions, control-value theory, linear algebra, mathematical working spaces.

Introduction

The research we present arises from the need to connect mathematical thinking and computational thinking in university teaching with students of the Bachelor's Degree in Mathematics (DM) and the Bachelor's Degree in Computer Engineering (DCE). Research has shown that engineering students have less interest in mathematics, even though it is essential knowledge for their studies. Mathematics contents (e.g. linear algebra) taught in the first courses of computer engineering present a great complexity for the student due to their high level of abstract reasoning (Stewart et al., 2018; Gómez-Chacón et al., 2015), so it is necessary to propitiate actions and resources that materialize reflection on contents and highlight actions of "control" of mathematical work.

To study students' emotions when performing a mathematical tasks related to computational thinking in algebra, the control-value theory of emotions of Pekrun (2006) was used in coordination with the characterization of the control action in didactics carried out from the Theory of Mathematical Working Spaces (Kuzniak & Nechache, 2023; Gómez-Chacón & Marbán, 2024). This coordination of theoretical frameworks allows categorizing the type of epistemic emotions experienced by students when they engage in processes of solving computational thinking tasks related to concepts of the subject of linear algebra. This study addresses the following research question: What evidence is there of relationships between epistemic emotions and mathematical control actions experienced by DM students and by DCE students in solving computational thinking task?

Theoretical framework

Epistemic emotions

Pekrun (2006) considers academic emotions as the set of emotions that are triggered in academic contexts, classifying them into: social emotions, thematic emotions, epistemic emotions and achievement emotions. Epistemic emotions are defined as emotions that arise when their object is knowledge and the process of knowing (Gómez-Chacón, 2017; Pekrun et al., 2017). They are

triggered by knowledge, the characteristics of the tasks and the cognitive activity of the subject when solving them. These investigations agree in pointing out control, value, novelty, complexity and achievement (or epistemic goals) as antecedents of epistemic emotions. Epistemic emotions are related to knowledge characteristics of cognitive activities. Empirical results in mathematics education support the idea that epistemic emotions can influence learning and performance (D'Mello & Graesser, 2012; Gómez-Chacón, 2017; Gómez-Chacón & Marbán; 2024; Schukajlow et al., 2017; Schubert, Pekrun, & Ufer, 2023).

Control-value theory provides an integrative framework for analyzing the antecedents and effects of epistemic emotions (Pekrun, 2006). This theory focuses on two variables that influence internal evaluations of an epistemic process and cognitive processes: (1) the control (control appraisals) they have over the activity and (2) the value (value appraisals) they assign to the activity. Control appraisals indicate the extent to which learners see themselves in a position to construct and solve the problem, relating it to the knowledge needed and related skills. Value refers to the importance the learner attaches to the activity.

Control actions in didactics

The use of control in mathematics teaching has its roots in Polya's (1945) reflections on mathematical problem solving and, later, in Schoenfeld's problem-solving approach to mathematics education (Schoenfeld, 1985). More recently, and in connection with didactic theories, the nature of controls is being deepened. Thus, in the development of the methodological aspects of the *Theory of Mathematical Working Spaces* (ThMWS), control activities have been highlighted as an aspect to be deepened, being developed from different approaches. Kuzniak and Nechache (2023) from the ThMWS characterize the nature and role of controls in mathematical work, proposing an analysis methodology based on different criteria of the ThMWS: conformity of the resolution processes to a mathematical paradigm, the completeness of the work flow in the MWS and, finally, the correctness of the results obtained. In the ThMWS framework was introduced the concepts of semiotic, technological and theoretical controls: *Semiotic control* refers to the selection and use of a semiotic tool based on the use of signs and representations. It ensures that these signs have been properly chosen and that they have been interpreted. Associated with semiotic genesis, it guides and validates the visualization process.

Technological control refers to the decision taken to select one or more technological tools (physical or digital artifacts, algorithms). This type of control is used to ensure the correct use of these tools as a technological instrument. Combined with instrumental genesis, it guides and validates the construction process.

Theoretical control refers to decision-making on the choice of theoretical tools (theorems and properties of the theoretical frame of reference) and the forms considered valid in the paradigm adopted in the reference ThMWS. Associated with the discursive genesis, it orients and validates the demonstrative discourse of the proof.

These three types of control work together to validate the interactions between the different genesis of the mathematical working space.

Objectives

The following objective is proposed: To identify what connections are established between epistemic emotions and control actions experienced by DM students and by DCE students when solving computational thinking tasks in linear algebra.

Method

The study is part of a teaching experiment (Cobb, et. al., 2003) carried out with two groups of students, one from the DM from the UCM university (55 students) and the other from the DCE from the URJC university (44 students). Both groups of students were asked to form teams containing students from both degrees (interdisciplinary groups) to design and develop a digital tool for teaching matrices to 5th and 6th grade students.

Task statement:

> The objective of this practice is to make a first prototype (web and mobile) of a digital tool, serious game or video game that works mathematical skills. To do so, we will consider a mathematical object highly used in many aspects of our life: the matrix. [...] Therefore, this tool is going to be asked to explain in an exhaustive and formal way the concepts of matrix, matrix addition, matrix subtraction and matrix transposition. Specifically, it is requested to include activities or resources that allow the user to assimilate all of the above in a simple way, but without losing the mathematical background by working from real world examples.

The most advanced concept considered is the transpose of a matrix. This requires the associated theoretical foundations: operation, properties and applications. In addition, the mathematical and computational algorithms used must be considered.

The development process followed was as follows:

- Groups of 4 or 5 people are formed in each degree and interdisciplinary teams are formed with a group from the Degree in Mathematics and a group from the Degree in Computer Engineering.
- The different interdisciplinary teams were given the task statement and additional information to help them in the process of creating the digital tool.
- The teams begin to create a prototype of the digital tool. There is constant communication between the DM students and the DCEs that make up the interdisciplinary teams.
- When there is a first version of the tool, the DM students carry out an expert evaluation.
- With the data obtained, a second version of the tool is made. The evaluation of this prototype is carried out by the DCE members of the interdisciplinary teams.
- A third version is made based on all the comments received and a heuristic evaluation of the prototype is carried out by the DM students of the team itself.
- The final version of the tool is made, and a list of improvements is given.

The sources of data collection are varied: the different prototypes of the digital tools developed by the interdisciplinary teams, partial and final reports on the computational development of the tool, questionnaires on user interaction with the digital tool, audio and video recordings of user interactions

with the tool, communications via WhatsApp and/or email between the members of the interdisciplinary teams and individual self-assessment questionnaires on epistemic emotions and control actions. Figure 1 shows some examples of items from the latter questionnaire.

3. Indicate how often you have experienced some of these emotions: Surprise (E1), Curiosity (E2), Enjoyment (E3), Interest (E4), Anxiety (E5), Confusion (E6), Confidence (E7, Frustration (E8), Boredom (E9), and it is given as response options: Not at all, Rarely, Sometimes, Often, and Always.

4. Choose the one you have experienced most frequently:
Emotion: ----------

4.1 Now focus on the emotion you have chosen What were you doing in the problem when you experienced *that emotion*?

4.2. Indicate how often you have experienced the following processes when experiencing the chosen emotion:

I controlled the situation (C1), I understood the situation well (C2), I made enough effort (C3), I thought I could influence to solve it (C4), I was able to predict what was going to happen in that situation (C5), I was attentive and focused on the problem (C6), I was able to break it down into simpler problems (C7), and it is given as a response option: Not at all, Rarely, Sometimes, Often and Always.

Figure 1: Examples of self-assessment questionnaire items

Since two types of data were used (discursive responses to the questionnaire and scale-type responses), two analytical approaches were employed. For the discursive data, a qualitative approach based on cross-checking the responses by three researchers was used. The inductive analysis process generated categories organized in two dimensions: epistemic emotions and control actions (semiotic, technological and theoretical) in order to identify types of control that are encompassed in the set of interactions between students of the Degree in Mathematics and the Degree in Computer Engineering that can be described thanks to the circulation of work in computer applications. And for the quantitative analysis, the implicative statistical analysis is applied for modal variables (Lagrange, 1998), with 5 modalities (respectively to the values 1, 0.75, 0.5, 0.25 and 0.). The variables emotions (E1, E2,..., E9) and control actions (C1, C2,..., C7)). The cohesive tree, which allows us to obtain a set of rules and meta-rules that express causal relationships between the epistemic emotions and control actions variables used by the students in the task. Cohesion arises as a measure of the propensity quality of a rule of type R: a → b as an asymmetric relationship between two variables, where their values lie within the range [0, 1].

Results

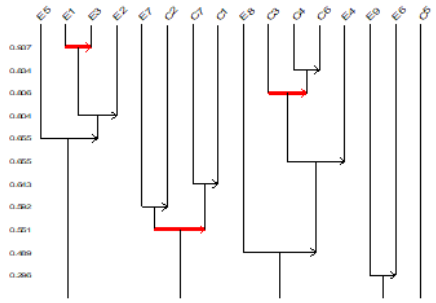
Relationships between epistemic emotions and control actions

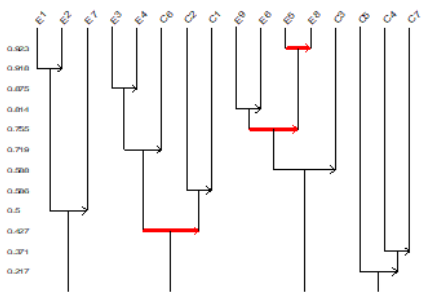
We analyzed the responses of the questionnaires related to epistemic emotions and control dimensions, exploring the similarities and cohesion between variables in order to identify clusters and establish R-rules that allow us to affirm associations between variables and between dimensions.

In the DM, the variables gathered up to level 14 of classification have a low similarity index and the significant node is the union of emotion and control variables: (((E7 C7) (C1 C2)) ((C3 C4) (C5 C6))). Thus, the deduction we can draw from these relationships is that “people who have confidence (E7), know how to decompose into simpler problems (C7) and understand the problem-situation (C2) tend

to think they can influence the problem (C4) and make an effort (C3) because they can predict the resolution (C5) and are attentive and focused (C6)". The variables with the highest similarity index are at level 1 with an index of 69% (E5 E8), allowing us to affirm that those with anxiety (E5) tend to be frustrated (E8).

In the DCE, the variables gathered up to level 14 of classification have a low index of similarity and the significant node is the union of variables of emotions and control: (((E7 C7) (C3 C4)) ((C1 C2) (C5 C6))). Thus, the deduction we can draw from these relationships is that "people who have Confidence (E7), know how to decompose into simpler problems (C7), make an effort (C3) and think they can influence the problem (C4) tend to think they are able to control the situation (C1), understand the problem-situation (C2), predict a resolution (C5) and be attentive and focused (C6)". The variables with the highest similarity index are at level 1 with an index greater than 90% (E5 E8), allowing us to affirm that those with anxiety (E5) tend to be frustrated (E8).





Bachelor's degree in mathematics (DM)	**Bachelor's degree in computer engineering (DCE)**
	
Level 1 of classification: (E1 E3) cohesion: 0.937 Level 3 of classification: (C3 (C4 C6)) cohesion: 0.806 Level 9 of classification: ((E7 C2) (C7 C1)) cohesion: 0.551	Level 1 of classification: (E5 E8) cohesion: 0.923 Level 5 of classification: ((E9 E6) (E5 E8)) cohesion: 0.755 Level 9 of classification: ((E1 E2) E7) cohesion: 0.5 Level 10 of classification: (((E3 E4) C6) (C2 C1)) cohesion: 0.427

Figure 2: Cohesive tree task by students of the Bachelor's DM and Bachelor's DCE

In the DM this non-symmetrical classification of the classes brings us closer to the reality of the data. We indicate that only those variables with an implicative intensity greater than 0.5 have been joined and then organized according to cohesion (Fig. 2). The cluster with cohesion greater than 0.5 is ((E7 C2) (C7 C1)), whose meaning is located in the association of epistemic and control emotion variables and allows us to state: "people with confidence (E7) and who understand the problem-situation well (C7) tend to decompose the problem into simpler problems (C2) and control the situation (C1)". Also, we highlight the cluster (C3 (C4 C6)) established at a level higher than 0.806 of cohesion and in red in the tree, since it is a significant node. Its meaning is located in the association of variables of the control dimension and allows us to state: "In general, people who have made an effort (C3) usually think that they could influence to solve it (C4) and have been attentive and focused on the problem (C6)". The cluster with a cohesion index of 0.937 (E1 E3) refers to epistemic emotions and allows us to state that: "those who have experienced surprise (E1) usually experience joy (E3) in the resolution". In the DCE, the significant nodes are at levels 1, 5, 9 and 10 (Fig. 2). We highlight the cluster ((E9 E6) (E5 E8)) established at a level of almost 0.75 of cohesion and significance. This cluster integrates

variables of epistemic emotions and the meaning of the class is: “those who experience boredom (E9) and confusion (E6) often experience anxiety (E5) and frustration (E8)”. Also, in relation to the epistemic emotions experienced we find the cluster (E5 E8): “those who experience anxiety (E5) often experience frustration (E8)”. Referring to the relationship between epistemic and control variables, the cluster (((E3 E4) C6) (C2 C1)) stands out with an index of 0.42. This allows us to state that “those who experience joy (E3) and interest (E4) and pay attention and concentration (C6) tend to understand the problem (C2) and think they can control the situation (C1)”.

Control actions

An overall qualitative analysis of the responses of the interdisciplinary teams and the transcription of communications via WhatsApp and/or email between the team members allows us to qualify some aspects of control by the DM students when they review what has been elaborated by the DCE students within the interdisciplinary team itself. Related to the concept of matrix itself, they point out the need to explicitly include the definition of matrix in the prototype. Several of them indicate that it is not enough to put the image of the matrix, but that it must be written formally. This constitutes an element of semiotic control.

A theoretical control element would be the indication that the basic elements that form a matrix must be defined: row, column and order. It is emphasized that these properties are necessary not only to understand what a matrix is, but also for the proper development of a transposition algorithm. Another element of theoretical control is the inclusion of real applications and examples, which help to better understand the concept and the elements associated with it.

If we analyze the control elements related to the transposition itself, we can find that by not being clear about the concepts of matrix, row, column and order, this leads to a poor understanding of how the transposition works. Therefore, this again reflects an element of theoretical control. In addition, the explanation of the process itself is not understandable and is requested to be clearer, more formal and supported by practical examples. This is reflected in the following dialogue between students from one of the interdisciplinary teams regarding the explanation of the transpose matrix:

DM student 1:	Okay, you just told us that you don't understand the explanation of the transpose.
DCE student 1:	Could you give us an example of how to explain it easier?
DM student 1:	We have explained it first with a 2x2 matrix and in steps and then he did it well.
DM student 2:	I think that in general it is fine, but the most important thing is to reinforce the explanations at the beginning. Because otherwise they get very lost, like what columns and rows are and how they work.

One element of technological control that is indicated is to drag the elements instead of simply pointing to them. This clearly aids the user in their resolution work because it is more intuitive to make the change they need to make.

Discussion and conclusions

In this study we investigated the connections between epistemic emotions experienced by computer engineering and mathematics students when solving tasks that require control in mathematical work in computational thinking tasks in algebra. To study the connections between epistemic emotions and

reasoning, theoretical notions from control value theory (Pekrun, et al., 2017) and mathematical work theory (Kuzniak & Nechade, 2023) were combined.

The data show that the study of the similarities between the variables in the DM and DCE students does not show any difference between them. In both groups, the control variables are linked to confidence in knowing how to solve adequately. Anxiety is linked to frustration in the failure to solve.

In the case of the causal relationship between variables -expressed by the cohesion index-, we can observe differences between the students of both grades. In the case of the GMs, there is a strong association of control variables, relating effort, ability to influence the problem and concentration. This can be explained by the importance given by mathematicians to formalization when explaining mathematical concepts. In addition, it reflects the importance underlying the training they receive that concepts must be constructed from the most basic and without ever losing sight of the objective to be achieved. In addition, it appears related to control variables the emotion of confidence, which, as we have indicated above, has to do with a good result in the work performed (Gómez-Chacón, 2017).

In the case of DCEs, significant associations appear between negative emotion variables. Boredom, confusion, anxiety and frustration are related. And with high cohesion, anxiety and frustration in relation to mathematical content (Stewart et al., 2018; Gómez-Chacón et al., 2015). It should be noted that the relationship between joy and interest (positive emotions in this case) and the elements of concentration control, understanding and control of the problem (which also appeared in a certain way in the DMs) appears in a slight way. Implicative statistical analysis reveals that the DCEs give greater weight to emotions, and this leads them to the mathematical control elements in the task. Qualitative analyses of conversations between the student groups about intermediate control steps during solving allow us to qualify the interaction between emotion and type of control. Frequently the indications by DMs are related to the theoretical contents associated with the transposition of matrices while DCEs refer to the instrumental and technological control dimension. Therefore, we can conclude that DMs give more importance to control elements linked to formal content when facing the task while DCEs give priority to the emotions they feel and play a more important role when developing that same task. Finally, we note that for an extension of the research and that the results may allow generalizations about the elements compared, it is important to consider the limitations derived from the roles in the interdisciplinary groups and their involvement in the task; and the validity of the conclusions by triangulating the responses in different contexts.

"Calculating with numbers and then finding a specific result" – Exploring students' conceptions about mathematics and doing mathematics and possible relations to mathematics teaching

Ramona Hagenkötter

University of Siegen, Germany; ramona.hagenkoetter@uni-siegen.de

Based on the student conceptions of mathematics framework, the present paper aims to explore students' conceptions about mathematics and, especially, doing mathematics as well as possible relations to mathematics teaching by also considering the mathematics teacher's conceptions and intention to teach mathematics. For this purpose, I analysed additional data from 12 9th graders and their mathematics teacher from an exploratory interview study. The results indicate that the teacher's intention to convey to her students that mathematics is a coherent system and that doing mathematics is a sense-making process does not get through to most of her students, who associate mathematics and doing mathematics primarily with arithmetic and finding results. Possibilities for counteracting this are discussed.

Keywords: Students' conceptions, mathematics teachers' conceptions, doing mathematics, mathematics teaching.

Introduction

Students' conceptions about mathematics, which represent a "set of conscious beliefs" (Furinghetti, 1996, p. 20), are likely to be interrelated with their learning, motivation and self-concept (e.g., Grouws et al., 1996; see also, e.g., review by Østergaard, 2024). For example, the results of a study by Grouws et al. (1996) reveal differences in students' conceptions of doing and learning mathematics between mathematically talented and average high school students: While mathematically talented students consider doing mathematics as a sense-making process in which one must rely on personal thought and reflection to establish the validity of knowledge, for average high school students doing mathematics often means implementing known procedures and formulas and accepting mathematically truth as established by others than depending on logical thought to deduce mathematical knowledge. As, for instance, the results of the Third International Mathematics and Science Study (TIMSS/III) for Germany (Köller et al., 2000) show, such limited conceptions of students about mathematics as a mere application of solution algorithms may negatively influence their interest, learning and, thus, achievement.[1] The conceptions of students about mathematics are probably largely based on their experiences in mathematics class (e.g., Schoenfeld, 1994), which, in turn, consist of perceptions that originate from mathematics teachers, schoolmates and learning materials. In particular, mathematics teachers have a major influence, among other things, through their curricular decisions (e.g., Furinghetti & Pehkonen, 2000). With regard to mathematics teaching,

[1] Please note that Köller et al. (2000) actually investigated students' epistemological beliefs about mathematics. However, following Thompson (1992, p. 130), "the distinction [between beliefs and conceptions] may not be a terribly important one". Therefore, the present paper also draws on research on beliefs about mathematics.

Schoenfeld (1994, p. 53), for example, emphasizes the importance of engaging students "in the practices of doing mathematics and, as a result, […] [having] them develop a sense of discipline (i.e., a mathematical perspective) consistent with that held by mathematicians." This seems to be of particular importance when considering mathematic classes in terms of figured worlds (e.g., Boaler & Greeno, 2000) in which students are not only viewed as learners of mathematics, but as individuals negotiating a sense of self. Against this background, the present paper aims to explore students' conceptions about mathematics and, especially, doing mathematics as well as possible relations to mathematics teaching by also taking the mathematics teacher's conceptions and intention to teach mathematics into account.

Theoretical background

According to Schoenfeld (1994, p. 58), "mathematics is a 'hands-on', data-based enterprise for those who engage in it […] [and] doing mathematics is doing science", meaning systematizing knowledge based on observations, study and experimentation carried on in order to determine the nature or principles of what is being studied. What makes it mathematics for him, compared to the natural sciences, is the unique character of the objects being studied and the tools of the trade. However, as the results of a review by Østergaard (2024) on students' beliefs about mathematics as a discipline – in which the terms beliefs and conceptions were considered as similar – show, students often do not view mathematics as described by Schoenfeld (1994), but as a static, rigid and rule-based discipline. For example, students often believe that mathematical problems only have one correct answer and can only be solved using the correct rule, formula or procedure, usually shown by the teacher. Moreover, students regard mathematics as a fragmented set of rules and formulas that they have to memorize and apply appropriately. This represents the dualistic perspective on mathematics as opposed to the relativistic perspective, from which mathematics is seen – in line with Schoenfeld's (1994) description – as a dynamic, relativistic and applicable "science of patterns". The results of the review further reveal that these conceptions about mathematics are not conductive for students' learning, motivation and self-concept. For example, as already mentioned, in their study on students' conceptions about mathematics, Grouws et al. (1996) found differences in students' conceptions of doing and learning mathematics between mathematically talented and average high school students. Referring to Schoenfeld's work, among others, they distinguish in their *student conceptions of mathematics framework* seven dimensions of students' conceptions about mathematics, namely composition of mathematical knowledge, structure of mathematical knowledge, status of mathematical knowledge, doing mathematics, validating ideas in mathematics, learning mathematics and usefulness of mathematics. For each dimension, they distinguish between two poles, which correspond to the dualistic and relativistic perspective on mathematics described above. Figure 1 provides an overview of the dimensions and their poles. For more detailed descriptions of the single dimensions and their poles, see Grouws et al. (1996). With regard to students' conceptions about doing mathematics, the results reveal that most mathematically talented students view doing mathematics as a process of sense-making that involves figuring things out more than just applying known procedures and facts. Moreover, most of them do not believe that the ability to use a formula accurately is sufficient to understand the mathematical concepts underlying the formula. In contrast, for the majority of the average students, the accurate use of formulas represents understanding and

good problem solving depends on the availability of formulas. Regarding students' conceptions about learning mathematics, the results further show that the average students associate learning mathematics more strongly with memorization than the mathematically talented students.

Dualistic	⟷	Relativistic
1. Composition of mathematical knowledge		
Facts, formulas and algorithm	⟷	Concepts, principles and generalisations
2. Structure of mathematical knowledge		
Collection of isolated pieces	⟷	Coherent system
3. Status of mathematical knowledge		
Static entity	⟷	Dynamic field
4. Doing mathematics		
Results	⟷	Sense-making
5. Validating ideas in mathematics		
Outside authority	⟷	Logial thought
6. Learning mathematics		
Memorizing	⟷	Constructing and understanding
7. Usefulness of mathematics		
School subject with little value	⟷	Useful endeavor

Figure 1: Overview of the dimensions of the student conceptions of mathematics framework by Grouws et al. (1996) and their poles ranging from the dualistic to the relativistic perspective on mathematics (see also Østergaard, 2024, p. 54)

As emphasized, for instance, by Schoenfeld (1994), students' conceptions about mathematics arise from their experiences with mathematics that predominantly take place in the mathematics classrooms. Therefore, he claims:

> […] if we believe that doing mathematics is an act of sense-making; if we believe that mathematics is often a hands-on, empirical activity; […] if we believe that learning mathematics is empowering and that there is a mathematical way of thinking that has value and power, then our classroom practices must reflect these beliefs. (Schoenfeld, 1994, p. 60f.)

However, as, for example, the results of an interview study by Boaler and Greeno (2000) reveal, students often depict a different picture of their mathematics lessons. Most of the students surveyed describe their mathematics lessons mainly through their teacher reviewing homework, explaining methods at the board and assigning questions to be completed and, thus, portray an image of mathematics teaching that afforded received knowing. Given that "students do not just learn mathematics in school classrooms, they learn to *be*" (Boaler & Greeno, p. 188), the practices of teaching do not only define the knowledge that is produced, mediated by the beliefs that students develop about mathematics and learning in response to different teaching methods, but also their sense of self. As a result, many able students may leave mathematics because they do not want to author their identities as passive receivers of knowledge. At the same time, students may choose

mathematics as their main field of study based on their experiences in class and their limited conceptions about mathematics, which may lead to significant problems as studying mathematics in upper grades, such as secondary schools or at university, requires different components of mathematics (see also, e.g., Pehkonen & Törner, 1999). How mathematics classes are organized and conducted depends, in turn, on how mathematics teachers view mathematics (e.g., Grouws et al., 1996) and on their curricular decisions (e.g., Furinghetti & Pehkonen, 2000). For example, the results of a case study by Cooney (1985) indicate that the teacher's conception of mathematics as problem solving influences his instructional decision and the curriculum he implemented. However, mathematics teachers likely choose to become school teachers of mathematics because they preferred the practice of mathematics teaching they had experienced in school, namely mainly receiving knowledge and, thus, continue teaching received forms of knowing (e.g., Boaler & Greeno, 2000).

Against this background, the present paper aims to obtain a (more) comprehensive view of students' conceptions about mathematics and possible relations to mathematics teaching. For this purpose, students' and their mathematics teacher's conceptions and intention to teach mathematics are considered together. In light of, on the one hand, the differences between mathematically talented and average students' conceptions about doing and learning mathematics found in the study by Grouws et al. (1996) and, on the other hand, the importance of engaging students in the practices of doing mathematics in order to develop a mathematical perspective (Schoenfeld, 1994), I focus especially on the conceptions about doing mathematics.

Methods

To address this research objective, I analysed additional data from an exploratory interview study (see Hagenkötter et al., 2022) that has not yet been analysed. Here, I focus on a subsample of 12 9th graders (age: $M = 14.08$, $SD = 1.31$; 83% male; interest in mathematics between 1 = no interest and 6 = high interest: $M = 4.08$, $SD = 1.31$; school grade in mathematics between 1 = very good and 6 = unsatisfactory: $M = 2.08$, $SD = 0.90$) and their mathematics teacher (female; 5 years teaching experience). I interviewed the students as well as the mathematics teacher in June and July 2021 using semi-structured interviews. The whole interviews with the students lasted between 9 and 16 minutes and with the teacher around 30 minutes. The interview protocol contained the following three parts, with additional questions for the mathematics teacher about her teaching of mathematics: (1) View on mathematics and doing mathematics, (2) Typical mathematical activities of mathematical scientists, (3) Typical mathematical activities during mathematical hands-on experimentation. To address the research objective of the present paper, I analysed students' and the teacher's responses to the questions of the first part of the interview (which have not yet been analysed).

In the first part of the interview, the students and the mathematics teacher were asked the following questions: "What is mathematics for you?" and "What does it mean to you to do mathematics?" I also asked the mathematics teacher what it means to her to teach mathematics. In addition, both students and the mathematics teacher were asked to present at least one example of a task in their schoolbook that they felt required typical mathematical activities and to explain their choice. I analysed the data using qualitative content analysis following Kuckartz (2018). In doing so, I used a deductive-inductive category system, in which the deductive categories arise from the student conceptions of

mathematics framework by Grouws et al. (1996; see also Figure 1). More specifically, I first marked the relevant parts (i.e., words, lines and segments) of the students' and teacher's answers for achieving the research objective of the present paper. I then categorized these parts into the dimensions of the student conceptions of mathematics framework and assigned them, if possible, to one of the poles. For this, I did not consider the single statements separately, but in the overall context of the interview. Finally, I related the students' answers to the teacher's answers and formed inductive categories.

Results

Mathematics teacher's conceptions about mathematics and doing mathematics and intention to teach mathematics

With regard to the mathematics teacher's conceptions about mathematics and doing mathematics, the results show that the mathematics teacher interviewed regards mathematics as the "language of science". For her, mathematics is a coherent system in which "everything builds on each other somehow […] and it's not just knowledge that exists side by side, so it's not knowledge that can be simply memorised". Accordingly, with regard to the teaching of mathematics, it is important for her to make it clear to her students that "everything builds on each other […] [and] how much it's all connected". When asked what she considers to be typical mathematical activities for her grade 9 students, she listed the mathematical subjects they had dealt with during the school year: "We have done the Pythagorean theorem and the intercept theorem. We have discussed linear functions and systems of linear equations. Now, we are currently doing power. […] And the circle […]. So, a lot of geometry and a bit of functions." For her, especially application tasks with real-world contexts, which they deal with "relatively often in class, but not nearly as much as we should", are tasks in which students carry out typical mathematical activities. In addition, she named proving as typical for doing mathematics, but also mentioned that this "doesn't happen very often in lower secondary education". Nevertheless, in her mathematics lessons, the students, for example, carried out a proof of the Pythagorean theorem and a hands-on exploration of Pi.

In summary, the mathematics teacher interviewed shows conceptions that can be assigned to the relativistic perspective of mathematics. In her mathematics lessons, she particularly aims to convey to her students that mathematics is a coherent system and uses tasks demonstrating that doing mathematics is a sense-making process (i.e., proof of the Pythagorean theorem, hands-on exploration of Pi) and that mathematics is a useful endeavour (i.e., application tasks with real-world contexts).

Students' conceptions about mathematics and doing mathematics

With respect to students' conceptions about mathematics and doing mathematics, I observed that all of the students interviewed ($n = 12$) associate mathematics and doing mathematics primarily with numbers and arithmetic. For example, S4 answered to the question of what it means to do mathematics: "Calculate as much as you can in your head and if you can't do it anymore, then use the calculator if there are too many numbers." In this context, many students explicitly refer to finding results ($n = 8$), which corresponds to the dualistic perspective of doing mathematics. S5, for instance, states: "Doing mathematics is actually just calculating the task you're given. […] When I do that, I simply calculate the task for a very long time until I have a good way of calculating and then, finally,

also the correct solution." Similarly, S7, as quoted in the title of the present paper, answers: "Calculating with numbers and then finding a specific result". Students' choices of exemplary tasks that they felt require typical mathematical activities also demonstrate that they associate doing mathematics mainly with arithmetic, as most of them chose exercises which merely require arithmetic, such as solving systems of equations or calculating areas. Regarding students' conceptions about the usefulness of mathematics, the results reveal a mixed picture. While three students consider mathematics only as a "school subject" (e.g., S3), five students emphasise the relevance of mathematics and working mathematically outside of school. In doing so, the students refer to concrete everyday life situations, such as "calculating prices in the supermarket" (S5), or more generally to the fact that they learn "very important basics for everyday life" (S8). Furthermore, two of them also point out that mathematics is a "science that involves working with numbers in some way" (S8). Moreover, with regard to the learning of mathematics, two students explicitly refer to memorizing. For example, when presenting an example of a task in the schoolbook that he felt requires typical mathematical activities, S13 noted: "Above all, you have to know the formulas […] you have to learn them by heart". In contrast, individual students refer to "logical thinking" (S5) when solving tasks or to "brain teasers" (S11).

In summary, most of the students interviewed tend to hold a rather dualistic perspective of mathematics associating mathematics and doing mathematics primarily with calculating and finding results. Nevertheless, some students also demonstrate a partially relativistic perspective of mathematics by emphasizing the relevance of mathematics and working mathematically outside of school and considering mathematics as a science. However, overall, many of the students interviewed had difficulties answering the questions about what mathematics is and, in particular, what doing mathematics means to them. When asked about typical mathematical activities, they often referred to mathematical subjects, their general approach to solve tasks or listed professions that require mathematics. Furthermore, when explaining their choice of the exemplary tasks that they felt require typical mathematical activities, they often did not refer to typical mathematical activities involved in completing the tasks, but chose them for other (personal) reasons, such as "because that was the last topic" (S6), "because I was actually very good at it" (S4) or because "that is, for example, the topic I'm not very good at" (S13).

Discussion and outlook

The present paper aimed at obtaining a (more) comprehensive view of students' conceptions about mathematics and, especially, doing mathematics as well as possible relations to mathematics teaching by simultaneously also taking the mathematics teacher's conception and intention to teach mathematics into account. For this purpose, I analysed additional data from an exploratory interview study with 12 students and their mathematics teacher. The results indicate differences in students' conceptions about mathematics and doing mathematics – even though they all attended the same mathematics class. Although the mathematics teacher attempts to make it clear to her students that mathematics is a coherent system and states that she often implements application tasks with real-world contexts or tasks demonstrating that doing mathematics is a sense-making process, all of the students from her mathematics class interviewed associate mathematics and doing mathematics mainly with numbers and arithmetic. This result reflects the findings of previous research on students'

conceptions about mathematics (see, e.g., review by Østergaard, 2024). Some students also demonstrate a partially relativistic perspective of mathematics by emphasizing the relevance of mathematics and working mathematically outside of school and considering mathematics as a science. Nevertheless, in summary, the results indicate that the teacher's intention to convey to her students that mathematics is a coherent system and that doing mathematics is a sense-making process does not get through to most of her students. This could be related to the fact that it was difficult for her to answer the question of what doing mathematics means and to name typical mathematical activities, meaning that she likely did not address this (explicitly) in class. Similar to some of her students, she instead listed the mathematical subjects they had dealt with during the school year. This could possibly be related to her own, likely limited experiences with mathematics as a student (see, e.g., Boaler & Greeno, 2000). However, in the present paper, only the conceptions and intention to teach mathematics of one individual teacher and her students' conceptions were analysed. The small sample size and, thus, the limited generalizability of the findings constitute a limitation of the present paper, which should be addressed in future research. Moreover, especially students with a high interest and good grades in mathematics participated in the study. Thus, the findings appear particularly problematic, as these students may choose mathematics as their main field of study based on their limited conceptions, but studying mathematics in upper grades requires more components of mathematics than numbers and arithmetic (see, e.g., Boaler & Greeno, 2000; Pehkonen & Törner, 1999). Another limitation of the present paper relates to the fact that only the teachers' personal statements from the interview could be taken into account. In future studies, these insights may be further extended through, for instance, classroom observations in order to capture how teaching practices align with or deviate from the teacher's intention.

Despite this, the results of the present paper highlight the need to foster both students' and mathematics teachers' conceptions about mathematics and, in particular, doing mathematics. In line with Schoenfeld's (1994) claim quoted earlier, this requires mathematics teachers to expand their own experiences gained as a student and become aware that mathematics is an act of sense-making and often a hands-on, empirical activity. Only then they will be able to increasingly convey this in their mathematics lessons and, thus, enable authentic experiences for their students. For this purpose, for example, teacher training is needed that specifically focuses on what mathematics is and what it means to do mathematics. Furthermore, with regard to mathematics teaching, it seems necessary to teach mathematics as a process rather than as a finished product. Another possibility to offer both students and teachers (more) opportunities to gain authentic experiences with mathematics and, thus, foster more adequate conceptions relates to cooperating with mathematicians who describe their perspective on mathematics and their work to teachers and students. In addition, it would be promising to have students carrying out activities similar to those of mathematicians and reflecting on their approach in mathematics lessons.

Mathematics teachers support on valuing mathematics: The role of mathematical self-concept

Anwaril Hamidy[1,2], Maike Vollstedt[1] and Christoph Duchhardt[1]

[1]University of Bremen, Department of Mathematics and Computer Science, Bremen, Germany; ahamidy@uni-bremen.de

[2]UIN Sultan Aji Muhammad Idris, Department of Mathematics Education, Samarinda, Indonesia

This study examines the relationship between mathematics teacher support (MTS), mathematical self-concept, and the value facet of mathematical resilience (Value). Using self-report data from 863 Indonesian students, we applied Maximum Likelihood Structural Equation Modelling with robust standard errors to analyze how emotional and instrumental mathematics teacher support and self-concept contribute to the development of Value. The results show that the indirect effect of instrumental MTS on Value via mathematical self-concept is significant, while the indirect effect of emotional MTS does not exist. Nevertheless, emotional MTS directly affects Value. The results particularly confirm the framework suggested by the expectancy-value theory and provide a better picture of the relationship between internal and external factors of mathematical resilience, especially on valuing mathematics.

Keywords: Mathematics teacher support, value, mathematical self-concept, expectancy-value theory.

Introduction

The global prevalence of mathematics anxiety indicates the necessity for a psychologically safe mathematics learning environment that promotes well-being (Johnston-Wilder & Lee, 2024). In the classroom context, mathematics teachers play a vital role in realizing this. For instance, teaching practices that cultivate mathematical resilience "ensure that the relationships between teachers and students are nurturing, respectful, and warm" (Johnston-Wilder & Lee, 2024, p. 3). Such teacher support enables students to persevere, progress in mathematics, and address negative attitudes when facing challenges.

In a previous study (Hamidy et al., accepted), we found a positive direct relationship between mathematics teacher support (MTS) and the value facet of mathematical resilience (*Value*). This implies that mathematics teacher support enables students to unveil the benefits of mathematics for their current and future goals and then motivates them to keep learning mathematics despite the challenges. Since teacher support can be categorized into emotional and instrumental support (Federici & Skaalvik, 2013), exploring these two types of support may highlight each of their unique contributions.

Furthermore, the finding also aligns with the expectancy-value model of achievement (Eccles & Wigfield, 2020). It proposes a relation between socializers' beliefs and behaviours (here: MTS) and one of the subjective task values: utility value, which is similarly conceptualized as *Value*. Yet, this effect is indirectly regulated by the perception of the socializers' beliefs and behaviours as well as one's self-concept and abilities. Based on this framework, we enrich the significance of teachers in promoting *Value* by examining the relationship between each type of MTS and *Value* via

mathematical self-concept. This, in turn, could enhance the understanding of how teacher support ensures their students keep progress in mathematics.

Theoretical framework and research questions

Mathematical resilience is the ability to adjust to emotional struggles when facing any challenges in mathematics (Johnston-Wilder & Lee, 2024). This positive attitude helps navigate mathematics difficulties and keep engaged and persistent in mathematics (Neumann et al., 2021). Mathematical resilience is developed from four aspects: *Value*, *Struggle*, *Growth*, and *Support* (Kooken et al., 2016; Lee & Johnston-Wilder, 2017). In this contribution, we focus on *Value*, which refers to the capacity to persist in learning mathematics by recognizing its importance to current and future goals, for instance, by being useful (Kooken et al., 2016). Being useful is also central to utility value, one of the subjective task values in expectancy-value theory (EVT), that Eccles and Wigfield (2020) conceptualize as the subjective fit of an activity or task with individuals' current and future goals.

In our previous study (Hamidy et al., accepted), we could show that students' *Value* is positively influenced by their perceived support from their mathematics teacher. However, support provided by mathematics teachers may have several dimensions. For instance, Federici & Skaalvik (2013) suggest that teacher support can be differentiated into emotional and instrumental support. Emotional support is characterized by nurturing relationships such as caring empathy, encouragement, esteem, and friendliness, while instrumental support is closely related to action-facilitating support that enhances students' understanding, such as clarifying, correcting, elaborating, and demonstrating (Federici & Skaalvik, 2013; Semmer et al., 2008). Subsequently, operating emotional and instrumental support could provide a more detailed understanding of the relationship between MTS and *Value*. For English as a subject, the findings of Han et al. (2022) suggest that students who believe that they receive stronger emotional support tend to believe that their teachers value the subject more. They, in turn, benefit from these beliefs in the form of increased utility value and achievement in the subject. In addition, Federici and Skaalvik (2014) found that students' perception of the utility value of mathematics was positively related to the perceived instrumental support from their mathematics teachers. In the current study, we simultaneously examine the role of both types of MTS. Thus, our first research question is RQ1: How do students' perceived emotional and instrumental support from mathematics teachers relate to the students' *Value*?

In addition, according to the EVT framework, subjective task values are connected to one's goals and self-beliefs (Eccles & Wigfield, 2020). As one of the self-beliefs, self-concept in an academic context refers to the individuals' self-awareness and beliefs regarding their performance (Bong & Skaalvik, 2003). Despite the relationship between competence beliefs and subjective values is not clearly specified (Pintrich & Schunk, 2002; Wigfield & Eccles, 2002), studies found that self-concept is one of the individual factors influencing the development of mathematical resilience (Xenofontos & Mouroutsou, 2023). Therefore, we argue that an individual's mathematical self-concept contributes to *Value* development. We investigate this relationship in RQ2: How does mathematical self-concept relate to *Value*?

Furthermore, the EVT framework suggests that one's beliefs in competence are related to one's perceptions of socializers' behaviour (Eccles & Wigfield, 2020), such as social support. Lee and

Simpkins (2021) found that MTS is critical to developing students' mathematical self-concept, while Oda et al. (2021) showed that instrumental and emotional MTS positively correlated with mathematical self-concept, albeit weakly. Specifically, Wang (2023) found that instrumental support such as cognitive activation has a positive impact on students' mathematical self-concept. Then, we re-examine the relationship in RQ3: How do emotional and instrumental MTS relate to mathematical self-concept?

The past paragraphs imply that mathematical self-concept may also regulate the relationship between MTS and *Value*. That is, the quality of support provided by mathematics teachers affects students' beliefs in their mathematics competence, shaping their perceived value of mathematics. A study of Lyakhova & Neate (2019) supports this idea, indicating that there is an association between students' value of Further Mathematics, their mathematics teacher support and confidence in their own mathematical abilities. In addition, the characteristics of the two types of MTS may cause different dynamics between the constructs. Thus, RQ4 is: What is the role of mathematical self-concept on the relationship between emotional and instrumental MTS and *Value*?

Methods

We conducted a correlational study to answer RQ1-4 using data obtained from self-report scales. To measure perceived emotional and instrumental MTS, we used Federici and Skaalvik's (2013) MTS scale consisting of two subscales: 6-item emotional support (e.g., "My math teacher is friendly") and 6-item instrumental support (e.g., "My math teacher is good at explaining challenging math problems"). To measure students' mathematical self-concept, we used the 5-item mathematical self-concept scale from PISA 2012, for instance, "I learn mathematics quickly" (OECD, 2014). Finally, we used the 8-item *Value* subscale of the mathematical resilience scale of Kooken et al. (2016), for instance, "Math is essential for my future". We made some wording adjustments to the scales to better fit the context of secondary school students and translated them into Indonesian. The translation was reviewed by an experienced researcher fluent in both English and Indonesian, together with several Indonesian mathematics teachers. All items were measured using 5-point Likert scales, with high values indicating high levels of agreement except for one item on the mathematical self-concept scale, which was negatively worded and recoded prior to analysis. We used the final scales to collect data from 877 Indonesian 9^{th} and 10^{th} graders. Their participation was anonymous and voluntary. To ensure data accuracy, we applied a data screening procedure by Ward and Meade (2023) to identify students who responded carelessly to the survey. Fourteen students were excluded from the data set. Finally, 863 (60.8 % female, 2.9% did not answer) respondents were included in this study (average age: 15;2).

For data analysis, we conducted confirmatory factor analyses (CFA) and omega reliability estimation to check the psychometric quality of the scales and the dimensionality of the MTS scales. We calculated the descriptive statistics and correlations as preliminary results. Finally, we developed a model for each research question (due to page limitations, only the model for RQ4 is presented in the results section). We analysed them by structural equation modelling. For estimation, we applied maximum likelihood with robust standard errors to control for missing values. We also used a bootstrap procedure with 1,000 subsamples for the mediation effect. The criteria for assessing model

fit included CFI > 0.90, TLI > 0.90, RMSEA < 0.08, SRMR < 0.08, and factor loadings > 0.4. The lavaan package (Rosseel, 2012) in R (R Core Team, 2023) was used for analysis.

Results

The results of the CFA indicate that one item from the mathematical self-concept scale should be excluded because the factor loading was less than 0.4. In addition, both one-dimensional and two-dimensional (emotional and instrumental support) models of MTS meet the criteria for a good fit, yet the two-dimensional model is considered better. We excluded the item and adjusted the MTS construct into a two-dimensional model so that the overall measurement model is improved and meets the criteria for a good fit.

Table 1 shows the omega reliability coefficients, means, standard deviations, and correlation matrix. The scales are acceptably reliable (ω > 0.7). Overall, participants perceive high levels of emotional and instrumental teacher support, as well as a strong sense of *Value*. Yet, their mathematical self-concept is comparatively lower. Furthermore, the correlation matrix shows positive and significant associations between the constructs, especially between the two facets of MTS, which is also found in the previous study (Federici & Skaalvik, 2013).

Table 1: Descriptive statistics and correlations

Variable	ω reliability	M	SD	1	2	3
1. Emotional MTS	0.848	4.084	0.575			
2. Instrumental MTS	0.905	4.208	0.581	0.916***		
3. Mathematical self-concept	0.851	3.135	0.735	0.311***	0.377***	
4. Value	0.926	3.895	0.669	0.495***	0.496***	0.485***

Note. *** $p < 0.001$; Likert scales ranging from 1 to 5 (5 indicating high agreement); MTS = mathematics teacher support

To address RQ1-3, we examined three structural models (Model 1-3) separately. All of the models demonstrate an acceptable fit (see Table 2). The results of Model 1 indicate that emotional and instrumental MTS are positively related to *Value* (Emotional MTS: $\beta = 0.213$, $p < 0.05$; Instrumental MTS: $\beta = 0.282$, $p < 0.001$). The result of Model 2 shows that mathematical self-concept is also a positive, significant predictor of *Value* ($\beta = 0.440$, $p < 0.001$). Furthermore, there is a positive relationship between instrumental MTS and mathematical self-concept in Model 3 ($\beta = 0.403$, $p < 0.001$), while emotional MTS is not significant ($\beta = -0.075$, $p > 0.05$).

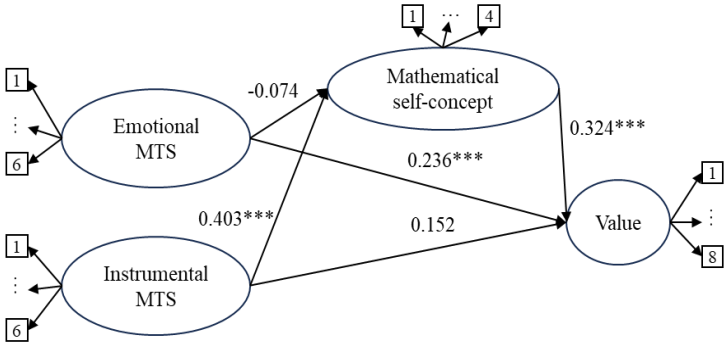

Table 2: Fit Statistics for Models 1-3

Model	*Df*	χ^2 (N = 863)	CFI	TLI	RMSEA	SRMR
1	167	613.523	0.946	0.939	0.063	0.039

2	53	249.691	0.957	0.946	0.077	0.036
3	101	342.026	0.960	0.953	0.058	0.036
4	246	759.629	0.950	0.943	0.054	0.038

Note. CFI = comparative fit index, TLI = Tucker-Lewis index, RMSEA = root mean square error of approximation, SRMR = standardized root mean square residual

To address RQ4, we examined Model 4 in Figure 1. The SEM results show an acceptable model fit (see Table 2) and confirm the results of Models 2 and 3. Yet, the direct effect of instrumental MTS in *Value*, as identified in Model 1, was reduced when mathematical self-concept was included (β = 0.152, p > 0.05). Nevertheless, it is found that the indirect effect of instrumental MTS on *Value* was found to be significant via mathematical self-concept (β = 0.131, p < 0.001). In contrast, the indirect effect of emotional MTS is absent (β = -0.024, p > 0.05).

Note. ***p < 0.001; latent constructs are shown in ellipses.

Figure 1: Model 4 and its measured relationships

Discussion and Conclusion

This study aims to examine the relationship between emotional and instrumental MTS, mathematical self-concept, and *Value*. The results of Model 1 show that both students' perceptions of emotional and instrumental MTS are significant predictors of students' understanding of the benefits of mathematics, thus enriching our previous study (Hamidy et al., in press). The significance of emotional MTS confirms that the findings of Han et al. (2022) are transferable to mathematics. The importance of instrumental MTS is also expected. Federici and Skaalvik (2014) explain that it may increase the utility value of mathematics by enhancing the understanding of mathematics problems and improving mathematics skills. Furthermore, the significance of both types of MTS on Value may also suggest that MTS does not need to be distinctly categorized into emotional and instrumental support, as they are also highly correlated. Federici and Skaalvik's (2013) argue that the strong correlation between both types of MTS means that the supportive mathematics teachers typically provide emotional and instrumental support. Additionally, students may perceive their instrumentally supportive mathematics teachers as being emotionally supportive as well. Nevertheless, the unique role of both types of MTS is found in the Model 3 and 4, which we discuss later. To sum up, the findings highlight that the social environment plays a crucial role in fostering mathematical resilience, particularly regarding *Value* (Eccles & Wigfield, 2020; Johnston-Wilder & Lee, 2024; Xenofontos & Mouroutsou, 2023).

In addition to the social environment, self-concept plays a significant role in predicting *Value*, as shown in Model 2. The more students believe in their mathematical abilities, the more they value mathematics for their current and future goals and perceive the importance of excelling in it. The results contribute to the clarification of the relationship between competence beliefs and subjective values (see Pintrich and Schunk, 2002; Wigfield and Eccles, 2002), and confirm the importance of psychological factors in the development of mathematical resilience (Xenofontos & Mouroutsou, 2023). To conclude, helping students to develop confidence in their mathematical abilities will help them to see the value of mathematics and then feel motivated to progress through challenges.

Instrumental MTS is one way to facilitate students' development of their mathematical self-concept, as shown in Model 3. Providing support such as clarification, correction, elaboration, and demonstration (Federici & Skaalvik, 2013; Semmer et al., 2008) not only helps students to understand and solve mathematical problems, but also develops their confidence in their mathematical competence. On the other hand, emotional MTS does not have a significant effect on students' mathematical self-concept. This suggests that the different characteristics of each type of MTS are related to the development of students' belief in their mathematical competence. Friendly, caring, and warm mathematics teachers may create a safe environment in the classroom (Federici & Skaalvik, 2013), but may not have a significant effect on students' belief in their mathematics competence as these characteristics are not strongly related to understanding. The findings clarify the weak correlations between instrumental and emotional MTS and students' mathematical self-concept found by Oda et al. (2021), support the study of Wang (2023) and contribute to a deeper understanding of the findings of Lee and Simpkins (2021).

The results of Model 4 show that the significance of instrumental MTS found in Model 1 is missing when mathematical self-concept is taken into account, while emotional MTS retains its significance. Given that both mathematical self-concept and instrumental MTS are related to students' competencies in mathematics, it is plausible that these constructs overlap on *Value* so that their effect is reduced: mathematical self-concept remains significant, whereas the significance of instrumental MTS disappears. Although the direct effect is not significant, the results show a significant indirect effect of instrumental MTS on *Value* via mathematical self-concept. Hair et al. (2021) refer to this situation as indirect-only mediation. The results underline the significant role of mathematical self-concept as a regulator of the indirect effect of instrumental MTS in promoting students' value of mathematics. This clarifies the relationship suggested by Lyakhova & Neate (2019) that providing students with tangible support when they encounter difficulties in mathematics helps them to grow in their belief in their mathematical competencies and then to value it as an important asset to be developed. Furthermore, the results suggest teachers should ensure that their support emphasizes students' competence rather than providing quick-fix and path-smoothing so that students really perceive their competence and are then motivated to progress in mathematics.

In addition, the lack of significance in the indirect effect of emotional MTS may be due to a lack of relevance between emotional MTS and belief in competence. This indicates that each type of MTS has a unique mechanism to develop students' Value despite the high correlation between them. Furthermore, regarding the indirect effect of instrumental MTS, the results confirm the EVT framework that self-belief regulates the relationship between social environment and subjective task

values (Eccles & Wigfield, 2020). Moreover, the results provide a more detailed picture of the interplay between external and internal factors in the development of mathematical resilience as suggested by Xenofontos and Mouroutsou (2023).

Yet, this study has several limitations. As it was conducted in a cross-sectional setting, the result could not provide sufficient support for causality. Therefore, longitudinal studies of the same model should be considered for further research to address the limitations of this study. In addition, the gender imbalance of this study may also affect the results, so that future research should be based on a gender-balanced sample. Finally, conducting the same or more complex research framework on the other facets of mathematical resilience and social support should be considered to provide a deeper understanding.

Bridging commognition and complexity theory for the study of identity and ritual participation in mathematical learning

Einat Heyd-Metzuyanim

Technion – Israel Institute of Technology einathm@technion.ac.il

This paper integrates commognitive and complexity theory, specifically, the Dynamic Systems Model of Role Identity (DSMRI), to analyze an eighth-grade student's mathematical identity. I start by outlining the main concepts taken from the two frameworks. I then exemplify the utility of the unified framework by analyzing one middle-school student's discourse during a problem-solving task, taken from a mathematical interview followed by an identity interview. The analysis suggests that the student's subjectifications cohered with her mathematizing, which was mostly ritual and focused on procedures that she attempted to recall from memory. These subjectifications in turn cohered with her role-identity narratives that revolve around "succeeding" in mathematics for instrumental goals, all forming an attractor state in the complex dynamic system of her role identity.

Keywords: Identity, mathematical discourse, commognition, complexity, rituals.

Introduction and theoretical background

The intersection of identity and learning has become a focal point in mathematics education research, especially as it relates to how students develop a sense of self within the discipline, in relation to various norms, teaching practices and cultural narratives (Graven & Heyd-Metzuyanim, 2019; Gresalfi & Hand, 2019).

The commognitive framework provides a robust toolset for analyzing the construction of mathematical identities through discourse (Heyd-Metzuyanim, 2015; Sfard, 2008). However, it offers limited tools for explaining how certain identity narratives stabilize into persistent patterns over time. To address this, I turn to complexity theory (Hilpert & Marchand, 2018), particularly the DSMRI framework (Kaplan & Garner, 2017), as a complementary lens for understanding the dynamic evolution and solidification of mathematical identities. The goal of this paper is to initiate the theoretical integration of commognition and DSMRI by illustrating how their combined use can enhance our understanding of the co-shaping of identity and mathematical learning. This integration is demonstrated through the case study of an eighth-grade student, highlighting the potential of this approach for future research and practice.

According to Sfard & Prusak (2005), identity is a collection of reified, significant narratives about a person, which can be told by the person about herself (1st person narratives), or by others about her (2nd person or 3rd person). These narratives are further divided into two complementary subsets: **current identity narratives** and **designated identity narratives**. Current identity includes the stories individuals tell about themselves in the present—how they see their mathematical abilities and roles at this moment. Designated identity includes the narratives they construct about who they expect or desire to become in the future.

More generally, the commognitive theory (Sfard, 2008) is based on the premise that thinking is based on individualizing socio-culturally established discourses with mathematical thinking being viewed

as a specific type of discourse. In this approach, learning is a process of becoming a participant in the mathematical discourse, and one's mathematical identity is constructed and shaped through participation (or non-participation) in this discourse.

In order to examine the process of becoming a participant in the mathematical discourse, commognition suggests to examine not just students' mathematizing (their communication about mathematical objects) but also their subjectifying (communication about themselves). **Subjectifying** statements are the transient, more local and non-reified statements associated with one's identity narratives. In 1st Person, subjectifying involves the attribution of characteristics or capabilities to oneself, which can range from descriptions of specific actions (e.g., "I forgot this") to broader assessments of personal traits (e.g., "I'm bad at math").

Previous commognitive research has shown that students' identities are linked with specific patterns of participation (e.g. Heyd-Metzuyanim, 2015). For examples, identities of failure or having "learning difficulties" in mathematics were linked with **ritual participation**, which is focused on the execution of procedures, rather than on the product of these procedures (namely, the narratives produced by them) (Lavie et al., 2019).

The main constituents of participation according to commognition are routines, defined as a pair consisting of a task (the goal of the routine) and a procedure. This procedure often takes form of a series of sub-routines (or sub-tasks) that the performer enacts to achieve the overall task. Routines can be characterized along a continuum from rituals to explorations (Lavie et al., 2019). Novices often perform ritual routines, while experts perform explorative routines. Ritual routines have several defining characteristics:

Procedural focus: Learners prioritize the steps of the procedure over its overarching goal.

Lack of Agentivity: Learners rely on external authority (e.g. teachers or textbooks) for validation rather than independently producing and endorsing mathematical narratives.

Lack of bondedness, substantiation and flexibility: Ritual routines often lack connections between steps, substantiation of conclusions, or flexibility in applying the routine to different contexts or using different procedures for the same task.

For example, a student solving a fraction problem might follow a memorized procedure like "invert and multiply" without producing or endorsing narratives that explain why this procedure is mathematically valid. The student focuses solely on completing the steps correctly and rely on the teacher for confirmation. Such ritualized participation, if repeated, can foster narratives like "I'm bad with fractions", particularly when the memorized steps fail to produce correct results.

So far, commognition has documented the ways by which certain identity narratives of disability and lack of competence go hand in hand with ritual participation (Heyd-Metzuyanim, 2013, 2015). However, commognition lacks theoretical tools for modeling how specific patterns of mathematizing stabilize and get reified into maladaptive identity narratives. A potential theoretical enhancement, which may aid in filling this gap, can be found in complexity theory. **Complexity theory**, often applied to fields ranging from biology to social sciences, emphasizes the non-linearity, dynamic and emergent nature of learning systems (Hilpert & Marchand, 2018). This perspective offers a way to

conceptualize how identity narratives and mathematical participation might stabilize into 'attractor states'.

Attractor states, a concept from complexity theory, refers to stable patterns of action within a dynamic system. These states emerge through the interactions and feedback loops within the system, which gradually reinforce certain configurations and make them resistant to change (Hilpert & Marchand, 2018). In the context of identity stabilization, attractor states represent recurring patterns of discursive participation that solidify over time, shaping how an individual engages with particular tasks. To further explore the stabilization of identity narratives within a dynamic system, Kaplan and Garner's (2017) **Dynamic Systems Model of Role Identity (DSMRI)** offers a framework that connects identity elements – such as self-perceptions and goals – with the broader dynamics of participation and discourse.

DSMRI conceptualizes role identity as a complex dynamic system comprising self-perceptions, goals, beliefs, and action possibilities. These elements can be mapped onto Sfard and Pruask's (2005) "collection of narratives" that constitute identity: self-perceptions align with **1st-person identity narratives** about current mathematical abilities; goals correspond to **designated identity narratives** about future aspirations. Ontological and epistemological beliefs map to **endorsed narratives about mathematics and how it is learned;** and action possibilities correspond to **precedents of routines of interaction** (Lavie et al., 2019) - recurring ways of engaging in mathematical discourse that learners consider relevant in a given situation. Together, these narratives interact dynamically, stabilizing into attractor states that form learners' patterns of participation in mathematics.

In the following case study of one student named Liat (pseudonym), I use the unified commognitive-complexity toolset to ask: in what ways did Liat's mathematizing, subjectifying and role-identity narratives cohere into an attractor state of ritual participation?

Methods

Liat, a beginning eighth-grade student, participated in a larger study on the development of algebraic discourse in middle school students. She was selected for the present analysis due to her relatively explicit subjectifying talk during her engagement with mathematical tasks. Data were collected through a "think-aloud" interview in which Liat solved a series of algebra problems, followed by an "identity interview" which asked Liat about her interests, goals and evaluations of herself as a mathematics student. The interview was recorded by two cameras and fully transcribed.

The analysis proceeded in three stages. First, Liat's discourse was organized into tasks and sub-tasks, identifying the routines she enacted at each stage of the problem-solving process. This provided the foundation for the second stage, where Liat's mathematizing routines were analyzed for their ritual and explorative dimensions. In parallel, subjectifying utterances – where Liat referred to herself or her actions (e.g. "I think", "I forgot", "I'll do") – were highlighted in relation to the routines and sub-routines she enacted. Third, these patterns were synthesized with the commognitive counterparts of DSMRI elements, such as 1st-person and designated identity narratives. These were compared to assess the coherence between Liat's mathematizing, subjectifying during the problem-solving task, and her more reified role-identity narratives. This comparison enabled an exploration of whether

ritual mathematizing was contributing to the formation of an attractor state with Liat's identity narratives.

Analysis and findings

I use the episode where Liat attempted to solve one problem from the mathematical interview, to exemplify the ways by which Liat's identifying, subjectifying and mathematizing cohered as an attractor state. The analysis is structured into three stages: detailed examination of Liat's mathematizing and subjectifying, The task posed to Liat, named "the student council problem", is presented in Figure 1.

> In the student council elections, Yonatan received 1/3 of the votes and Nadav received 1/4 of the votes. Naama received 40 votes which are all the remaining votes. How many students voted in the student council elections? Present a solution.

Figure 1: The student council problem (translated from Hebrew)

The total time in which Liat engaged with the problem was 10 minutes. This time was divided into two parts: 5 minutes during the first trial, then 5 minutes at the end of the interview, where she revisited the problem. In both of these, Liat was unable to solve the problem. During this time, Liat posed to herself no less than 9 sub-tasks which are listed in Table 1.

Table 1: The series of sub-tasks Liat posed to herself

1	$\frac{1}{4}+\frac{1}{3}+40=$	**4**	$27x12=$	**7**	$\overline{73)}\,3$
2	$40x12=$	**5**	$12\,x\,37=$	**8**	$\overline{73)}\,4$
3	$\overline{487)}12=$	**6**	$\frac{73}{120}=$	**9**	$\overline{73)}\,5$

The next excerpt shows the beginning of Liat's engagement with the problem

157 Liat (Reads the question out loud, twice). Oh, OK. A quarter plus a third plus forty equals ...I need to make a common denominator now, right?
158 Liat I forgot how to make a common denominator. I know how to make a common denominator ..
159 Liat (Starts writing, see Figure 2). It's one, so it's like twelve ,the closest to both and now if I do it then it will be..
160 Liat If it's twelve and it's twelve.. oh then I multiply that by twelve too?
161 Liat I forgot it It's double this ..Yes ,I also multiply it by twelve

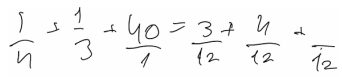

Figure 2 - Liat's writing during her initial engagement with the student council problem

This excerpt illustrates key characteristics of Liat's participation that were eminent in her solution of the task.

Liat's mathematizing: In general, Liat's mathematizing is highly ritual in this excerpt. First, there is a clear focus on procedures ("make a common denominator" [157], "If I do it" [159], "I multiply that" [160]). Second, there are indicators of reliance on external authority. These can be found in the "I need to" [157] which implies accountability to externally given rules, as well as the turns to the interviewer for some assistance ("right?" [157], "I multiply that by twelve too?" [160). Another ritual characteristic of Liat's discourse is lack of bondedness between the situation described in the written task and the chosen procedure. In particular, this lack of bondedness is related to the syntactic treatment of fractions. Whereas the written task refers to "1/3 of the votes", Liat treats the 1/3 as a standalone number, ignoring it's function in the task-wording as an operator on a quantity ('of the votes'). Moreover, her treatment of numerators and denominators is unrelated to their roles as part of a rational number. Rather, she only relates to the numbers as parts of a procedure of "making a common denominator", the rationale and substantiability of which seem to remain hidden to her.

Liat's subjectifying: Table 2 presents a collection of the subjectifications produced by Liat during her attempts to solve the "student council" problem. This Table is not exhaustive of all of Liat's subjectifications, but it represents the main stories she told about herself.

Table 2: Liat's subjectifying during her engagement with the students' council problem

Line no.	What is said (implied/context)
157-158	I need to … I forgot how to… . I know how to**..**
169	Oy, I don't think (that works) … I don't like it
171	Naama (her previous math teacher) would have killed me now over this
176	(while performing the long multiplication) at least this I know how to do
183	(After multiplying and producing an answer to a sub-task) Good, Liat. Now go on
189	(When multiplying 12x47 and hoping to find the result is 487). Yes! Boom! (excited) … No (disappointed) Yes! (excited) Boom! (higher tone)… Oh, no, no… No.. (lowered voice, sighing)
323-325	I know what I did wrong here! … I just did all this calculation for nothing. OK, I think I know what to do. If I succeed then I succeed (meaning: let's give it another chance).
338	(Facing a sub-task she posed to herself of 37/120, after requesting and being denied a calculator): How I don't like mathematics. Who created this?!

As can be seen in Table 2, Liat's subjectifications generally cohered with her ritual mathematizing. She talked about herself as "knowing how to do" certain procedures, or as "forgetting" them [157-158]. These statements subjectified her as either remembering or not remembering a certain procedure, but not as able to figure out or make sense of the problem in new or creative ways. Her emotional responses, including the "Boom!" "Yes!" "no..", with the highly excited, followed by

disappointed and slightly depressed tone, all revolved around succeeding or failing to enact procedures. Her evaluation of this failure or success was not related to the situation described in the written task. Thus, for example, the excited "Yes! Boom!" in line [189] appeared when, for a moment, Liat expected her long multiplication procedure to produce 487, a number she expected to receive when she decided to divide 487 (which was the result of 480+3+4, the numerators in her calculation) by 12. This expectation was part of a procedural sub-task Liat posed to herself, but was not bonded to the original task. That is, Liat emotional responses related to her expectation that a solution to the 487:12 task, if whole, would somehow prove that her procedure was correct. Yet this expectation had little to do with the original numbers described in the task.

Liat's role identity narratives

Following is a summary Table of Liat's role identity narratives, retrieved from the identity interview.

Table 3: Role identity narratives authored by Liat during the identity interview

1st Person identity narratives (general participation evaluations, attributes and membership)
I like succeeding in mathematics but **I don't like mathematics** [377] But when I don't succeed then it's like, **I get tired of it and I give up** [390] **I'm a good (sababa) student**. I was on the honors roll, despite the Advanced Placement class (being harder). And I think **I am capable of that** (of practicing hard) but one needs a lot of will power for that [396] I think **in math I have a bit of an ADD problem** and sometimes that lowers my grade [398] **I once had a fail** (on an exam) but say **the classwork and homework that I always do,** that raises my grade
Narratives about purpose and goals of learning mathematics, designated identity narratives
If I'd known better mathematics, and I'd better understand, then it's fun to succeed [376] (*implied: I don't know and understand math as much as would like)* (What is the subject in school **most important for you to succeed in?) I think that math** [413] **Because with math I can get into many things**. [415] (in relation to the subjects she will want to take in high school) I think that, for instance **Math 5 units I will take** (5 units is the highest math track)
Narratives about math learning and what it takes to succeed in math
As much practice as possible, **that will always work**, but one doesn't always like to practice a lot (Interv: right). Right? You don't like doing homework and that, so it's like **whoever can persist in it (would succeed**). [392-394] And I think I am capable of that (**of practicing hard**) but **one needs a lot of will power for that** [396]

In general, there is much coherence in Liat's system of role identity narratives. Most of them cohere around "succeeding" as the ultimate goal in mathematics. There is some gap between Liat's current and designated identity narratives in that her current identity narratives describe her as only partially successful, suffering from a "bit of an ADD problem" and getting tired when she is unsuccessful. In contrast, her designated identity narratives are about enrolling in the highest mathematics track, and about mathematics being one of the two most important subjects in school. In that sense, the gap between Liat's current and designated identity may be conducive for learning as it can propel Liat to

work hard on her mathematics studies. Yet when closely examining Liat's narratives about what succeeding in mathematics means, one can see that closing this gap means for Liat to simply exert more effort and "practice more". This emphasis on practicing and making effort is coherent with Liat's repeated attempts to solve the student council problem, even in the face of much obstacles. There is no mention in Liat's role identity narratives about "learning", "enjoying" or being interested in mathematics for its own sake. The only slight disruption of this coherent system is Liat's mention of wishing to "better understand" mathematics [376], yet it is unclear if by "better understanding" she means sense making, or simply "knowing how to do" the procedures**.** The general coherence between Liat's mathematizing, subjectifying and role-identity narratives indicates that her ritual participation may indeed function as an attractor state.

Discussion and conclusions

The integration of commognitive theory and complexity theory enhances our understanding of how students' mathematical identities and mathematical learning shape each other, particularly in cases of stabilizing of ritual participation. The findings in this study, exemplified by the case of Liat, illustrate how identity narratives—shaped by both individual experiences and socio-cultural narratives—become entrenched in unproductive patterns of mathematical engagement.

From the perspective of complexity theory, Liat's identity as a ritual participant in mathematics can be seen as an attractor state—one that achieves coherence through alignment of the role identity narratives, subjectifications during mathematizing, and enacted mathematical routines. Moreover, there is good chance that this system is resistant to change. Without role identity narratives that value sense making and producing mathematical narratives for their own sake, there is little chance that Liat's mathematizing would shift towards more productive, explorative forms of participation. This is unfortunate, since based on the non-canonical results that Liat's rituals are producing already at this stage, there is little chance that she will qualify for the highest mathematics track she aspires to become a member of in the long run. In that sense there is a *mathematizing-identifying barrier* that prevents Liat's role identity system from cohereing towards her designated identity of becoming a "5 units student". She is unaware (that is, she is not subjectifying herself) as someone who is malfunctioning in those particular aspects of her mathematizing that need to change. Rather, she designates herself to "practice more" or to show "more persistence", actions which would probably not propel her towards better success in mathematics in the long run.

It is important to note that this study is based on a single case and examines identity stabilization at a single point in time. While the findings offer valuable insights into the potential of a combined commognitive-complexity theory for understanding identity stabilization, they remain preliminary and require further investigation. Future studies should build on this framework by examining identity dynamics longitudinally and across diverse contexts to further validate and refine the proposed theoretical integration.

The integration of commognition and complexity theories may have broader implications for mathematics education. It suggests that interventions aimed at disrupting unproductive learning patterns must operate on multiple levels. Simply attempting to enhance conceptual understanding, or providing more explorative opportunities to learn, may not be sufficient since they do not attend to

identity narrative that preserve ritual participation. At the same time, interventions that only target identity narratives may be similarly ineffective, since they do not attend to the students' patterns of mathematizing. Instead, interventions need to target the full system of role identity narratives and mathematical participation, as well as the broader systems in which these role-identity narratives develop over time. Multi-level changes in tasks (or more broadly, curriculum), changes in socially produced narratives about what it means to succeed in math, and better assessment practices, which would allow students to better align their current and designated identities around doing mathematics, may be necessary to allow students to break away from attractor states of ritual mathematizing.

Problem posing and motivation: Does reformulating problems into easier versus more difficult versions affect students' expectancies for success, task value, and costs?

Janina Krawitz[1] and Katharina Wiehe[2]

[1]University of Cologne, Germany; janina.krawitz@uni-koeln.de

[2] University of Münster, Germany

Problem posing was found to be a promising approach for enhancing motivation in mathematics classes. This study examines the impact of problem-posing prompts on students' motivation. A sample of ninth- and tenth-graders (N = 78) was asked to reformulate given real-world problems into an easier and a more difficult version. Students then evaluated their expectancies for success, task values, and perceived cost associated with reformulating problems into easier versus more difficult ones. The results showed that reformulating easy problems, compared to difficult ones, led to higher expectancies for success, greater utility and attainment value, and lower perceived costs. However, no significant effect was found on intrinsic value. These findings highlight the distinct nature of task-value components and suggest that incorporating prompts for easier problems in problem-posing tasks can positively impact students' motivation.

Keywords: Expectancies for success, task values, cost, problem posing, task-based motivation.

Introduction

A key question in problem-posing research is how different prompts influence the process and outcomes of problem posing (Cai et al., 2023). Recent findings suggest that encouraging students to pose problems of varying difficulty levels (e.g., easy, medium, and difficult) leads to greater complexity in their self-generated problems and thus improved problem-posing performance compared to asking them to pose three problems without any conditions (Cai et al., 2023). While prompting students to pose a single difficult problem may be sufficient to improve achievement-related outcomes, asking them to pose easy problems could play an important role in enhancing their motivation. While some studies have investigated the impact of prompts in problem posing on achievement, there is scarcely any research focusing on their effect on motivation. Initial findings on this topic come from a study focusing on problem generation (Krawitz & Wiehe, 2024). The present contribution extends this research by examining problem reformulation. The aim is to explore whether students are able to change given real-world problems into easier and more difficult versions and investigate how prompts to reformulate problems of varying difficulty impact students' motivation, including their expectations for success, task values, and perceived costs (Eccles & Wigfield, 2020).

Theoretical background and research questions

Expectancies for success, task value, and costs

There is widespread agreement on the necessity of supporting student motivation. Expectancy-value theories highlight the importance of students' expectancies for success and their perceived value of

academic tasks in determining their motivation, performance, and educational choices (Eccles & Wigfield, 2020). Expectancies for success are defined as students' beliefs about their future performance on upcoming tasks, while task values reflect their personal importance they place on tasks. Both of these constructs are situated and sensitive to the objects targeted, which means they vary depending on the task and context (Schukajlow et al., 2023). Eccles and Wigfield (2020) differentiate between intrinsic value (the enjoyment and interest derived from the task), attainment value (the task's significance to personal identity), utility value (its relevance to current or future goals), and costs (the negative aspects associated with the task).

Several factors influence the development of expectancies for success and task values. One critical factor is task complexity. The way students perceive the difficulty of a task can significantly impact their expectancies for success and the values they assign to it (Eccles & Wigfield, 2020). Higher perceived difficulty often leads to lower success expectations and greater perceived costs. Since task values and expectations of success are positively related, higher difficulty can be expected to be associated with lower task values (Eccles & Wigfield, 1995). Consistent with these considerations pre-service teachers (Böswald & Schukajlow, 2022) and high school students (Krawitz & Schukajlow, 2018) were found to report lower expectancies for success and lower task values for complex modelling problems compared to simpler intra-mathematical problems. However, too easy problems can lead to boredom (Schwartze et al., 2024) and thus to lower intrinsic value. In addition, studies have shown that the complexity of reality-based mathematical problems is a significant contributor to intrinsic value for both university students (Fielding et al., 2022) and primary school students (Russo & Hopkins, 2017). Therefore, tasks perceived as complex and challenging may actually increase intrinsic value.

Mathematical problem posing

A commonly accepted definition of problem posing encompasses both the reformulation of existing problems and the generation of new ones (Silver, 2013). In reformulating a problem, the problem solver modifies a problem into a revised version. In generating a problem, the student constructs a new problem e.g. by finding mathematical questions for a given real-world situation. The broad application of the term problem posing, which includes conceptually distinct activities like reformulation and generation, complicates the interpretation and comparison of research findings. Consequently, there is a need to systematize the various types of problem-posing tasks and approaches (Silver, 2013). Here we focus on reformulating problems.

A problem-posing task comprises two components: the problem situation and a problem-posing prompt (Cai et al., 2023). The problem situation is basis for problem posing and can be for example, a mathematical figure, an equation, a real-world situation, or a prior problem. Problem-posing prompts tell the students what to do with the problem situation. For example, they can ask for finding a mathematical question for a situation (problem generation) or to reformulate a given problem (problem reformulation). In addition, prompts can also specify certain conditions that should be met for the posed problems. A typical prompt is, to vary the level of complexity in the posed problems like the prompt given in the Swimming Pool Task in Figure 1.

Swimming Pool

After the winter break, the outdoor swimming pool in Münster is being prepared for the upcoming swimming season. Soon, visitors will be able to train again on the three lanes of the 50-meter long sports pool. After a thorough cleaning, the pool will be filled with water. There are water pipes available for this purpose, which can be operated independently. It takes 6 hours to fill the pool using the first water pipe and 9 hours using the second water pipe.

How long will it take to fill the pool if both pipes are used simultaneously?

Change the task to create one easy and one difficult mathematical problem for your classmates

Figure 1: Swimming Pool Reformulation Task adapted from Schupp (2002)

Here, we focus on problem situations that are based on real-world situations. Reformulating such problems is related to mathematical modelling, as it requires transformation processes between the real world and mathematics (Hartmann et al., 2023). This approach allows students to explore the real-world situations by modifying problem conditions, deepening their understanding of these situations and the importance of making assumptions. Additionally, prompting students to reformulate problems into versions with varying levels of difficulty in addition challenges them to analyze and adapt the problem's structure.

The use of different problem-posing prompts was found to affect learners' achievement-related outcomes, such as the complexity of their posed problems (Cai et al., 2023). However, research also indicates that problem posing can be challenging for students (Hartmann et al., 2021), and it remains unclear to what extent they can carry out problem-posing prompts.

Further, problem posing is considered as beneficial for students' motivation (Cai & Leikin, 2020), the impact of problem-posing prompts on students motivation is rarely studied. Krawitz and Wiehe (2024) showed for problem generation, that prompting students to pose easy compared to difficult problems has a positive effect on students attainment value and utility value, no effects on intrinsic value and negative effect on the perceived costs. Since, problem generation and reformulation are different constructs that also vary in their relation to other variables, it is an open question whether these results also hold for problem reformulation.

Research questions

These considerations led to the following research questions:

RQ1: Does prompting students to reformulate easy problems, in comparison with difficult problems, affect the complexity of their reformulated problems?

RQ2: Does prompting students to reformulate easy problems, in comparison with difficult problems, affect (1) their expectancies for success, (2) their task values, and (3) their perceived costs?

Regarding RQ1, we expect on the basis of prior research (Cai et al., 2023) that students reformulate more complex problems when they are prompted to pose difficult problems. Regarding RQ2, based on expectancy-value theory (Eccles & Wigfield, 2020) and prior research (Eccles & Wigfield, 1995; Krawitz & Wiehe, 2024), we expect a positive relationship between perceived task difficulty and students' expectancies for success, attainment value and utility value, as well as a negative relationship with costs. Since perceived difficulty may also increase intrinsic value, we do not have a specific hypothesis for this relationship.

Methods

Sample, instruction, and procedure

The study involved 78 ninth- and tenth-grade students from two middle-track and one high-track school in Germany (50% female, 48.7% male), with an average age of 15.6 years. Students received a brief instruction on problem reformulation before the test. The aim of the instruction was to explain, how they can reformulate problems by adding or removing information to the problem statement. Therefore, the Toothpaste problem ("How many centimeters of toothpaste are used in one month?") and a reformulated version of the problem ("How many centimeters of toothpaste are used in one month, if a person brushes his teeth two times a day and uses 1.5 cm toothpaste each time?") was shown and briefly discussed in class. After the instruction, each student was provided with a test booklet containing four real-world problems including the Swimming Pool Task depicted in Figure 1. For each real-world problem, students were asked to reformulate the problem to an easy and a difficult new mathematical problem ("Change the task to create one easy and one difficult mathematical problem for your classmates."). After students completed reformulating an easy and difficult problem for each given real-world problem, they filled out a questionnaire assessing their expectations for success, task values, and perceived costs related to reformulating the easy and the difficult problem.

Measures

To assess students' expectancies for success, task values, and perceived costs when reformulating easy versus difficult problems, students rated their agreement with statements on a 5-point Likert scale (1 = not at all true, 5 = completely true) corresponding to these constructs. Task-based measures were used, which means that for each given real-world problem such as the Swimming Pool Task, students were asked to report their expectancy of success for reformulating the Swimming Pool Task into an easy version and additionally into a difficult version. Responses related to reformulating easy and difficult problems were aggregated across the four given real-world problems into ten separate scales: expectancy of success, intrinsic value, attainment value, utility value, and costs related to reformulating easy problems and related to reformulating difficult problems. Each scale consisted of four items, one for each of the given real-world problems. The following statements were used: For expectancies for success, "I am sure that in the future I will be able to change the problem on the subject of [problem situation] into a(n) [easy/difficult] problem"; for intrinsic value, "I find it interesting to change the problem on the subject of [problem situation] into a(n) [easy/difficult] problem"; for utility value, "I find it useful to be able to change the problem on the subject of [problem situation] into a(n) [easy/difficult] problem"; for attainment value, "I find it important to be able to

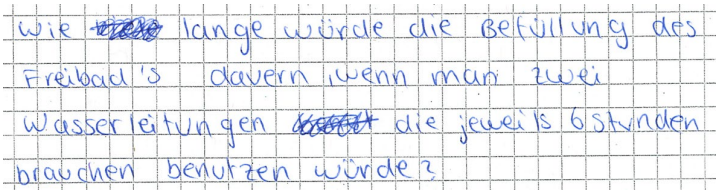
change the problem on the subject of [problem situation] into a(n) [easy/difficult] problem"; and for costs, "Changing the problem on the subject of [name of task] into a(n) [easy/difficult] problem exhausted me." All scales showed satisfying levels of internal consistency (Cronbach's $\alpha \geq .72$).

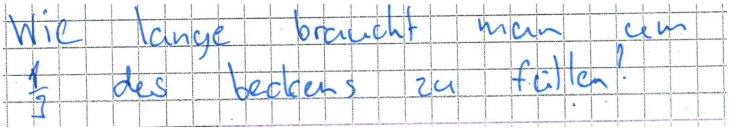
To assess the complexity of the reformulated problems, we coded whether the problem was modified to have lower (scored 0), the same (scored 1), or higher complexity (scored 2) compared to the original problem. For complexity, we focused on the complexity of the mathematical model, necessary to solve the problem (see sample problems in the results section). Additionally, other types of responses, including non-mathematical problems, no changes, or minor changes that did not affect the complexity of the mathematical model (such as adding unnecessary information), as well as missing responses were coded as "other" (all scored 0). The interrater reliability for the coding was satisfactory ($\kappa \geq .67$, $M = .83$).

Results

For answering RQ1, we compared the complexity of reformulated problems posed in response to the prompts to pose an easy problem compared to the problems posed to the prompt to pose a difficult problem. McNemar-Bowker tests revealed a significant difference in the frequencies in terms of complexity across all given problem situations (all ps $< .04$) (see Table 1).

Table 1: Frequencies of problems with lower, same, or increased complexity reformulated in response to the prompts to pose easy vs. difficult problems





Problem situation	Renovation		Swimming Pool		Promenade		Greenhouse Gases	
	Easy	Dif.	Easy	Dif.	Easy	Dif.	Easy	Dif.
New problems with lower complexity	15	5	29	16	21	12	14	8
New problems with same complexity	30	31	6	23	10	17	15	15
New problems with increased complexity	2	9	1	2	0	3	7	18
Other	31	33	42	37	47	46	42	37

Note. "Easy" = Reformulate into an easy problem and "Dif." = Reformulate into a difficult problem.

Results from a paired sample t-test showed that students posed more complex problems in response to the prompt to pose difficult problems compared to the prompt to pose easy problems ($M_{easy} = 0.26$, $SD_{easy} = 0.29$, $M_{diff} = 0.48$, $SD_{diff} = 0.39$; $t(77) = -5.52$, $p < .001$, $d_{Cohen} = 0.34$). Figure 2 presents three student solutions illustrating reformulated versions of the Swimming Pool Task with varying levels of complexity. In the first solution, the complexity is reduced compared to the original problem; in the second, it remains the same; and in the third, the complexity is increased.

A high number of students kept the original problem and made only slight changes, such as adding superfluous information, or kept the problem completely as it was. This occurred particularly for the prompt to reformulate into easy problems, with 22.13% of problems responding to the prompt to reformulate into easy problems, compared to 10.25% for the prompt to reformulate into difficult problems.

Table 2: Examples of students' reformulated problems to the Swimming Pool Task with lower, maintained, or increased complexity than the initial problem

Complexity	Example
Lower complexity:	 *[How long would it take to fill the swimming pool if you used two water pipes, each taking 6 hours?]*
Same complexity:	 *[How long does it take to fill 1/3 of the pool?]*
Increased complexity:	 *[How long does it take to fill the pool if the first water pipe stops working after 3 hours?]*

Regarding RQ2, the results showed that learners reported significantly higher expectancies for success when reformulating the problems into easier versions compared to more difficult ones (M_{easy} = 3.01, SD_{easy} = 1.05; M_{dif} = 2.77, SD_{dif} = 1.10; $t(76)$ = -2.88, p = .003; d_{Cohen} = 0.71).

For attainment value and utility value, students reported that they find it more important (M_{easy} = 2.35, SD_{easy} = 1.15; M_{dif} = 2.06, SD_{dif} = 0.97; $t(76)$ = 2.62, p = .011; d_{Cohen} = 0.97) and more useful (M_{easy} = 2.33, SD_{easy} = 1.07; M_{dif} = 2.04, SD_{dif} = 0.98; $t(76)$ = 2.74, p = .008; d_{Cohen} = 0.66) to be able to reformulate problems into easier version compared to more difficult ones. However, for intrinsic value, students did not perceive reformulating problems into easier version as more or less interesting than reformulating them into more difficult ones (M_{easy} = 2.33, SD_{easy} = 1.14; M_{dif} = 2.25, SD_{dif} = 1.09; $t(76)$ = 0.89, p = .378; d_{Cohen} = 0.66).

Consistent with our expectations, learners reported higher perceived costs when reformulating problems into more difficult versions compared to easier ones (M_{easy} = 1.96, SD_{easy} = 1.06; M_{dif} = 2.34, SD_{dif} = 1.20; $t(76)$ = -3.84, p < .001; d_{Cohen} = 0.99).

Discussion future directions and limitations

The goal of our study was to examine how prompting students to reformulate problems with varying difficulty levels impacts the complexity of their reformulated problems and their motivational outcomes, specifically their expectations for success, task values, and perceived costs.

Our findings demonstrate that prompting students to reformulate problems into more difficult versions, compared to easier ones, increases the complexity of the reformulated problems. However, many students struggled to follow the prompt, indicating that reformulating real-world problems and specifically addressing problem complexity is challenging for students. Future research could explore scaffolding techniques or instructional strategies to better support students in problem reformulation tasks.

Previous research has emphasized the importance of problem-posing prompts on achievement-related outcomes (Cai et al., 2023) and on motivation when problem generation is focused (Krawitz & Wiehe, 2024). Our findings extend these results by showing that students' motivation varies when they reformulate problems into easier versus more difficult versions. Consistent with prior findings, we found that reformulating easy problems, compared to difficult ones, leads to higher expectations of success, utility value, and attainment value as well as to lower costs supporting theoretical insights from expectancy-value theory (Eccles & Wigfield, 1995).

In line with research on problem generation (Krawitz & Wiehe, 2024), we found no significant relationship between complexity and intrinsic value. Intrinsic value may differ from other value components since complexity can be a source of interest (Fielding et al., 2022; Russo & Hopkins, 2017). Moreover, the differing impacts on intrinsic value compared to other task-value components highlight the need for a nuanced understanding of the task value construct and the importance of differentiated assessments. The research primarily focused on the reformulation of real-world problems. Including a wider variety of problem types (e.g., intra-mathematical problems) could help determine whether this finding holds across different contexts and problem formats. In addition, qualitative research on this issue could provide further insight into the differences between value components in problem posing.

On a practical level, our findings suggest that prompting students to reformulate easy problems can be beneficial, even if it does not improve their problem-posing performance, because it can enhance their motivation.

Decoding emotions in relation to perceived difficulty: How primary students engage with mathematical tasks

Bianca Nicchiotti[1], Ilaria Paternoster[1] and Camilla Spagnolo[2]

[1]Free University of Bozen/Bolzano, Italy; bianca.nicchiotti@unibz.it

[2]University of Ferrara, Italy

This study explores emotional factors influencing primary school students' perceived difficulty when solving mathematical tasks. The research involved 49 students aged 7 to 9, with 20 of them being interviewed. The aim was to identify emotions related to perceived task difficulty through qualitative analysis of semi-structured interviews. Students engaged in collaborative, geometry-focused activities using Lénárt spheres. The results indicate that while emotional factors, both positive and negative, emerged, students often struggled to articulate these emotions. The findings suggest that emotions are meaningful and independent contributors to perceived difficulty. Further research is required to deepen understanding of the role emotions play in students' learning experiences.

Keywords: Mathematics education, qualitative study, perceived difficulty, emotions, primary school.

Introduction and theoretical framework

Research in mathematics education has long dealt with difficulties in mathematics. Focusing on students' difficulties related to solving mathematical tasks, factors such as the mathematical content and affective factors have an influence on them (see, for example, Zan, et al., 2006). On the contrary, the issue of perceived difficulty has not been analysed with the same attention. The *difficulty* and the *perceived difficulty* of a task are deeply interconnected; however, they are different. In fact, the difficulty of a task is usually objective and evaluated in retrospect based on the results obtained from the sample to which the task was proposed (Mehrens & Lehmann, 1991), while perceived difficulty is related to individual perception, and it is more personal. In mathematics education, there is currently no agreed-upon definition of the perceived difficulty of a task, although this aspect has been analysed in different fields, including cognitive psychology (see, for example, Efklides & Touroutoglou, 2010).

Concerning students, there are very few studies analysing their perception of difficulty and the factors influencing it and, in those studies, difficulty and perceived difficulty are not explicitly distinguished and the focus is on the cognitive side of the process, meaning that the factors described are merely linked to the objective characteristics of the task (Lee & Heyworth, 2000). Recently, some qualitative research highlighted the factors that contribute to the perceived difficulty according to students with respect to mathematical tasks (Saccoletto & Spagnolo, 2022; Spagnolo & Saccoletto, 2023). Those factors were organised into five non mutually exclusive macro-categories (Resolution Strategies, Capabilities and Experience, Emotions, Task Formulation, Self-considerations), further detailed in more specific subcategories. The macro-categories come from textual analysis of secondary students' open-ended answers, when asked to solve mathematical tasks, evaluate their difficulty and explain their reasons. The analysis was performed according to Constructivist Grounded Theory (Mills et al., 2006), therefore the macro-categories of factors influencing perceived difficulty have been

determined inductively from data. The first macro-category is "Resolution strategies" and it refers to the strategies necessary to solve the task or the fact that elements were needed to reach a solution. The second macro-category is "Capabilities and experience", and it includes students' self-perceived competence, skills as well as eventual prior experiences in solving similar tasks, and therefore their familiarity with them. Within this macro-category, we can find also students' reflections on their doubts and challenges faced during problem-solving and the time spent doing it. The third macro-category, named "Emotions", regards the emotional aspects. The fourth macro-category, "Task formulation", refers to the formulation of the task itself, both in its textual and non-verbal elements. Finally, the fifth macro-category is "Self-considerations", and it includes references to students' personal reflections related to their own success and effort in mathematics. Qualitative research involving secondary school students, carried out using the macro-categories, showed that the "Emotions" one results systematically underrepresented or not represented at all (Spagnolo & Saccoletto, 2023; Nicchiotti & Spagnolo, 2024). In fact, secondary school students seem not to give importance to subjective aspects when dealing with mathematics and tend to mention the emotional side only when directly asked about it (Nicchiotti & Spagnolo, 2024).

Research in mathematics education has shown an increasing interest in affective aspects concerning mathematics from the beginning of the 2000s while, until then, it had focused mostly on cognitive factors, with rare exceptions such as mathematics anxiety (Schukajlow et al., 2023). McLeod (1992) conceptualizes emotions in mathematics learning considering them as part of an affective range together with belief and attitudes, with emotions being the most intense but the least stable among the three. Furthermore, Ekman's theory of basic emotions (1992) has been used in research about problem solving in mathematics education (Hannula, 2015), but it emerged that basic emotions would be rare in learning context. Therefore, there is the need to investigate emotions emerging strictly in the educational context (Lehman et al., 2008). We referred to achievement emotions (Pekrun, 2006, 2011), which are defined as emotions linked to activities or outcomes, evaluated according to achievement-related quality standards. In particular, we adopted the novel three-dimensional taxonomy of achievement emotions (Pekrun et al., 2023), which includes the following 12 emotions: enjoyment, hope, pride, relaxation, assurance, relief, anger, anxiety, shame, boredom, hopelessness, disappointment. According to Pekrun and colleagues (2023), individual perception, including perceived difficulty of a task, can influence emotions. However, emotion can mutually impact the environment and the perceptions associated with it, even though this side of the reciprocal causation still needs to be investigated (Pekrun et al., 2023).

Research aim

Under these premises, it appears that students' perceived difficulty needs to be investigated further, focusing on the possible emotional factors influencing it. Antognazza and colleagues (2015) show that primary school students, when asked straightforward questions about the emotions felt before and during problem solving, mention different emotions, both positive and negative; these emotions are related to their assessment of the difficulty of the problem (Antognazza et al., 2015). We are interested in exploring whether emotions would still emerge with different and more open prompts, not explicitly mentioning them, and check if students' emotions would allow us to characterize more precisely the concept of perceived difficulty.

In this first explorative study, we focused on primary school students, as research still needs to explore the emotions experienced by children in that age group (Lichtenfeld et al., 2012). Our research question can be expressed as follows: which types of emotion related to perceived difficulty emerge, if any, from primary school students when dealing with mathematical tasks?

Methods

We carried out a qualitative exploratory study, involving 49 primary school students aged 7 to 9, who were attending an optional after-school course. The students were 21 girls and 28 boys, and they were from different classes and had been grouped into two new classes for the course (hence, each of them knew only some of the other children). They participated in five sessions, lasting two hours each, held over the course of a week. The activities were guided by two researchers in mathematics education; the mathematics class teachers were present only to supervise the students and they interacted sporadically to voluntarily participate in some of the activities with the students. The course consisted of activities with active involvement of the learner, in the sense proposed by Emma Castelnuovo (see, e.g., Castelnuovo, 1963).

The course was titled "The geometry of soap bubbles" and was focused on activities regarding comparative geometry, namely the comparison between Euclidean and spherical geometry in our case. During the sessions, the students worked in small groups collaboratively using Lénárt spheres to reflect on geometrical concepts and their characterisation on the plane and on the sphere; they investigated and built geometrical objects and definitions. The tasks proposed were selected among the ones experimented with children from different school grades and pre-service teachers using the Lénárt spheres, already present in the literature (Gambini, 2021; Gambini & Lénárt, 2021). Some of the tasks required children to discover the counterpart of segments, lines and triangles (which they knew on the plane) on the sphere. The tasks were introduced in a discursive and playful manner: we started recollecting the knowledge the students already had about plane geometry; then students were asked what they thought would happen if they tried to construct the same geometric entities on the sphere. They found out that lines on the sphere are maximum circumferences, and therefore on the sphere it is indeed possible to build three perpendicular lines, and that on the sphere the sum of the internal angles of a triangle could be greater than 180°. Much time was dedicated to their discussion and explanation of the construction and reasoning of each group.

At the end of the last session, we randomly selected 20 students and interviewed them in 7 small groups, keeping together the ones that had worked together during the sessions. Each group of students was interviewed separately; we let them express their opinions freely and sometimes asked clarifying questions. We asked them how they perceived the tasks, if they were easy or difficult and why, then we asked what they would change, being the teacher, to make the tasks easier. We decided to evaluate perceived difficulty after solving the task as we were interested also in the elements related to strategies implemented to solve it. We recorded the audio of the interviews and later analysed the transcript qualitatively, focusing on the answers to the first questions. The analysis was carried out using the software MAXQDA Analytics Pro 24 (v. 0.4). Specifically, we imported the interview transcripts into the software, where they appeared in the "Documents" section. Subsequently, we created 17 distinct codes within the "Code" section, each corresponding to a specific subcategory

within the five macro-categories of factors influencing perceived difficulty (Spagnolo & Saccoletto, 2023). Each macro-category's code was assigned a unique and casual colour and each code was labeled according to its respective subcategory. Following this preparatory phase, we proceeded with the analysis of each interview by reading and identifying words or sentences that were relevant for our research, and assigning each excerpt an appropriate code. Upon completion of this step, the "Code" section displayed numerical values next to each code, indicating the frequency of the code application throughout the dataset. Finally, we analysed in depth any reference to the macro-category "Emotions", using achievement emotions (Pekrun, 2023) as a reference, highlighting each specific emotion expressed by students. The coding phase was carried out independently by two of the researchers, who then compared their results with each other and with the third researcher to reach a consensual coding.

Results and discussion

We started analysing children' perceived difficulty of the tasks proposed. The answers varied from "some [tasks were] easy and some difficult", "medium difficulty" and "differently easy". None of the children stated that they were all easy or difficult and most of them then provided punctual examples of tasks solved during the sessions that they found easy or difficult. We noticed that there was no accordance between the children in defining the same activity easy or difficult, even with children from the same small group. Each student had their own perceived difficulty regarding each one of the tasks, and their perceived difficulty was influenced, but not determined, in absolute terms by the group they worked in.

Regarding the factors influencing perceived difficulty, we could find reference to each of the five macro-categories. In Table 1 we reported a summary with the number of references classified in each of them and the percentage. Being the macro-categories non mutually exclusive, the same part of the transcript might be categorised in more than one of them and therefore coded with different codes. It occurred with high frequency to find short statements in which elements pertaining to different macro-categories were mentioned. A representative example is the phrase "[Drawing three parallel lines on the sphere was difficult] because I had drawn a circle, another one on it and one more had to be done crossway, and I had done it kind of sideways", which belongs to the macro-category "Capabilities and experience" because of the reference to the obstacle encountered but also to "Resolution strategy" because the child explains the procedure needed to solve the problem.

Table 1: Distribution of the references among the macro-categories

Macro-categories	Number of references	Percentage
Resolution strategies	11	22,45%
Capabilities and experience	17	34,69%
Emotions	6	12,24%
Task formulation	5	10,20%

Self-considerations	10	20,41%

As shown in Table 1, we identified 6 references to the macro-category "Emotions". The emotional factors were mentioned by 4 out of 7 groups interviewed: only once, the fact that a student mentioned emotions during the interview sparked a discussion in the group about the theme, resulting in more children considering them. Moreover, the emotional factors do not seem to be systematically related to other specific macro-categories, meaning that the children who mention emotions consider also other factors when explaining their perceived difficulty, but those factors vary depending on the child.

Moving on to describe the emotions emerged, we identified both positive and negative emotions, which coexist even within the same group of children. In Table 2 we show the parts of the transcript coded with the code "Emotion", associated with the specific achievement emotion that we assigned during the analysis.

Table 2: Interview excerpts referring to emotions, associated with the achievement emotion involved

Excerpt	**Achievement emotion**
[The task regarding the spherical triangle was difficult] because Child A did everything, because I had not understood [how to do it].	Shame
[The activities] were fun.	Enjoyment
Because I like geometry, well, the subjects I like are also easier in my opinion.	Enjoyment
[Working] alone is easier but together is more fun.	Enjoyment
[Working] alone [is easier] because alone you are more satisfied	Pride
[It was hard because] the first time I said oh my dear! spherical geometry what is that?	*Hopelessness*

Not all the achievement emotions have been identified in the interviews; however, the model seems suitable for our analysis as the emotions expressed by children were classifiable as such. The only exception is the last excerpt. It was part of a student's longer and broad discourse regarding also their previous experiences with mathematics and other school subjects, in which they said that when you see something for the first time you might think it is very hard but then you look back at it, you study and understand it perfectly. In this case, the emotions are conveyed through interjections and exclamations rather than a specific word or expression. We could identify this emotion as *hopelessness*, but it does not seem to fit precisely, as the phrase in its context seems to communicate something more similar to surprise, which is not part of the achievement emotions.

Another aspect to consider is the influence of the type of task on the emotions experienced by children. Firstly, not all children consider the type of task when motivating their perceived difficulty.

They discuss the task, but do not really consider explicitly their general characteristics, such as the fact that it is very distant from their everyday schoolwork, even though they are absolutely clear about that when asked if they have already done something similar. Secondly, the students that elaborate on the type of task and link it to emotional aspects, do it in different ways. For instance, two children say that working alone is easier: one of them links the autonomous work with a positive emotion (pride), while the other links the group work with a different positive emotion (enjoyment), even if they find it more difficult. Hence, the type of activities (in the sense of Emma Castelnuovo) seems to encourage the development of positive emotions, but it is not the only condition to do so.

Analysing the coded excerpts as a whole, we could finally make a general observation: children seem not to be able to describe their emotions, nor to give them a name. To communicate them, they rely on stories, mimical expressions and tones, more than words. This might be for two main reasons: the first possibility is that their young age makes it difficult to them to understand their emotional states; the second one is that their emotions are clear to them, but they lack the verbal skills and terminology to communicate them. Obviously, since the sample is very small, we cannot generalise our findings; however, they might be hypothesis to be taken into account and investigated with further research.

Concluding remarks

In this paper, we presented results of a first qualitative study aimed to explore if and how emotions are mentioned in relation to perceived difficulty by primary school children. To do so we focused on tasks which are far from the usual schoolwork, and we investigated children's opinions through semi-structured interviews. We could conclude that emotions are expressed among the factors influencing primary school children's perceived difficulty. In addition to that, both positive and negative emotions are considered (in accordance with Antognazza et al., 2015), and they do not seem to be subordinated to other factors. This means that emotions were present in children's responses independently of the presence of other factors and not only associated with some of them, suggesting that they are one of the independent macro-categories of factors influencing perceived difficulty also for primary school students. To generalize our findings, we need to be cautious due to the small sample size, and further research is required to validate and strengthen the results.

The need for the study originated from the underrepresentation of the macro-category "Emotions" in other qualitative studies (Spagnolo & Saccoletto, 2023; Nicchiotti & Spagnolo, 2024), while the findings of the present research are contradicting that. This might depend on several elements: the activity proposed, the age of the participants and the method of data collection. In fact, in the other studies, the tasks were not collaborative, with active involvement of the learner and distant from the usual ones done in class. Secondly, we involved primary school students, while in the other studies only high school students participated. Finally, in the other studies perceived difficulty had always been analysed through questionnaires of different types, and not always associated to interviews. We do not want to reduce the complexity of such an image isolating one key element to unlock the expression of emotions, nor we think it would be useful or possible. Anyway, the elements discussed have to be held present in successive investigations.

Finally, we see that the research on emotions as factors influencing perceived difficulty might be developed in many directions. Looking at the whole picture, we have primary school children which

express emotions but often struggling and they have difficulties in describing and naming their emotions. On the other hand, previous research shows that secondary school students often neglect emotions, not even mentioning them at all (Nicchiotti & Spagnolo, 2024). Therefore, there is the need to close the gap studying what happens in between the two moments. It is important to understand whether students simply lose or not develop the ability to describe their emotions as they grow older, or if they do not express emotions because they have still difficulties doing so as in primary school, but growing up they come to disregard emotions, because anything they have difficulties expressing basically does not exist.

Strategy-based motivation regarding questioning: Self-efficacy, values, costs, and gender

Stanislaw Schukajlow[1], Pia Köhler[1] and Alexander Westhölter[1]

[1]University of Münster, Institute of Mathematics Education and Computer Science Education, Münster, Germany; schukajlow@uni-meunster.de

Motivation and strategies play a crucial role in students' learning. In this study, we examined the motivation behind using the questioning strategy while solving modelling problems (i.e., the strategy to generate questions about the situation described in the task). Using the expectancy-value theory, we analyzed the relationships among three components of strategy-based motivation: self-efficacy, values, and costs, as well as gender differences in these three components. To address our research questions and test hypotheses, we collected data from a study involving 121 lower-secondary school students, assessing their motivation. The findings revealed (1) a positive relationship between self-efficacy and values, but no relationship between costs and other components, and (2) lower self-efficacy in the questioning strategy in female students. These results suggest that gender differences should be considered in research and practice when examining strategy-based motivation.

Keywords: Motivation, gender differences, learning strategies, self-efficacy, value.

Introduction

Motivation is a key concept in theories of affect (Hannula et al., 2019). It serves as the reason behind human behavior (Middleton & Spanias, 1999) and includes a variety of affective constructs. One of the most influential motivational theories in educational psychology, which received recently increased attention in mathematics education (Rach, 2023; Schukajlow et al., 2023), is Eccles's expectancy-value theory of achievement motivation (Eccles & Wigfield, 2020). This theory posits that expectations of success (including self-efficacy expectations), task values and (perceived) task costs are key determinants of students' educational choices and academic outcomes, such as the decision to pursue an advanced mathematical career, their school grades, performances, and competencies.

Motivation—similar to other affective constructs—can be directed toward various aspects such as learning in general as well as mathematics, specific mathematical topics or competencies, strategies, or tasks like problem solving and modeling tasks (Schukajlow et al., 2023). This study focuses on the concept of strategy-based motivation, which involves the characteristics and use of specific strategies (Karabenick et al., 2021; Schukajlow et al., 2022).

Prior research on solving modelling problems (i.e., problems that required demanding transition between real-world situation and mathematics) demonstrated that students already have difficulties with understanding the situation. Using strategies, such as generating a question to a situation described in the task, can improve learning. Prior studies indicate that learner-generated questioning can enhance reading comprehension (Song, 2016; Weinstein et al., 2010). As reading comprehension is a crucial ability in solving modeling problems, generating questions for a modelling task can improve modelling performance. Thus, this study focuses on strategy-based motivation regarding

learner-generating questioning while solving modelling problems. Additionally, we explored gender differences in questioning strategy. Specifically, this study aimed to analyze the relationships between self-efficacy, task values, and costs related to the questioning strategy and to examine gender differences in motivation for using this strategy.

Theoretical background

Self-efficacy, values, and costs

According to expectancy-value theory, students' subjective beliefs play a crucial role in their career choices, performance, and strategy use in the context of education and learning (Eccles & Wigfield, 2020). Expectancies refer to one's beliefs about their ability to perform a task, such as generating a question about a given situation. Expectancies are closely related to self-concept of ability and self-efficacy expectations, which were used in the past to assess expectancies. The construct of self-efficacy expectations was introduced by Bandura (2003) in social-cognitive theory. For the questioning strategy, students with high self-efficacy expectancies would respond positively to the question "Can I generate a question?". Other key components of expectancy-value theory are task values. Students who place high values on a strategy are more likely to use it frequently. Those who value the questioning strategy would respond positively to the question "Do I value generating a question?". Task values can be categorized into three types: attainment value, intrinsic value, and utility value. Attainment value suggests that an activity, like generating a question to solve a problem, is integral to one's personal identity. Intrinsic value reflects the enjoyment derived from the activity, such as the pleasure of generating questions. Utility value indicates the perception that the activity will help achieve goals, for instance, using a questioning strategy to solve a problem. Task costs are another critical aspect of motivation, encompassing the time cost and effort cost which students are willing to invest in an activity. Students who have low task costs associated with the questioning strategy might affirm, "Am I free of blockages that prevent me from investing time and effort into generating questions?". Originally, costs were considered to be a part of values (Eccles & Wigfield, 2020). In recent discussions, researchers have shown that cost is a distinct factor, have differentiated between different types of costs, and have analyzed the relationships of cost to values and expectancies as well as to other motivational and achievement constructs.

Expectancies, values, and costs have been found to predict learning outcomes, including educational choices and academic achievement in mathematics (Eccles & Wigfield, 2020; Rach, 2023). In one of the studies, researchers observed that self-efficacy expectations and the task costs of using a drawing strategy influenced the quality of students' drawings and their performance in solving geometry modelling problems (Schukajlow et al., 2022). This result indicates that strategy-based motivation can be an important predictor of strategic behavior and academic achievement.

Relationships between expectancies, values, and costs

The relationships between self-efficacy, values, and costs have implications for whether these components can be distinctly measured. However, these relationships have not yet been the central focus of research and require further exploration of different motivational objects. Whereas several studies included information about the relationships of self-efficacy, values, and costs of

mathematics, there is barely any evidence about the relationships of motivational components regarding other objects such as strategies. For example, with the questioning strategy, a key question is whether students who believe they can successfully generate a question also value this strategy more and perceive lower task costs associated with it compared to those who are uncertain about their ability to use this strategy effectively in problem-solving.

Based on the expectancy-value theory, one can posit that students who assign high values to an activity will more deeply and more often engage in it, develop greater proficiency in this activity, and subsequently report higher self-efficacy regarding that activity. Additionally, self-efficacy may be linked to task costs: students who see an activity as less costly may engage in it more frequently, achieve greater success, and, as a result, improve their self-efficacy. Expectancy-value theory (Eccles & Wigfield, 2020) suggests that several factors influence students' task values and costs. For instance, students' past experiences, which are related to self-efficacy expectations, can affect their emotional responses (such as anxiety toward the activity), which in turn influence task values and costs. The theory posits a close relationship between values and costs, with Eccles and Wigfield (2020) assuming that the overall value of a task depends on its costs. If students perceive an activity as too time-consuming or challenging, they may perceive it as less valuable. For example, if students believe that generating a question is not worth the time or effort, they may value the questioning strategy less than students who perceive it as less costly, regardless of the benefits.

Most studies have found significant relationships between the three components of motivation. For example, the relationship between expectations and the intrinsic value of mathematics for U.S. school students ranged from .36 to .68 (Gaspard et al., 2020). In a study of adolescent students in Korea, cost was negatively related to both expectancies (-.24) and task values (-.23) in mathematics (Jiang et al., 2018). To the best of our knowledge, only one study analyzed strategy-based motivation for drawing strategy, and no study focused on motivation regarding questioning. In the case of learner-generated drawings, self-efficacy was found to be positively related to values (.39 and .48) and negatively to costs (-.39 and -.15) (Schukajlow & Rellensmann, 2022).

Gender and motivation

Gender differences have been a central focus in the development of expectancy-value theory, which suggests that disparities in STEM choices between genders can be attributed to variations in expectancies and values, rooted in societal gender stereotypes (Eccles & Wigfield, 2020). Even in some recent studies, gender was recognized as a continuum, many studies still use gender as a binary concept (Becker & Hall, 2024). The reason for this conservative view is lower girls' performances in STEM subjects—especially among high-achieving students—as well as girls' lower self-efficacy in mathematics and higher anxiety across different countries and cultures (Encinas-Martin & Cherian, 2023). Thus, gender differences remain a great concern and that must be addressed in research, educational policy, and teaching practice. Students' motivation is suggested being one of the prevalent reasons for the gender gap in mathematics (Becker & Hall, 2024; Encinas-Martin & Cherian, 2023).

Expectancy-value theory posits that students are more likely to value activities that align with their social and personal identities (Eccles & Wigfield, 2020). Participating in these activities allows them

to express their identities. In many societies, mathematics is often perceived as a male domain, leading many female students to feel that mathematics is not a part of their identity, and thus they tend to value it less than their male counterparts. Gender role stereotypes were found to be related to lower expectations of success in girls and higher expectations of success in boys (Wolff, 2021). This contributes to the observed gender gap in expectancies and values. For instance, in the 2022 PISA study, female students in Germany reported lower self-efficacy in mathematics compared to male students, with Cohen's *d* values of 0.34 vs. 0.45 for easy vs. demanding tasks, respectively (Diedrich et al., 2023, p. 100). Similar results were observed also for value-related constructs such as interest (Schiepe-Tiska & Schmidtner, 2012).

However, it remains unclear how gender differences in self-efficacy, values, and costs are specifically related to strategy use, such as generating questions for problem-solving. To the best of our knowledge, only one study has analyzed strategy-based motivation by assessing students' use of the drawing strategy (Schukajlow & Rellensmann, 2022). In that study, female students reported lower self-efficacy in making drawings but placed a higher value on this strategy compared to male students. The task costs did not differ between female and male students.

Given that questioning is integral to the problem-solving process in mathematics, it is reasonable to hypothesize that female students may have lower expectations of success in this area. This hypothesis is supported by evidence of gender differences in anxiety and self-efficacy related to the drawing strategy (Schukajlow et al., 2019; Schukajlow et al., 2022). However, we do not have specific predictions regarding differences in values and costs. It is possible that female and male students may value the questioning strategy similarly and perceive a comparable level of costs when using it.

Research questions and hypotheses

In this study, we analyzed the following research questions and posed the following expectations:

Q1. Are self-efficacy, task values, and costs related to each other with respect to the questioning strategy?

H1. We hypothesized a positive relationship between self-efficacy and task values and a negative relationship between both self-efficacy and task values with costs.

Q2. Do female and male students differ in self-efficacy, task values, and costs with respect to the questioning strategy?

H2. We expected that female students will report lower self-efficacy expectations for the questioning strategy than male students. No clear hypotheses on gender differences regarding values and costs with respect to the questioning strategy could be derived from motivational theories.

Methodology

Sample and procedure

To answer the research questions and examine the hypotheses, we developed questionnaires for strategy-based motivation regarding questioning strategy and distributed them to low-secondary students. One hundred and twenty-two students from three middle-track schools (German Realschule) participated in this study. 82 students were males, 34 were females, three reported being of non-binary

gender and two did not report the gender. Thus, the sample utilized in this study was one hundred and sixteen students ($N = 116$). The mean age of participants was 14.3 years of age.

Students received modelling problems and were asked to generate two questions about the situation. After that, they estimated their understanding of the situation and filled out questionnaires on self-efficacy expectations, task values, and costs with respect to the questioning strategy.

Measures

We employed 5-point Likert scales to measure self-efficacy, task values, and task costs regarding the questioning strategy. The responses ranged from 1 (not at all true) to 5 (completely true). The items were adapted from previous studies on motivation, learning strategies in mathematics, and the drawing strategy in modelling (Schukajlow et al., 2022), tailored to focus specifically on generating questions for solving challenging word problems. Self-efficacy in using the questioning strategy was assessed through three items (e.g., "I am confident that I can always ask helpful questions about difficult word problems"; internal consistency Cronbach's $\alpha = .467$). Task value was measured across three dimensions: interest value (2 items; e.g., "I enjoy asking questions about difficult word problems"), attainment value (3 items; e.g., "Asking questions about difficult word problems is typical for me"), and utility value (3 items; e.g., "I believe asking questions is important because it helps me solve difficult word problems"). The overall task value scale demonstrated sufficient internal consistency (Cronbach's $\alpha = .75$). Personal cost was assessed using three items which refer to the time and effort needed for generating questions (e.g., "Asking questions about a difficult word problem requires significant effort from me"; Cronbach's $\alpha = .516$). Although the scales for assessing strategy-based motivation regarding questioning were adapted from prior studies, the internal consistency for value and cost was unexpectedly low. Thus, the results should be interpreted with caution. The low internal consistency is a significant limitation of the study.

Results

Relationships between self-efficacy, values, and costs with respect to the questioning strategy

Firstly, we explored the relationships among three components of motivation based on the expectancy-value theory: self-efficacy, values, and task costs. To investigate this, we analyzed Pearson's correlations. Consistent with hypothesis H1, the analysis revealed a positive relationship between self-efficacy expectations and values with respect to the questioning strategy (.581; $p < .001$). However, unexpectedly, we did not observe a negative correlation between self-efficacy and cost (-.065; $p = .250$). Furthermore, task values and task costs were not negatively related (.118; $p = .209$) as assumed in expectancy-value theory. These findings partially supported initial expectations.

Differences in self-efficacy, task values, and costs between female and male students

We addressed the second research question on gender differences in motivation by calculating multivariate ANOVA with independent variable gender and dependent variables self-efficacy expectation, values, and task costs (see descriptive statistics in Table 1). The statistical analysis confirmed differences between female and male students regarding motivation, $F(3, 111) = 3.161$, $p = .013$, $\eta^2 = .079$. As expected, we observed lower self-efficacy expectations in female students $F(1,$

113) = 3.087, p = .011, η^2 = .045. Values and costs did not differ between female and male students (values: $F(1, 113) = 0.042$, p = .784, η^2 = .001; costs: $F(1, 113) = .185$, p = .668, η^2 = .002).

Table 1: Gender, self-efficacy, task values, and costs with respect to questioning strategy

	Self-efficacy *Mean (SD)*	Values *Mean (SD)*	Costs *Mean (SD)*
female	2.07(.77)	2.47(.76)	3.26(1.01)
male	2.43(.75)	2.43(.76)	3.18(.89)

Discussion

This study explored the relationships between motivational components and examined gender differences. Grounded in the expectancy-value theory (Eccles & Wigfield, 2020) and initial findings about the possible positive effects of generating questions on reading comprehension (Song, 2016; Weinstein et al., 2010) and modelling, we focused on questioning strategy as an object of motivation (Schukajlow et al., 2023). An important limitation of this study is addressing a strategy that students might not be familiar with, which suggests the need for qualitative methodology in future research.

Our findings revealed a positive correlation between self-efficacy and task values. Students with higher self-efficacy for using the questioning strategy tend to prior findings about questioning strategy, highlighting a potential feedback loop where increased value leads to greater engagement, enhancing performance, and boosting self-efficacy in questioning strategy. Interestingly, our data did not confirm the hypothesized relationships between self-efficacy and cost and between values and costs. One explanation might be that students had difficulties estimating how costly is this strategy and because of that, their reports about costs were biased. Even though we asked students to generate questions about a given situation before assessing motivation in this study, this could be not sufficient, as the questioning strategy is not a typical strategy that students apply in mathematical classes. This finding, along with the generally weak correlations involving costs, suggests that cost should be considered a distinct motivational component in future research. Prior findings indicated that costs' relationships with self-efficacy and value are not stable (Schukajlow & Rellensmann, 2022) and might be influenced by students' problem-solving experiences with the task that students attempt to complete such as generating questions in this study. Our study contributes to the broader understanding of motivational components by extending the predictions of expectancy-value theory to the context of self-generating questioning in problem-solving. The results of this study add to prior findings on the relationship between motivational components in mathematics (Gaspard et al., 2020) and strategy-based motivation (Schukajlow et al., 2022; Schukajlow & Rellensmann, 2022). The investigation of strategy-based motivation in this specific context is a novel aspect of our research and offers fresh insights into the dynamics of self-efficacy, values, and cost. In future research, factors such as prior questioning experiences and prior knowledge should receive more attention.

The analysis of gender differences revealed significant disparities in self-efficacy between male and female students. Female students reported lower self-efficacy compared to their male counterparts,

consistent with previous research on gender gaps in mathematics-related self-efficacy (Becker & Hall, 2024; Diedrich et al., 2023; Encinas-Martin & Cherian, 2023) and in drawing strategy-related self-efficacy (Schukajlow & Rellensmann, 2022). The explorative analysis of gender differences in values and costs revealed that students value the questioning strategy independently of gender and that female and male students estimate the strategy as similarly costly. This finding suggests that traditional gender stereotypes in mathematics do not uniformly apply across all motivational components and types of problem-solving activities, particularly those involving value and cost with respect to creative strategies such as questioning in this study (see also results for value of the drawing strategy in Schukajlow & Rellensmann, 2022). These findings have important practical implications for mathematics education. Female students' self-efficacy needs stronger support in the classroom not only in mathematics in general but also with respect to strategies.

Perceived difficulty of a mathematical task: do in-service and pre-service teachers have a common view?

Camilla Spagnolo[1] and Chiara Andrà[2]

[1]University of Ferrara, Italy; camilla.spagnolo@unife.it

[2]University of Eastern Piedmont, Italy

This qualitative study investigates how pre-service and in-service teachers perceive the difficulty of mathematical tasks and examines the factors that shape their evaluations. Using two tasks from the national large-scale assessments INVALSI, we aimed to identify whether perceived difficulties align with those of students and to explore any discrepancies between the two teacher groups. Our findings reveal significant differences between pre-service and in-service teachers, particularly in their handling of open-ended versus structured tasks. In-service teachers generally demonstrated alignment with students' evaluations for simpler tasks, while pre-service teachers exhibited emotions with respect to complex tasks. In our interpretation, these results highlight both the influence of teacher experience on perceived difficulty and the importance of addressing both cognitive and affective factors in teacher professional development.

Keywords: Mathematics education, perceived difficulty, pre-service teachers, in-service teachers, qualitative analysis.

Introduction

Difficulties in mathematics have been investigated in several researches, being one of the most open and studied topics in mathematics education. Difficulties can be classified into different categories depending on the focus: difficulties related to mathematics as a discipline or difficulties related to students in terms of deficits or their specific relationship with mathematics (Zan et al., 2006).

In our research, we focused on the difficulties of mathematical tasks, specifically on the *perceived difficulty* (PD) of in-service and pre-service teachers after solving a mathematical task. Literature distinguishes between difficulty *before* versus *after* a task has been attempted or solved (Eccles & Wigfield, 2020; Efklides & Touroutoglou, 2010); this is an important distinction in terms of perception of difficulty, yet in what follows we articulate a definition of PD that works in either cases. The difficulty of a mathematical task seems to depend on a set of factors, including the mathematical content (Thevenot & Oakhill, 2005; Radmehr & Drake, 2017), the formulation of the problem (Bolondi et al., 2018), text comprehension (Spagnolo et al., 2021), students' abilities or capabilities (Vicente et al., 2007), and affective factors (Zan et al., 2006). During the task-solving process, in fact, a student may encounter multiple difficulties that can depend on both the student's individual characteristics (such as abilities, knowledge, beliefs, and attitudes) and the specific characteristics of the task (such as the text or the mathematical content involved). These features of the mathematical task can influence both the student's and the teacher's perception of the task and, consequently, its PD. Thus, while closely connected, difficulty and PD are two different aspects (Spagnolo & Saccoletto, 2023). Furthermore, a student's PD does not necessarily coincide with the teacher's PD, as shown by Arzarello and Ferretti (2021). The mismatch between teachers' PD of a mathematical tasks and the actual success rates of those tasks opens up reflections related to research on teachers' beliefs about what students think (Philipp, 2007), as effective teaching and learning are believed to

develop from the alignment between teachers' and students' beliefs (Kumaravadivelu, 1991). Our goal is to highlight how pre-service and in-service teachers perceive a task—whether it is easy or difficult—and what factors lead them to this evaluation, while also identifying potential mismatches. Specifically, we aim to investigate which view, between pre-service and in-service teachers' ones, is closer to the students' one.

Theoretical and context background

Currently, in Mathematics Education, there is no widely accepted definition of PD, despite its recognized importance as a factor influencing students' behavior when approaching and solving tasks (Eccles & Wigfield, 2020; Saccoletto & Spagnolo, 2022; Doz et al., 2023). In contrast, in metacognition research, the issue of subjective difficulty has been explored over the past 30 years under various terms (e.g., Eccles & Wigfield, 2020; Doz et al., 2023). At times, PD has been considered a form of self-efficacy, though this connection does not seem entirely appropriate (Eccles & Wigfield, 2020). However, related or overlapping concepts have been defined, such as the "feeling of difficulty" (FOD), which was elaborated by Efklides at various points between the late 20th century and 2011. FOD is described as a "metacognitive experience that monitors cognitive processing as it takes place" (Efklides & Touroutoglou, 2010, p.172) and is explicitly distinguished from PD due to its "experiential nature".

Although conceptually distinct, "feeling of difficulty" and PD are sometimes treated interchangeably (Nuutila et al., 2021). Acknowledging their differences, in this paper, we have drawn on some characteristics of both concepts and adapted them to the context of mathematics education research. From this perspective, the synthesis proposed by Doz et al. (2023) was especially helpful and aligned with our viewpoint. It suggests that the nature of the "feeling of task difficulty" is metacognitive, stemming from the monitoring of ongoing task processing, and awareness of this process influences self-regulation, effort, emotions, and strategy use.

The factors influencing PD of math tasks have mainly been studied in relation to students' perspectives (Saccoletto & Spagnolo, 2022). For our analysis, we began with the factors characterizing students' PD, as qualitatively identified by Saccoletto & Spagnolo (2022), and compared these to those reported by teachers in our data. According to this study, PD in mathematics can be classified into five categories: *Resolution Strategy*, *Capabilities and Experience*, *Emotions*, *Task Formulation*, and *Self Consideration*. Note that these categories are not mutually exclusive.

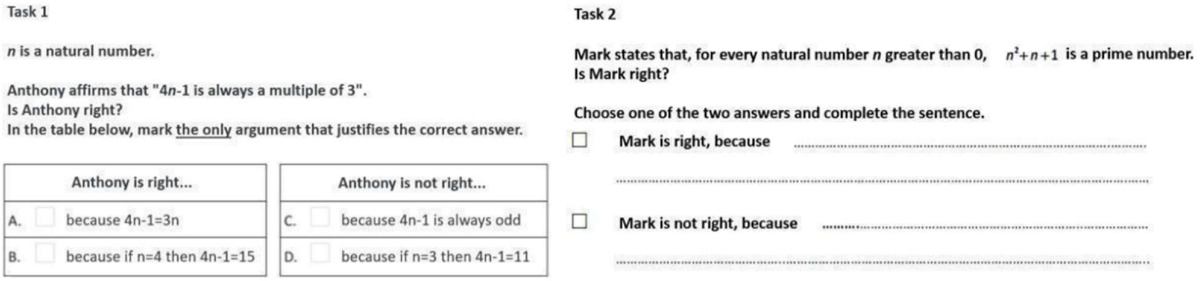
The category *Resolution Strategy* includes responses that explicitly mention the approach or method needed to solve the task, according to students, or highlight key elements like calculation or reasoning required to reach a solution. The category *Capabilities and Experience* encompasses answers that reflect students' views of their capabilities and abilities, as well as their prior experiences with similar tasks, which contribute to their familiarity with the problem. Answers that suggest a problem is easy because it resembles something previously encountered also fall into this category. Additionally, it includes responses related to students' self-perception, doubts about their solutions, and difficulties they faced, including the time spent on the problem. The category *Emotions* pertains to responses involving emotions. The category *Task Formulation* comprises responses that refer to the task's formulation, particularly its textual aspects. Finally, the category *Self Consideration* relates to students' personal reflections on their success in mathematics.

Research aim

Under these premises, our goal is to highlight how pre-service and in-service teachers perceive the difficulty of a mathematical task and to examine the factors that contribute to their evaluations. Furthermore, we aim to identify any discrepancies or differences between the perceptions of these two groups of teachers. A key focus of our investigation is to determine which of the two perspectives is more aligned with students' views of task difficulty, providing insight into how teacher experience influences their understanding of student challenges.

This study seeks to elucidate the multifaceted interplay between teacher experience and the PD of mathematical tasks. By employing a qualitative approach, the research not only investigates the cognitive dimensions of task evaluation but also delves into the affective responses that underpin teachers' judgments.

The research questions guiding this study are:



RQ1: How do pre-service and in-service teachers perceive the difficulty of a mathematical task, and what factors contribute to their evaluations?

RQ2: Are there notable discrepancies between the two groups of teachers?

RQ3: To what extent do their perceptions align with those of students?

Methods

We carried out a qualitative deductive study, involving 52 pre-service teachers and 49 in-service teachers of secondary school. All the teachers were from different Italian regions. Teachers filled in an online questionnaire through Google Forms, containing two tasks, some specific questions related to each task and three general questions. Each teacher worked on the questionnaire on their own, without knowing the other participants' answers. The questionnaire was the same used for students in Saccoletto & Spagnolo (2023), as we considered the categories determined by them for students, as an initial reference for teachers' results. We asked the teachers to solve the tasks (Figure 1) and, for each one, answer specific questions related to PD. Additionally, there were specific questions aimed to investigate attitudes and beliefs towards mathematics.

Task 1

n is a natural number.

Anthony affirms that "4*n*-1 is always a multiple of 3".
Is Anthony right?
In the table below, mark the only argument that justifies the correct answer.

Anthony is right...		Anthony is not right...	
A. ☐	because 4n-1=3n	C. ☐	because 4n-1 is always odd
B. ☐	because if n=4 then 4n-1=15	D. ☐	because if n=3 then 4n-1=11

Task 2

Mark states that, for every natural number *n* greater than 0, n^2+n+1 is a prime number.
Is Mark right?

Choose one of the two answers and complete the sentence.

☐ Mark is right, because .....

.....

☐ Mark is not right, because .....

.....

Figure 1: Task 1 administered to Grade 08 Italian students by INVALSI in 2017 and task 2 administered to Grade 10 Italian students by INVALSI in 2014, www.gestinv.it

We choose two mathematics tasks from the INVALSI tests, as they are statistically validated and were also used in Spagnolo & Saccoletto (2023). In the Italian educational context, INVALSI tests—administered since 2008 in grades 2, 5, 8, 10, and 13 by the National Institute for the Evaluation of the Educational System—allow us to track some of the difficulties students experience over time.

These tests, designed to measure student competence in relation to the Italian curricular guidelines, offer a quantitatively validated tool that complements our qualitative analysis. Our focus was on argumentative questions within the Numbers area. The two tasks (Figure 1) share mathematical similarities, while also exhibiting some differences. Task 1 was a multiple-choice question requiring the identification of a correct argument, whereas Task 2 was an open-ended question that asked for the creation of an argument. Both tasks, however, were based on literal calculation and could be solved using the same strategy—proving the falsity of a statement by providing a counterexample. We remark that the two tasks have been given to students in grades 8 and 10 and they turn out to be difficult in the INVALSI tests, namely a few number of students gave the correct answer. In the study of Spagnolo and Saccoletto (2023) these tasks were administered to students at different grades: grade 8 students (at the end of the school year) and grade 9 students (at the beginning of the school year). The tasks were selected together with the class teachers.

The questions in the questionnaire for tasks 1 and 2 were identical and aimed at probing teachers' ideas, linking them—strictly in a qualitative way—to teachers' attitudes, beliefs, or specific features of the INVALSI tasks. The study adopted a deductive approach to data analysis, starting from the categories identified in Spagnolo and Saccoletto (2023) and working towards a broader understanding of overarching patterns and trends.

All analyses were carried out with Excel for the calculation of average values and for the graphical representation of the data, while the qualitative analysis of the teachers' evaluation of motivation was developed with the software MAXQDA 24 (v. 4.0), using as codes the macro-categories of factors influencing PD (Spagnolo & Saccoletto, 2023).

Results and discussion

Qualitative analysis of teachers' answers highlight important distinctions between how pre-service and in-service teachers perceive the difficulty of mathematical tasks, particularly when comparing Task 1 and Task 2.

Task 1, a multiple-choice question, was generally perceived as less challenging by both pre-service and in-service teachers, though the reasons behind their evaluations differed. In-service teachers, being more familiar with structured tasks, found Task 1 relatively straightforward. Pre-service teachers, while acknowledging the simplicity of the task, raised concerns regarding the clarity of the task formulation. Both groups perceived task 2, an open-ended question, as more difficult. On one hand, in-service teachers found the need for constructing a mathematical argument challenging, but their experience helped them cope with the complexity. Pre-service teachers, on the other hand, attributed much greater difficulty due to the open-ended nature of the task, reporting a reflection focused on the anxiety of answering an open-ended question. Below (Table 1), we present the distribution of responses in percentage terms for each category.

Student's PD does not seem to be related to the ability to answer the question correctly (Saccoletto & Spagnolo, 2022) and seem to refer much more often to the text, personal preparation, specific content, or aspects related to the production of explanation or argumentation to support their results. Also completely missing are aspects related to emotions, but much more present are self-considerations on how to improve one's performance.

We report the distribution of the categorized responses of students, pre-service and in-service teachers in the table below. In particular, for students we refer to the analysis in Spagnolo & Saccoletto (2023), so we report number and percentages for teachers, and only percentages for students.

Table 1: Distribution of the responses to Tasks 1 and 2 of students, pre-service and in-service teachers according to macro-categories identified in Saccoletto & Spagnolo (2023). The column with students' percentages is derived from Saccoletto & Spagnolo (2023).

Macro-categories	Students Task 1	Pre-service teachers Task 1	In-service teachers Task 1	Students Task 2	Pre-service teachers Task 2	In-service teachers Task 2
Resolution strategies	51,8%	40,38% (21 teachers)	59,18% (29 teachers)	33,6%	36,54% (19 teachers)	57,14% (28 teachers)
Capabilities and experience	39%	21,15% (11 teachers)	26,53% (13 teachers)	41,2%	30,77% (16 teachers)	46,94% (23 teachers)
Emotions	0%	36,54% (19 teachers)	6,12% (3 teachers)	2,9%	42,31% (22 teachers)	4,08% (2 teachers)
Task formulation	15,3%	28,85% (15 teachers)	18,37% (9 teachers)	5,3%	19,23% (10 teachers)	14,29% (7 teachers)
Self-considerations	47,8%	11,54% (6 teachers)	2,04% (1 teacher)	44,8%	5,77% (3 teachers)	4,08% (2 teachers)

Both for Tasks 1 and 2, pre-service teachers focused mostly (respectively 40,38% and 36,54% of teachers in each task) on *Resolution strategies*, identifying the correct strategy to solve the task, using logical elimination methods common in multiple-choice formats for Task 1, whereas for Task 2 emphasized the challenge of developing a strategy to construct an argument. For example, one teacher states that "if you often solve multiple choice questions, it becomes easier for you. That way you know it's important to start with the options and go by exclusion using logic". This answer was also categorised under *Capabilities and experience*. In-service teachers give also importance to experience and prior familiarity with similar tasks. 6% and 4% in-service teachers referred to the *Emotions* commenting Tasks 1 and 2 respectively, and 2% and 4% on *Self-Considerations* categories, commenting that "if I would have given more open-ended questions to my students during classes, they would have been less in trouble". In short, a few in-service teachers elicited emotions and self-considerations. Some teachers hypothesised problems in comprehension of the task (for both Task 1

and Task 2) connected with *Task formulation*. For example, one teacher stated, "For both tasks, I noticed that the wording could potentially cause some confusion, especially for students who struggle with calculations with letters. However, the instructions are clear enough for those with some experience in solving similar problems".

Pre-service teachers also focused on problem-solving strategies, in particular the answers of 21 pre-service teachers (for Task 1) and 19 pre-service teachers (for Task 2) were categorised below *Resolution strategies*. In both tasks, also *Capabilities and experience* and *Task Formulation* were dominant factors influencing PD of pre-service teachers. However, pre-service teachers frequently elicit emotional factors. Most of the answers under macro-category *Emotions* are related to negative emotions; for example, "Arguing something that has never been seen before in class [referring to '4n-1 is always a multiple of 3'] could generate a lot of anxiety in students", or "If you don't think of using a counterexample, proving a sentence in general can start panic". The emotional impact was most pronounced in Task 2 for pre-service teachers, highlighting the importance of preparing their future students to handle the cognitive and emotional demands of open-ended tasks.

In terms of alignment with student perspectives (for results of students see Spagnolo & Saccoletto, 2023), Task 1 was more easily aligned with students' evaluations, particularly by in-service teachers. This suggests that experienced teachers have a clearer understanding of how students approach and evaluate simpler, structured tasks. Task 2, with its open-ended format, revealed a greater mismatch, especially among pre-service teachers, who overestimated the difficulty, likely due to their limited experience in such tasks with students.

In direct response to our research questions, the results indicate that for RQ1, both pre-service and in-service teachers exhibit distinct perceptions of mathematical task difficulty, with pre-service teachers generally overestimating difficulty due to a greater emotional response and limited experience, whereas in-service teachers demonstrate a more balanced approach rooted in cognitive strategies and familiarity with task structures; in addressing RQ2, clear discrepancies are evident between the two groups, with pre-service teachers' evaluations being more influenced by affective factors and in-service teachers' judgments aligning more closely with analytical reasoning; and concerning RQ3, the alignment between teachers' and students' perceptions is notably stronger among in-service teachers, suggesting that practical experience enhances the ability to accurately estimate student difficulties.

Concluding remarks

The aim of the research is to compare how in-service and pre-service teachers perceive the difficulty of a task, and to see how much they differ from students' PD. PD has a strong affective connotation, as it entails beliefs, self-efficacy and emotions. The categories of resolution strategy, capabilities and experiences (which in our view are linked to beliefs), emotions, task formulation and self-consideration emerge in a previous study (Saccoletto & Spagnolo, 2023) and it has been observed that they might overlap, namely that a same teacher might consider more than one category when formulating their account for why they perceive a task as difficult or easy. Even if overlapping also in our study, these categories emerge with different intensity among groups of in-service and pre-service teachers. We have noticed, in fact, that resolution strategies, capabilities and experiences, and task formulation categories emerge in in-service teachers' accounts. This is also in line with literature

on *difficulty* of mathematical tasks, as Vicente *et al.* (2007) stress the central role of students' abilities and capabilities, Bolondi *et al.* (2018) and Spagnolo *et al.* (2021) maintain that difficulty depend on the formulation of the problem and text comprehension, respectively, and Thevenot and Oakhill (2005) and Radmehr and Drake (2017) link difficulty to the mathematical content, which can be related to the category of resolution strategies.

We have also highlighted that Zan *et al.* (2006) argue that affective factors play a central role in the difficulty of a task, and pre-service teachers in our study focus on emotions quite significantly.

The students' perceptions are more in line with in-service teachers' ones, as if, on one side, as Kumaravadivelu (1991) posits it, there is a (positive, in our view) alignment between students' and teachers' beliefs, but on the other side it seems that emotions are elicited by those who are somehow further from everyday life in mathematical classrooms, namely pre-service teachers.

The relatively small sample size and qualitative nature of the study limit the generalizability of the findings. However, the consistent trends identified across both tasks provide a useful foundation for further exploration into how task type and teacher experience influence PD of mathematical tasks. Moreover, despite the differentiation of factors influencing PD, our definition appears to be adequate in capturing the perception of difficulty across different cases. The categories we identified, while with different distributions, help us categorize the responses of both groups of teachers (pre-service and in-service). They highlight the multifaceted nature of the construct, reinforcing the idea that PD encompasses both cognitive and affective dimensions, as well as task-related and individual-related aspects.

In conclusion, our results indicate clear differences in how pre-service and in-service teachers perceive the difficulty of tasks. Experience plays a key role in shaping these perceptions, and understanding these dynamics is crucial for improving teacher professional development and ensuring that teachers are better equipped to assess and address students PD face in solving mathematical tasks.

The effects of classroom quality on students' lesson-specific mastery experiences on easy, medium difficulty, and hard tasks

Karin E. S. Street[1], Lars-Erik Malmberg[2] and Gabriel J. Stylianides[2]

[1]Western Norway University of Applied Sciences, Institute for Pedagogy, Religion and Social Studies, Sogndal, Norway; karin.street@hvl.no

[2]University of Oxford, Department of Education, UK

The importance of classroom quality on students' learning outcomes is well documented, but the impact of classroom quality on students' mastery experiences, especially in the context of tasks of different levels of difficulty, has received less attention. Investigating this issue is important to understand the role of different domains of classroom quality on student outcomes. In this article, we present our preliminary analysis of how quality of student-teacher interactions predicted students' mastery experiences across a sequence of four lessons. Students reported their end-of-lesson mastery experiences. These reports were linked with observed scores for certain classroom quality domains: emotional support, classroom organisation, instructional support, and student engagement. Across two types of models, which examined within- vs. between-teacher variability, a similar pattern was replicated, highlighting the significance of instructional support for students' mastery experiences.

Keywords: Mastery experiences, classroom quality, teacher-student interactions, level of difficulty, multilevel structural equation model.

Introduction

Classroom quality is important to student outcomes. Many studies demonstrated that high quality classroom interactions are related to positive student outcomes such as social competence, engagement, and learning (see, e.g., Allen et al., 2013; Patall et al., 2018). In mathematics, Zhu and Kaiser (2022) found that teachers' social-emotional support and instructional quality were associated with student outcomes such as students' self-efficacy and interest. König et al. (2021) found that teachers' competence was associated with their instructional quality, while instructional quality (cognitive activation) was associated with students' mathematics outcomes. Expanding our knowledge regarding the role of classroom quality on students' perceived mastery experiences can help unwrap the role of different dimensions of classroom quality on important student outcomes. Furthermore, domains of classroom quality might be differentially related to students' experiences of mastery on tasks of different levels of difficulty, which can have implications for teachers' instructional strategies.

We define *mastery experiences* as students' perceptions of succeeding on tasks, e.g., on learning mathematics during the previous lesson. Mastery experiences are important in at least two ways. First, they are a proxy for students' actual performance experiences, and thus an indication of what they have learnt. Second, as appraised performance experiences they are powerful predictors of students' self-efficacy for learning mathematics (Byars-Winston et al., 2017), which we know is related to their engagement, perseverance, socio-affective states, and mathematics performance (Street et al., 2024).

In this article we focus on students' mastery experiences of learning mathematics for different levels of task difficulty. The ICMI Study Volume on Task Design (Watson & Ohtani, 2015) reflects the importance of tasks as elements of mathematics instruction with important influence on students' opportunities to learn mathematics. The tasks used in the classroom not only convey messages about what doing mathematics entails (e.g., Zaslavsky, 2005), but they also become the objects of students' mathematical activity and shape their experience.

We know that students' (negative) attitudes towards particular mathematical topics are related to their perceptions of task difficulty (Mielicki et al., 2021). Furthermore, we know that difficult tasks are related to steeper changes (growth) in students' mathematics self-efficacy over time (Street et al., 2022), and that the relationship between self-efficacy and performance differs according to perceived task difficulty (Reinhard & Dickhäuser, 2011). These studies highlight the benefit of differentiating between types of outcomes in mathematics, e.g., according to task difficulty. However, we know little about how various classroom factors, such as classroom quality domains, can (differentially) support students' experiences of mastery on tasks of different levels of difficulty. This kind of knowledge might inform teachers' decisions on both task selection (e.g., difficulty level) and type of teacher support (e.g., emotional vs instructional support).

Teachers can support students' mastery experiences both through the types of tasks made available to students and the types of teacher support provided for different tasks. In this study, we focus on classroom quality in relation to classroom interactions, i.e., teacher-student interactions. We draw on the Teaching Through Interactions theoretical framework (TTI; Hamre et al., 2013) where quality in teacher-student interactions is conceptualised through three broad domains, namely emotional support, classroom organisation, and instructional support. Student engagement is included as a separate domain, which can be seen as both a predictor and an outcome of classroom quality. The TTI is operationalised through the Classroom Assessment Scoring System (CLASS; Pianta et al., 2012), in which the three domains are operationalised through 12 dimensions (e.g., positive climate, behavioural management, quality of feedback) and 43 indicators (e.g., relationships, clear expectations, building on student responses). Each indicator is exemplified with several behavioural markers, which are directly observable.

One affordance of classroom quality observation manuals, such as CLASS, is the operationalisation of latent constructs into observable classroom interactions. This enables a deconstruction of the role of different kinds of classroom quality for different kinds of student outcomes. König et al. (2021) conceptualised classroom quality according to the domains of student support, classroom management, and cognitive activation. Of these, only cognitive activation predicted lower secondary students' mathematics performance (König et al., 2021). Patall et al. (2018) found that when students perceived their (science) classwork to be more difficult than usual, this was associated with decreased perceived competence and increased dis-engagement. However, these effects were minimised when the students perceived their teachers to be supportive of their autonomy. In these studies, classroom quality was measured through a novel observation manual (König et al., 2021) or through student reports (Patall et al., 2018). In our study we use an established and standardised observation manual to investigate how quality of student-teacher interaction predicts students' mastery experiences at the end of each lesson during a sequence of four lessons when a new mathematics topic was introduced.

The research question guiding our study was: What are the within- and between-teacher effects of domains of classroom quality (emotional support, classroom organisation, instructional support, and student engagement) on end-of-lesson student mastery experiences for different levels of task difficulty? We present in these proceedings preliminary analyses to this ongoing study.

Methods

170 Norwegian students and their nine mathematics teachers took part in the study across three to four mathematics lessons, where the students were introduced to a new topic in the first lesson of the sequence. Students reported on 597 end-of-lesson mastery experiences for easy, medium difficulty, and hard tasks respectively. In the analysis we report herein, student reports were linked with 34 observations of classroom quality in the second half of each lesson. In future analyses, we intend to include beginning-of-lesson self-efficacy and overall classroom quality as predictors of end-of-lesson mastery experiences.

We administered nine questionnaire items to measure students' mastery experiences at the end of each lesson, three per difficulty level. Students responded on 11-point scales (0 = not at all true; 10 = completely true) to how successful they had been with learning mathematics during the previous lesson, for different levels of perceived task difficulty (example items: *During today's lesson in mathematics, I managed to solve all the tasks that appeared easy to me*; medium difficulty task: *All the tasks that appeared of medium difficulty to me*; hard task: *All the tasks that appeared difficult to me*). Individual differences in changes in mastery experiences are presented in Figure 1.

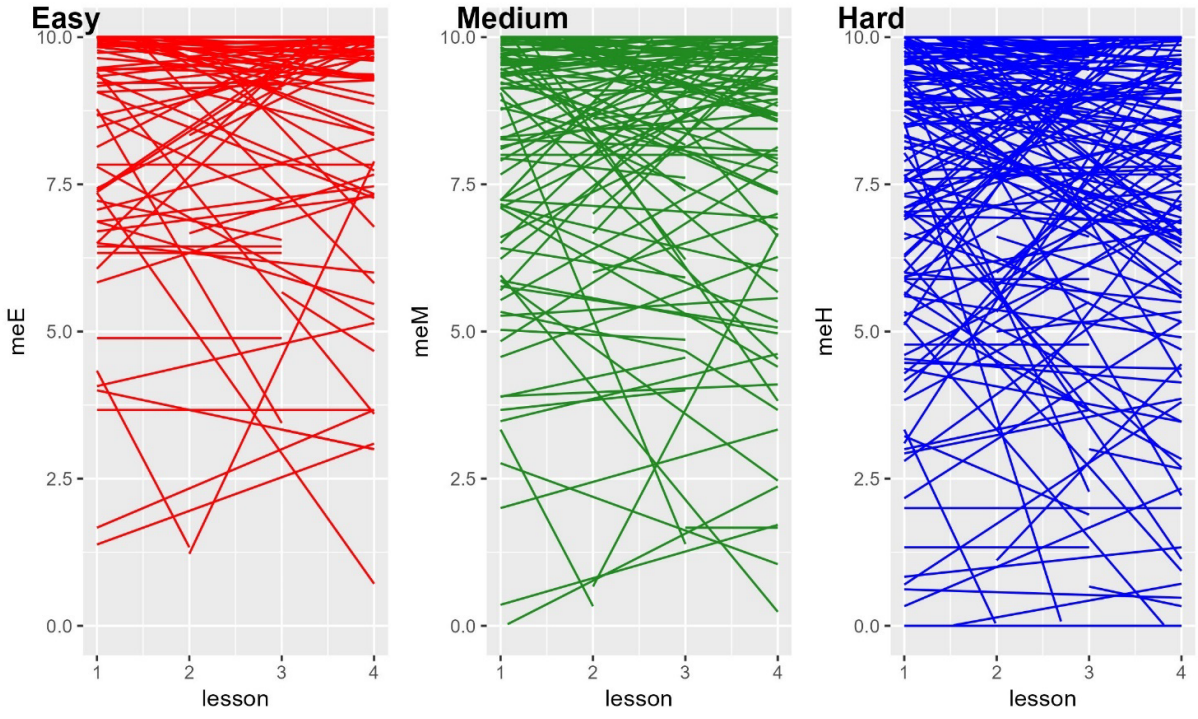

Figure 1: Individual differences in starting point and change in students' mastery experiences for perceived easy, medium difficulty, and hard tasks (predicted linear trajectories).

We used CLASS (Pianta et al., 2012) to measure classroom quality. One certified observer conducted in-vivo scoring according to the CLASS manual, including numeric quality scoring on a seven-point scale (1 = low quality, 7 = high quality) of each dimension of classroom quality. Scoring with CLASS requires observers to complete a certification course and a test to learn how to reliably assess the available evidence for each of the 12 dimensions considering the presence of (observable) behavioural markers. Scoring is conducted on classroom segments of minimum 15-minute duration. Domain-scores were obtained through averaging the dimension scores for each domain. Observed end-of-lesson quality for each domain, for each classroom (teacher) is presented in Figure 2.

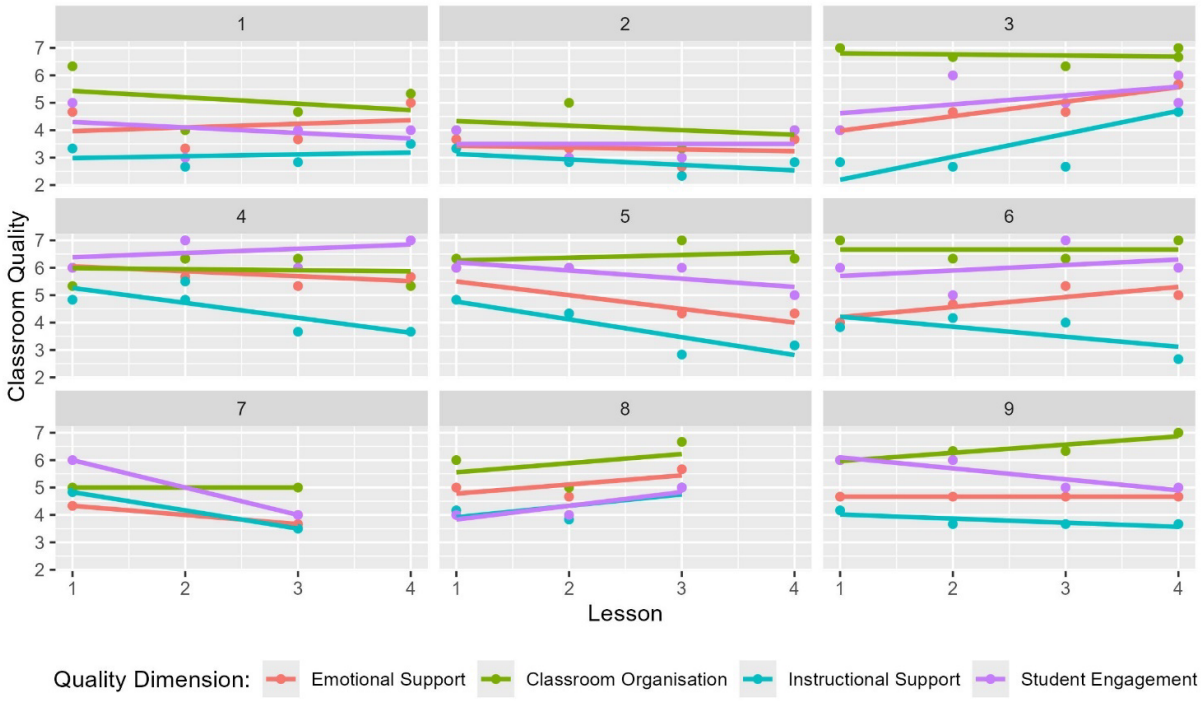

Figure 2: Observed end-of-lesson classroom quality (four dimensions) of nine teachers

We specified cross-classified multilevel models in which lessons (four lessons in a sequence) were nested in both students and in teachers using the Bayesian estimator (Asparouhov & Muthén, 2020; Muthén & Asparouhov, 2012). This way we can assess the effect of quality at the lesson-level, taking account of differences between students and between teachers. An initial multilevel model for change suggested that individual trajectories were linear. As shown in Figure 3 the cross-classified model was specified for time-points (lessons) nested in both students and teachers. This way it was possible to link the observed quality (scored at the classroom level) to each student's lesson-specific report. Models were carried out in Mplus 8.8 (Muthén & Muthén, 2017-20) using the Bayesian estimator. We specified 12 models, three for each quality domain, so that separate models were run for mastery experiences of easy, medium difficulty, and hard tasks.

At the within-level (lessons) we regressed mastery experience for easy, medium difficulty, and hard tasks on lesson-order (0, 1, 2, 3) and observed quality, in separate models (see Figure 3). We specified a random term for lesson, meaning that we allowed individual student trajectories of mastery

experiences to vary across students and for different teachers. This means each student had different starting points and change over time. At the between-level we observed the average mastery and average mastery-on-lesson slopes.

To answer our research question, we ran all models twice: first with within-teacher-centred (centred within cluster, CWC) observed quality as predictor, and then using the grand-mean-centred (GMC; Singer & Willett, 2003) observed quality as predictor. When centring within cluster we subtract the cluster-mean from the individual observation (i.e., $x_{ij} = X_{ij} - \bar{X}_j$). When we grand-mean centre we subtract the grand-mean from the individual observation (i.e., $x_{ij} = X_{ij} - \bar{X}_{..}$). The effect of the within-teacher-centred predictor is interpreted as such: when a teacher deviates from his or her own mean, this has an effect on the outcome. The effect of the grand-mean-centred predictor is interpreted as such: when a teacher deviates from the average of all teachers, this has an effect on the outcome.

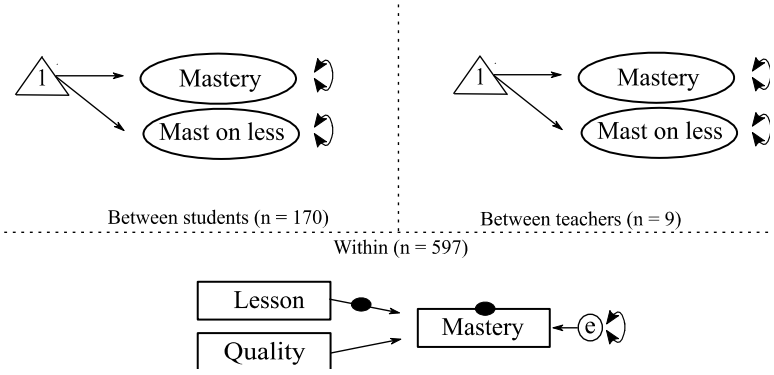

Figure 3: Cross-classified models of students' mastery experiences and observed classroom quality

Results

For the within-teacher effects the quality effects are shown below (Table 1): All four teaching-quality domains predicted students' mastery experiences for easy tasks. Classroom organisation, instructional support, and student engagement predicted students' mastery experiences for medium difficulty tasks. Instructional support predicted students' mastery experiences for hard tasks.

Table 1: Effects of classroom quality on students' mastery experiences: Within-teacher centring

Quality is centred within teachers	Easy		Medium		Hard	
Fixed effects	beta	cred	beta	cred	beta	cred
Emotional support	0.296	*	0.157		0.120	
Classroom organisation	0.268	*	0.245	*	0.124	
Instructional support	0.212	*	0.257	*	0.325	*
Student engagement	0.274	*	0.239	*	0.260	

*95% credible interval

For the grand-mean centred effects (see Table 2), the same pattern was replicated with the addition of a student engagement effect on mastery experiences for hard tasks. In terms of interpretation, the

models where classroom quality is centred *within* teachers indicate that when the quality of instructional support is higher than a teacher's own average across lessons, this has a positive impact on the mastery experiences of the students in her classroom (for tasks of all levels of difficulty). Similarly, the models where classroom quality is centred *across* (or between) teachers indicate an effect on students' mastery experiences when quality of instructional support *or* student engagement is higher than that of the average lesson, of the average teacher.

Table 2: Effects of classroom quality on students' mastery experiences: Grand-mean centring

Quality is grand-mean centred among all teachers	Easy		Medium		Hard	
Fixed effects	beta	cred	beta	cred	beta	cred
Emotional support	0.298	*	0.175		0.157	
Classroom organisation	0.272	*	0.257	*	0.163	
Instructional support	0.233	*	0.287	*	0.365	*
Student engagement	0.281	*	0.258	*	0.310	*

*95% credible interval

Discussion

In our study, cross-classified multilevel models demonstrated variations in classroom quality, both within and across teachers. Furthermore, increased classroom quality was associated with stronger perceptions of mastery experiences, both when classroom quality was compared to a teacher's own average lessons, and when it was compared to average lessons across teachers. While the effects were somewhat stronger when classroom quality was grand-mean centred, this conveys a positive message that classroom quality a) is important, and b) can vary from one part of a lesson to another and from one lesson to another. Knowing that there is individual variability across both students' and teachers' engagement and learning experiences (Li et al., 2024; Malmberg & Hagger, 2009), and across classroom quality (Mashburn et al., 2008), it is important to investigate which kinds of classroom quality factors might be associated with variations in which kinds of student outcomes.

While all the included classroom quality domains predicted students' mastery experiences on easy tasks, fewer predicted their mastery experiences on medium difficulty tasks, and only instructional support (and, partially, student engagement) predicted students' mastery experiences on hard tasks. König et al. (2021) similarly found a direct effect of cognitive activation (comparable to instructional support in our study) only on student performance in mathematics. These studies thus highlight the role of instructional support for both performance and affective outcomes in mathematics. In the TTI framework, instructional support includes teachers' work to facilitate conceptual development and strategic processing of information through, e.g., responsive feedback and instructional dialogues. While such instructional moves can directly influence students' task performance, interactions in other CLASS domains are likely related to students' mastery experiences through more indirect paths (through, e.g., increasing their sense of belonging or the time spent on relevant learning tasks).

Succeeding on harder tasks is obviously harder than succeeding on easier tasks, and while teachers' work to support students emotionally and ensuring learning is well organised has a bearing on students' experiences of mastery for easier tasks, our findings point to the importance of teachers' instructional moves that directly support students' effective learning strategies when it comes to harder tasks. Teachers' work to enhance student engagement, which can be seen as both a predictor and an outcome of classroom quality, is also important for students' mastery experiences.

Although our study included 597 reports of mastery experiences of 170 students, a limitation is that there were only 34 observations of 9 teachers available, and the context is limited to Norwegian classrooms. Future studies would need to include observations of more teachers across more lessons. Studies in other national contexts, e.g., countries with more stratified educational systems, would also be valuable. Furthermore, observation scoring was conducted in-vivo by a single observer, thus observer reliability could not be calculated. However, CLASS is a standardised protocol which requires observers to regularly re-certify to retain their observer status, to limit bias. Finally, the analyses we reported in this paper included quality scores from half the lesson only; we plan to include overall classroom quality in subsequent models we will explore as part of our ongoing analysis.

ChatGPT is going to replace us! Or not? "Narrative Insight" about secondary-tertiary transition in mathematics

Gaia Turconi[1], Domenico Brunetto[2] and Giulia Bernardi[2]

[1]Università Telematica Pegaso, Faculty of Human Science, Naples, Italy; gaia.turconi@unipegaso.it

[2]Politecnico di Milano, Italy

This study explores the use of Narrative Insight, a personalised GPT model, to analyse undergraduate students' journals in the context of secondary-tertiary transition in mathematics education. The goal is to evaluate the extent to which artificial intelligence can support the researcher in narrative analysis by identifying relevant themes to categorise keywords and highlight emerging themes from student texts. The results show that Narrative Insight can offer new thematic perspectives, although it requires human supervision to ensure accurate interpretations. The model has proven to be a promising tool for automating part of the analytical process for qualitative data, especially in its preliminary stages, without giving up the depth of the research.

Keywords: secondary-tertiary transition, AI, narrative analysis, qualitative analysis.

Introduction

Qualitative research has assumed a central role in the educational sciences, allowing for a deeper understanding of phenomena in the field. In mathematics education, qualitative analysis of narrative data, such as interviews and texts produced by students, has emerged in the past two decades as one of the fundamental methods in affect research (Di Martino & Zan, 2015; Hannula, 2002), because they allow the "inner world" of the student to be explored as authentically and realistically as possible, showing also how social and cultural aspects are grounded in it (Radford, 2008). Unlike quantitative studies, which can often be conducted with relatively large numbers of students using statistical tools and software, qualitative studies require prolonged attention to detail and a considerable amount of time to collect and analyse data (Creswell, 2014), which require intensive coding and interpretation. This often implies the need to reduce the number of participants or sacrifice the depth of the analyses conducted, in favour of research with smaller samples, which allows for detailed exploration of participants' experiences, at the expense of a greater possibility of generalisation of results or class group analysis in its entirety (Jirwe, 2011). Despite the lack of literature on the subject, this issue is a well-known fact within the academic and scientific community, confirmed by the presence of very few works conducting qualitative investigations of large groups and university classrooms (Whitt & Kuh, 2017), and particularly in the mathematics education field.

In this context, generative artificial intelligence (e.g., ChatGPT) may emerges as an innovative resource for qualitative analysis, accelerating processes such as coding and theme identification due to its ability to handle large amounts of textual data. Based on advanced artificial intelligence technologies (Radford et al., 2018), MyGPT can adapt to different needs (Montenegro-Rueda et al., 2023; Gabashvili, 2023), supporting both quantitative and qualitative analysis. The possibility of customization through the "builder" tool makes it a versatile instrument for researchers, allowing them to automate part of the analysis process and provide an initial interpretation of the data.

In this study, we explore the use of MyGPT for analysing journals of students enrolled during mathematics at the degree program of Architecture of the Politecnico di Milano, focusing on the transition from secondary to tertiary mathematics education. Artificial Intelligence has already been used to analyse texts produced by students, mainly to provide didactic and evaluative feedback (Wang et al., 2013), but rarely to understand narrative content. We ask, therefore: to what extent can a MyGPT (i.e., a customised GPT model) be used as a tool to support the qualitative analysis of students' narrative data in the context of secondary-tertiary transition in mathematics education? We will discuss this issue by assessing Schoenfeld's (1998) *robustness* of the model, which we will explain in more detail in the next section.

Methods and Research Context

In the present study, a customised GPT model (MyGPT) was developed to assist researchers in the narrative analysis of texts produced by students, with a focus on topics related to mathematics education in the transition from secondary to tertiary education (STT). This model will be evaluated in terms of *robustness* in Schoenfeld's (1998) sense: how well a model can be applied to different cases, maintaining sufficient flexibility and adaptability without losing its explanatory power. In order to do this, we will carry out a four-step analysis in which we will measure, in particular, the ability to assign keywords to predetermined subject categories (explanatory potential) and the ability to extrapolate categories a priori and subsequently assign keywords to these categories (flexibility, adaptability and variation in explanatory potential). After verifying the robustness of the model, we will go over the analyses carried out in our previous research (Bernardi et al., 2024) using GPT as the only tool. Being a first approach to the topic, the measurement of the model's characteristics was carried out in a qualitative manner, and we chose to use the graphical representation using Venn diagrams to visualise and monitor the evaluations, attributions and "choices" made by the machine, and their variability.

We decided to use the narrative data collected during the mathematics course for the Architectural design degree program. These are collections of journals written by first-year students and had already been analysed by this team in light of the STT themes (Bernardi et al., 2024). Those study involved 180 first-year Architecture students (ages 18–22) from Politecnico di Milano, who provided informed consent to participate. Each student was asked to submit four reflective journals during the semester with no requirements related to structure, length, or content, but suggesting, however, to focus on their experiences, thoughts and feelings related to the course. To foster participation, additional points were awarded for students who completed all four submissions. Only a designated tutor (the first author) accessed these journals, ensuring anonymity when reporting general insights to instructors. In the previous work, after a data selection process, journals related to the entire course written by 54 students were analysed, and from these we identified six a priori categories to which keywords extrapolated from the texts could be assigned, choosing them from the words used most (and least) frequently by the students: Self-Regulation (S-R), Structural Differences (SD), Social Integration (SI), Instrumental vs Relational View of Mathematics (I/R), Identity (Id). Only one word was present across all themes ("test"), making it difficult to categorise; it was therefore chosen to isolate it from the others (see Figure 1).

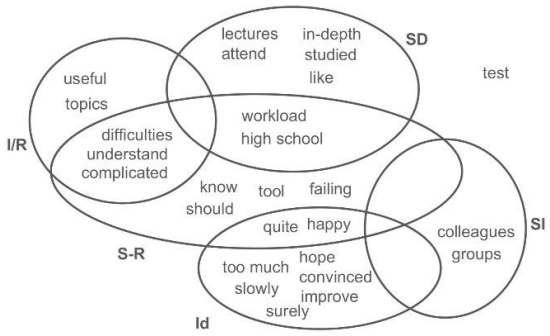

Figure 1: Classification of the selected words (Bernardi et al., 2024)

To observe how the Large Language Model carried out the categorisation of meaningful words used by students; we created a MyGPT called "Narrative Insight" (NarrI). First, we provided NarrI with the texts from the relevant scientific literature on which we based the study and identification of the a priori categories in our previous work, and which dealt with STT via Clark and Lovric's (2008) *rite of passage* theory (Social Integration and Identity categories), the new challenges in terms of study method, autonomy, organisation and self-regulation (Self-Regulation and Structural Differences categories) (De Guzmán et al, 1998; Zimmerman, 2000), and the necessary shift from an instrumental view of mathematics to a relational one (Instrumental/Relational category) (Skemp, 1976). On the basis of these works and the categories determined on them, we submitted to NarrI the identified keywords (which can be seen in Figure 1 already divided into groups with respect to the previous classification) and ask the machine to divide them with respect to our categories; in this way, we wanted to check the explanatory potential of the machine through the understanding and use of the categories and keywords related to the STT theme.

We then asked NarrI to identify a priori categories that, in its opinion, were relevant to STT issues, again based on the relevant literature. We list below the seven categories identified together with NarrI's own brief explanation of them (in *italics*) and our comment to underline the correspondence with the previous categories:

1. Phases of Mathematical Transition: *how students adapt to different learning environments and expectations in mathematics, including shifts in learning style, curriculum complexity and level of independence required*. It therefore contains themes in the Self-Regulation and Structural Differences categories;
2. Mathematical Self-Concept: *students' perceptions of their own mathematical abilities and identity*, which we can correspond to the category Identity;
3. Relational vs. Instrumental Mathematical Views: *whether students view mathematics as connected, relational field or as a set of rules and procedures to follow*, which corresponds exactly to category Instrumental/Relational;
4. Navigating Emotional Barriers: *how students manage feelings like anxiety, fear, or frustration related to learning mathematics*. This theme, which is very present in the literature on STT, had not been taken into account by us neither in the a priori nor in the a posteriori analysis: since the students always expressed *what* triggered certain emotions in them, we were always able to categorise the *cause* of them in the categories we initially chose;

5. Adjusting to Mathematical Discourse: *students' ability to engage with and understand the language and communication styles used in higher-level mathematics*. Even this category had not been perceived as necessary by the team, as it was often attributable — in our opinion — both to the necessary transition to a relational view of mathematics and to the change of cultural institution of reference, which required a more specialised and "high" language;
6. Developing Autonomy in Learning: *the process by which students become more independent and take responsibility for their learning in mathematics*, corresponding to the Self-Regulation category;
7. Social and Academic Integration: *how students balance social and academic demands, and their sense of belonging in the academic environment*, which partially refers to both the Social Integration and Self-Regulation categories.

This request allowed us to assess the machine's ability to extrapolate macro-themes from foundational texts, demonstrating its flexibility and adaptability to the educational context: in fact, despite the fact that we might suppose that a possible user-researcher already has certain categories of reference in mind, they might be interested in identifying others in order to observe the collected data in a different way, either by asking NarrI to identify relevant themes, or by integrating some already highlighted by the user.

In this way, we verified that Narrative Insight was a sufficiently robust model for further investigation, going on to assess its usefulness as a support tool for the researcher who wants to carry out a qualitative analysis of narrative data.

To test the usefulness of NarrI in the analysis of narrative data, we retraced the steps taken in the analysis previously carried out (Bernardi, et al., 2024), using, however, NarrI as the only tool. In this way, we were able to experience the need to automate certain actions of the machine, thus implementing its construction via the building interface. For example, we needed a list of stop-words to be neglected in the counting phase of the frequencies of the terms present in the texts; or again, we set up those variations in gender or numerosity of the terms to be neglected, aggregating all concordances under the masculine singular term.

Finally, we asked NarrI to extract the data from the files, containing the student's narratives and broken down by author, and create a table containing a number associated with each student, the STT categories into which his or her narratives could fit, and textual citations justifying the choice.

Results

The first categorisation carried out by NarrI of the 27 proposed words, and examples of sentences in which they were used by the students, was very similar to the one we carried out: 19 words remained unchanged even partially, while 8 were categorised completely differently (Figure 2).

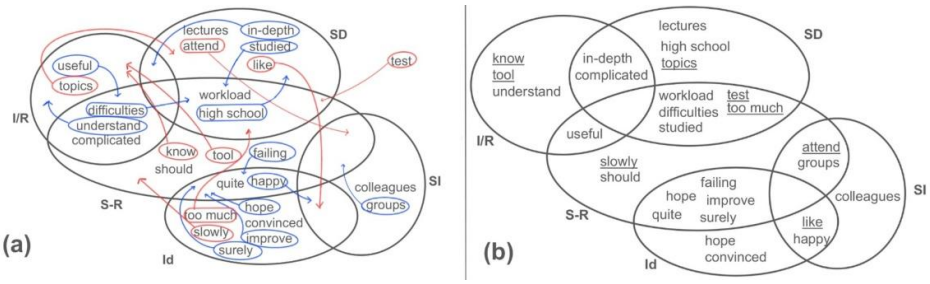

Figure 2: (a) Changes in categories from the previous categorisation: in red completely changes, in blue partial changes; (b) new categorisation of the selected words

To better understand the differences between the two categorisations, we also asked NarrI to explain the reasons for the various assignments. The discrepancies that emerged seem to stem from the interpretative nuances present in the narrative data. For example, words such as "attend", which in our study had been categorised in "Structural Differences" between secondary and tertiary education, were placed by NarrI in the categories "Self-Regulation" and "Social Integration". Our choice was based on the novelty introduced into students' lives by optional participation in academic life and lessons, as these aspects are left to the individual's organisational capacity, autonomy and desire to become involved in the academic environment, NarrI opted for other categories. This suggests that NarrI grasped aspects of student behaviour differently than human researchers, probably also due to different ways of understanding the educational context. This, that may be seen as a limitation, can also be a potentiality: NarrI seems to be able to make an original and motivated classification, just as it might happen to two researchers who independently categorise a set of words on the basis of predetermined and fixed themes, acting as a useful tool for the researcher for a preliminary analysis and a one-way "discussion" with the machine, having a different — and valid — interpretation of the collected narrative data.

Observing from afar the themes that NarrI has identified as fundamental for the analysis of the STT phenomenon, we note, as already pointed out, that these are similar to those of our working group: the cognitive aspect, the social aspect, the affective aspect and the cultural aspect. This is not surprising, as these are macro-topics frequently dealt with both in mathematics education and in the pedagogical field in general. As we get closer, however, we notice that the focus NarrI has placed on these topics is, in some aspects, different from ours, and this is particularly noticeable for categories 4 and 5 highlighted by the machine. The user-researcher asking NarrI to identify categories from scratch may want a different viewpoint on his data, or may be approaching this area of investigation for the first time and seek guidance on where to direct his work.

We report in Figure 3 the categorisation of keywords made according to these categories. Again, we asked NarrI about the rationale behind its choices and concluded that they too were well-founded and consistent with the themes of the STT.

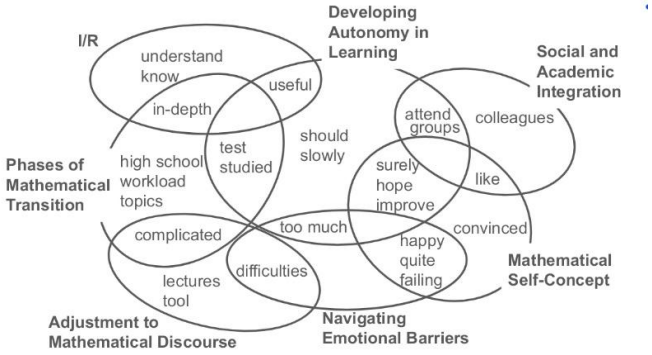

Figure 3: Categorisation of the keywords based on the STT groups selected by NarrI

Finally, we shared the files containing the students' journals with Narrative Insight, asking the machine to identify the most frequent and least frequent words present, without any particular request on the list of stop-words used. We expected to obtain results similar to those identified in our previous research using a free corpus analysis toolkit designed for text analysis, but this was not the case: NarrI was not able to correctly identify the occurrences of the words it considered important. For example, the term "difficulties" (and its variants) was only counted 10 times by NarrI (and 136 by us), and the result did not improve even after several attempts at correction.

We therefore chose to have the machine classify each student individually, analysing all the narratives they had written (four, during the entire duration of the course) providing the categories within which it would place the topics, and examples to justify its choice. The results of this task, which we can consider to be both *counting* (considering each student individually) and *assigning* (of the category according to the theme), behaved as we expected, considering the previous results: it identified and classified the themes dealt with adequately, also presenting contextual examples, but it took more than 5 requests to obtain this classification on all the students considered in our reference sample, in each experiment tried.

Conclusion

This study is among the first to explore the application of a customized generative Artificial Intelligence tool, Narrative Insight (NarrI), for qualitative analysis of student-generated narrative data within the context of the secondary-tertiary transition (STT) in mathematics education. One of the primary challenges in qualitative research, especially with large groups, is managing substantial amounts of data while maintaining analytical depth. By automating parts of the thematic categorisation process, NarrI demonstrates a promising approach to scaling qualitative research without losing insight into individual experiences. This strength is particularly valuable for large datasets, where traditional qualitative methods might struggle to capture complexity. Through the analysis of reflective journals, NarrI enabled us to capture complex, multifaceted insights into students' cognitive, social, and emotional experiences.

In our study, we evaluated the robustness (Schoenfeld, 1998) of NarrI in supporting narrative analysis related to secondary-tertiary transition (STT) in mathematics. This model was customised based initially on academic reference texts, working both with a priori categories derived from previous

work (Bernardi et al., 2024) and determined by the model itself. The results indicate that the use of Artificial Intelligence allows for sufficiently accurate analysis of large amounts of data without sacrificing complexity and precision in the interpretation of central themes. The comparison of manual and automated categorisation revealed a broad correspondence between the two methods, but also the ability of NarrI to detect subtle differences and propose equally valid alternative interpretations, in line with existing literature (Clark & Lovric, 2008; De Guzmán et al., 1998). This flexibility and capacity to suggest alternative perspectives are key strengths of the NarrI model, that seems to have the potential to reduce the manual workload for researchers by speeding up coding and categorisation processes, especially in the preliminary stages of analysis. However, our findings suggest that the use of Artificial Intelligence still requires careful human supervision: discrepancies in frequency and categorisation analysis indicate the need for continuous interactions and a thorough understanding of the domain to ensure accurate interpretations, that surely can be partly considered a limitation of this method although researcher supervision is a fundamental part of any research regardless of the method used (Creswell, 2014; Whitt & Kuh, 2017).

It is necessary to specify that in order to have a more complete and complex evaluation of the tool, it would be necessary to verify specific characteristics recognized by the scientific community as key elements for the reliability of a method or tool, such as the consistency of test scores across repeated applications; since the repetition of the same prompt ChatGPT responds by producing different outputs each time, it is immediately clear that the evaluation of this research/measurement tool is extremely complex. Some inherent features in this type of technology, such as its continuous updating, make it impossible to use the currently existing validation models recognized by the scientific community. For this reason, it was decided here to use the definition of robustness, although not contextual to mathematics education. A challenge to be faced in the future, then, is precisely to adapt or develop an appropriate method of evaluation and validation of research tools using AI, such as NarrI. In addition, it would be interesting to observe how models similar to NarrI might behave in other research contexts and on other topics, maintaining a crucial role for human expertise in guiding and verifying analyses produced by Artificial Intelligence (Montenegro-Rueda et al., 2023; Gabashvili, 2023).

Can artificial intelligence, then, replace us? Not yet, or at least not totally: the limitations outlined in this paper highlight the inevitable and crucial role of the human researcher, particularly in issues that require the analysis and interpretation of narrative data, which are fundamental to areas of research such as affect (Di Martino & Zan, 2015; Hannula 2002).

Lower secondary pupils' academic motivation in a collaborative problem-solving intervention

Hanna Viitala

University of Helsinki, Faculty of Educational Sciences, Finland; hanna.l.viitala@helsinki.fi

In many countries, there is a need to address the descending trend of secondary pupils' mathematics performance (between cohorts) and pupils' mathematics-related affect that develops negatively throughout the school years (within cohorts). To address these trends, a 1-year collaborative problem-solving intervention was implemented in six mathematics classes in the academic year of 2019-2020. In this paper, the combined effect of the intervention and the COVID-19 pandemic is studied through pupils' academic motivations. The results show that while pupils value learning mathematics, they do not think they need to show competence or avoid showing incompetence in mathematics lessons. Similar results were gained both on a personal and on a classroom level. The implications of these results are discussed.

Keywords: Mathematics-related affect, academic motivation, goal structures, collaborative problem solving, lower secondary school.

Introduction

Previous research has shown the positive effects of problem solving on pupils' performance and affect in mathematics (e.g. Felmer et al., 2016; Liljedahl & Cai, 2021). Despite this, there is a lack of studies on the systematic, daily use of problem solving in Finnish mathematics classrooms. Based on studies on Finnish pupils' mathematics performance and affect, such studies are much needed. Following the international trend, Finnish pupils' mathematics performance has decreased constantly during the past two decades (OECD, 2023). Furthermore, like in many other countries, Finnish pupils' affect in mathematics start declining from a very early age (Niemivirta et al., 2024). Exceptional is, that Finnish pupils' view of mathematics is distinctively negative (Mullis et al., 2020).

This paper reports from an intervention study that had its purpose on increasing pupils' mathematical thinking and learning, as well as engagement in mathematics through collaborative problem solving (CPS). CPS has received increased research attention recently (Liljedahl & Cai, 2021; OECD, 2017). It makes pupils' mathematics learning visible to teacher and peers while developing their social skills and engaging them into learning mathematics (Liljedahl, 2014, 2021).

The intertwined relationships between mathematics-related affect, problem solving and mathematical thinking and learning (e.g. Schoenfeld, 1992; Hannula et al., 2018) are also the starting point for the 1-year CPS intervention reported in this paper. Lower secondary pupils' mathematics-related affect is studied through pupils' personal and classroom goal structures (Midgley et al., 2000) as part of their academic motivation (Kaplan & Maehr, 2007). The paper aims to answer the following research questions:

1. How can pupils' mathematics-related personal and classroom goal structures be characterised in the beginning of the intervention?

2. How can pupils' mathematics-related personal and classroom goal structures be characterised over the span of the 1-year collaborative problem-solving intervention?

Theoretical framework

Affect in mathematics education is a well-established research field that lacks, to this day, consensus on the concepts and their structures used in the field (Haser et al., 2023). Hence, it is important to start by saying that, in this study, affect is understood as an umbrella term for the cognitive, motivational, and emotional aspects of affect (e.g., beliefs, attitudes, and feelings; Hannula, 2012). Furthermore, affect is studied as an individual psychological trait, indicating to the more stable aspects of pupils' mathematics-related affect (Hannula, 2012).

One of the goals for the intervention study reported in this paper, was to engage pupils in learning mathematics (Viitala, 2022). One way of looking at dispositions towards engagement is to study pupils' purpose to learn (mathematics) through pupils' academic motivation (Kaplan & Maehr, 2007). Academic motivation in this study is understood as pupil's mathematical learning goals that direct their behaviour in mathematics lessons (cf. Hannula, 2012). Academic motivation has often been studied through achievement goal theory in complex and social situations (Urdan & Kaplan, 2020), that is, in situations such as CPS (Liljedahl & Cai, 2021). So is done also in this study.

Pupils' academic motivation, and more closely, their achievement goals have generally been studied through mastery goal orientation (developing competence), performance-approach goal orientation (demonstrating competence), and performance-avoid goal orientation (avoiding demonstration of incompetence) (Urdan & Kaplan, 2020). While the first orientation is focused on the task of learning and understanding mathematics, the latter two orientations are focused on the self and how the self is presented amongst peers (Midgley et al., 2000). Previously, mastery goals have generally been associated with positive emotions, interest, and deep learning strategies, performance-approach goals with higher achievement, and performance-avoidance goals with negative emotions, disengagement, and low achievement (Urdan & Kaplan, 2020).

Based on previous research on CPS (e.g. Liljedahl, 2021; Liljedahl & Cai, 2021; Felmer et al., 2016) and results from this intervention (Viitala, 2023, 2024), the expectation would be that pupils' mathematics-related affect develops positively during the intervention, or at least remains on the same level as in the beginning. That would mean a positive development on mastery and performance-approach goals, and a negative development on performance-avoidance goals. However, the intervention was interrupted by the global COVID-19 pandemic which has shown to have a negative effect on pupils' mathematics-related affect (Metsämuuronen & Nousiainen, 2021). The results represent a joint effect of the intervention and the pandemic.

The intervention

The 1-year CPS intervention was implemented in six lower secondary mathematics classrooms during the academic year 2019-2020. During the intervention, pupils worked collaboratively with problem-solving tasks in their daily mathematics activities following a teaching paradigm called Building Thinking Classrooms (BTC; Liljedahl, 2021). The BTC paradigm has previously shown to increase pupils' engagement and social skills in mathematics classrooms, among other things (e.g. Liljedahl,

2014). CPS is defined as "the capacity of an individual to effectively engage in a process whereby two or more agents attempt to solve a problem by sharing the understanding and effort required to come to a solution and pooling their knowledge, skills and efforts to reach that solution" (OECD, 2017, p. 47). In this study, collaboration is part of the environment where problem solving takes place (Liljedahl & Cai, 2021).

Seven months after the beginning of the intervention, the schools were closed due to the global COVID-19 pandemic. During this two-months' time, the pupils studied at home in isolation from their peers. The intervention ended, together with the school year, two weeks after the school closures ended and the pupils returned to schools – continuing to practice social distancing.

Methods

Participants

The data used in this paper are from two grade 8 classes (N=40) and three grade 9 classes (N=43). One grade 8 class dropped out from the intervention halfway through the academic year and its data is not used for this paper. In Finland, grade 8 pupils are 14-15-year-olds and grade 9 pupils are 15-16-year-olds. All but two (N=81) pupils answered the pre-questionnaire. However, due to the on-going pandemic, not all pupils returned to schools for the last two weeks of the school year (e.g. for health reasons). Hence, the post-questionnaire was answered only by N=49 pupils. In the missing answers were also one whole mathematics class.

Data collection

The data were collected using pre- and post-questionnaires. The pre-questionnaire was answered during the first school week (mid-August 2019) and the post-questionnaire during the last two school weeks of the school year (end of May 2020). The questionnaires were answered individually during mathematics lessons. To study pupils' academic motivation, Midgley and colleagues' (2000) Patterns of Adapted Learning Scales (PALS) was chosen because the validated scale includes aspects of personal *and* classroom goal structures. This dual focus was considered as important because the intervention is based strongly on collaboration in mathematics lessons, highlighting both individual and commonly built classroom-level structures.

From PALS, (revised) personal achievement goal orientations and perception of classroom goal structures were included in the study (see Midgley et al., 2000). Both categories included questions regarding mastery goals, performance-approach goals, and performance-avoid goals (cf. Urdan & Kaplan, 2020). Also questions regarding avoiding novelty were added since the intervention implemented working methods that were new to the pupils (e.g. daily problem solving). The statements were adapted so that they were directly connected to mathematics (e.g. "It's important to me that I improve my skills this year." → "It's important to me that I improve my mathematics skills this year."). Data were collected through Likert-scale from 1 = Fully disagree to 5 = Fully agree.

Data analysis

Due to the small sample size, the data are analysed through descriptive statistics and correlations. Reliability of the sum variables is tested using Cronbach's alpha. Significance of the descriptive statistics is tested using paired samples t-test.

Results

Personal achievement goal orientations

Pupils' personal achievement goal orientations were studied through mastery goal orientation (five statements, e.g. "It's important to me that I improve my mathematics skills this year."), performance-approach goal orientation (five statements, e.g. "It's important to me that other students in my class think I am good at mathematics.") and performance-avoid goal orientation (four statements, e.g. "It's important to me that I don't look stupid."). All the sum variables were between highly reliable and acceptable (mastery pre α=.90, post α=.90; performance-approach pre α=.93, post α=.94; performance-avoid pre α=.73, post α=.84). Also, the sum variable of avoiding novelty (five statements, e.g. "I prefer to do work as I have always done it, rather than trying something new.") was reliable (pre α=.83, post α=.85).

Table 1: Descriptive statistics, personal sum variables

	Mean		**Median**		**St. Deviation**	
	Pre	Post	Pre	Post	Pre	Post
Mastery goal orientation	**3.61**	**3.13*** **	3.60	3.20	.852	.974
Performance-approach goal orientation	2.07	1.93	2.00	1.80	.977	.892
Performance-avoid goal orientation	**2.45**	**2.26***	2.5	2.25	.900	.945
Avoiding novelty	3.45	3.46	3.40	3.55	.861	.833
* Difference is fairly significant, $p<.05$ (2-tailed); *** Difference is highly significant, $p<.001$ (2-tailed)						

The descriptive statistics for personal achievement goal orientations and avoiding novelty, together with the significance tests, are presented in Table 1. The results show that pupils think that it is important to learn new skills and understand mathematics (pre: M=3.61, SD=.852; post: M=3.13, SD=.974). However, the decline in the mastery goal orientation over the intervention year is highly significant, remaining only slightly on the positive side ($t(49)=3.516$, $p<.001$). A closer look at the pupils' answers reveals that there are 19 % points increase on the proportion of pupils that disagree with the statements (25 % and 44 % respectfully, sum variable between 1–3). There is a moderate correlation between the pre- and post-test answers ($r(48)=.48$, $p<0.001$).

Performance-approach goal orientation show that it is not important to pupils to show that they are good at mathematics or that mathematics is easy for them (pre: M=2.07, SD=.977; post: M=1.93,

SD=.892). Their view does not change significantly during the intervention. There is a moderate correlation between the pre- and post-test answers ($r(48)=.51$, $p<0.001$).

Performance-avoid goal orientation reveal that pupils do not think it is important not to show lack of competence in mathematics lessons (pre: *M*=2.45, *SD*=.900; post: *M*=2.26, *SD*=.945). At the end of the intervention, their view is fairly significantly lower than in the beginning ($t(49)=2.098$, $p<.05$). There is a moderate correlation between the pre- and post-test answers ($r(48)=.56$, $p<0.001$). Furthermore, there is a strong correlation between the pupils' performance-approach goal orientation and performance-avoid goal orientation within the pre- and the post-tests (pre: $r(79)=.79$, post: $r(48)=.84$). That is, if the pupil does not worry about looking "smart" in mathematics class, they probably do not worry about looking "stupid" either.

Lastly, pupils want to avoid novelty, that is, stick to familiar concepts and class work (pre: *M*=3.45, *SD*=.861; post: *M*=3.46, *SD*=.833). There are no differences between pre- and post-tests, nor is there mentionable correlations.

Perception of classroom goal structures

Pupils' perception of classroom goal structures was studied through mastery goal structure (four statements, e.g. "In our class, how much you improve is really important."), performance-approach goal structure (three statements, e.g. "In our class, getting right answers is very important,") and performance-avoid goal structure (four statements, e.g. "In our class, it's very important not to look dumb."). The reliability of performance-approach and performance-avoid goal structures were between acceptable and highly reliable (performance-approach pre α=.78, post α=.84; performance-avoid pre α=.90, post α=.88). Interestingly, the reliability of mastery goal structure was not acceptable (pre α=.63, post α=.26), and will be studied through separate statements.

Table 2: Descriptive statistics, classroom sum variables

	Mean		**Median**		**St. Deviation**	
	Pre	Post	Pre	Post	Pre	Post
Performance-approach goal structure	**2.59**	**2.29***	2.67	2.00	.827	.950
Performance-avoid goal structure	2.17	2.07	2.00	2.00	.941	.807
* Difference is fairly significant, $p<.05$ (2-tailed)						

The descriptive statistics for classroom goal structures, together with the significance tests, are presented in Table 2. The results on performance-approach goal structure show that, on a classroom level, pupils' do not think that it is important to get the right answers or good grades in mathematics (pre: *M*=2.59, *SD*=.872; post: *M*=2.29, *SD*=.950). The negative development is fairly significant ($t(49)=2.406$, $p<.05$). There is no mentionable correlation between the pre- and post-tests. However, personal and classroom performance-approach structures correlate moderately within pre- and post-test (pre: $r(78)=.58$, post: $r(48)=.58$). Furthermore, the proportion of pupils disagreeing strongly with

the statements (sum variable between 1–2) increases by 24 % points between the pre- and post-tests (28 % and 52 % respectively). There are no differences in the pupils who agree with the statements.

The results on performance-avoid goal structure show that the pupils do not think it is important not to look bad in class or make mistakes in front of everyone (pre: M=2.17, SD=.941; post: M=2.07, SD=.807). There is no significant change or mentionable correlation between pre- and post-test. However, there is a strong correlation between performance-approach and performance-avoid goal structures within pre- and post-tests (pre: $r(78)$=.63, post: $r(48)$=.75), and personal and classroom performance-avoid structures within pre- and post-test (pre: $r(78)$=.83, post: $r(48)$=.68).

Since classroom mastery goal structure did not form an acceptable sum variable, the statements are studied separately. The results show that, on a classroom level, pupils have very neutral views on the importance of trying hard and understanding in mathematics (M=2.84, SD=.934, M=3.18, SD=.984). They do not think that improving in mathematics is important (M=2.73, SD=.976) but strongly agree that it is OK to make mistakes as long as learning is happening (M=4.04, SD=1.038). Moderate correlations are found in the pre-test between understanding and trying hard ($r(77)$=.50, p<.001), understanding and improving ($r(75)$=.44, p<.001) and trying hard and improving ($r(76)$=.60, p<.001). In the post-test, these correlations did not appear anymore.

Summary and discussion

The purpose of this paper was to study lower secondary pupils' mathematics-related affect during a 1-year CPS intervention. Mathematics-related affect was studied through pupils' personal and classroom goal structures (Midgley et al., 2000) as part of their academic motivation (Urdan & Kaplan, 2020). The results are examined in the beginning of the study (research question 1) and over the span of the intervention year (research question 2).

In the beginning, pupils reported having positive mastery goal orientation that has generally been associated with positive emotions and deep learning strategies (Urdan & Kaplan, 2020). Interestingly, trying hard and improving in mathematics were not considered to be that important on a classroom level, though making mistakes were acceptable. This implies to a very individualistic view of learning mathematics: *"It is important to me that I am improving, but I don't really care about the others"*.

In the beginning, pupils reported having negative performance-approach and performance-avoid goal structures both on a personal and classroom level, with a strong within test correlation. The message is clear: *"I don't mind looking smart or stupid in mathematics class, nor do I care if others do"*. In previous research, high performance-approach goals have been associated with high performance, and high performance-avoidance goals with negative emotions, disengagement, and low achievement (Urdan & Kaplan, 2020). The results imply again to a very individualistic view without high academic ambitions, but it is also looking away from negative emotions, disengagement, and low achievement.

The development during the intervention that was interrupted by the COVID-19 pandemic, can be characterised as mixed. On a task level (mastery goal orientation, Midgley et al., 2000), pupils' goals remain on the positive side even though showing highly significant negative development (cf. Metsämuuronen & Nousiainen, 2021). On a "self" level (performance-approach and performance-avoid goal orientations; Midgley et al., 2000), pupils cared less if someone was demonstrating

competence in class or if they themselves were demonstrating incompetence. From the collaborative point of view, this is good news: pupils do not have to stress over their appearance in mathematics lessons and can collaborate with their peers more freely.

In their article on the state of the art-research on achievement goal theory, Urdan and Kaplan (2020) call for research that integrate systems of perceptions, beliefs, goals, and affect. In previous papers, Viitala (2023, 2024) reported from the same intervention but looked at the development of pupils' mathematical views through pupils' view on their ability, effort, enjoyment, difficulty and success in mathematics, and the views' connections to pupils' performance level. The results showed negative development trends (Viitala, 2023) similarly as the development on pupils' personal mastery goal orientations in this study. However, a closer look revealed that the development was mainly due to one performance group: low average performers (Viitala, 2024). For further study, it would be interesting to see if pupils' different performance levels differ also in respect to academic motivation.

This study has many limitations such as low number of participants and a lack of control groups. It is also impossible to differentiate the effect of the intervention and the pandemic from the results. Hence, more research in the form of a new research cohort is needed to understand better the effects of daily collaborative problem solving on pupils' thinking, learning and engagement in mathematics.

Mindset and Mathematics Achievement: Mediating Effects of Anxiety and Learning Motivation

Shaoyilin Wang[1] and Yan Zhu[1]

[1]East China Normal University, School of Mathematical Sciences, Shanghai, China;
51264800006@stu.ecnu.edu.cn

Keywords: Growth mindset, mathematics achievement, mathematics anxiety, mathematics learning motivation

Introduction

Students with a growth mindset tend to achieve superior academic outcomes, including higher academic performance. While existing research has largely focused on the influence of mindset within specific countries or regions, there is a notable gap in understanding how these mindsets vary across different cultural contexts.

Methods

The objective was to evaluate the impact of mindset on mathematics achievement and to uncover subtle differences in the effects of mindset across diverse cultural, educational and economic contexts, as well as investigate the underlying reasons for these variations using data from the PISA2022 assessment, with a specific focus on contrasting East Asian countries/economies with OECD countries/economies (excluding Japan and Korea). This study employs the structural equation model established by Dong et al. (2023).

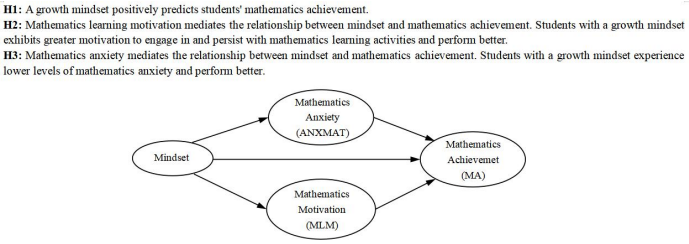

Figure 1 Hypothetical Model

A structural equation model was conducted under the hypothetical model for data analysis through Mplus8.3 and SPSS26 with mathematics achievement as dependent variables. Students' mindset was measured by their levels of agreement with the question on a scale from "1-strongly disagree" to "4-strongly agree", the students who show disagreement hold a growth mindset and who show agreement hold a fixed mindset.

Findings

For East Asian countries/economies, the results indicate that ANXMAT is negatively correlated with MA for both advantaged and disadvantaged students. In contrast, MLM was found to have a significant positive correlation with MA. While a growth mindset(GM) was significantly and negatively correlated with MA among disadvantaged students, no significant correlation was found

among advantaged students. This outcome is inconsistent with H1, which suggests that the benefits of GM may not be equally applicable across different socioeconomic backgrounds.

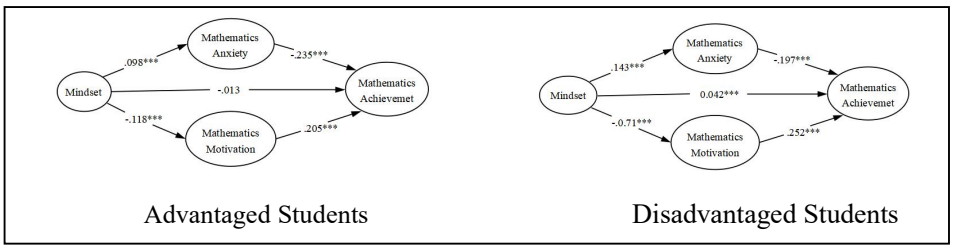

Figure 2 SEM-East Asia

As evidenced in Figure 2, a notable positive indirect effect of GM on MA is observed among the disadvantaged. Similarly, the results for advantaged students corroborate H2 and H3.

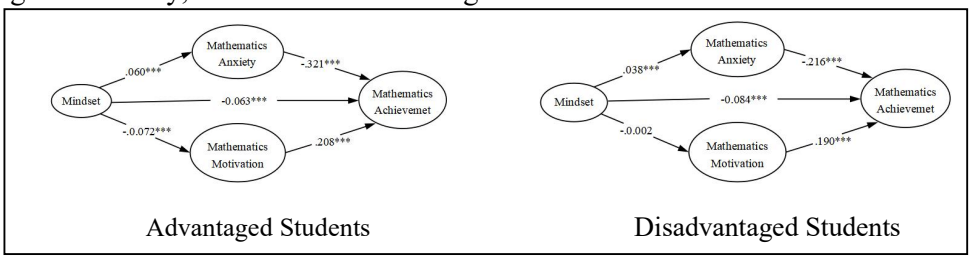

Figure 3 SEM-OECD

For OECD countries/economies, MA is positively correlated with GM for both groups, which is consistent with H1. MLM demonstrated a significant positive correlation with MA for both groups while ANXMAT exhibited a negative correlation with MA for both groups.

Concerning indirect effects, ANXMAT functions as a pivotal mediator in the relationship between mindset and MA for students from disadvantaged backgrounds. In contrast, the mediating role of MLM was found to be non-significant, which contradicts H3. For students from advantaged backgrounds, both ANXMAT and MLM were identified as significant mediators, a positive indirect effect of GM on MA. This finding lends support to H2 and H3.

Discussion and Conclusion

The findings reveal significant regional variations in the influence of mindset on academic performance. The contrasting trend in East Asia and OECD indicates that the relationship between mindset and academic achievement may be associated with culture. The educational environment in East Asia emphasizes hard work rather than strategic thinking, fostering a "false growth mindset" centered on effort rather than on intelligence malleability.

Furthermore, discrepancies in educational policies and the distribution of resources are of paramount importance. OECD countries emphasize educational equity, and superior educational standards. Conversely, East Asia grapples with an inequitable distribution of educational resources, giving rise to discrepancies in both the quality of education and student performance. In this context, even if disadvantaged students develop a growth mindset, their educational system lacks support for their development, potentially increasing anxiety and negatively impacting academic performance.

Theoretical framework linking teacher feedback and students' mathematics self-efficacy, attributions, and mathematics achievement

Rohit Daniel[1]

[1]Western Norway University of Applied Sciences, Faculty of Education, Arts, and Sports, Sogndal, Norway; rohit.daniel@hvl.no

Keywords: Self-efficacy, attribution theory, mathematics achievement, feedback.

Background

As shown in the review by Street et al. (2024), the relationship between students' mathematics self-efficacy and their mathematics achievement is well-documented. However, a significant gap remains in our understanding of how students appraise information from various sources to calibrate their self-efficacy. This systematic review will focus on teachers' feedback practices as a primary mechanism influencing students' appraisal of self-efficacy information, with a particular focus on students' attributions as a potential mediating factor. In doing so, this review aims to answer the following research question: What are the relationships between teacher feedback, students' self-efficacy, and students' causal attributions of their performance in the domain of mathematics?

Self-efficacy is an individual's belief in one's capabilities to organize and execute the courses of action required to manage prospective situations (Bandura, 1997, p. 3). Particularly in mathematics, strong self-efficacy empowers students to tackle complex problems, persevere through challenges, and ultimately grasp concepts more deeply (e.g., Martin et al., 2015; Pajares & Graham, 1999). Bandura conceptualizes self-efficacy as a dynamic construct that is continuously updated through self-efficacy information from four key sources: mastery experiences, vicarious experiences, social persuasion, and physiological states. Importantly, the cognitive appraisal of information from these various experiences is what shapes one's self-efficacy. Research has shown that effective feedback, characterized by being specific, timely, and growth-oriented, can significantly impact students' beliefs in their abilities (Shute, 2008; Wiliam, 2011). Conversely, negative feedback can diminish self-efficacy and confidence. Additionally, attributing success to effort and effective strategies, rather than innate ability, reinforces a growth mindset—the belief that performance can be improved through perseverance and dedicated practice (Graham & Williams, 2009).

Method

This systematic review adheres to PRISMA 2020 guidelines (Page et al., 2021), ensuring a rigorous and transparent approach. Two comprehensive searches were conducted across five academic databases—Academic Search Elite, ERIC, PsycINFO, Scopus, and Web of Science—on November 12, 2024, using search terms that captured a broad scope of research, accounting for synonyms, related concepts, and terminology variations. The searches were limited to peer-reviewed empirical reports published in the English language. The search results were screened through two stages. The initial abstract screening included studies that examined relationships between at least two of the three constructs in the domain of mathematics and focused on lower secondary school students. The second full-text screening focused on the conceptualisation of (1) self-efficacy as future-oriented

statements reflecting specific contexts and goal-referenced confidence in one's ability; (2) attributions as domain-specific causal ascriptions; and (3) feedback as contextualized information (e.g., on task, process, self-regulation, attributions) provided by teachers, either orally or in writing. A risk of bias assessment for experimental studies was conducted using the Education Endowment Foundation's Padlock tool (Education Endowment Foundation, 2019). Search #1, which included all three constructs combined with the 'AND' operator in the title field, yielded 156 unique records across the five databases. Search #2, which included pairwise 'AND' combinations in the title field under the same search restrictions, yielded an additional 398 unique records. The two-stage screening yielded a final selection of two qualitative, six observational, and 10 experimental studies.

Findings

The synthesis of the selected studies resulted in two theoretical models—one based on observational studies and the other on experimental studies. Both models included strong associations between teacher feedback and students' self-efficacy, as well as a bidirectional relationship between students' attributions and self-efficacy. The experimental model further identified causal links between teacher feedback and both attributions and self-efficacy. Additionally, both models delineated a pathway in which teacher feedback influenced students' attributions and self-efficacy, shaping their cognition and learning behaviours and, ultimately, their mathematics performance.

Emotion graphing: Tool to study emotions and foster meta-affect

V. Rani Satyam

Virginia Commonwealth University, United States; vrsatyam@vcu.edu

Keywords: Emotions, graphing, affect.

Emotions may be defined as "rapidly-changing states of feeling experienced consciously or occurring preconsciously or unconsciously" (DeBellis & Goldin, 2006, pp. 135). The quick, rapidly changing nature of emotions also makes this construct difficult to measure. Understanding emotions is vital however because they occur in the moment and thus are malleable – by teacher, environment, etc. - and so are a way to change deeper-seated affect (Middleton et al., 2017). Attitudes may also be formed from repeated habitual emotions (Grootenboer & Marshman, 2016).

I present a tool called *emotion graphing*, where students are asked to draw a graph of their self-perceived emotions during an experience. I explore the affordances of emotion graphing for studying participants' emotions and fostering a larger theorized structure of *meta-affect*, "the individual's monitoring of affect" (DeBellis & Goldin, 2006, pp. 136). By looking across studies of emotion graphing from undergraduates learning how to prove mathematics to middle school students in a geometry camp, emotion graphing serves a vehicle for more effective communication during interviews as well as a form of experience-based sampling, with pedagogical use as exit tickets.

Methods: Emotion Graphing as an Instrument

Pictorial methods can capture shifts in affect, through drawing maps or pictures (Gómez-Chacón, 2000). Emotion graphs consist of an x-axis representing time and y-axis representing valence of emotion (positive and negative). Participants retrospectively sketch how their emotions changed in intensity over an experience, here a proof construction task (Figure 1). Participants then marked on the horizontal axis and/or annotated their graph with short captions at inflection points where they felt emotions shift. We explore the affordances of emotion graphs as used in two populations: The first study with N=12 undergraduates in a course focused on learning how to prove, over a series of interviews. The second study regards N=35 middle school students (ages 11-14) in a geometry summer camp.

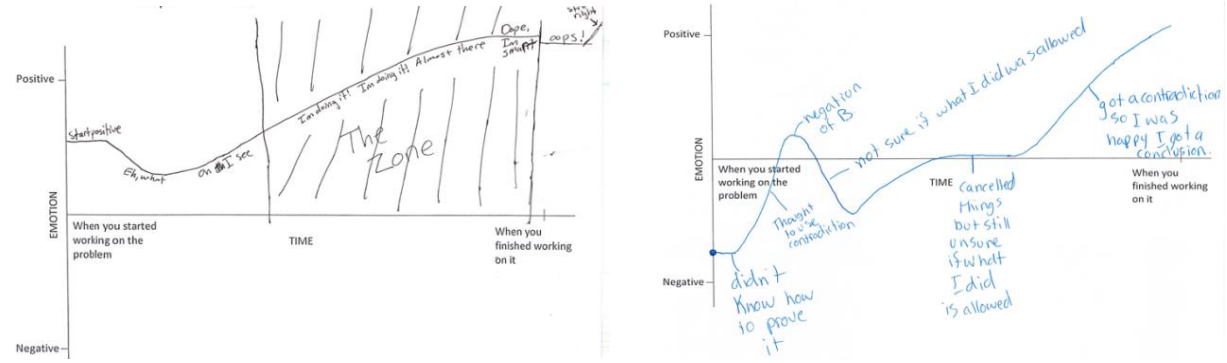

Figure 1: Example emotion graphs from undergraduates working on proof constructions

Discussion

In Satyam et al. (2022), we analyzed three studies with undergraduate students graphing affect and found four clear benefits: (1) temporal ordering of recollections, (2) explicit representation of change over time, (3) reduced dependence on verbal data, and (4) the creation of visual objects (the graph) for discussion. Emotion graphs can be used to describe variations in students' emotions ranging from years to single problem-solving episodes (e.g., Andrà & Scalvini, 2013).

Emotion graphing has shown promise with middle school students as well. In a recent study conducted during a geometry summer camp, we used experience sampling methods to study students' emotional engagement. After every math activity, N=35 students filled out a lesson exit ticket, which included a blank emotion graph and a suggested emotion word bank for them to label their graph with corresponding emotions. In total, we collected approximately 455 emotion graphs over the span of one week. Data analysis is underway, and we anticipate insights about the potential of emotion graphing with middle school students. In a post-survey, students reported emotion graphing helped them "realize where I was confused", "express about the topic", "if I didn't like it I had hope it would change", and "I liked you hearing my opinion."

In summary, an emotion graph tool serves as an instrument for assessing students' recollections of their emotions. This work advances research on emotions by providing students a process through which they can track, monitor, and reflect on their emotions. Through this process, students can identify barriers, strategize changes, and improve their own mathematical learning experience.

TWG 09: Interaction, Communication and Language in Mathematics Education

Interaction, communication and language(s) in mathematics education: The work of TWG09

Jenni Ingram[1], Kirstin Erath[2], Máire Ní Riordáin[3], Alexander Schüler-Meyer[4] and Ingólfur Gíslason[5]

[1]University of Oxford, UK; Jenni.Ingram@education.ox.ac.uk
[2]Martin Luther University Halle-Wittenberg, Germany
[3]University College Cork, Ireland
[4]Eindhoven University of Technology, The Netherlands
[5]University of Iceland, Iceland

In this paper, we report on the work of TWG09 at CERME 14 while exploring a central tension in our field: whether it is possible to attend simultaneously to the social and cultural dimensions of language and communication and to the mathematical content in focus. TWG09 brings a diverse set of perspectives, methodologies and foci to consider the interplay between mathematics, language and culture. Mathematics is taught and learnt through interaction, using communication and language, and as such is a cultural, social and linguistic activity. The meaning mathematics has for us is shaped by and through communication, and this communication is fundamental to deepening mathematical understandings. Furthermore, ignoring the social and cultural dimensions creates and perpetuates inequities. The presentations within TWG09 illustrate, reveal and challenge this central tension with important implications for the teaching and learning of mathematics at all levels.

Keywords: Language, interaction, communication, discourse.

Introduction

TWG09 brings a diverse set of perspectives, methodologies and foci together to address questions around interaction, communication and language(s) in mathematics education. The growth and maturity of research with such a focus is reflected in the diverse theoretical and methodological approaches within this TWG, but also in the range of special issues and edited books dedicated to this area of research. Accordingly, the presentations at the conference provoked deep discussions around a range of mathematical topics (e.g., angles, equivalent fractions, zero), and mathematical linguistic practices (e.g., explaining, naming, responding), drawing on a range of theoretical and methodological perspectives. This paper introduces and reflects on the diversity of perspectives and insights shared within TWG09 at CERME14.

Can we pay attention to the social and cultural dimensions of language and communication at the same time as the mathematical content in focus?

At CERME14, TWG09 dedicated a session to an Oxford-style debate exploring a central tension in the field: whether it is possible to attend simultaneously to the social and cultural dimensions of language and communication and to the mathematical content in focus. Two members argued in favour of this possibility, while two opposed it. The debate highlighted many aspects of our research focusing on interaction, communication and language, and the tensions that arise in our research designs, analysis and communication of findings to peers, teachers and beyond. We have organised

this introductory paper around the key points that arose during this debate, highlighting how these issues were more widely discussed and debated in the presentations and discussions in the group.

The Interplay of Mathematics, Language, and Culture

Mathematics is both taught and learned through language and social interactions. Mathematical knowledge is socially constructed and mediated through language, communication, and cultural context. If learning mathematics is fundamentally a process of meaning-making, then it can be argued that attending to both language and social and cultural dimensions is not a distraction from content learning but rather an essential component of conceptual development. Yet the question posed focuses on whether these aspects can be attended to *at the same time*. It is not an argument about whether mathematics should be taught without acknowledging these dimensions, which would ignore the fundamental role of communication and cultural context in meaning-making. This is exemplified in much of the work focused on multilingual classrooms, where more than one language is used in mathematics classroom talk (Gregurević & Fetzer, 2025; Revina & Schüler-Meyer, 2025), including presentations at this conference on the interaction between Maltese and English in learning equivalent fractions (Farrugia, 2025), between German and English in learning 0 (Bürgstein & Söbbeke, 2025), and between German and Croatian in learning about doubling and halving (Deegener et al., 2025). Yet much of our research on this interplay foregrounds language and communication and perhaps neglects, to some extent, the mathematical content. This may partly be a consequence of the constraints in reporting the results of any analysis (e.g., length restrictions, journal guidance, reviewer feedback). We are seeing more research that addresses this concern, and this is exemplified by research that focuses on how language influences the meaning developed for key mathematical concepts, such as negative numbers in the paper by Fabian and Kortenkamp (2025) and angles in the paper by Kimber et al. (2025).

Mathematics as a Cultural, Social and Linguistic Activity

Mathematics is not an isolated, culture-free discipline. Mathematical concepts and practices are socially constructed and vary across cultures. Mathematics has often been framed as a universal language that transcends culture. The field of ethnomathematics has demonstrated that different cultures develop distinct numerical systems, measurement techniques, and spatial reasoning frameworks. While there are six universal mathematical activities: counting, locating, measuring, designing, playing, and explaining; how these are expressed varies culturally (Bishop, 1991). Other mathematical activities can vary considerably in different cultural contexts (Barton, 2008). Mathematical reasoning develops within cultural contexts, and acknowledging these differences enriches learning rather than distracting from it. Different languages stress (and ignore) different aspects of mathematical objects and activities in their words for the objects.

The challenge of integrating social, linguistic and mathematical dimensions is reflected in our work developing analytical tools to examine the interplay of these different dimensions. Much of the research in this area focuses on sociomathematical norms (Yackel & Cobb, 1996), and teacher or student talk moves (Erath et al., 2021; Gustafsson, 2024). Aumann and Erath (2025) presented four categories of student initiations which influence the norms of interaction within which they arise. Both Bessenyei (2025) and Julsgård (2025) focused on teacher prompts, with Bessenyei examining

group problem-solving and Julsgård examining one-to-one tutoring sessions. Drageset and Skoglund (2025) focused on how an expert teacher positioned their students in the learning process, for example as thinkers, explainers, and listeners. These ideas are also explored by Jonker et al. (2025) in peer-to-peer dialogue. Finally, Revina and Schüler-Meyer (2025) considered teacher moves in response to students' multilingual contributions during a lesson on solving quadratic equations. Each of these studies illustrates the different aspects of learning mathematics in classroom interaction. The framework presented by Kimber et al. (2025) brings together many of these dimensions, with the aim of making the connections between these different aspects.

Language and Communication Deepen Mathematical Understanding

Mathematics is about thinking, reasoning, and making sense of problems. Language is the medium through which this happens. Language plays a fundamental role in mathematical reasoning and problem-solving. Mathematics is often described as a specialised discourse (Halliday, 1978; Schleppegrell, 2007) characterised by unique syntactic structures and semiotic representations that differ from everyday communication. Various theories from sociology, psychology, and linguistics underpin much of the research within TWG09, where learning is seen as occurring through social interaction and is mediated by language. Mathematical concepts become internalised as students engage in discussions and verbal reasoning. Another key idea underpinning much of the research in this group is that of Halliday (1978) who describes mathematics as a "register of language" with its own specialised vocabulary and grammar. Students must learn to navigate formal mathematical discourse alongside everyday language, as was exemplified by the presentations described above, illustrating the language associated with particular mathematics concepts in different named languages (Bürgstein & Söbbeke, 2025; Deegener et al., 2025; Farrugia, 2025). This issue is also key to learning through one language. Lomas and Wessel (2025) illustrated this in their analysis of students learning the scalar product, while Mähnert and Erath (2025) illustrated this with examples from design research focused on fraction division. Meaney et al. (2025) also explored this in their work with pre-service teachers focusing on how algebraic variables and constants are described.

Interestingly, the growing use of generative AI, such as large-language models (LLMs) or chain of reasoning models, not only gives us further insight into the relationship between language and mathematics but can also play a role in the teaching and learning of mathematics. Eckhardt and Thurm (2025) used an LLM to prompt students' mathematical explanations using ideas from research on prompting and dialogue in mathematics teaching, while Gíslason (2025) asked preservice teachers to 'teach' the LLM how to solve a mathematical logic problem, which required them to craft prompts that directed the AI to the key mathematical ideas. Interactions with these AI models highlight how reasonable and predictable many of the mistakes or misconceptions made by students are.

Students construct mathematical meaning through participation in structured classroom interactions. Ignoring the role of interaction in mathematical thinking undermines students' abilities to articulate, justify, and refine their reasoning. Focusing on the early years, Henschen and Teschner (2025) showed how spontaneous language used in interactions can reflect emerging mathematical understanding, while Carlén et al. (2025) focused on the shift in textbooks from informal language and visuals to more formal mathematical symbols and routines. Both emphasised the importance of

exploratory and informal language in learning. Yet we are still learning more about how language and interaction influence the learning of particular concepts.

Ignoring Social and Cultural Dimensions Creates Inequities

A mathematics curriculum (enacted or prescribed) that ignores linguistic and cultural diversity privileges certain students while disadvantaging others, e.g., multilingual learners, learners with additional learning needs. There is now substantial research showing that multilingual students benefit from leveraging their full linguistic repertoire in problem-solving (Planas & Chronaki, 2021). Many students engage more deeply when mathematics is connected to their lived experiences. Furthermore, mathematics is not just about the key ideas underpinning it—it is also about thinking, reasoning, and problem-solving, all of which occur through language and within cultural contexts. By embracing communication and cultural diversity, we make mathematics more engaging, inclusive, and accessible for all learners (e.g., Lenz et al., 2024; Prediger et al., 2022). Indeed, ignoring social and cultural dimensions creates inequities in mathematical learning, as without attention to these factors, many students are disadvantaged, leading to unequal learning outcomes. One example of this was presented through Ebel et al.'s (2025) analysis of mathematics school-leaving examinations, revealing the language barriers associated with the different tasks included, with consequences for students in these high-stakes assessments. Another example was presented by Ebbelind and Ivanov (2025), who analysed a spatial reasoning activity for young children, and how language mediated the diagnostic purpose of the activity.

These presentations highlighted how the integration of language and mathematics must be done with careful consideration of cognitive demands, ensuring that language and culture support rather than hinder mathematical reasoning. They also illustrate the consequences when certain students are disadvantaged through the linguistic and mathematical opportunities or barriers they experience.

Implications for teaching and learning

Teaching is complex. Learning is complex. One argument for focusing on the social and cultural dimensions of communication sequentially and iteratively with a focus on the mathematical content, is that this demarcation can support both teaching and learning. The complexity of classroom interaction is widely acknowledged, and one of the teacher's roles is to support students to navigate this complexity. This is reflected in the large growth of research focused on teacher development in this area (e.g., Kasari & Meaney, 2024; Planas et al., 2024), and in relation to how we, as researchers, listen to and respect the expertise of teachers (e.g., Drageset & Ell, 2024; Planas et al., 2025). Several studies in the working group focused on teacher education. Rave-Agudelo and Planas (2025) and Kimber et al. (2025) illustrated the complexity of communicating in the context of professional development focused on angles, considering too the role of gestures in that communication, and Revina and Schüler-Meyer (2025) examined the possibilities for teachers to take up students' multilingual ideas to create learning opportunities.

Conclusion

Ultimately, the question is not whether we can pay attention to linguistic, social and cultural dimensions in mathematics education—it is how we can do so effectively, critically, and equitably.

The research presented in TWG09 at CERME14 not only shows how lively this field of research is, but also how we, as a group, push the boundaries for new ideas for language inclusion, language- and culturally-responsive teaching, and for truly multilingual mathematics classrooms with equal opportunities for all. Accordingly, the productive discussions and constructive exchanges in the group also show that the participants in TWG09 have a great interest in familiarising themselves with the various presented studies, identifying new links and building new collaborations on this basis.

Characterisation of students' initiatives in whole class discussions

Christoph Aumann[1] and Kirstin Erath[1]

[1]Martin Luther University Halle-Wittenberg, Germany; christoph.aumann@mathematik.uni-halle.de

From an interactionist perspective, learning mathematics at school is primarily about participation in the classroom discourse, which is mainly represented by public classroom discussions. The participation can be of a very different nature. In this paper, we focus on students' contributions that arise without any compulsion from the teacher, the so-called students' initiatives. We argue that these initiatives can make a significant contribution to explaining hidden, implicit expectations and norms. For this purpose, we present four categories of students' initiatives we found in the video recordings of 18 mathematics lessons from a classroom at the beginning of the secondary school. The categorisation of the initiatives of five selected pupils shows different patterns of contributing in the form of initiatives and we see how initiatives from the various categories lead in practice to different expectations and norms being explicated to a certain extent.

Keywords: Communication, interaction, classroom discourse, norms.

Introduction

Participating in mathematics classrooms is a crucial part of learning mathematics in school (e.g. Sfard, 2008). The ways in which students participate can vary and do not necessarily have to be characterised by active speech acts (Krummheuer & Brandt, 2001). Nonetheless, active contributions play a special role, as they bring the students' thoughts into the classroom discourse. While in teacher-dominated classrooms the IRE scheme (Mehan, 1979) is very present, we want to focus on those student contributions which are not a direct response to an initiation from the teacher, but the students initiate themselves. These student initiatives represent a special form of participation, as they break the discursive flow (Drageset, 2015) and introduce new topics or aspects into the classroom discourse. An examination of these special types of contributions therefore appears promising for a deeper analysis of students' participation in mathematics classrooms.

Theoretical background

The importance of participation for learning mathematics has already been emphasised in many studies (e.g. Cobb & Bauersfeld, 1995; Sfard, 2008). From an interactionist point of view, individuals construct their own reality through interaction, based on the meaning that objects or situations have for them (Blumer, 1986; Garfinkel, 1967). In these interactions, the interactants display each other their individual interpretation of objects or situations which may lead to an interpretation, that is regarded as shared (Krummheuer, 1983). This "shared" interpretation is sufficiently suitable, so that the interactants can go on with their interaction, which marks the starting point for successful learning processes, since learning, seen as learning-as-participation (Sfard, 2008), takes part in interaction. Such collective negotiations of meanings in the classroom mostly take place in public class discussions. The defining aspect of these whole class discussions is, that they (at least in theory) are more or less accessible for everyone, although the participation in these polyadic interactions can

vary from hearer or recipient to speaker and many other roles, which may also change over time (Krummheuer & Brandt, 2001). Participation in whole class discussions is therefore essential for learning success, whereby active involvement in the form of verbal contributions plays a prominent role, as the word is the realisation of the thought (Vygotskij et al., 1962) and therefore represents a window to one's cognition, a publication of one's individual interpretation of an object or a situation.

By acknowledging the importance of students' contributions in the whole class discussions for the investigation of students' participation, the various ways open up to us, in which they can be shaped. Drageset (2015) differentiates between five superordinate categories of student comments: explanations, partial answers, teacher-led responses, unexplained answers and student initiatives. The first four categories can be seen as categories for utterances that are made as responses within student-teacher interactions and associated practices. The last one, student initiatives, on the other hand, describes comments that are more proactive in nature, as students "break the communicative flow" (Drageset, 2015, p. 35) to contribute own intentions or content. This kind of student's utterances seems therefore very interesting, as, again speaking with Vygotskij et al. (1962), the initiative represents the realisation of the student's thought, which is not forced by questions from the teacher but has developed through the interaction without any social compulsion to contribute anything. Since successful, appropriate participation in (mathematics) classrooms is mostly a question of fulfilling the teacher's expectations respectively following the norms (e.g. Aumann & Erath, 2024; Garfinkel, 1967; Yackel & Cobb, 1996), initiatives are a particularly delicate form of student utterances, because, firstly, there is no direct expectation of the teacher as there is no open question, and, secondly, because initiatives make it possible to make previously implicit aspects explicit and therefore can help to identify (normative) expectations (Aumann & Erath, 2024) or "hidden rules" (Jablonka, 2008) from the teacher. Hence, an investigation of student initiatives seems promising.

Our framework for the examination of student initiatives is based on the presented definition from Drageset (2015). We define students' initiatives as a break in the communicative flow, where students contribute their own intentions or content. This means, that there is no compulsion for the students to say anything, but they do it from an intrinsic motivation, making the initiative itself proactive. According to the distinction between social and sociomathematical norms, a distinction between utterances regarding (social) behaviour and actions and utterances regarding (mathematical) objects and actions seems close to hand. This differentiation between action-related and object-related utterances allows us to categorise the initiatives on a content level and draws parallels with the terms "regulative" and "instructional discourse" (Bernstein, 1996). In addition to this distinction, we want to differentiate concerning the referential context or the discursive orientation of the initiative. While Sfard (2008, p. 58) introduced the terms "proactive" and "reactive" for the categorisation of meta-discursive intentions, we want to stay on a content level. Although, as stated above, all initiatives are proactive by definition regarding their discursive function, they can be proactive or reactive on a content level, as it depends on the referential context and the kind of contribution they make. To delimit it more clearly, we want to distinguish the direction of the initiatives between backward-looking and forward-looking initiatives. The defining characteristic of the first is, that in this case no new own (mathematical) content is contributed, and the contextual reference is clearly set in the past which makes it more repetitive or reactive. In contrast, forward-looking initiatives introduce new

(mathematical) topics or aspects with a focus on the future, which makes them contributing and proactive on a content level.

The questions therefore arise as to what extent the categories presented are useful for describing student initiatives and how they can help to identify expectations in the classroom.

Methods

The data used in this study was obtained from a video study conducted in a fifth-grade classroom at a German upper-secondary school (German: "Gymnasium") in a medium-sized city. The first four weeks of regular mathematics lessons after the transition to secondary school were video recorded, resulting in a data corpus comprising 18 lessons of video material, which were all recorded in their entirety.

For further research, we chose five pupils out of the class, namely Adem, Elijah, Lukas, Merle and Maja. Two of them were also part of the previous video study on the last lessons of the fourth grade in primary school, three other children intuitively caught our attention during the study due to their very different participation patterns in the classroom. Firstly, we reduced the data material by marking every public utterance from the five pupils. These utterances, together with the preceding and following turns, each represent situations of public participation of one of the five students. Of these situations, those that corresponded to our definition of students' initiatives were then selected and, as the categories presented in the previous chapter form a categorial system, sorted using qualitative content analysis based on video-graphed data (Dinkelaker, 2016; Kuckartz, 2018).

Empirical insights

In the following sections, we want to give insight into our categorisation. The distinction between object-related and action-related utterances in one dimension and forward-looking and backward-looking utterances in a second dimension allows the utterance to be categorised in a 2 by 2 table. We therefore present a prime example for each of the four cases. For clarity, each transcript is numbered starting at 1, but the situations are from different lessons at different times.

Action-oriented and backward-looking

In the second lesson, the pupils counted their pets and documented them on a tally sheet. Afterwards, the teacher introduced the bar chart as a form of representation for data. At the end of this lesson, this short sequence took part.

1	Oskar:	What should we write into the bar chart? The pets again?
2	Teacher:	Yes, please note as homework: bar chart and in brackets: pets. Then you know it. [Adem points up] Adem?
3	Adem:	So, should we now turn this table into a bar chart?
4	Teacher:	[points the thumb-up to Adem] Yes, correct.

In line #1 Oskar asks, what he or she has to do. The question is very precise and is about, what data has to be "written" into the bar chart. He directly asks if it's still about the pets, that they talked about earlier in this lesson. The teacher confirms and summarises, that as homework they should make a bar chart and that they should add "pets" so that the pupils don't forget what they have to do (line #2). Now Adem points up, signalling that he wants to make an initiative, as no question is asked.

After getting called up, he summarises and asks in his own words whether what he has understood as homework is what needs to be done. The teacher confirms orally and gesturally. In this short sequence, we can identify Adem's initiative as an *action-oriented* question, as his questions do not aim at the mathematical object of a bar chart, but at the confirmation of his understanding of the homework given by the teacher. This question is by no means unnecessary, as it clarifies for him what he has to do to complete the task in an accepted manner. But in his question, he is also *backward-looking*, as he refers to something already said and does not contribute any new content of his own.

Action-oriented and forward-looking

An example of an also action-oriented but *forward-looking* initiative is the following. In the second lesson, the teacher starts with a so-called "daily exercise". After the correction, the pupils tell the teacher, how many points they achieved. Directly after that, Maja points up.

1	Maja:	[points up]
2	Teacher:	You have a question, Maja?
3	Maja:	Are we allowed to write in notebooks in mathematics?
4	Teacher:	No, because I will give you worksheets from time to time and you may also have to staple out a sheet and hand it to me

The teacher's question in #2, if Maja wants to ask something makes it clear one more time, that Maja's raised hand and the associated wish to make a contribution are to be seen as an initiative, as it seems, that there is no open question, that could motivate Maja's hand raising. Maja's question in #3 confirms this impression, as she asks, whether they are allowed to write in notebooks (instead of folders). She doesn't refer to something said before this sequence but opens a new topic. This new topic is not really about a mathematical object, it is about, how to work in mathematics classrooms properly. Additionally, this new topic seems not to be really relevant for the moment, as there was no prompt to write something in their folders, but it has high relevance for the future, as it makes it explicit, what the teacher expects from the pupils to do, respectively how to work in mathematics classroom. The initiative is therefore *forward-looking* and *action-oriented.*

Object-oriented and forward-looking

In the sixth lesson, the class works on several exercises to determine predecessors and successors of natural numbers. In one task, the number given is zero. After a short discussion of what the predecessor of zero could be, the following sequence took part.

1	Teacher:	So, the correct answer is to draw a dash at this point. There is no predecessor because we are in the number system of natural numbers. We have now justified that, we go on. Task j is still missing. Where did we leave off? With Merle.
2	Merle:	908, 909 and 910. I wrote "not solvable" in the previous task, is that also possible?
3	Teacher:	You can do that too, exactly.

In this short sequence, it is interesting, that Merle gets the word from the teacher to present her solution to the Task j in #1. She does it and adds directly after that her initiative regarding the discussion just finished (#2). That could indicate, that for her the outcome of the discussion was not totally satisfying. However, she presents an alternative solution to the dash, which the teacher highlights as the correct answer. She therefore contributes an own new suggestion and, by asking for

the validity, helps to make alternative possible solutions explicit, which makes her initiative *forward-looking.* The teacher accepts her initiative and confirms the solution as correct (#3). It gets clear, that it is not so much about the way she wrote it, which could make it action-oriented, but more about the object of the denomination of the predecessor of zero, which makes it *object-oriented.*

Object-oriented and backward-looking

This case was the most uncommon in our video study. In the eighth lesson, the power notation is introduced. On the blackboard, there is a table with "big numbers" notated digit for digit and the corresponding power notations. Additionally, there is a number written in power notation, but not sorted by the powers.

1	Teacher:	So, the next one going to the board has to sort it in his head- do you have a question? *[leans over and looks to Lukas]*
2	Lukas:	It says … in the lower line, two times ten plus eight plus nine … nine times ten?
3		*[indistinct chatter]*
4	Teacher:	So, we just found, that I didn't sort it, what must not happen is, that one exponent occurs twice. Let's have a look. *[points on the exponents one by one]* We have the eight, the five, the six, the seven, the four, of what do we have to think here when there is nothing written, Lukas? That bothered you a bit.
5	Lukas:	The three?
6	Teacher:	No, which exponent? Eight times ten to the power of what equals eight? That's how you need to think.

After there is no answer from Lukas and another pupil gives the correct answer to the question in #6, the teacher directly goes on with the next task. Again, the question from Lukas in #2 breaks the interactional flow as it interrupts the explanation from the teacher (#1). Therefore, Lukas seems to have important reasons, why he wants to make a contribution. When given the word, he doesn't refer to the teacher's explanation but starts to bring something else, a number written on the blackboard, into the focus (line #2). He starts to read what is written and refers to the "lower line" (#2), which sets the focus not on the entire term, but on special parts of it. Obviously, he has some problems with it as he makes some pauses and does not formulate a proper question. That gives the impression, that he himself is not quite sure what problem he has with the term, but something is bothering him. Here we can find an indicator of the *backward-looking* character of his initiative. The teacher then starts with an explanation of probably what she thinks his problem could be. With lines #4, #5 and #6 it seems likely, that Lukas was not able to comprehend the term 10^0, respectively the translation process there, if no power of ten is written behind a number. That makes it clear, that his initiative aims at the object level of this term, which makes it an example of an *object-oriented* contribution.

Discussion

As we can see, we are able to classify contributions in the form of initiatives in the four categories presented above. However, the mere categorisation of individual utterances is not expedient here, as there may be good reasons for attempting each category and we do not want to take the liberty of assigning a value here. As stated above, student initiatives offer the possibility to make implicit norms or requirements explicit. By categorising the students' initiatives, we can see what type they are, if they address object-related or action-related discourse and whether they are more proactive or

reactive. Figure 1 shows the frequencies of the students' initiatives from the five chosen pupils in the first 18 lessons for each of the presented categories and the respective total numbers of initiatives.

Table 1: students' initiatives from Adem, Elijah, Lukas, Merle and Maja

	Obj.	Act.
F.	2/15	3/15
B.	1/15	9/15
Adem		

	Obj.	Act.
F.	2/4	0/4
B.	0/4	2/4
Elijah		

	Obj.	Act.
F.	2/10	6/10
B.	1/10	1/10
Lukas		

	Obj.	Act.
F.	5/8	2/8
B.	0/8	0/8
Merle		

	Obj.	Act.
F.	1/5	4/5
B.	0/5	0/5
Maja		

Table 1 highlights that there are large variations in the total number of initiatives in the observed first lessons in the new school. While Adem started 15 initiatives followed by Lukas with 10, Elijah and Maja have not even started their initiatives half as often. These figures should be treated with caution due to the statistically not particularly reliable scope, but we can still recognise clear trends. The variation in the total numbers could be an indicator that Adem and Lukas see more need for clarification in class, or that they are more socialised to bring their own thoughts into the classroom discourse more often. However, an interesting aspect here is that Lukas and Maja were in the same primary school class, so they were socialised within the same mathematics classrooms and yet Lukas initiates twice as often as Maja. Yet, more interesting than the total numbers is the respective distribution regarding the direction and the type of discourse addressed. When looking at Adem's initiatives, we can see clearly a trend toward backward-looking and action-oriented initiatives. In the presented prime example, we have seen that this is mostly a repetitive question about what was said what is to do. This makes it likely that it may often not be possible for him to follow the instructions in such a way that he knows what to do, which is why such an initiative is necessary. With this kind of initiative, he makes the expectations of the teacher explicit (Aumann & Erath, 2024) and is therefore able to fulfil them, which is a worthwhile goal. At the same time, it may show, that Adem is not as successful as the other pupils to understand (more or less) "hidden rules" (Jablonka, 2008) and therefore this action-oriented discourse seems restricted to him (Bernstein, 1996).

Elijah's initiatives are, as already mentioned, significantly less frequent than Adem's. Again, the numbers are not too reliable, but we can recognise indications of patterns consisting of an accumulation of initiatives in the categories object-oriented/forward-looking and action-oriented/backward-looking. The second case might be, as with Adem, a sign of missing understanding of what was said what is to do, although the trend is not as strong as with Adem. Meanwhile, the object-oriented and forward-looking initiatives show contributing character, as here new (own) content is suggested and brought into the classroom discourse, which can become the object of negotiation processes and can lead to a common interpretation of this content and its meaning (Krummheuer, 1983). For the process of learning, this kind of initiative seems to be very substantial.

Meanwhile, Lukas' and Maja's initiatives show a trend towards a forward-looking action-orientation. The situations are categorised in this way when the type of discourse is about the (social) behaviour but there is no backward reference to something already said. Therefore, they can be interpreted as a

preliminary evaluation of the teacher's expectations as to how to behave. In contrast to Adem's typical pattern, this case seems to be rather a productive and proactive one. Evaluating the expectation helps to make it explicit and to act in an appropriate and accepted way and therefore to participate successfully.

While Maja's initiatives are most often categorised as action-oriented and forward-looking, but there was no situation to categorise as backward-looking, Merle's table shows a similar pattern. She also initiated always forward-looking, but less action-oriented and more object-oriented. So, while Maja seems to try to evaluate the norms and expectations regarding actions and participation, Merle's initiatives are more about the mathematical objects, and she is in this cluster similar to Elijah. These patterns can also be described as forms of creating autonomy (Yackel & Cobb, 1996), which is again a crucial part of learning as participation.

Conclusion

The suggested categories draw an interesting picture of student initiatives, as they show signs of patterns of participation. Although, as stated above, there are many forms of participation (Krummheuer & Brandt, 2001). We discovered that student initiatives are a crucial way for the students to recognise and identify norms and (situational or normative) expectations of the teacher, which is central for appropriate participation in mathematics classrooms (Aumann & Erath, 2024; Bernstein, 1996; Jablonka, 2008). The patterns discovered should be treated with caution but following the work of Drageset (2015) they indeed show, how different the pupils contribute to the classroom discourse in their initiatives and therefore participate in mathematics classrooms. While Adem's pattern shows an accumulation of initiatives, that might be interpreted as attempts to make already given work instructions clear for him, Lukas' and Maja's pattern can be interpreted as a try to evaluate accepted behaviour in advance. This discovery is exciting, as both were in the same primary class. Their similar pattern might be an indication of their similar earlier socialisation. The examination of their participation in the last weeks of primary school will be part of further research. Also, a further investigation of participation patterns in other types of students' utterances as answers in teacher-led discussions might add a different point of view on the pupils' competence to participate in different situations, where different types of discourse and different competencies are addressed and required. Finally, a longer observation period and the resulting larger number of student initiatives would also be advantageous in order to obtain a more reliable picture of the patterns. Nevertheless, the categorisation of student initiatives presented here seems to be useful for examining student attempts to recognise expectations and norms.

Teacher guidelines during group work

Dorottya Bessenyei

University of Debrecen, Hungary; bessenyei.dorottya@kossuth-gimn.unideb.hu

This research aims to explore the role of teacher-student interactions in the process of group mathematical problem solving, with a particular focus on prompts. If the students make meaningful discoveries and set milestones by themselves, the teacher's prompting can be considered successful. To explore successful teacher prompting, the following research question was formulated: What kind of prompts did the teacher use, and how did they help the students to solve the task during a collaborative problem-solving session? Through the eyes of the researcher (who is the same as the teacher in this research), the teacher's prompts in the classroom showed a variety of diverse types, which helped to improve the efficiency of the problem-solving process.

Keywords: Group work, interaction, prompt, teacher interventions.

Introduction

Group work, collaborative problem-solving in small groups, has become an important tool for teaching mathematics, with many cognitive, metacognitive, and social implications (Hofmann & Mercer, 2016; Smith & Mancy, 2018). At the same time, this approach is challenging for the teacher, who has to monitor the progress of several groups and give prompts to individual groups or the whole classroom when necessary. This paper aims to contribute to understanding the richness and complexity of interactions by examining the impact of consciously designed intentional prompts and spontaneous, unintentional teacher reactions in the classroom and unveiling how teacher interactions activate students' problem-solving skills. This study investigates teacher-student interactions in a mathematics classroom where students in two small groups engage in collaborative problem solving. This simplified scenario helped document the interactions.

Teachers' knowledge, beliefs, goals, and established social and mathematical norms shape classroom interactions in mathematics teaching. Teachers make moment-to-moment decisions during interactions, carefully considering how to respond to students' thinking (Mason, 2015). These decisions involve balancing the discussed mathematical content, the interaction's objectives, and the students' needs. The complexity of managing these factors, combined with the occurrence of unexpected situations, can lead to cognitive overload for teachers, making planning essential to reduce this burden (Kondé et al., 2023). These factors' interplay significantly impact classroom learning's flow and effectiveness (Ingram, 2023).

The present research highlights the importance of the teacher's planning for the lesson, which includes not only selecting heuristic strategies for problem-solving but also designing possible prompts. To explore the problem, the following research question was formulated: What kind of prompts did the teacher use, and how did they help the students to solve the task during a collaborative problem-solving session?

The framework

The focus of the research was to study the role of prompts during the problem-solving process. Prompts are strategic interventions in the problem-solving process by the teacher to help students move forward in the problem-solving process without directly receiving the answers to their questions (Kramarski et al., 2013).

In this study, teacher prompts were analysed using two separate dimensions. The first dimension, derived from Giles and Gilbert (1981), categorises prompts as motivational, process-oriented, or product-oriented. The second dimension, based on Hofmann and Mercer (2016), classifies the prompts according to the teacher's role: authoritative, initiating, or continuing interactive. Each prompt was independently classified along both dimensions, providing a two-dimensional analytical framework.

Motivational prompts are intended to keep the students moving through the activity; for example, they reinforce students' contributions. Process-oriented prompts are intended to bring students' attention to methods or procedures, assuming they know them. An example is when the teacher asks for a drawing representing the problem, provided the students are already familiar with graphical representation as a heuristic strategy. Product-oriented prompts provide students with information that they are unable to proceed without. When the teacher directly corrects students' answers or explains the next step of the problem-solving process, a product-oriented prompt is given. When the teacher draws attention to a new approach, a heuristic strategy the learners may not have used before, it is also considered a product-oriented prompt. Another dimension of teacher interaction refers to the extent of the teacher's role. The intervention can be authoritative, where the teacher takes the lead; initiating, where the teacher leaves the continuation to the students; or continuing interactive (interactive in what follows), where the teacher responds to the students' ideas (Hofmann & Mercer, 2016).

In small group problem solving, teacher interactions should also support effective group work. Research indicates that group discussions are productive when students share ideas, discuss different views, and resolve them to achieve consensus. However, the literature is not in full agreement on what prompts and interactions teachers can use to achieve this aim (Hofmann & Mercer, 2016). Moreover, these characteristics are not commonly found in classrooms, and teachers find managing group discussions difficult. This research also aims to contribute to a better understanding of this phenomenon.

Method

The research is based on a small-group talent management program for 8th-grade students, aged 13-14, in which seven students participated. The program was organised in a school setting, but the sessions lasted 30 minutes instead of the 45 minutes usually spent in school lessons. This paper deals with one session, the first of the semester. The evaluation of the whole program is the subject of further research.

The teacher in the classroom was the author of the present paper. After transcribing the audio recording, the text was segmented, separating the teacher's voice and the in-group conversations. I

analysed the teacher's voices together with an experienced university colleague. Prompts were first identified and then categorised by double consensus. I marked the students with A, B, C, D, E, F, and G. The students worked in two groups, three in the first group (A, B, C) and the rest in the second. For the sake of simplicity, the group number is given next to the pupils' letter; for example, F2 means that student F is from the second group.

The challenge of the session was the following problem (Bolyai team competition for 8th grade students, National level, 2010/10. task):

In an empty pond, we release 50 hungry pike, which soon start to devour each other. A pike is called satiated and will not eat any more fish if it has eaten three other pike (hungry or satiated). How many of the 50 pike can be satiated in this pond in their lifetime?

To make it easier for readers to understand, the following demonstrates how 16 pike can be satiated. Count the pike from 1 to 50 and arrange them in order. The fourth pike eats the three before it. Now, the seventh pike has only three pike in front of him, which he eats. The same procedure is continued, i.e., the 10th pike is again preceded by three pike, etc. This way, the 4th, 7th, 10th, ..., and 49th pike can be satiated, a total of 16. Questions are raised as to whether more pike can be satiated or whether it is possible that fewer pike can be satiated if the rules are followed.

As this session was the first stage of the talent management series and the working method was unfamiliar to the students, I was mainly prepared for prompts to help them collaborate. Students were expected to find it difficult to understand the rules in the text at first reading, so I decided to directly answer questions about understanding the problem (product-oriented prompt). Moreover, concerning heuristic strategies, I prepared to give two prompts: encourage the students to represent the problem graphically (process-type prompt) and, if they get stuck, to understand the problem better with fewer pike (e.g., ten pike, product-oriented prompt).

The two groups sat at two tables, with a microphone recording the communication at each table. They were allowed to draw on a single large drawing board, each student using a different-coloured marker pen.

Results and Discussion

Although the teacher is the same as the author, the singular third person is used for the teacher's voice from now on. Looking at the course of the lesson, first, the moments that triggered the teacher's interventions were examined. The most important ones are also illustrated through examples of how the teacher reacted to the situation and to whom. The selection was based on the interventions that contributed most to the success of the task, and on the need to present as many different types of prompts as possible.

Students first asked questions about the interpretation of the task. The questions were addressed to the teacher, but the answers were addressed to the whole class, as they were important feedback for everyone. In the following discussion, members of both groups participated. The original questioner must have known the information was relevant to both groups, so he asked his question 'out loud'. As earlier mentioned, the teacher was prepared for the need for clarifying interaction.

D2: "During their lifetime" means that not only once [...]
A1: Well, he could die.
E2: If it was eaten, it could not eat […]
D2: No, my question is, if he is satiated once, can he still be hungry afterwards?
Teacher: No. Once he is satiated, he cannot eat any more. So, he is already satisfied in this respect.
A1: The text states that he cannot consume any more fish.

D2 thinks of the everyday experience: after we are satiated, we can be hungry again. The class reacts to D2's suggestion in a lively way, even if they do not initially understand the question. Later, D2 formulates the question accurately. The teacher clarifies the interpretation with an interactive, product-oriented prompt to the whole group, but A1 does the same nearly simultaneously.

After clarifying the questions, the participants of the two groups made drawings according to the teacher's instructions (process-oriented prompt). Figuring out a graphical representation of the problem was an effortless process for students; however, they differed in idiosyncratic characters. The groups' drawing sheets show that the students started drawing separately; however, students in group 2 used the same coding approach. After about 8 minutes of work, the teacher noticed that the students were getting stuck, so she suggested they investigate the problem for ten pike. This initiating, product-oriented prompt was intentional, and the teacher designed it in advance. The aim was to get experience with the problem. Solving the original problem with smaller numbers may be a well-established strategy. However, the fact that the two groups interpreted the teacher intervention differently presented a difficulty and an additional challenge. Group 1 ignored the instruction because they were immersed in their work. Three members of group 2 (D2, F2, G2) worked on the instruction, and the fourth member (E2) went his own way.

Teacher: I would like to ask you a question: Do you consider this 50 to be a lot? Or couldn't you try it on fewer fish first? I would say try it on ten pike and see how it goes.

Group 1 essentially ignored the teacher's suggestion. They did not want to give up their own train of thought, which they had already started, and continued with the 50 pike.

B1: What? To ten?
A1: I understand, but let's look at this first; let's finish it.

Group 2 seemed to have followed the teacher's instructions, but not in the way the teacher intended. They stayed with the 50 pike, but fish were divided into groups of 10, bringing them to a possible solution.

F2: Now, how many is that? [Thinking of the left part of Figure 1, explaining the process from top to bottom.][1] Now, that's ten. And three of them were satiated.

D2 approves the solution, but G2 finds it confusing that some satiated pike will be eaten during the process. D2 and F2 explain it, and in the end, G2 recites the process using the figure.

F2: OK, we can make it four more of these [we can repeat this process four more times], so three will always be satiated, and one will always stay [alive]. […] The solution is 15. [Referring to the full dots in Figure 1]

[1] Brackets refer to the non-verbal manifestation of the student or to the comment made by the author.

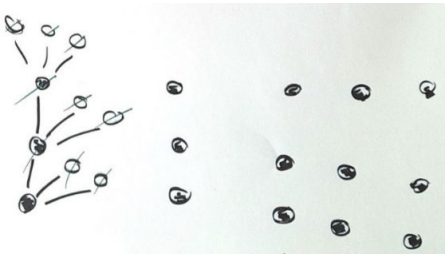

Figure 1: The representation of group 2 for the case 10 pike

It was important for the teacher to have the students explain their thinking to each other to reinforce collaboration and clarify the several individual idiosyncratic approaches. The teacher saw an interesting drawing in group 1, the group that did not follow the teacher's instruction concerning ten pike. The teacher asked the student to interpret his drawing (Figure 2), so it was an interactive, process-oriented prompt for him. The drawing is a perfect representation of the problem. The pupil was thinking in a linear process and marked the hungry and satiated pike differently from the previous drawing. (Read the drawing from top to bottom and from left to right.)

Teacher: This is very interesting. Can you tell me how to interpret this drawing?
B1: The circled ones are the ones who have eaten someone, but then they are eaten afterwards. So maybe they are eaten by being eaten at once.

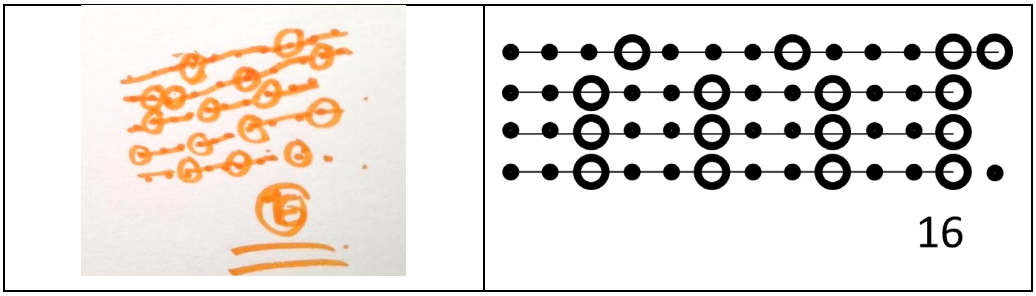

Figure 2: The representation of student B1 (original and edited figure)

While the students were drawing, they sometimes shouted their solutions out loud. The teacher noticed 17 and, as 17 pike could not be satiated, she addressed the group intending to clarify.

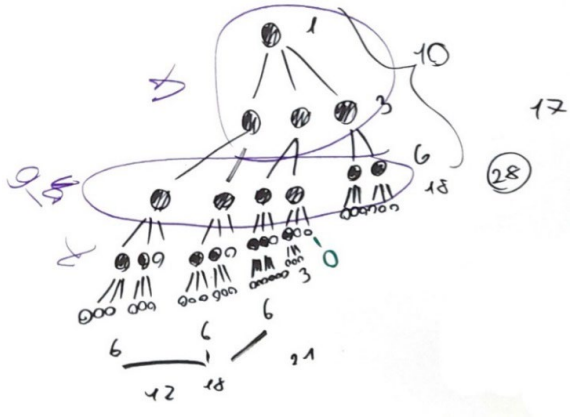

Figure 3: F2's false solution

The interpretation of the student's drawing is as follows. There are 49 circles in the figure representing the pike (Figure 3). The 50th circle was drawn by another student (in a different colour), but this did not play a role in the solution. The full circle represents the satiated pike, and the empty circle is the hungry pike. The pupil drew 17 satiated pike but missed the picture because three pike have eaten only two others and are still shown as satiated.

The following transcript shows an interactive, product-oriented prompt where the teacher explicitly points out the error. This was appropriate because the students, by their own statement, had already found the solution several times.

F2:	17 comes out.
E2:	Already, three people counted it. It is 17.
F2:	However, it seems suspicious.
Teacher:	[Pointing to one of the wrongly satiated circles.] It's not satiated because only two lines are coming from there […]
D2:	But these are no good either.

In the same group, another student (E2, who followed his own path and did not join the group work) reached the 17 pike, but his solution was essentially correct. He just counted the number of pike wrongly, the teacher noticed and, using an interactive, motivating prompt, asked him to explain. Then two of his groupmates (D2 and G2) noticed the mistake immediately and corrected it.

Teacher:	Okay, can you show me how 17 pike can be satiated? Somebody tells me, let us say E2, what is happening, how can this 17 […]
E2:	I started the whole thing by saying that there is a pyramid, the top one is filled, or the last one […] and at the bottom of the pyramid there are 27 [pike], the nine satiated ones ate 27 in total, and then, I don't know, there are nine satiated ones, three satiated ones [one row above the row containing the nine satiated pike], here three more, and one at the top […].
Teacher:	Yeah, and where are the 17 that are satiated? The ones who got satiated?
E2:	With that [thinking of the top one], yes, I think, that's it. But maybe I miscalculated.
D2, G2:	It is 16. [D2 wrote the number 16 on the drawing sheet.]

Figure 4: The representation in Transcript 5 (E2's original and edited figure)

In the session, the students came up with some solutions, and it turned out that no solution was found for 17 satiated pike. However, the question remained open whether 17 pike could really not be satiated. Due to time pressure, the teacher took more control using an authoritative, product-oriented prompt and, reverted to the planned heuristic strategy of "solve the problem for a smaller number of

elements," i.e., for ten pike. However, the students did not seem to understand why the teacher insisted on ten pike and kept returning to the original problem during the discussion. They are talking about the left part of Figure 1.

Teacher:	So, for ten pike, let's say three can be satiated. Right? That was on your drawing.
C1:	But then four can be satiated.
Teacher:	Well, how can four be satiated?
C1:	[We continue the drawing with] the little branch on the right, the one that's not there yet, right? [C1 continued the algorithm and mentally added another three circles to the picture.]
Teacher:	But there are only ten pike […] right? So, four can't be [satiated], and then 3, 2, and 1 [can], you could draw that.

Summary

The data quantify the 41 longer and shorter teacher prompts during the session. To address the research question, in terms of the extent of the intervention, more than half of these were interactive, around a third were initiating, and only a sixth were authoritative. The teacher mostly used process-oriented and product-oriented prompts; motivational prompts were only present to a limited extent. Process-oriented prompts, such as encouraging students to use graphical representation, helped them effectively use familiar heuristic strategies. Product-oriented prompts, including clarification of misunderstandings and encouraging the strategy for breaking down problems into smaller cases, directly facilitated students' progress when they got stuck. While product-oriented instructions often successfully guided students, they sometimes caused confusion or partial misunderstanding, suggesting that these instructions need to be carefully aligned with students' current problem-solving state. This phenomenon points to the need for the teacher to be sufficiently flexible and to build a rich schema around the problem (Kondé et al., 2023).

The problem solving was successful, as both groups independently found good solutions to a possible number of satiated pike, supported by explanations. With a little help, they could work out all the solutions and explain why there were no more solutions. The success of the lesson was also due to the inspirational nature of the task and the skill of the students, but it was certainly a good example of how students can do well under more restrained teacher guidance.

This article also highlighted the need to link planned prompts with the dynamic and often unexpected demands of teaching at the moment. I have reported that the teacher may not have achieved the intended effect with the planned prompt. As Mason (2015) discusses, the ability to perceive and respond flexibly in real time is a feature of professional teaching that bridges the gap between preparation and implementation in practice.

Limitations

The author acknowledges her dual role as researcher and teacher in the study. While the dual role provided valuable insight and context, it also introduced potential biases in interpreting interactions and prompts.

Acknowledgment

This study was funded by the Research Program for Public Education Development of the Hungarian Academy of Sciences (KOZOKT2021-16).

Contrasting meanings of ‘0’ in bilingual primary school settings

Malte Bürgstein[1] and Elke Söbbeke[1]

[1]University of Wuppertal, Germany; buergstein@uni-wuppertal.de

Current findings from mathematics didactics and foreign language research highlight the potential of contrasts for learning processes. The presentation of mathematical concepts in bilingual lessons not only leads to a linguistic contrast, but can also contrast different mathematical conceptual facets. Against this background, the current PhD project aims to investigate and characterise the role of the different languages (German and English) in bilingual lessons for the learning of mathematics in more detail. For this purpose, both languages are considered as complementary components in order to initiate a contrastive approach. The article uses a bilingual learning setting on the topic of ‘0’ to show how children’s interpretations differentiate and how their reflection on different meanings of the number ‘0’ arises.

Keywords: Bilingual education, English (second language), mathematical concepts

Introduction

The commission of the European Union (2003) recommends that member states ensure effective language learning and linguistic diversity from an early age, with the teaching of at least two foreign languages in kindergarten and primary school. In addition to the regular foreign language teaching that takes place in the majority of German primary schools, bilingual teaching is another component of second language learning. The establishment of bilingual learning opportunities corresponds with the recommendation to supplement pure foreign language lessons in elementary school with the preparation of learning content in order to enable a deeper understanding of language functionality (KMK, 2013). In essence, bilingual teaching, such as CLIL, entails the unique combination of a foreign language with subject-specific learning situations within a subject (e.g. mathematics). The aim thereby is not only to acquire language skills during lessons, but also to teach subject-specific content. In light of this, such bilingual teaching and learning processes are also of particular interest for mathematics education research. With regard to mathematics teaching at primary level, this content-related link represents a field that has so far been little researched with regard to “process-oriented studies […] that allow insights into classroom interaction, favourable circumstances of language learning and beneficial conditions of competence development” (Viebrock, 2013, p. 53). While there are already findings from research concerning the development of language learning in bilingual lessons, there is a lack of empirical research on the development of subject-specific mathematical competence in CLIL contexts.

The PhD project aims to investigate the role of the different languages (German and English) in bilingual lessons in primary school for the learning of mathematics. The project is at an early stage of the research process, in which an initial learning setting to the topic of ‘number 0’ has been developed and tested in a bilingual primary school. This article uses documents and a short episode from the current case study to present initial findings on whether the learning setting can cause mathematical reflection on the meaning of the number ‘0’ among the learners.

Language and mathematical learning processes

From a process-oriented perspective, mathematical learning and language are inextricably intertwined. Language takes on two different functions in learning processes (Maier & Schweiger, 1999). On the one hand, language serves as a tool to organise one's own thinking and to open up new possibilities of thinking and knowledge (*cognitive function*). On the other hand, processes of exchange and communication with others are also important in order to expand one's own mathematical knowledge. At this juncture, language assumes its *communicative function* by acting as a medium of communication. The communicative and cognitive functions of language should therefore not be understood as separate entities. Rather, they are inseparably linked. This is corroborated by empirical findings from numerous studies that have identified language competence as one of the most significant predictors of mathematical learning ability (Prediger et al., 2019).

Several studies in mathematics education emphasise that the negotiation of different perspectives and subject-specific insights with the teacher or other learners is fundamental important for the further development of mathematical knowledge (Nührenbörger & Schwarzkopf, 2016; Steinbring, 2009). In particular, young learners, who are not yet autonomous learners, depend on such collective negotiation processes in which all participants stimulate each other (Miller, 1986). For this purpose, the diversity and heterogeneity of learners can be particularly fruitful when dealing with a common learning object. This also applies to language as one of many dimensions of heterogeneity, as different languages can provide different conceptualisations for mathematical concepts (Barton, 2008). Bilingual teaching can exploit this by employing a variety of linguistic terms to represent a mathematical concept in a multifaceted manner. Beyond this, empirical studies highlight that the implementation of the student's first language (i.e. Turkish) in mathematics lessons have shown advantages for mathematics learning. Kuzu (2019) found some evidence that among other things, cognitive multiperspectivity can be productive by linking conceptual nuances that are close to different languages, as in the case of understanding fractions (secondary school). For primary school, Maisano (2019) has shown that the use of Turkish, in addition to German, offers potential for describing and explaining. With the help of bilingual podcasts, Klose (2019) has been able to demonstrate the appropriate use of technical language in the conceptualisation process of primary school children in German and English. Against this background, the PhD project aims to investigate and characterise the role of the different languages (German and English) in bilingual lessons for initiating mathematical learning processes in more detail. The focus is to create contrasts through language diversity in order to initiate productive irritations for mathematical learning processes. Productive irritations have been identified in mathematics education research as valuable starting points for learners' mathematical reflection, negotiation and understanding.

Productive irritations and mathematical learning processes

One purpose of mathematics instruction is to facilitate the progressive development of reasoning and argumentation skills, both within the context of individual learning and through collaborative discourse. In order to achieve this goal, it is crucial that the initiation of argumentation is not solely dependent on interactions with the teacher. Instead, it should be authentic and derived from a subject-specific perspective itself. This is particularly effective when learners challenge their established

expectations when working on mathematical tasks or making mathematical observations. This phenomenon is referred to as *productive irritations*, a concept derived from Piaget's work on cognitive conflicts. It occurs when children develop new ideas when they are confronted with ideas or facts that contradict their initial expectations (Nührenbörger & Schwarzkopf, 2016). Productive irritations can de defined as deviations from a preconceived expectation that require clarification and can be resolved through arguments (Nührenbörger & Schwarzkopf, 2016). In addition, it is conceivable that productive irritations may not only emanate from the subject matter itself, but also from the linguistic tools employed to convey it. In particular, bilingual teaching offers the potential to contrast two languages, thereby facilitating the occurrence of productive irritations. For this, it is important to understand the different roles of the languages in bilingual learning processes.

Bilingual learning and contrasting languages

In light of the various criteria that inform the designation of bilingual programs, such as CLIL, Immersion, etc., Diehr (2012) proposes a typology that differentiates bilingual concepts according to the role the languages play in the learning process. In her tripartite typology, she distinguished between the use of the foreign language in relation to the first language and the associated didactic functions. The first type A is characterised by monolingual teaching, which permits the use of the foreign language solely as a medium of learning, thereby considering the first language as inappropriate as language of instruction and excluding it. Type B is characterised by a limited integration of the first language. Nevertheless, the foreign language continues to be the dominant language in the classroom interaction. In contrast, in type C, both languages are regarded as equally valid. The concept of bilingual teaching in which two languages are used in a meaningful way, extends beyond type B in that is assumes an independent and specific contribution of the language of instruction to the students' learning progress. With regard to type C, Diehr (2012) specifies that it is insufficient to merely consider isolated technical terms from bilingual vocabulary lists. Rather, it is necessary to relate the two languages to each other, in order to teach a *contrastive approach*. This will enable the cultural construction of specialist terminology to be addressed, cultural multiperspectivity to be ensured, and intercultural awareness to be promoted.

Implications for the research project

A comparison of the perspectives derived from foreign language research (Diehr, 2012) with the findings from mathematics didactics research described above (Miller, 1986; Nührenbörger & Schwarzkopf, 2016; Steinbring, 2009) reveals a high degree of correspondence with regard to the productivity of contrasts. In particular, the linking of different perspectives through productive irritations in negotiation processes is seen as a crucial factor in the development of new mathematical knowledge. Bilingual teaching, which uses both the first and the foreign language as complementary elements, thus opens up a rich environment for comparing, contrasting and negotiating certain facets of the subject matter and the language.

For the research project, basic linguistic and subject-specific terms in German and English from the national standards of the mathematical learning in primary schools have been analysed on a subject-specific, linguistic and etymological level to identify potentials from a didactic perspective. This didactic and linguistic analysis entailed an examination, which exhibited both linguistic and

mathematical conceptual differences, including in their fundamental concepts. On this basis, it was possible to work out different mathematical topics and types of bilingual resources ((1) *derivation*, (2) *word-analysis*, and (3) *contextualisation*; Bürgstein et al., 2023), that can be used for the empirical survey in the research project. The bilingual learning setting presented in this paper corresponds to type (3) *contextualisation*. This type is characterised by the fact that there are more terms for a particular concept in one language than in another, depending on different contexts.

The number '0' exemplifies this phenomenon. In German, regardless of the context in which the number is embedded, the same number word is used, namely 'Null'. In contrast, in English different terms are used depending on the context. For example, the term 'love' is only used in the context of tennis, whereas in football 'nil' is used, the term 'oh' is often utilised to encode or nominate something, for example telephone or bus numbers. The term 'zero' is usually used to describe quantities, for counting or calculating (Bürgstein et al., 2023). We assume that these terms, which are used differently depending on the context, can produce a moment of productive irritation and give children an impulse to reflect about different meanings of the number '0'. It is essential that learners understand that numbers can represent not only quantities (cardinal aspect), but also other concepts (ordinal aspect, numbers to calculate, nominate aspect etc.), depending on the context in which they are used (Padberg & Benz, 2021). Establishing relationships between different aspects of numbers is essential for the development of comprehensive knowledge about numbers and their use and representation (Cockburn et al., 2008; Padberg & Benz, 2021). This doesn't mean that children should explicitly name different number aspects, but they should develop an awareness of diverse meanings associated with numbers.

Against the background of theoretical explanations, the linguistic and mathematic-conceptual differences in the context of the number '0', and the few studies on subject-specific mathematical learning in primary bilingual lessons, there is a desideratum to investigate the role of the different languages (German and English) for reflecting about mathematics. This leads to the formulation of the following research question: *How can learners' individual interpretations of the number '0' be characterised in bilingual negotiation processes using language contrasts*?

Method

A bilingual learning setting was developed to collect the empirical data. This was conducted in the form of a case study for an initial pilot study with a group of seven third graders in a bilingual class at an international school in western Germany. The case study method (Lamnek, 2010) makes it possible to identify typical aspects of learners' mathematical interpretations. Before first insights are presented, the learning setting and the analysis method are described. Children with English as their first language (L1, in this article: Ryan & Anna) and children with English as a second language (L2, in this article: Caro) were selected for the case study.

The learning setting is divided into two distinct phases. In *phase one*, two or three children engage in monolingual activities in German or English. The learners are required to collect and compile examples in which they encounter the number '0' in everyday life. To fulfil this task, the pupils can utilise provided materials, illustrations and audio files. Additionally, they can employ pieces of paper to record their ideas and examples, either in written form or as drawings. Subsequently, the learners

are required to sort their examples, to reflect different meanings of '0' and to find appropriate headings for the different meanings. In the *second phase*, two children who have previously worked in different languages in phase one work now together in a bilingual phase. The learners present the results of their work from the first phase. Subsequently they are asked to sort their examples together, giving reasons. Finally, they write down a number word that is particularly suitable for the '0' in the respective examples and find a suitable heading. The moment when the children realise that there are different names for the number '0' in English as opposed to German can be a moment of productive irritation. The expectation to utilise a singular term for the mathematical concept of '0' in each situation may be disrupted during such a joint negotiation process. This can lead learners to clarify the conflict by contemplating the mathematical concept in greater depth and to enter into a mathematical dialogue about different meanings of the number '0'. After the bilingual phase, interviews were conducted with the children.

The data generated in this first pilot study was analysed with the help of the "epistemological triangle" (Steinbring, 2009). The epistemological triangle is a meaningful analytical tool for the present research interest, as it reconstructs the emergence of mathematical conceptual interpretations and their underlying reference contexts. Mathematical "concepts" (e.g. here number '0') require certain "signs" in order to be grasped and encoded. The meaning of the signs must be created by the learners, who use familiar "reference contexts" (Steinbring, 2009). In this article we analyse photos that show which objects the children chose to represent the number '0', how they sorted these objects and named their categories. Therefore, we work out which *signs* the children interpret, which familiar *reference contexts* they use for this and which *conceptual interpretations* can be reconstructed. The analysis offers initial insights into the data, which at this stage of the research project can provide initial indications of meaningful reflections by the children.

First insights

Phase 1: Ryan and Anna (English setting)

The children Ryan and Anna speak Mandarin and English as their first languages. In phase 1 they collected and sorted examples for the number '0' (see Figure 1 a)-d)). The objects and images they put together can be understood as *signs* that represent the number '0' for the children. For the task of sorting these representatives and forming categories, they use everyday experiences as a familiar *reference context* by naming their categories in relation to concrete everyday objects and experiences (e.g. a) body parts, food; b) public transport; c) maths; d) sports; see Figure 1a)-d)).

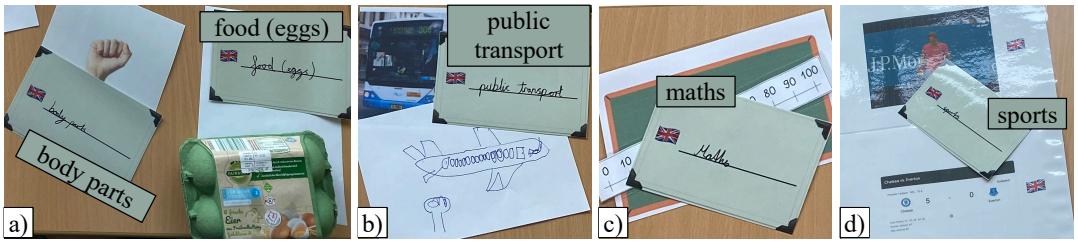

Figure 1 a) – d): Sorting from phase 1 (monolingual English)

At this stage, the categories do not illustrate any mathematical relationship to the representatives. For example, the picture of the bus with the number 308 is an appropriate example for the category public transport, but this category does not describe a mathematical function of the number. Such function could be, for example, that numbers on buses or airplanes are used to precisely number traffic lines or encode flights.

Phase 2: Ryan and Caro (bilingual setting: English and German)

In phase 2 Ryan works together with Caro (Caro worked in the first setting in the German speaking team). They bring together their results, discuss them and develop a new joint sorting. Here, too, the objects and pictures that the children have chosen could be understood as *signs* which represent the number '0'. During the negotiation process between Ryan and Caro, their categorisation evolves into a more mathematics-based perspective (e.g. a) count; b) number; c) calculating; d) sport results; see Figure 2a)-d)), so that it can be assumed that their *reference context* has changed.

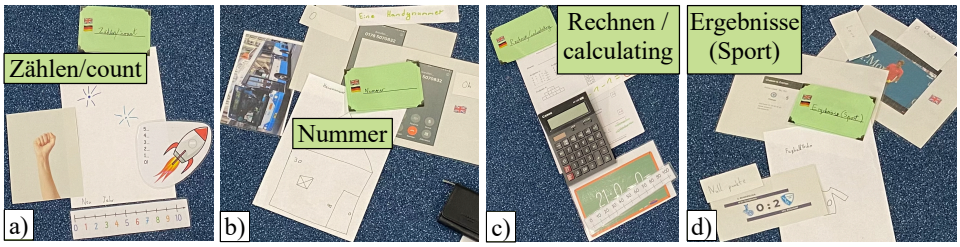

Figure 2 a) – d): Sorting from phase 2 (bilingual: German and English)

The comparison of Figure 1and 2 gives a first indication that the children may have adopted a new perspective. While in Figure 1 the picture of the hand (Figure 1a) was labelled as an example of "body parts", Ryan and Caro now establish a relationship between the picture of the hand and mathematics. Thus, the hand is categorised as a representative of counting ("count") together with other examples such as the number line or the rocket countdown (Figure 2a). While in the first phase the blackboard picture and number line (Figure 1c) were categorised in a rather general way as "mathematics", the children now name a specific function for which the numbers can be used: calculating (Figure 2c). After the children have sorted the examples, they are asked to label the categories with the corresponding number words for '0' in German and English (German: Null; English: e.g. oh, nil, or love). Prompted by the interviewer's question as to whether they had learned anything new about '0' in English and German, the two children enter into an exchange that moves beyond the concrete examples to a meta-level:

1	Caro:	That there can be, erm, are a lot of different zeros in English, so how you can say it differently. And I've never noticed how often you come across the shape or the number zero […]
2	Ryan:	For example, I wonder why you say oh, nil, and love because you can put it all in just one thing […]

Interestingly, Ryan (L1: Engl.) reflects on the efficiency of a single number word for the number '0', while Caro (L1: Ger.) emphasises the variety of number words in English and reflects in this context that she had never before realised how often she encountered '0' as a shape or number. The children's comments seem to be an initial indication that they were encouraged on a conceptual level to think in a more differentiated way about the meaning of the number '0' and the variety of number aspects.

Discussion

In order to investigate to what extent learners' interpretations of and reflections on the number '0' can be initiated by bilingual negotiation processes (see research question), a learning setting was developed in which children engage with contrasting terms for the number '0' in German and English. The analysis of initial data (students documents, video or transcript excerpts) using the epistemological triangle provides cautious indications that the children's *reference contexts* change from more everyday terms to more mathematic-related terms through activities of joint sorting and negotiation. Furthermore, it appears that the particular design of the learning setting can open up *irritations through language contrast* by confronting leaners with phenomena that contradict their original expectations. In the empirical data above, both children seem to discover new and surprising aspects in relation to the denotation and occurrence of the number '0': While Ryan emphasises the efficiency of a single term for the number '0', Caro expresses her surprise about the high frequency of the number '0' ("*And I never noticed how often you come across the shape or the number zero*") and how many different terms are used for it in English. With regard to the research interest, it is less relevant, that the children learn to use different terms for the number '0' (language skills). Rather, the aim is to provide learners with meaningful opportunities for reflection on a mathematical level (mathematical skills). Based on the first data, it can be assumed that the contrastive approach of the languages can create a catalyst for thinking with learners about different mathematical meanings of numbers (numbers for calculating, counting, coding, etc.). This process seems to be important in order to promote not only the linguistic but also the mathematical skills of learners in bilingual lessons. For further research, it must be determined whether these insights can also be reconstructed in other cases and to what extent meaningful mathematical reflection processes can be initiated for other mathematical concepts using language contrasts.

Mathematical discourse changes during the introduction phase of the early years - A textbook perspective

Irina Johansson Carlén[1], Clas Olander[1] and Ulrika Ryan[1]

[1]Malmö University, Malmö, Sweden; irina.johansson-carlen@mau.se

The aim of this paper is to investigate the mathematical discourse, as communicated by textbooks, during the introduction phase of early years mathematics education, and to identify how it changes over this short period of time. While textbooks play a central role in communicating this discourse, less is known about how the discourse as communicated by textbooks changes during the introduction phase, i.e., the first months of school. We use commognitive concepts to examine part of the discourse, specifically routines and visual mediators, of the first 100 tasks in three textbooks for Grade 1 in Sweden. Our findings reveal a rapid increase in the routine of re-organization and the use of symbols as visual mediators, implying a swift change from a discourse characterised by colloquial visual mediators and germinal routines towards a more formal mathematical discourse.

Keywords: Mathematics, discourse, commognition, early years, textbook.

Introduction

Research about early years mathematics education is vital for understanding the initial encounters with the school mathematical discourse and its potential consequences. Research in this field has been conducted for several decades but there is still a knowledge gap about the mathematical discourse during the introduction phase of early years education (i.e., the first months). To address this gap, Rezat (2024) suggested that research should focus on the interrelationships between textbooks, mathematical discourse, and other entities such as teachers, students, and the subject of mathematics itself. The present study contributes to this body of research by investigating textbooks and how discourse changes is established during the introduction phase. Mathematical discourse is characterised by four interrelated, what Sfard (2007, 2020) termed, tenets. The tenets are *keywords* (vocabulary and word use), *visual mediators* (images, graphs, symbols, and signs), *narratives* (stories about mathematical objects), and *routines* (patterns of repeated actions). In this paper, we assume the mathematics textbook to be a "second teacher", i.e., an experienced and authoritative interlocutor who requests students to perform specific actions and provides exemplifications of mathematical discourse tenets. The guiding questions are: *What characterises the mathematical discourse as communicated by textbooks during the introduction phase of early years' mathematics education?* and *What changes in the mathematical discourse as communicated by textbooks can be identified during the introduction phase?* To answer the questions, we examined how the routines and visual mediators change in the initiation and closure of the first 100 tasks in three Swedish mathematics textbooks for Grade 1 (seven-year-old students).

Mathematics textbooks and the early years

Research has shown that textbooks hold a prominent role as a curriculum resource in mathematics education because it is commonly viewed as a ubiquitous, trustworthy (and

therefore authoritative), and comprehensive resource for teaching and learning (Rezat, 2024). Textbooks can provide a consistent curriculum, and, when used with the teacher's guide, a complete set of suggested teaching methods, examples, concrete materials, and assessment tools (Van Steenbrugge & Ryve, 2018). Mathematics textbooks pose questions in specific ways that prescribe to students and teachers what the school mathematics discourse is. Hence, by foregrounding some content and activities, textbooks influence teachers' and students' conceptions of what and in what ways mathematics should be taught and learnt (Rezat, 2024). In virtue of this influence, textbooks are often used as a medium for the national curriculum and for fostering educational traditions (Kim & Remillard, 2020; Rezat, 2024; Van Steenbrugge & Ryve, 2018). For example, the central role of the mathematics book often downplays reform-oriented approaches for the benefit of more formal traditions (Nachlieli & Tabach, 2019; Rezat, 2024). For instance, textbook tasks offer opportunities for students to engage in the mathematical discourse in ways that may restrict students' opportunities to participate in mathematical exploration (Christiansen et al., 2023).

In Sweden where the present study was conducted, roughly 90% of students use textbooks for learning (Norberg, 2021). Students are often expected to work silently while the teacher guides students individually (Van Steenbrugge & Ryve, 2018). Many textbooks in Sweden are designed for use from the early years (Norberg, 2021) which position the textbook as a core resource for learning during the introduction phase. An important part of mathematics education in the early years is the development of foundational number sense (Andrews & Sayers, 2015). This refers to the understanding of relationships between numbers, which is essential for learning arithmetical operations, place value, and problem-solving. Foundational number sense includes understanding how mathematical objects are visualised in different ways, such as viewing numerals as sets of objects. Recent research on textbooks and textbook tasks for Grade 1 in Sweden has shown significant differences in the distribution of number sense content depending on the book series (Norberg, 2021). Norberg (2021) mapped resources for communication in number sense-related tasks (subtraction) from the complete set of curriculum programs in Sweden. Her results showed that the most requested answer form for these tasks is in the form of mathematical symbols.

Theory

In our study, learning is viewed as a process of individualising the mathematical discourse according to the theory of commognition (Lavie et al., 2019; Sfard, 2020). This process includes talking, writing, drawing, and thinking as part of communication (Sfard, 2020), regardless of whoever the interlocutor is, e.g., with-self, a classmate, a teacher, or as in our case a textbook. As we study the discourse tenets in textbooks, we interpret the textbook as representing the voice of a more knowledgeable other. The textbook, as the voice of a more knowledgeable other, introduces and maintains rules for participation in the mathematical discourse that apply to meta- and object-levels (Sfard, 2007). Meta-level rules have traditionally been characterised by several key features: direct instruction, emphasis on memorisation, a teacher-centred approach, standardised methods and routines, textbook reliance, and a focus on assessment (Kim & Remillard, 2020). During the introduction phase, object-level rules frequently address various categories of number sense, which often represent the largest distribution of content

areas (Sayers et al., 2021). This is not surprising, since developing foundational number sense is central in early years education.

For the present study, the use of the two discourse tenets routines and visual mediators are key for understanding how interpersonal communication such as communication between teacher, student, and textbook, is performed when verbal language is omitted. Routines are either process-oriented rituals or outcome-oriented explorations (Christiansen et al., 2023; Lavie et al., 2019). One central process of learning is understood as routinisation (Lavie et al., 2019), i.e., adopting previous experiences to a larger extent towards mastering a specific procedure or action. To increase participation in the mathematical discourse, children must master several important, so called *germinal routines* (Lavie et al., 2019). Germinal routines are the most foundational routines in mathematics discourse, e.g., comparing sets and counting. As students develop knowledge of mathematical discourse they encounter new more complex routines, which can require a series of different germinal routines to be performed in a systematic pattern (Lavie et al., 2019). Thus, knowledge of previous germinal discourse routines is part of more demanding mathematical discourse routines. Consequently, germinal routines are crucial for developing knowledge about more complex routines, such as re-organising quantities, and endorsing or rejecting narratives about mathematical objects. For this exploration to occur, students need to be comfortable and autonomous in deciding which routine to perform in a given situation, hence the importance of practicing rituals through tasks (Nachlieli & Tabach, 2019). Visual mediators are "perceptually accessible aspects of material reality […] employed as 'helpers'" (Lavie et al., 2019, p. 15). Examples of visual mediators are symbols, e.g., numerals or mathematical signs, connecting lines, images of objects e.g., cats and balls, and circles. Different visual mediators can play different roles in mathematics. For example, symbols are signifiers of mathematical objects, connecting lines can illustrate relationships, images of objects are often used as (colloquial) representations of real-world mathematics, circling objects can mean classifying by properties. The choice of visual mediators is either determined beforehand by explicit instructions, e.g., "draw three cats", or open to the student to independently choose a visual mediator to provide the solution.

Since textbook tasks play an integral role as a teacher's voice during the introduction phase, they play a significant role in determining the mathematical discourse. A textbook task "serves as a context where the students explore the content, and they indicate what students are required to do" (Kim and Remillard, 2020, p. 31). Mathematical tasks, according to Nachlieli and Tabach (2019), are roughly organised as initiation (requirement of specific actions), procedure (performance of specific actions), and closure (communication of the result of the specific actions). Here we draw on what characterises mathematical discourse as communicated by textbooks. Hence, this study does not focus on how students perform textbook tasks. Rather, our focus is on the voice of the textbook in terms of what actions it asks students to perform (initiation), and how it requires ways of communicating results (closure). To understand how the initiation of the task is communicated by the textbook, we view the routines as the action that the initiation of the task requires the students to perform. To understand how the closure of the task is expected to be communicated by the student, we view what students are asked to produce when mediating their closure to a given task.

Methods

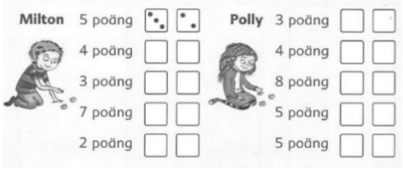
In Sweden most students formally encounter a mathematics textbook for the first time in grade 1, at the age of 7. Following theory and previous research, which suggest that mathematics education is often "task-driven", relies on textbooks, and emphasise certain discourse characteristics (Kim & Remillard, 2020; Van Steenbrugge & Ryve, 2018), we investigated three books available in schools in Sweden to answer our research questions. The mathematics textbooks were selected by their popularity on the market for school textbooks. Since there is no formal national review board of curriculum material in Sweden, the market is open for any textbook author to publish material independent of scientific validation.

All three books were designed for students' individual work, with the possibility to draw and write directly in the book. The data material (n=300) consists of the first 100 tasks about number sense in each of the textbooks. We focused on number sense tasks because number sense is important in the introduction phase (Andrews & Sayers, 2015). The examined tasks covered approximately the first two months of lessons in school year 1. Each task was qualitatively coded for routines (initiation) and visual mediators (closure). We compared our categorisations and applied intercoder reliability (O'Connor & Joffe, 2020). Firstly, we based our coding of routines on key words from Lavie et al. (2019). Our aim was to identify examples of mathematical discourse routines: counting, quantifying sets, comparing sets, and naming a number on a line. Other routines, such as endorsing or rejecting, and estimating were rarely present (below 1%), hence their absence in the findings. The routine re-organising was added abductively to code tasks that require students to re-organise elements in a set which is more complex than germinal routines. Consequently, tasks coded as re-organising required students to perform more than one germinal routine. Secondly, the categories for visual mediators were inductively coded as coloured field, drawn image, drawn line, circle, and written symbol.

How many? Write the number.

Figure 1: Task featuring a routine [counting] and a visual mediator [a written symbol]

Write the dots that the dice might show.



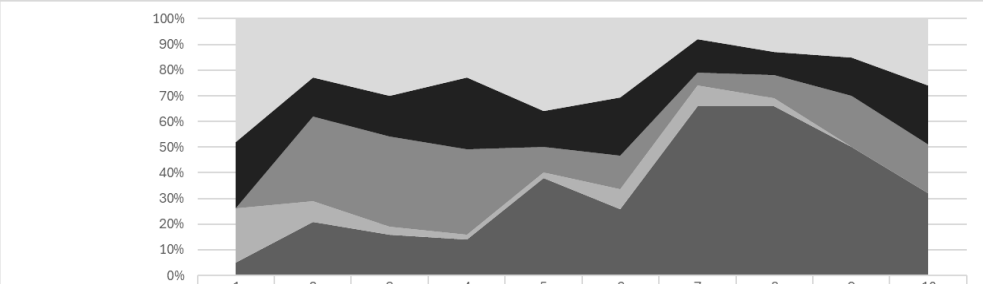


Figure 2: a task featuring a routine [re-organising] and a visual mediator [a drawn image]

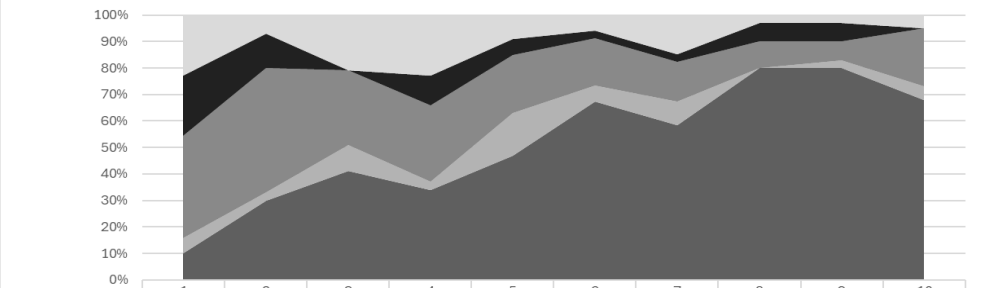
There were no other types of visual mediators that the textbook tasks requested. Figure 1 shows an example of the task "How many? Write the number", i.e., requesting a ritual performance that was coded as counting routine, with the visual mediator coded as written symbols. Figure 2 shows a task coded as the routine of re-organising, asking the student to draw the dots that the dices might show, that is, parting the numbers into sets of 2. After coding, the data sets were merged into one large set and divided into 10 sections of 30 tasks, i.e., 10 from each of the three books as there were no significant differences between the distribution of discourses in the

books. This procedure facilitated the analysis and the graphical presentation (see figure 3 and 4 in the Findings section) of gradual change.



Findings

In this section, we describe the main results related to change over time in the mathematical discourse during the introduction phase, one about routines (task initiation) and one about visual mediators (task closure). In addition, we point towards an interpretation considering routines and visual mediators taken together.

	1	2	3	4	5	6	7	8	9	10
Counting	48%	23%	30%	23%	36%	31%	8%	13%	15%	26%
Quantifying sets	26%	15%	16%	28%	14%	23%	13%	9%	15%	23%
Comparing sets	0%	33%	35%	33%	10%	13%	5%	9%	20%	19%
Naming a number on a line	21%	8%	3%	2%	2%	8%	8%	3%	0%	0%
Re-organising	5%	21%	16%	14%	38%	26%	66%	66%	50%	32%

Figure 3: Frequencies of routines (10 groups of 30 tasks)

	1	2	3	4	5	6	7	8	9	10
Circle	23%	7%	21%	23%	9%	6%	15%	3%	3%	5%
Drawn line	23%	13%	0%	11%	6%	3%	3%	7%	7%	0%
Drawn image	39%	47%	28%	29%	22%	18%	15%	10%	7%	22%
Coloured field	6%	3%	10%	3%	16%	6%	9%	0%	3%	5%
Written symbol	10%	30%	41%	34%	47%	68%	59%	80%	80%	68%

Figure 4: Frequencies of visual mediators (10 groups of 30 tasks)

Firstly, our findings show that all five routine categories were present in our data. In relation to frequencies, Figure 3 shows a gradual change from germinal routines towards more demanding routines. Four of the germinal routines (counting; quantifying and comparing sets; naming a number) decrease from approximately making up 80-90% of the tasks at the beginning to 50-60% at the end. The more demanding routine (re-organising) increases from making up 5-20% of the tasks at the beginning to 30-50% at the end. Secondly, our findings show that all five categories for visual mediators were present in our data. In relation to frequencies, Figure 4 shows a gradual change in visual mediators from colloquial towards more discourse-specific examples. Four visual mediators (coloured field; circle; drawn lines or images) decrease from approximately 80% to 25% and one (written symbol) increase approximately from 20 to 75%.

In summary and taken together, the two findings above indicate how the mathematical discourse rapidly (considering that this is the introduction phase) move from being more playful, colloquial, and informal towards being more formal and disciplinary.

Discussion

This study investigated changes in the mathematical discourse during the introduction phase of early years' mathematics education. Here we interpreted the results as showing how the mathematical discourse rapidly became more formal. Our findings show that the visual mediator *symbols*, as a task closure, increases during the span of the introduction phase, while *circles* and *connecting lines* diminishes. The results show similar patterns for task initiation. The observed connection between the use of symbols and re-organisation routines suggests that the textbook presumes that students' familiarity with symbols is sufficient to perform more advanced routines at this stage. However, introducing more advanced routines and formal symbols early might increase the intellectual load on young learners. This rapid change could pose challenges for students who struggle with the development of number sense (Andrews & Sayers, 2015), when trying to grasp relationships between mathematical objects and their different signifiers, in this case, sets of objects and their corresponding numerals. Our research findings are consistent with those of Norberg (2021), demonstrating the change towards mathematical symbols becoming the predominant closure.

Another notable change in the mathematical discourse that the textbooks communicated was that while tasks involving germinal routines tended to diminish, they did not completely vanish. This persistence is crucial as it facilitates routinisation which enable students to engage in similar mathematical situations (Christiansen et al., 2023; Lavie et al., 2019). However, we noted a gradual reduction in the variety of visual mediators. Consequently, students' experiences with more informal visual mediators, such as coloured fields, and drawings, may become less emphasised, thus introducing a new meta-level rule of mathematics discourse. Although children might enjoy using coloured pencils, our results indicate such practices are not part of the formal methods for communicating mathematical solutions. Our study confirms that the textbook communicates a meta-rule that says that mathematics is about re-organising routines, and a meta-rule that says that mathematics is communicated with symbols. These two meta-rules are foundational aspects of the formal mathematical discourse described by Kim and Remillard (2020) and Norberg (2021). Sayers et al. (2021) showed how the distributions of tasks in textbooks place emphasis on routines in number sense-related tasks to various degrees throughout the first semester of Grade 1. This indicates that, even though the introduction phase involves tasks that aim at using symbols and re-organising quantities, other types of routines and visual mediators might appear in later stages of the school year. However, students' first impression of mathematics might be crucial for their understanding of the mathematical discourse. Viewed as a central source of opportunities for participation in mathematical discourse, textbooks might limit the ways that students can engage with and understand the meta-level rules of mathematics education and we agree with Norberg (2021) who stresses the importance of providing tasks and exercises that offer a variety of mathematical situations to avoid simplified understandings of number sense. The reviewed literature made clear that textbooks, as teaching materials, play a central role in forming teaching practices (Norberg,

2021; Van Steenbrugge & Ryve, 2018). The emphasis shown in our results on certain routines and visual mediators can shape what students and teachers perceive as important in mathematics. This could lead to a narrow understanding of the mathematical discourse due to limited experiences, which could interfere with exploration routines where independent decision-making is crucial (Christiansen et al., 2023; Lavie et al., 2019).

Limitations and future research

This study has limitations. 100 tasks in three mathematics textbooks do not necessarily encompass the full variation of how a textbook in general communicates the mathematical discourse. However, based on findings that mathematical textbooks usually are similar in character (Van Steenbrugge & Ryve, 2018), we argue that the findings of the present study still provide relevant insights about the mathematical discourse during the introduction phase. The textbook, although important, is only one resource used by teachers. Students encounter the mathematical discourse and its changes in other ways too. Furthermore, almost all children who enter Grade 1 in Sweden have already participated in a pre-school mathematical discourse during the pre-school years, where they have encountered several germinal routines and explored different visual mediators. There are however differences between the mathematical discourse of the pre-school and the more formal school mathematical discourse. Future research on mathematical discourse and its changes in the early years could pursue various trajectories. By mapping other commognitive tenets like narratives and vocabulary, or by extending the data collection to a longer period, more extensive quantitative research could further inform the changes in the mathematical discourse during the introduction phase.

Impacts of multilingualism on mathematical learning in primary school - Focusing on everyday language differences

Sonja Deegener[1], Marei Fetzer[1] and Marijana Gregurević[1]

[1]University of Wuppertal, Germany; deegener@uni-wuppertal.de

The influence of language on mathematical learning is undeniable. At the beginning of primary school, the everyday language appears especially relevant. Moreover, in an increasingly super-diverse society, such as Germany, there are numerous children who speak more than just one language in their daily lives. Therefore, it seems crucial to consider all their multiple language skills. In this study we investigate the impacts of these competences on mathematical learning processes. We focus on differences between everyday language registers of several languages. Initial empirical findings are presented.

Keywords: Mathematical learning processes, language, multilingualism, primary education, everyday language.

Everyday language and mathematical learning in primary school

According to current research, language plays a crucial role in mathematical learning processes (Ingram et al., 2023). If we take a closer look at the learning of mathematics in school, we will observe the use of different linguistic forms (Meyer & Tiedemann, 2017). Depending on the foci of interest in research on the correlation of mathematical learning and language, reference is made to different theoretical frameworks. One internationally strongly recognized approach is Halliday's (1978) concept of linguistic registers, which is based on the assumption that language is used functionally in communicative situations.

In Germany, there are three registers that are repeatedly discussed in the context of mathematics education. These are a technical-mathematical register, an everyday language register and a school academic register (Meyer & Prediger, 2017). The mathematical register consists of technical terms and typical syntactic structures, such as those used in formal proofs or theorems and aims to represent a mathematical structure as precisely and accurately as possible. In contrast, the function of everyday language is to facilitate unhindered conversation between people who are mostly physically in the same place, resulting in short, often grammatically fragmentary sentences supported by gestures and facial expressions. According to Feilke (2012), the school academic register mediates between the other two registers. It is not specific to communication about mathematics, but rather to academic communication in general and to educational situations. Complex and grammatically correct sentences are characteristic for this register. In research, a strong influence of both, technical and educational language on mathematical learning processes is proven (Meyer & Tiedemann, 2017). However, competences in these two registers cannot be expected from students, especially at the beginning of primary school, and must be developed in school first. However, viewed from another perspective, almost all students have everyday language skills when they start school. Everyday language skills therefore form the linguistic basis for learning mathematics in primary school.

This raises the question of the role that everyday language plays in mathematical learning processes. Previous research has already examined the relationship between everyday language and students' conceptual understanding. According to the idea of *Grundvorstellungen*, which is widespread in Germany, the linking of formal mathematical concepts with practical experiences and real situations is essential for the individual conceptual development (Leufer et al., 2019). However, these practical experiences and real situations are often acquired in everyday life and are therefore linked to the everyday language register. Therefore, if the learner's experience is to be captured, the interwoven known linguistic means must also be considered. In this sense, everyday language plays an important role in conceptualisation in primary school (Ruwisch & Weigand, 2023). Although school academic and the mathematical registers become increasingly important in the later schooling, everyday meanings ascribed to mathematical terms can influence students' understanding of mathematical concepts even in higher grades (Antonpoulos et al., 2023).

When focusing on the relationship between students' everyday language skills and mathematical learning processes, it is important to note that in Germany, as in numerous other countries, a significant proportion of children grow up multilingual. These children have knowledge of several everyday languages, and their experiences are frequently related to these languages. Provided that there is a connection between everyday language and mathematical learning (in primary school), it can be assumed that being familiar with everyday language registers of different languages also has an impact on mathematical learning. Indeed, several research projects have demonstrated that the explicit inclusion of students' multilingualism can have a (positive) impact on their mathematical learning (Barwell et al., 2019). Nevertheless, there remain numerous questions regarding the concrete impact of everyday registers of different languages. Therefore, this paper focuses on the influence of multilingual learners' everyday language competence in their various languages on their mathematical learning processes.

Everyday language registers in different languages

In the course of investigating the everyday language registers of several languages and their potential impact on mathematical learning, our research group identified notable differences between some languages. For example, in the context of doubling and halving, the following expressions are often used in everyday German: "doppelt so viele" [*double as many*] and "halb so viele" [*half as many*]. In other (potential) languages of origin of the children in German classes, however, this (mathematical) relationship is formulated quite differently in everyday language. Everyday Croatian, for example tends to use expressions such as: "duplo/dvostruko više" [*double more*] and "duplo/upola manje" [*double/half less*]. Figures 1 and 2 show the use of these linguistic terms in whole sentences with literal translations into English.

German	Croatian
Amy hat 6 Buntstifte.	Amy ima 6 bojica.
Ben hat doppelt so viele Buntstifte.	Ben ima duplo* više bojica.
Amy has 6 coloured pencils.	*Amy has 6 coloured pencils.*
*Ben has **double as many** coloured pencils.*	*Ben has **double more** coloured pencils.*
	**alternatively: dvostruko* *[double]*

Figure 1: Doubling

German	Croatian
Amy hat 6 Buntstifte.	Amy ima 6 bojica.
Lisa hat halb so viele Buntstifte.	Lisa ima duplo* manje bojica.
Amy has 6 coloured pencils.	*Amy has 6 coloured pencils.*
*Lisa has **half as many** coloured pencils.*	*Lisa has **double less** coloured pencils.*
	**alternatively: upola* *[half]*

Figure 2: Halving

Looking more closely at the linguistic expressions, we can observe that the word “viele” [*many*] is used in both German contexts. In contrast, different words are used in Croatian: “više” [*more*] and “manje” [*less*]. These Croatian words indicate the direction in which the quantity is changing, whereas the German expression simply refers to the quantity itself. Another observation is that one word can be used in the different contexts in Croatian. The word “duplo” [*double*] actually corresponds to the word “doppelt” [*double*] and “upola” [*half*] corresponds to “halb” [*half*], but the word “duplo” can be used in both contexts. This phenomenon illustrates the connection between doubling and halving. In addition to these differences between the Croatian and the German everyday language, we also found differences between German and other everyday languages in similar content-related contexts (e.g. French, Russian, Arabic). Furthermore, negotiating with various native speakers, we learnt that there is no direct equivalent in Spanish for expressions such as “doppelt so viel” or “halb so viel”. Instead, Spanish speakers would use “el doble de” [*the double of*] or “la mitad de” [*the half of*]. Besides, the direct translations into English, which is used as the reference language in this paper, show that there are differences between English and all the other languages that have been mentioned so far. English native speakers would probably not use “double as many” (equivalent to German) or “double more” (equivalent to Croatian), but rather “twice as many”, which emphasises the multiplication by two.

The notion that there are instances where no direct, literal equivalents exist between different languages is not a novel one (Prediger et al., 2019). Instead, the idea that languages may offer alternative structures and conceptualisations, has been part of the scientific discourse for a long time. This suggests that similar observations about contrasts between languages may also be found in other everyday contexts, which are relevant to mathematical concepts in primary education. Furthermore, it can be speculated, that these differences between different everyday languages may influence mathematical learning processes in primary school. A wide range of influences, both positive and negative, are imaginable. On the one hand, students might be confused by the different linguistic expressions, which could result in mathematically incorrect approaches, ideas and conclusions. For example, students who speak Croatian and German may be confused that the German word “viele” [*many*] is used in contexts with doubles and halves. They might transfer their experience from the Croatian language, where the corresponding word indicates the direction in which the quantity changes. On the other hand, linguistic differences may prompt reflection on mathematical concepts, which could have beneficial impacts on mathematical learning. These effects may be further enhanced by the activation of additional linguistic resources and associated experiences. A number of research projects with multilingual students, mainly in higher grades, have already proven positive effects of language differences on the individual development of mathematical concepts. For example, Prediger and colleagues (2019) were able to demonstrate that language differences between Turkish and German on the topic of fractions can enhance the mathematical learning of Turkish-German bilingual students. However, particularly in primary education and with a focus on everyday language differences, there are numerous mathematical topics and various language combinations that still require research (Deegener, 2024). This paper therefore focuses on the differences between the everyday language registers of several languages, especially on those that seem to be relevant at the beginning of primary school in Germany.

Methods

Our research project consists of two parts. The first part is a theoretical investigation of typical mathematical topics in primary school and the corresponding everyday language expressions in German. In light of these observations, a comparison is made with the corresponding everyday language means of several other languages and differences are identified. The second, empirical part of the project investigates possible effects of linguistic differences on mathematical learning processes in primary school and how they can be used as a resource for learning and teaching.

An initial pre-study data collection was carried out with children of pre-school age (five- and six-year-olds). In June 2024, several interviews were conducted with bilingual children. Each interview involved two children who shared the same languages. In this paper, we refer to an interview with Spanish-German-speaking children. The interviewer had a basic knowledge of Spanish as a foreign language and only used German in the interview. However, at the beginning of the interview, the children were encouraged to utilise both languages. The topic of the interview was doubling and halving. Real objects and a machine (a large box) representing the doubling and halving process were chosen as a basis to encourage exchange about doubling and halving. Concretely, several objects were put into one side of the machine and half or twice as many objects were taken out on the other side. One direction of the machine represented doubling, the other halving (Figures 3 and 4). The children were prompted to describe what would happen to the quantities and to make predictions. The names of the children have been changed in this paper in order to ensure anonymity.

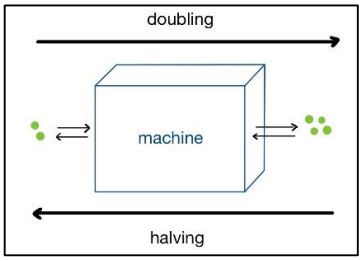

Figure 3: Sketch of machine

Figure 4: Machine in reality

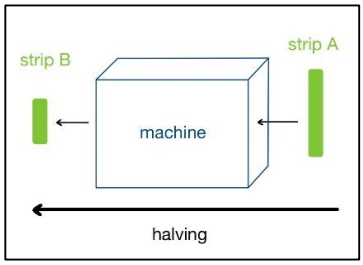

Figure 5: Strips of paper

First analyses of potential impacts

The following sequence has been chosen as representative, in which differences between Spanish and German everyday language seem to influence the focus of the learning process as well as the activation of basic action-related mathematical concepts. References to transcript turns are marked with <Turn x>.

Episode 1

Contextual information: Before the episode begins, the children had already observed and described various doubling and halving processes. Then they were asked to predict what would happen to a strip of paper (strip A, Figure 5) when it was pushed through the machine in the direction of halving.

15	Theo:	ich denke dass es dann halb ist *I think that it will be half then*
16	Interviewer:	was glaubst du? ((holds strip A in front of Lily)) *what do you think?*
17	Lily:	mmh klein ist ((moves her outstretched hands towards each other))

		mmh is small
18	Interviewer:	wollt ihr mir mal ungefähr zeigen was meint ihr wie groß ist es dann wenn ichs jetzt hier rausnehme ((places strip A on the table)) *would you like to show me roughly how big you think it will be when I will take it out here now*
19	Lily:	eins zwei drei ((inaudible)) fünfzehn ((moves her finger along strip A at this time)) *one two three ((inaudible)) fifteen*
20	Interviewer:	und [wenn? ja] *and [when? yes]*
21	Lily:	[und dann] ist glaube ich (.) fünf *[and then] I think it is (.) five*
22	Interviewer:	kannst du mir das ungefähr mit den Fingern [zeigen wie siehts dann aus auf der anderen Seite gleich?] *can you show me roughly with the fingers [what it will look like on the other side?]*
23	Lily:	[eins zwei drei] vier fünf ((moves her finger along strip A at this time until the centre)) bis hier ((points to the centre several times)) bis hier *[one two three] four five (.) until here (.) until here*
24	Theo:	ich denke das wär halb sein (.) ein Teil nicht und den anderen doch *I think it will be half (.) one part is not and the other still*
25	Interviewer:	((addressing Theo)) kannst du mir sagen wie lang das dann ungefähr ist (.) das neue Band *can you tell me roughly how long it is (.) the new strip*
26	Lily:	in die Mitte (.) in die Mitte *in the middle (.) in the middle*
27	Theo:	so ich denke (.) [eins] ((puts his finger on the left end of strip A)) *so I think (.) [one]*
28	Lily:	[hier] ((points to the centre of strip A)) *[here]*
29	Theo:	ich denke bis da ((puts his finger on the centre of strip A)) *I think until there*
30	Interviewer:	Warum genau da? *Why exactly there?*
31	Lily:	Weil das ((points to the centre of strip A)) hier ist die Mitte *Because that (.) here is the middle*

In episode1 it is noticeable that Lily utilises expressions with "Mitte" [*middle*] <Turn 26; 31> and that she repeatedly points to the middle of the strip of paper <Turn 23; 28; 31>. In contrast, Theo utilises terms like “halb” [*half*] <Turn 15; 24> and refers to two parts <Turn 24>. The formulations used with “Mitte” and “halb” suggest different, but both sustainable, basic action-related mathematical ideas about halving lengths. The German term “Mitte” seems to be more in line with the basic action-related idea of cutting or folding the length exactly in the middle. Whereas the German term “halb”, seems to be nearer to the mental representation that halving a length results in two parts of equal length (each half as long as the other). From a German-speaking perspective, the utilisation of “halb” in halving contexts appears to be more natural, whereas the utilisation of “Mitte”, seems not wrong, but rather unusual. Looking more closely at the episode, Lily consistently uses this rather unusual term <Turn 26;31> and there doesn't seem to be any linguistic approximation to Theo. For example, even when she explains Theo’s prediction of how long strip A will be, she sticks to her formulation <Turn 31>. However, if we take a closer look at the Spanish meaning of “Mitte”, these observations appear in a different light, since there are at least three different terms that can be

considered as equivalents of "Mitte": “medio”, “centro” and “mitad”. The term “mitad” has already been mentioned, as it is used in Spanish for the equivalent of “half”. In addition, “mitad” can be used to describe the central point of a path. In the context presented here, with a strip of paper, both uses of “mitad” are appropriate (Figures 6 and 7). As a result, it is plausible that Lily chooses the term “Mitte” due to her familiarity with the use of “mitad” in similar halving contexts in everyday Spanish and “Mitte” appears to be the most suitable translation for her. The phonological similarity between “mitad” and “Mitte” may further influence her selection. This suggests that Spanish everyday language might activate a fundamental action-related concept in her thinking, which seems less obvious from a German-speaking perspective. Moreover, “mitad” seems to be able to transmit both basic action-related ideas presented. Therefore, from Lily's Spanish perspective, it is possible that she uses “Mitte” to represent these two ideas. This interpretation could explain her linguistic focus on the middle and the absence of linguistic approximation to Theo. In conclusion, it seems reasonable to suggest that differences between the everyday registers of different languages may affect which basic action-related ideas are activated and focused.

German	Spanish
Lisa hat halb so viele Buntstifte.	Lisa tiene la mitad de lápices de colores.
*Lisa has **half as many** coloured pencils.*	*Lisa has **the half of** coloured pencils.*

Figure 6: Overview use of “mitad” I

German	Spanish
Die Mitte des Weges	La mitad del camino*
*The **centre** of the path/ The **middle** of the path*	*The **middle** of the path/ The **halfway** point*
	*other formulations possible, e.g. with centro

Figure 7: Overview use of “mitad” II

The next sequence was selected because it suggests that Lily is in fact activating both basic content-related ideas, and also because the interviewer would not have expected this flexible thinking based on her own linguistic knowledge.

Episode 2

Contextual information: Episode 2 is derived from the same interview as Episode 1. There is approximately one minute of an interval between the two. During this period, strip A was put into the machine and strip B was taken out. The interviewer then gave the children both strips.

58	Lily:	((takes strip A and places it next to the strip B)) in die Mitte war das (.) das war hier (.) das war hier (.) ((points to the centre of strip A)) also in die Mitte war das (.) in die Mitte war das *it was in the middle (.) that was here (.) that was here (.) so it was in the middle (.) it was in the middle*
59	Interviewer:	bist du dir sicher? *are you sure?*
60	Lily:	ja guck mal *yes look*
61	Lily:	((points to the centre of strip A)) in die Mitte war das *it was in the middle*
62	Interviewer:	du darfst das hier ((points to strip A)) auch irgendwie anders legen wenn du magst *you may lay this (.) also somehow different if you like*
63	Lily:	((places the two halves of strip A on top of each other)) ((inaudible)) ich gucke ob das richtig ist *I'll check if that's right*
64	Interviewer:	Du schaust ob das richtig ist sagst du? *You check if that's right, you say?*

65	Lily:	ja ((places the folded strip A exactly next to strip B)) *yes*
66	Interviewer:	mmh (.) du darfst es richtig knicken (.) kannst du nicht kaputt machen *mmh (.) you can bend it properly (.) you can't break it*
67	Lily:	((looks at the srips)) jap das Gleiches, ja in die Mitte. du hast recht Theo *yes the same, yes in the middle. you are right Theo*
68	Interviewer:	((laughing))

Lily's confirmation of her prediction in combination with her statement that Theo is right <Turn 67> indicates that for her both basic mathematical ideas agree and that she activates both. However, the interviewer told us afterwards that she was very surprised by Lily's statement and so reacted with an uncertain laugh <Turn 68>. She thought that Lily had believed that her prediction was correct and that Theo's idea contradicted it. So she wondered why Lily was confirming her idea and agreeing with Theo's at the same time. She would probably have had a changed understanding of the situation and acted differently if she had known that the Spanish word "mitad" can be used in these different contexts. However, given her limited knowledge of the Spanish language, she miscalculated the linguistic compatibility of the two ideas, leading probably to an underestimation of Lily's flexibility in understanding.

Discussion

This paper highlights the importance of the everyday language register in mathematical learning processes at the beginning of primary school. For multilingual children, everyday language registers of all their languages appear to be relevant. Accordingly, this paper focuses on everyday language registers of several languages, emphasising their differences and their influence on mathematical learning processes. Initial insights from the first empirical data indicate that such linguistic differences may evoke the activation of specific, additional, or different basic action-related mathematical ideas. Thus, they may influence the focus and the progression of mathematical learning processes. Furthermore, there is an indication that these differences may also lead to a discrepancy in teachers' interpretation of the learning process if they are not informed about the linguistic differences. This could result in the inadvertent omission of additional, sustainable, and basic action-related ideas.

The empirical data presented indicate and specify the impact that multilingual everyday language registers can have on mathematical learning processes in primary schools. Our research aims to differentiate this relationship more specifically. We also try to clarify to which extent multilingual language skills of students at early primary school age can be seen as a challenge or as a resource in super-diverse (German) classrooms. In addition, our pre-study highlights the importance of looking more closely at the role of teachers. They are the ones who guide the children's learning processes and make a significant contribution to the development of basic mathematical skills through their evaluation of statements and actions. It is therefore worth discussing the value of making teachers aware of the differences between the everyday registers of different languages, as it is already the case with the differences between everyday and technical language (Antonopoulus et al., 2023; Meyer & Tiedemann, 2017). In this context, it would be valuable to consider whether teachers need to be sensitised to the linguistic differences between all languages, or whether sensitisation to selected languages would be sufficient.

Classroom discourse and positioning: A case study of a highly regarded teacher

Ove Gunnar Drageset[1], Malin Skoglund[2]

[1]UiT The Arctic University of Norway, Tromsø; ove.gunnar.drageset@uit.no

[2]Norwegian University of Science and Technology

The starting point of this study is that some teachers master the art of teaching mathematics and that studies of such practices can contribute to developing our understanding of mathematics teaching. This article reports on a study of a highly regarded teacher in grade two. The aim was to describe how the teacher used interactions during plenary talk and what this could tell about the teacher's positioning. To achieve this, we used frameworks for studying interactions to describe the practice and then positioning theory to understand how this builds a practice. We described seven aspects that together characterize this practice (alleviate, develop ideas, involve students, keep focus, conclude, tell, reduce complexity) and discussed how these related to positions and storylines.

Keywords: Classroom discourse, interactions, positioning theory.

Introduction

Mathematics classrooms are the main arena for studying mathematics teaching and learning, and arguably, the discourse is the most central element of the classroom (Erath et al., 2021; Cobb, 2000) and a large body of research on mathematics classroom discourse, communication, and interactions have emerged (Erath et al., 2021; Xu & Clarke, 2019). However, even though there is a growing consensus that shifting classroom interaction patterns toward more student talk and participation is beneficial (Alrø & Skovsmose, 2004; Kazemi & Hintz, 2014; Stein et al., 2008), change seems to be slow and difficult to sustain (Xu & Clarke, 2019). At the same time, some teachers have changed towards a participatory pattern, where students' mathematics talk and sharing ideas is a vital part of their practice. Studying such practices can add to our understanding of such practices and how to establish them. Thus, our research question is: Which aspects of a proficient teacher's practice can be described by studying the teacher's interactions during plenary discourse, and what can this tell about the teacher's positioning?

Literature review

Concepts and frameworks

Researchers have developed a large number of concepts and frameworks describing teacher interaction during mathematics teaching (e.g., Drageset & Ell, 2024, found 94 concepts in 44 articles). These concepts describe several exciting phenomena. For illustration, we will give three examples of how concepts describing teacher interactions can be combined into more general ideas. One phenomenon is simplification, which is described in different ways and nuances as the Topaze effect (Brousseau & Balacheff, 1997), guided algorithmic reasoning (Lithner, 2008), and hints (Wood et al., 2006). The effect of simplification is that it becomes easier for the student to reach an answer, but it contributes little to helping the student find the answer to the next task. In isolation, this seems like

a contra-productive teacher interaction. However, little is understood about how simplification might be a productive interaction with others, looking at other aims (mastery, motivation) in the long run. Another phenomenon is probing (Warshauer, 2015), which also links to concepts such as inviting (da Ponte & Quaresma, 2016) and eliciting (Fraivillig et al., 1999). These concepts describe how teachers try to help students think and solve problems without the teacher simplifying. A third phenomenon is uptake (Correnti et al., 2015), which describes situations where student ideas or reasoning are taken up for discussion. This requires that the teacher first gets access to the students thinking through interactions such as monitoring (Stein et al., 2008), eliciting (Fraivillig et al., 1999), or elaborating (Henning et al., 2012). By accessing, sharing, and taking student ideas up for discussion, students are positioned as owners of ideas and their thinking as a core element of teaching and learning. As these three examples illustrate, conceptualizing the classroom brings our understanding forward. Some authors have developed frameworks, either created to develop certain aspects of teaching (e.g., talk moves by Kazemi & Hintz, 2023) or created to be capable of describing all kinds of interactions in the classroom (e.g., the IC model by Alrø & Skovsmose, 2004). One such model is the redirecting, progressing, and focusing framework (Drageset, 2014), which describes 13 interactions in three groups. Redirecting describes interactions where the teacher aims to change the student's approach by putting aside, advising a new strategy, or correcting questions. Progressing describes interactions where the teacher aims to move the process forward, often towards an answer or solution, by either demonstrating, simplifying, using closed questions for each step, or using more open questions and probing. Focusing describes interactions where the teacher stops the progress to focus on something important by requesting students to enlighten details, justify or apply a method to similar problems, or by pointing out (through a recapitulation or telling the student to notice something).

Positioning theory

Positioning theory is a way to understand interaction by studying communication acts, positions, and storylines created when people interact (Davies & Harré, 1990; Harré & Moghaddam, 2003). Studying positions can shed light on how discourse and participation impact students' learning opportunities (Hiebert & Grouws, 2007) and can contribute to understanding the challenges teachers face when trying to change their practice. A key feature of positioning theory is that it seeks to understand the dynamic nature of social relationships, describing how people adopt and develop. This immanent nature of positioning theory makes it useful in mathematics education for studying how discourse unfolds and the consequences of that unfolding (Wagner & Herbel-Eisenmann, 2009).

A position is defined by its rights and duties (Harré & Moghaddam, 2003); thus, if you are a teacher, you typically have the right to lead the classroom but also the duty to help students learn. Storylines are loose clusters of narrative conventions (Harré & Moghaddam, 2003). These can emerge as participants interact, but past experience and longer-term storylines might mean that participants are simultaneously in different storylines without realizing it (Wagner & Herbel-Eisenmann, 2009). Communication acts are an integral part of positions and storyline building, but also where it becomes possible to identify positions and storylines.

Taking on a position is also about positioning others, and another layer to positioning theory, willingness, capability, and power (Davies & Harré, 1990), contributes to explaining why there are

differences in taking on positions during an interaction. This is particularly relevant for teacher-student interactions, where long-established dynamics shape discourse patterns. Willingness describes whether or to which extent participants accept a position or position others. Capability describes to which extent a person is capable of taking on a position. Power describes how and to which extent participants are allowed to take on positions (Harré & Moghaddam, 2003). Together, the three aspects of positioning theory (communication acts, positions, and storylines) and the understanding of how willingness, capability, and power affect positions provide a way to connect classroom interactions with longer-term storylines about mathematics teaching and learning.

Drageset and Ell (2024) used positioning theory to review the literature on concepts describing teacher interactions. First, they categorized 94 concepts into 14 communication acts. This was then used to identify five distinct teacher positions within three storylines. The first two positions, *a teacher who tells* and *a teacher who supports*, both describe teachers who position themselves as the ones who know and the students' needs to position themselves as listeners and to accept help. Thus, this creates a storyline of *teachers as providers of insight*. The third and fourth positions, *a teacher who uses student ideas to create learning* and *a teacher who orchestrates*, both describe teachers who position themselves as facilitators for learning and not providers of insight, thus creating the storyline of *teachers as facilitators of learning.* The fifth position, *a teacher who participates*, describes teachers who position themselves on the same level as students and work together to learn, thus creating a storyline of *teachers as participants in learning*. The authors emphasize that the immanent nature of positions means that these might change many times during a lesson.

Method

To answer our question and aim of studying a proficient teacher, we chose a teacher well known for conducting mathematical talk during lessons. This teacher has more than twenty years of experience in teaching mathematics, has a master's degree in mathematics education, is educated and working as a teacher specialist, and teaches colleagues how to teach dialogic and inquiry-based mathematics in the area. The teacher has a solid knowledge of research literature and is teaching a second-grade class (students aged 6-7), where she has been the main teacher since they started in grade one.

We observed all her mathematics teaching for two weeks to study the teacher's practice. The data were nearly ten hours of teaching, where the content of the lessons can be described as numbers, basic calculation, and number sense. One could discuss if this is sufficient to describe a teacher's practice, but it is close to the standards set by the Learners Perspective Study (Clarke et al., 2006), often referred to as best practice. The observation was done using a video camera and a microphone on the teacher. This captured everything the teacher said and what students said to the teacher or in plenary talk, and the video captured all activity and information on the blackboard and smartboard. We found that the interactions during plenary talk were more varied, and since much of the student talk was difficult to grasp outside of plenary, we chose to limit our study to plenary talk.

The analysis was conducted using nVivo in two phases. In the first phase, all teacher interactions in plenary were coded using the redirecting, progressing, and focusing framework (Drageset, 2014). The coding was done on a turn-by-turn basis (Linell, 1998), where each utterance was coded. Such coding of single utterances is not done in vacuums; each utterance must be understood in light of prior

utterances, particularly the last one. Significant adjustments were made to the framework during the coding by adding interactions (see Table 1). This is not surprising, as the original framework was developed based on five quite regular teachers, while this data is from a proficient teacher who knows the research literature on teacher interactions. In the second phase, we grouped the interactions in new ways to shed light on different aspects of the teacher's practice, using thematic analysis (Braun & Clarke, 2017). In this phase, we also used positioning theory as a tool to clarify each of these category groups. These phases were not pre-planned; instead, the first phase was done to explore, and the second phase came as a result of searching for meaning and answers to our research question.

Findings and discussion

During the coding of all teacher interactions using the redirecting, progressing, and focusing framework (Drageset, 2014), we changed the framework when we observed qualitatively different interactions (see Table 1)

Table 1: Overview of interactions observed

Interactions from the redirecting, progressing, and focusing framework (those in brackets were not observed)	Closed question - Correcting questions - Demonstration - Enlighten details - Justification - Open question - Put aside - Recap - Simplification (Advising a new strategy) - (Apply to similar problems) - (Notice) - (Request assessment from other students)
New interactions observed	Appreciate errors - Confirm - Connect - Correcting explanation - Encourage - Repeat - Request alternatives - Thinking time - Uptake

Using the concepts from the redirecting, progressing, and focusing framework (Drageset, 2014) and the additional interactions described during the analysis (Table 1), we developed a set of groups related to how interactions were used. These groups gradually developed into seven aspects of the teacher practice. Each aspect describes a part of the teacher's practice, and together, the seven aspects characterize this teacher's practice.

The first aspect, *alleviate*, describes interactions in which the teacher worked to reduce students' fear of trying and participating. *Alleviating* was particularly evident when the teacher encouraged students to work and share. This included reminders that errors were accepted and part of the learning process, such as saying, *"Yes, yes, but we can think wrongly, can't we? That's totally fine*."

The second aspect, *developing ideas (something to talk about)*, describes interactions where the teacher gives the students time to think alone or talk with peers (turn and talk). Thinking time was often given after open questions (open progress initiatives). We saw how simple interactions such as *thinking for a minute* or *turn*ing *and talk*ing are powerful, as they enable everybody to develop ideas or suggestions, and multiple ideas are necessary to create real discussion.

The third aspect, *involving students*, describes interactions where the teacher invites students to participate in the discourse. One way to do this was to *enlighten detail*, where the teacher requests

students to tell all the steps they used towards a solution, how they think about a problem or concept, or request *justification* of an answer or suggestion. In addition, the teacher did not stop at the first idea but instead requested students to share *alternative ideas*, such as this: *"Okay, did anyone think of another way to reach 45? "*. Sometimes, one or more ideas were taken up for discussion and further development (uptake), which was either done by challenging or directing attention towards an answer or idea. The effect of such interactions is that students are involved in the discourse and that ideas are shared and discussed, giving them opportunities to learn from each other.

Table 2: The seven aspects that characterize the observed practice. Aspects in the top row and the connected interaction concepts in the second row.

Alleviate	Develop ideas (or something to talk about)	Involve students	Keeping focus	Conclude	Telling	Reduce complexity
Encourage Appreciate errors	Open questions Think alone Think together (turn and talk)	Enlighten detail Justify Request alternative ideas Uptake	Remind Point out Repeat Confirm	Recap Connect Put aside	Demonstrate Correcting question Correcting explanation	Closed questions Simplification

The fourth aspect, *keeping focus*, describes interactions where the teacher worked on keeping the students focused on the task or discussion. Interactions such as *remind*ing, *pointing out*, *repeating,* and *confirm*ing were typical of how the teacher worked to keep the focus. While reminding and repeating are used to get the students back on track, pointing out is used to emphasize something important, and confirming can assure them that this is where the focus needs to be. One example of a reminder is when a student asks if just writing the answer is fine, and the teacher says: ”No*, you know that I do not think that is enough; you have to think about how you found the answer”.* This example also illustrates how reminders are used to keep focus on how they should work.

The fifth aspect, *conclude*, describes interactions where the teacher ended the discourse on a task or theme to move onto something new (another discussion, change to working on tasks, or ending the lesson). This was done by either *recap*, *connect*, or *put aside*. When using recap, the teacher summarized the discussion to conclude. When using connect, it was more pointed towards a connection that was important to remember. With put aside, it was also a way of ending a discussion by staying with an established answer or definition. One example of a recap is when the students and teachers discussed which way -7,5 should be rounded, as -7 is larger than -8, and the teacher ended the discussion by saying: *”As you say you should round towards the largest number, that is 8”*.

The sixth aspect, *telling*, describes interactions where the teacher tells or informs students about mathematical ideas or procedures. This was mainly done in two ways, by either *demonstrating* or *correcting*. When demonstrating, the teacher presented ideas or procedures while expecting students to listen, and this is often done in plenary and when introducing new ideas. When correcting, the teacher either corrected by a question or by explaining. An example of a correcting explanation is: *"Or the associative law tells us that we can choose which number we want to start with"*.

The seventh aspect, *reducing complexity*, describes interactions where the teacher made it easier for the students to solve a task or answer a question. This was done by either asking *closed questions* or by *simplification*. When the teacher used closed questions, they were often simple, one-step questions like this: *"Okay, so 34 minus 4, how much is that?"*. The use of simplification typically adds information about how to solve a task.

The seven aspects are presented in Table 2, with related interactions. The first four (alleviate, develop ideas, involve students, and keep focus) describe how the teacher organizes classroom discourses. There is consistent work on preparing the participation in discourses by ensuring the students feel safe and valued (alleviate) and that everyone has something to share (develop ideas). The discourses involve students in various ways by enlightening their thinking, requesting alternatives, focusing on justification, and taking ideas up for discussion. While this goes on, the teacher works on keeping focus. Looking at Drageset & Ell's (2024) five positions, these four fit well into the position of *a teacher who uses student ideas to create learning* as alleviate and develop ideas about creating opportunities for all to participate, involving students, and keeping focus on managing a discourse based on student ideas. This further belongs to the storyline *of teachers as facilitators of learning*, and facilitating is a precise description of these four aspects.

The last three aspects (conclude, telling, reduce complexity) describe different ways the teacher shares insight and knowledge. Concluding and telling belong to the position of *a teacher who tells* since both are about the teacher sharing knowledge. Reducing complexity belongs to the position of *a teacher who supports* since both closed questions and simplification are ways to help students find solutions. Consequently, concluding, telling, and reducing complexity fit into the storyline of *Teachers as providers of insight.*

While we separate into seven aspects, three positions, and two storylines to understand the practice, shifts between aspects happen frequently. This aligns with Wagner & Herbel-Eisenmann (2009), who state that positions and storylines are immanent and that several positions and storylines might exist simultaneously. This shifting of aspects and positions also means that students meet changing expectations during a lesson. *A teacher who tells* will try to position students as listeners, *a teacher who supports* positions students as receptive to help, while *a teacher who uses student ideas to create learning* positions students as owners of ideas and expects them to share these.

Conclusion

This article reported on a study of the practice of a proficient teacher with long experience and solid knowledge of research literature. We aimed to study the interactions and what this told us about teacher positioning. To do this, we used the redirecting, progressing, and focusing framework

(Drageset, 2014) as a starting point and further developed this with nine new concepts describing interactions. We then organized these interactions into seven aspects that characterized the practice. The first four (alleviate, develop ideas, involve students, keep focus) fit well into the position of *a teacher who uses student ideas to create learning* and the storyline of *teachers as facilitators for learning* (as defined by Drageset & Ell, 2024). The last three fit into the positions of *a teacher who tells* (conclude, tell) and *a teacher who supports* (reduces complexity) and the storyline of *teachers as providers of insight* (as defined by Drageset & Ell, 2024).

This article illustrates how interactions and positions are useful tools for characterizing practices and developing concepts that others can use. Concepts still need to be developed to characterize practices, as these can capture practices and nuances not described before. However, there is a growing need to review what we have and organize concepts describing limited interactions into more general ideas or frameworks.

On the linguistic complexity of mathematics school-leaving exams: Differences between subject areas

Louisa Ebel, Sascha Schroeder and Stefan Halverscheid

Georg-August University, Göttingen, Germany; louisa.ebel@mathematik.uni-goettingen.de

A common pool of mathematics tasks for the Abitur, the final high school exam, is provided by the IQB Institute in Berlin and is used by the 16 German federal states to create their exam questions in the areas of calculus, linear algebra, analytic geometry and stochastics. With the help of natural language processing, we compare lexis, syntax and changes in semiotic modality in these tasks for the different subject areas to evaluate the features of context-based task design that might be typical for those subject areas. Possible implications for the linguistic complexity of the tasks are discussed.

Keywords: Secondary school mathematics, assessment, Natural Language Processing.

Introduction

Given the importance of school-leaving examinations for society as a whole and their impact on school life and access to tertiary education, their tasks have been subject of discussion over the years; see Bruder (2021). In Germany, a common pool for the tasks of the final examination (Abitur) has been introduced in 2017 to centralise the tasks across the federal states. The pool aims to cover the content and competencies that the curriculum develops in the last two years of school. As described by Frenken et al. (2024), the tasks have a comparatively low cognitive potential. Furthermore, the design of the task often involves a context that needs to be understood to make sense of the mathematical activities with the amount of text in the tasks being criticised, see Jahnke et al. (2016). The aim of this project is to study the exam questions in terms of linguistic complexity. We investigate the differences between the subject areas of calculus, linear algebra, analytic geometry and stochastics as curricular differences might have an impact on the linguistic structure of the task text as well.

The design of Abitur tasks in mathematics

After the unsatisfactory results of German students in the PISA and TIMSS assessments in the early 2000s, the idea of centralising the curricula and the final examinations was developed. To achieve better comparability this led to the introduction of *educational standards* by the Standing Conference of the Ministers of Education and Cultural Affairs (KMK) in 2004, for the primary and lower secondary levels, and in 2012 for the upper secondary level and the Abitur examinations. The educational standards define argumentation, problem solving, modelling, the use of representations, the use of symbolic, formal and technical elements and communication as the central competencies in the subject of mathematics at the upper secondary level, which are to be worked on at three different levels of requirement. Abitur exams include at least two of the three subject areas calculus, linear algebra/analytic geometry and stochastics (KMK, 2012). In general, mathematics tasks in the common Abitur pool seem to contribute to a centralisation not only of the examinations but also of the preparations beforehand (IQB, 2024). Nevertheless, this form of assessment does not seem to be living up to expectations. On the one hand, a generally low and diverse level of cognitive potential

for mathematical skills is found in Abitur tasks (Frenken et al., 2024). On the other hand, it remains unclear which task elements influence task difficulty aside from mathematical performance**.**

Mathematical register and linguistic complexity in mathematics tasks

Different contexts require different linguistic resources, a register defined by the subject matter about which the communication takes place (Halliday, 1994). In the school register students are required to read and write texts according to certain conventions (Schleppegrell, 2001). Among others, this register can be characterised by technical lexis and structured clauses with logical relations, for example via the use of noun phrases, nominalisations, relative clauses, prepositions and conjunctions (Schleppegrell, 2001). As register is domain-specific (Halliday, 1994), language features in mathematics differ from those of other domains (e.g. Lee, 2006; Österholm & Bergqvist, 2013). First, in the mathematical register symbolic language and illustrations are used that complement the natural language (O'Halloran, 2015). Natural language plays a significant role in contextualised mathematics tasks, partly due to its use in the description of problem situations. "[However,] it is not clear how, or even if, mathematical texts […] can be described in common linguistic terms" (Österholm & Bergqvist, 2013, p. 762). First approaches to the mathematical register describe texts as syntactically dense and compact (Lee, 2006; Österholm & Bergqvist, 2013). Furthermore, the mathematical lexis consists of a mixture of mathematics-specific vocabulary, everyday language expressions and those to which a different meaning is assigned in mathematics, all of which have different effects on the complexity of mathematical tasks (Lee, 2006; Dyrvold et al., 2015). Following Halliday's (1994) idea of domain-specific language, it remains necessary to specify the 'register' of mathematics tasks in relation to (curricular) characteristics, as those might not only influence the situational contexts of the tasks, but their linguistic structure as well (e.g. Österholm & Bergqvist, 2013).

Students' language skills are closely related to their test performance or the difficulty of the task in mathematics (Peng et al., 2020). In recent years, a variety of studies in German mathematics education have combined several dimensions of language, such as syntax, lexis and structural features like word count, to estimate the linguistic complexity of mathematics tasks, partly using Natural Language Processing (NLP) to investigate several linguistic features at once, as well as larger text samples (e.g. Bednorz et al., 2024; Niederhaus et al., 2016). First, changes in semiotic register could reduce task difficulty, as they provide additional or explanatory information (Martiniello, 2009). Symbolic notation, however, follows its own grammar and therefore could also increase task complexity when there is no redundancy between symbolic sequences and natural language (Österholm, 2006). Gürsoy et al. (2013) show that elements of text length have a positive correlation with test performance, see also Niederhaus et al. (2013) and Österholm & Bergqvist (2013). Linguistic elements close to everyday experiences, such as personalisation (e.g. pronouns), familiar words and shorter sentences, might contribute to a lower task difficulty (e.g. Bednorz et al., 2024). Dyrvold et al. (2015, p. 1) suggest, however, that everyday vocabulary may as well increase the linguistic complexity of mathematics tasks as it is "uncommon" in the mathematical context. Academic language, on the other hand, with referential structures or unfamiliar vocabulary seems to increase task complexity (Schleppegrell, 2001), especially in mathematics (Bednorz et al., 2024; Dyrvold et al., 2015).

In this project we aim to identify the occurrence of factors of linguistic complexity in tasks of different subject areas: *Do school-leaving exam tasks differ in lexical and syntactical complexity or changes of semiotic modality according to their subject area?*

Sample and methods

Based on the studies presented above, we operationalised linguistic complexity through central linguistic features of three dimensions of the mathematical register: *change in semiotic modality, lexis* and *syntax,* see Table 1. For this study, a quantitative approach through Natural Language Processing (NLP) was chosen to identify patterns on a larger scale. The study excluded the morphological level, as well as the semantic level, as those are the ones requiring a manual or more qualitative approach instead of NLP. Furthermore, structural features, such as word count, as well as readability indices and coherence values were later added in the project but are not the focus of this study. The analysis was based on the Abitur tasks for the years 2017 to 2023 provided in the Common Pool of Abitur Tasks for the Federal States. These included 562 Abitur tasks with 2721 informative or instructive task sections. First, the tasks were categorised according to the subject areas they addressed. Pictures were separated from written language, and symbolic sequences were replaced by "XX". All verbal elements per task made up one unit of analysis. NLP was used to automatically measure the linguistic key figures, mostly the German language model of the Python library spaCy (Honnibal et al., 2020). In addition, the corpus SUBTLEX-DE (Brysbaert, 2024) for German subtitles, a corpus established based on German Wikipedia articles (Zenodo, 2024) and a corpus of the Abitur tasks themselves have been consulted to estimate the amount of everyday language, technical/academic language and the language in Abitur tasks. The degree of abstraction of the vocabulary was determined through the German list of extrapolated affective norms (GLEAN), which assigns empirical concreteness values to German lexemes (Lüdtke & Hugentobler, 2023). Finally, we approached syntactic density through indicators such as prepositions, as parts of prepositional phrases, in comparison to conjunctions, or the mean length of sentences, and, on the other hand, syntactic dependency through features such as pronouns or dependency distance in general. An ANOVA with pairwise t-tests and Bonferroni correction was used to determine differences between different subject areas. Where the graphical inspection indicated a violation of requirements, a Kruskal Wallis and Dunn test were applied.

Table 1: Elements of linguistic complexity that were examined, sorted by language dimension

Semiotic modality	Lexis	Syntax
• Symbolic sequences • Reference to pictures	• Everyday language • Non-mathematical technical language • Vocabulary of Abitur tasks • Variance • Concreteness	• Sentence length • Dependency distance • Entropy • Prepositions, pronouns, (coordinating and subordinating) conjunctions

Linguistic analysis

First, tasks from different subject areas show large differences with respect to their reference to semiotic modalities other than natural language, see Table 2. The investigation of the use of symbolic sequences and reference to pictures shows that stochastics tasks make comparatively less use of

symbolic sequences, while for calculus tasks the opposite is true. Meanwhile, tasks in calculus or analytic geometry refer significantly more often to visualisations.

The vocabulary used in stochastics tasks can be identified as closer to everyday language according to the frequency of its words in the subtitle corpus. The opposite is true for calculus and analytic geometry tasks. In addition, words in calculus tasks show a lower frequency in the Wikipedia corpus and therefore seem to be more distant to the academic register. The vocabulary used in stochastics tasks shows the least variable lexis in terms of unique words per task, which is significant in comparison to tasks of analytic geometry, in which the words used in the text also seem to be the most concrete. The most abstract vocabulary can be detected in calculus tasks.

Although there was no difference in sentence length or dependency distance, as can be seen in Table 2, there is a slight difference regarding the entropy values between the subject areas. Stochastics tasks show a lower entropy level which might hint to a lower information density. For words that convey dependencies within or across sentences or which contribute to syntactic compactness the findings are mixed. First, prepositions and pronouns appear in a higher proportion in calculus tasks, whereas the least were found in stochastics tasks, with a generally large difference in use of prepositions.

Table 2: Mean, standard deviation, variance analysis, pairwise comparison and effect size for linguistic characteristics of three language dimensions according to subject area

	Calculus (n = 182)	**Lin. Algebra** (n = 79)	**Stochastics** (n = 191)	**Anal. Geom.** (n = 110)	**Variance analysis**

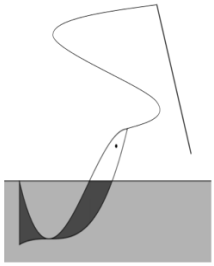
* $p < .05$; ** $p < .01$; *** $p < .001$; **** $p < .0001$

[1] total number; [2] mean word frequency in corpus; [3] number of unique tokens; [4] mean value; [5] in percentage of task text



Linear algebra and analytic geometry show higher proportions of coordinating conjunctions, while stochastics tasks were observed with the most subordinating conjunctions.

Discussion

In conclusion, none of the four subject areas shows an overall higher level of linguistic complexity. Instead, each of them can be characterised by different elements of complexity which may also need to be addressed differently in classes preceding the exams. This supports the hypothesis that the domain of a (mathematical) text determines the register used (Halliday, 1994). The different register features may lead to different factors influencing the linguistic complexity of the task.

Calculus tasks, see Figure 1 for an example, contain a comparatively high number of symbols and references to pictures. Although it remains unclear whether those characteristics increase their linguistic complexity or not (Martiniello, 2009; O'Halloran, 2015; Österholm, 2006), tasks of that domain seem more typical for the multimodal mathematical register (Lee, 2006; O'Halloran, 2015). The vocabulary used in the calculus tasks also seems to be typical for the Abitur tasks themselves, which may also stem from the fact that these together with stochastics tasks make up a larger proportion of the sample. For calculus there has been a debate as to whether the context of the Abitur tasks is necessary or if the actual focus still lies on calculating recurrent algorithms instead of adapting to the real-life situations (e.g. Frenken et al., 2024). From a lexical perspective, there is no indication of this in comparison to the other subject areas as the vocabulary in calculus tasks is not significantly less variable than that of other subject areas, which would have indicated a higher proportion of recurring task formulae. However, a further analysis of phrases in calculus tasks, and the register of

Die Abbildung zeigt das Logo eines Geschäfts für Anglerbedarf. Die obere Spitze der Schwanzflosse des Fischs liegt auf der Wasseroberfläche; die Strecke zwischen oberer und unterer Spitze der Schwanzflosse steht senkrecht zur Wasseroberfläche.

Bei Verwendung eines geeigneten Koordinatensystems kann die untere Begrenzungslinie des Fischs mithilfe der in IR definierten Funktion $u: x \mapsto \frac{1}{8}x^3$, die obere Begrenzungslinie mithilfe der in IR definierten Funktion $v: x \mapsto \frac{1}{4}x^2 \cdot (4 - x)$ beschrieben und die Wasseroberfläche durch die Gerade mit der Gleichung $y = \frac{5}{4}$ dargestellt werden.

Of all young people in a country between the ages of 14 and 25, 49.20 % are female. 47.10 % of young people regularly manage their financial affairs using a smartphone or tablet. The proportion of young people who are female and regularly handle their financial affairs using a smartphone or tablet is 19.68 %.
a Describe the factual context in a fully completed 2x2 contingency table.

Figure 2: Example of part of a stochastics task (introduction, subtask, & translation)

mathematics tasks in general, as well as a content analysis, is needed to verify this claim. Calculus tasks have a higher proportion of prepositions and pronouns, as referential structures, compared to tasks from other subject areas, which may increase syntactic complexity, but also contributes to a higher contextualisation and personalisation of the task text which reduces task complexity (Bednorz et al., 2024). On the other hand, calculus tasks seem to consist of a higher number of main clauses than other tasks according to their lower proportion of conjunctions. This may indicate that referential structures are established through symbolic sequences and more dense prepositional phrases.

Stochastics tasks seem to be less variable in terms of their reference to other semiotic modalities. They implement fewer or no symbolic sequences or references with respect to pictures; see Figure 2 for an example. On the other hand, the vocabulary can be characterised as closer to everyday language which may increase its linguistic complexity (Dyrvold et al., 2015) or as well decrease it being closer to the reader's everyday context (Schleppegrell, 2001). According to the elevated use of subordinating conjunctions, hinting to more unpacked syntactic structure, stochastics tasks appear less syntactically dense, also according to the entropy value, indicating a possibly lower task difficulty (Bednorz et al., 2024). However, the comparatively stronger use of subordinating conjunctions may indicate a more complex description of conditions and references in stochastics tasks. This could lead to a higher cognitive load as the solution of stochastics tasks often depends on the identification of such relations; further analysis is required here. Tasks in linear algebra cannot be characterised as (not) significantly complex. Only their use of non-mathematical technical language could be a factor to higher task difficulty (Dyrvold et al., 2015). Linear algebra tasks rarely refer to images and implement symbolic sequences roughly as often as do analytic geometry tasks. Especially without the implementation of supporting visuals the task difficulty might be increased (Martiniello, 2009). Coordinating conjunctions make up a higher proportion in linear algebra tasks. This potentially increases the referential structure but decreases syntactic density (Bednorz et al. 2024).

Abitur analytic geometry tasks show some similarities to linear algebra tasks, for example concerning the use of conjunctions. However, they contain a significantly greater number of references to visualisations, which might increase the task difficulty as this means a further change in semiotic register, but it might as well offer additional information (Martiniello, 2009; O'Halloran, 2015). The task lexis seems to be more variable, which might indicate a higher task difficulty (Bednorz et al., 2024). Furthermore, the vocabulary is more concrete, which suggests a diversity of real-life situations

in analytic geometry tasks, while it remains unclear whether this increases or decreases the task complexity.

Outlook

The concept of linguistic complexity in this study is based on a selection of linguistic parameters. Some of them have not been standardised, which makes the result less comparable and prevents an absolute interpretation of the complexity of Abitur tasks for different subject areas. Any type of comparison, whether it might be with Abitur tasks of a different subject, from a different time span, or with final examination tasks in other countries or tasks from textbooks (see Niederhaus et al., 2016) could usefully supplement the results of this linguistic analysis. This study also sets aside almost all investigations of the pictures and symbolic sequences used in the tasks which makes any estimation of the difficulty in understanding the whole task text obsolete, since the mathematical register is not represented in its entirety (O'Halloran, 2015). Especially calculus and analytic geometry tasks would show a different complexity structure as those make the most use of symbolic sequences and visualisations. Finally, the results of the linguistic analysis should be linked to the students for whom the tasks are designed. The main potential of this research lies in the possibility to compare linguistic elements in mathematics tasks with test performance, see e.g. Dyrvold et al. (2015), and reading behaviour to determine how and whether certain complexity factors influence the solution process.

On using operators to introduce negative numbers: How do students describe states and transformations?

Melina Fabian[1] and Ulrich Kortenkamp[1]

[1]Faculty of Science, University of Potsdam, Germany; melina.fabian@uni-potsdam.de

The aim of this paper is to focus attention on the use of the operator interpretation as an appropriate language-sensitive approach for introducing negative numbers. We derive the distinction between 'states' and 'transformations' from different theoretical considerations and utilise this as a framework for a qualitative content analysis. The study investigates which lexical means are used by 8th grade learners while giving examples for the use of negative numbers. Nine interviews were conducted and analysed, and the subsequent collection of learners' utterances offers insights into the lexical means enabled by the learners. From these utterances we can draw conclusions regarding their conceptual understanding of negative numbers. The empirical results can also be used for additional research on how building up an operational conception of negative numbers can be enhanced in mathematics lessons.

Keywords: Negative numbers, operator interpretation, numerical extensions, states, transformations.

Introduction

Learners encounter the concept of negative numbers on a theoretical basis usually by the start of secondary education. This can be explained by the fact that the introduction of integers emphasizes that learners become familiar with counting numbers and performing simple additions and subtractions on non-negative integers. Furthermore, these activities do not require learners to have a theoretical concept of negative numbers from preschool and elementary education. Teaching the sequence on numerical extensions in German schools corresponds to what Bruno and Martinón (1999) describe in the Spanish context as the learning progression: namely, by progressing from integers via positive rationals to rational numbers including negative numbers. Subsequently, with up to four years of operating with positive integers only and two more years that include positive rational numbers, that are used to build up mental representations of the concept of numbers, "new numbers are adjoined to the old system" (ibid, p. 792). This perspective can easily lead to students developing a *deficit understanding* of negative numbers as they are subsequently added to the previously known 'normal' numbers. Indeed, more than thirty years ago, Davidson (1987) remarked that introducing negative numbers in this manner "requires students periodically to overthrow their previously well-founded intuitions" (p. 431). Since negative numbers are not "representable concretely as manipulable objects" (ibid), learners experience that the concept of cardinality is *limited* to non-negative integers – a perception by which a deficit understanding of negative numbers is further promoted. This is also indicated by the results of Fabian (2023), who found that 7th grade learners' described negative numbers using expressions such as 'less than nothing' or 'the quantities beyond nothingness', suggesting that their conceptual understanding of negative numbers still seems to rely on cardinal interpretations.

Negative numbers are often introduced by the help of familiar real-word contexts or models, in which the use of negative numbers is the expression of a *state*, e.g., temperatures below 0°C, debts or

elevation. The difficulty of these contexts, as Freudenthal (1983) puts it, is that the negative numbers are "introduced as results of operations, which formerly were impossible" (p. 438), which again reinforces a deficit understanding rather than building up sustainable conceptions. An indication of this can be found in learners' language when reasoning about negative numbers as something that is 'less than nothing' or that indicates 'the quantities beyond nothingness' (Fabian, 2023).

These initial considerations show how *describing* negative numbers in a deficit way and having deficit *conceptions* of them could be linked. Conversely, for the introduction of negative numbers and to develop sustainable conceptions of negative numbers, learners need to get access to the crucial lexical means that can support the process of concept formation. In this paper, we argue that one possible approach for the introduction of non-positive integers, which doesn't rely on a deficit description of negative numbers, can be found in enhancing an *operational conception* of them. With the aim of supporting learners' language development, we investigate which lexical resources learners can activate when talking about negative numbers and how their use of lexical means can be linked to an operational conception of negative numbers.

Theoretical Background

This paper builds on the theoretical connection between language and thinking that has been discussed frequently in mathematics education research (e.g., Pimm, 1987; Sfard, 2008). These findings emphasized that language as a learning medium plays an important role in the process of developing conceptual understanding of a mathematical topic: Language unfolds 'epistemic power' and can make a significant contribution to building up sustainable conceptions as "it shapes the thinking" (Pöhler & Prediger, 2015, p. 1701). As the introduction of negative numbers should be taught in a way that combines lexical and conceptual learning in class, appropriate *lexical means* are required. By the term 'lexical means' we refer to words, sentence components, syntactical constructions, and graphical representations that need to be known – need to be mastered – by learners to, on the one hand, communicate about the concept of negative numbers and, on the other hand, construct the meaning of the concept (Pöhler & Prediger, 2015).

To learn more about how to enhance learners' understanding of negative numbers using lexical means, it's important to determine the mathematical concepts and mental representations that learners need access to. While numbers can be used to describe states in the world that surrounds us, they can also be used to describe processes or actions that transform one number into another, i.e., heating up and cooling down, spending and earning money, or shifting something to the left or right. With the introduction of *negative* numbers, these situations of use are extended to states 'below zero' and transformations that are applicable to *any* states, thus allowing unrestricted backward movement on the number line. Hence, two conceptions that appear to be crucial for the introduction of negative numbers can be found in using them to express *states* and *transformations* (Kirsch, 1977).

In our view, it is particularly the conception of *transformations* that can support learners' understanding of negative numbers and of operations with integers, as a didactical approach proposed by Sfard (1991). Sfard distinguishes between 'structural conceptions' and 'operational conceptions' as two different stages of concept formation learners must go through. What Sfard indicates for mathematical concepts in general is also applicable to negative numbers. Before a person can treat

negative numbers as an (theoretical) object and recognize their meaning as a subset of integers (structural conception), the person needs to become skilful in performing subtractions (operational conception). Therefore, when dealing with negative numbers, an operational conception needs to be developed *first* and only afterwards can a structural conception slowly evolve from the previously established operational conception. With reference to Jourdain (1956), Sfard (1991) denotes negative numbers as "nothing but a type of process" (p. 12).

Considering both lexical and conceptional perspectives, our initial point of research is founded in what Sfard (1991) concludes her paper with: "We ought to ask ourselves what means should be used to ensure that the students go safely through these doubts-about-meaning periods when they still feel certain uneasiness about the object they have to manipulate" (p. 34). Since the operational conception seems to be handled mainly through verbal representations[1] (Sfard, 1991), it is the *lexical means* that become even more important as they can help learners make the operational conception cognitively accessible. The study reported in this paper aimed to investigate the lexical resources that learners can (already) enable and to identify potential connecting points for supporting learners in language. Hence, the research question is: How do learners describe *states* and *transformations* while giving examples for the use and usefulness of negative numbers?

Methods

The study draws on the distinction between *states* and *transformations* that is considered as an important mental representation when introducing negative numbers and that is also made by Sfard (1991) as she addresses 'structural' and 'operational' conceptions in the context of learning and teaching mathematical concepts. With the aim of collecting lexical means that learners use to describe states and transformations in the context of negative numbers, the first author of this paper conducted nine interviews with 8th grade German students (aged 13-14).

In Germany, negative numbers are usually introduced in 7th grade. Therefore, it can be assumed that the interviewees have already had the chance to develop their conceptional understanding of negative numbers and to develop the lexical resources that are necessary for dealing with them. The sample included four students attending a grammar school (*Gymnasium*) and five students attending a comprehensive school. The length of the interviews varied from 8 to 14 minutes. The interviews were semi-structured and consisted of two parts: First, the students were asked to explain what they understand by the term 'negative numbers' and to give examples and possible contexts for the use of these numbers. To get an indication of which lexical means learners can enable, and how they can be linked to an operational conception of negative numbers, the learners' vocabulary and the structure of their utterances were the focus of the study. The participants were asked questions such as *What do you need negative numbers for? In what kind of situations do negative numbers appear to be important?* Second, they were requested to perform different tasks on comparing and operating with

[1] Since "verbal encoding […] must be processed sequentially, so it seems more appropriate for representing computational procedures" (Sfard, 1991, p. 7).

negative numbers. The second part of the interview is not within the scope of this paper, thus, only the analysis of the first part is described below.

All interviews were videotaped, transcribed, and subjected to a qualitative content analysis according to Mayring (2015). The expression of *states* and *transformations* were deductively taken as the two basic codes of the analysis. Within the data, learners' answers that either included describing states explicitly or that indicated a structural conception of negative numbers were assigned to the code *States* (S). Likewise, learners' statements were coded as *Transformations* (T), if they verbalized transformation situations explicitly or if they indicated an operational conception. For example, the statement "If I have minus ten euros in my account now"[2] was coded as S while the statement "For example, if you are at the 4 [*puts a finger at the edge of the table*] and then go six steps minus that is backwards [*gestures a jump to the left with the finger*], you end up at the –2" was coded as T. To investigate the characteristics of the given descriptions further, sub-codes were then developed inductively. Namely the codes S1 (non-exist/non-possess), S2 (lack/need), S3 (negative magnitude or quantity) and S4 (static representation) as sub-codes of S and T1 (return/neutralize), T2 (arithmetic operation), T3 (operator interpretation for comparing numbers) and T4 (dynamic representation) as subcodes of T were added to the inventory of codes. The interviews were coded separately by both authors of this paper. Validity and reliability were established by comparing the two sets of results, clarifying codes and re-coding data until agreement.

(An Excerpt from the) Research Results

The empirically obtained results of the research consist of both the differentiated category system and the collected descriptions – being them state-bound or transformation-bound – that 8th grade learners gave when giving examples for the use of negative numbers. With regard to the paper's research question, the inventory of codes first shows that *both* types of descriptions (states and transformations) can be identified in learners' utterances. The developed sub-codes can then provide an initial indication of what the learners' descriptions of states and transformations are characterized by. By investigating the coded utterances in more detail, additional information on *how* the learners described states and transformations, when giving examples for the use of negative numbers can be collected, e.g.: which *lexical means* they used for describing states and transformations, what kind of *situations* and *contexts* they thought of when giving those descriptions, whether the given examples appear to be *suitable* for either describing states or transformations, at which points the learners seem to show *difficulties* explaining their examples (indicated by e.g., pauses in speaking, interruptions or searching for words) or *change the strategy of explaining* (from being state-bound to being transformation-bound and vice versa). In total, 50 utterances were coded for the first part of the interviews, of which 36 were assigned to the category *States* (S) and 14 to the category *Transformations* (T).

Due to the limited scope of this paper, the full category system will not be discussed in detail. As most of the coded utterances have been assigned to the category S, we will focus on presenting the *state* descriptions we found. Therefore, we will first show an excerpt from the inventory that depicts

[2] All utterances were translated from German into English by the authors for this paper.

an overview of the sub-codes S1 to S4 as well as examples for utterances that have been coded into the respective category (Table 1). Later, we will provide deeper insights into some of the interview transcripts to enrich the reported findings.

Table 1: Sub-codes of the category 'States' with illustrations from transcripts

Code	Example	Number of occurrences
S1 (non-exist/non-possess)	"Minus numbers, because you're just taking something that isn't there."	15
S2 (lack/need)	"And then you just go into debt because you still need three euros, […], that's minus three euros that are missing."	9
S3 (negative magnitude or quantity)	"So, you just have negative money."	11
S4 (static representation)	"For example, if you have a debt of ten euros. That's also minus ten at the bottom when you look at your account balance."	1

When the learners were asked to think of examples for the use of negative numbers, it was noticeable that they described a situation in which negative numbers are being used as an expression of a state rather than a transformation. The created situations were mainly characterized by states of 'non-existing' or 'lacking' with negative numbers used to express something 'deficient'. For example, the utterance "[You need negative numbers] to represent something with numbers that something is not there, but even less" (S1) indicates a deficit conception that the learner might have of negative numbers. Some learners also made use of lexical means that verbalize the (contradictive) state of having a negative quantity or magnitude, e.g.: "And Lisa has absolutely no money right now, so she still has minus twenty money" (S3). It turns out that some learners even tried to give state descriptions for situations that would have been more suitable for describing transformations, illustrated by the following transcript:

Interviewer:	Can you think of another example or situation in which negative numbers are being needed?
Student:	Hm, for example, when you buy something and you – you want to buy something that costs maybe five euros.
Interviewer:	Mhm.
Student:	But you only have two euros for instance.
Interviewer:	Yes.
Student:	And then you just go into debt because you still need three euros, and when you do the maths, that's minus three euros that are missing.
Interviewer:	Mhm. Can you describe again where exactly the negative numbers are important in your example?
Student:	They are important because they are not there, and they are missing. And because they– Yes, I'm not sure [*shakes head*] Äh [*4 sec*] Because if you had five euros now, for example, that would be zero that would be missing.

Because there are three euros missing, that's minus three euros, because they're not there and you need them.

The learner created a situation that could have been perfectly described as a transformation, since 'buying something' can be characterized as a process of action. One operation that would be suitable for that situation is: $2 - 5 = -3$. However, the learner only made use of state descriptions (e.g., 'you only *have* two euros', 'you still *need* three euros') and tried to connect them to grasp the whole transformation that is being processed within the situation. Two observations can be made regarding the learner's reasoning. Firstly, that the learner seems to struggle with describing the role of negative numbers in their example by only referring to states. This is seen by several interruptions in speaking, by many attempts of re-formulating the situation ('they are not there', 'they are missing', 'you need them') and by their self-verbalized insecurity ('I'm not sure'). Secondly, the learner seems to identify the negative number itself ('minus three') with the state of 'not-existing' or 'lacking', which led to incorrect descriptions ('that's minus three euros that are missing'). Those difficulties in explaining the concept of negative numbers, and describing situations of use, were observed with other learners too as the following transcript shows:

Student:	They [negative numbers] indicate the quantities beyond nothingness so after zero.
Interviewer:	Could you explain again what you mean by that?
Student:	There's even less of the nothingness. I have absolutely no idea how I can explain it in any way– so I don't know how I can explain it, that is– hm, it's– with temperatures for example there is zero degrees Celsius, for example, and then it goes up and down. There are still minus degrees then...

Again, a rather deficit conception of negative numbers was being verbalized by the learner who mainly made use of static descriptions. For example, the learner referred to a state of 'not-existing' ('There's even less of the nothingness') and to negative quantities ('quantities beyond nothingness'). The learner seemed to find it challenging to explain their understanding of negative numbers, as the learner interrupted themselves multiple times assumably trying to find the right words and explicitly repeating not to know how to explain any further. Thus, their utterances were being characterized by incomplete sentences and by an unprecise use of lexical means. The only description that could be read as an expression of transformation can be found in 'then it goes up and down'. This process seemed to be cognitively assigned to the context of temperatures for the learner; however, the relation to negative numbers was not made explicit.

We conclude the presentation of the research results by also taking a brief look at learners' utterances that have been coded into the category *Transformations* (T). Although we cannot provide detailed analyses of those utterances at this point, we would at least like to mention the following observations: The coded statements indicate that some learners seem to have a dynamic perspective on negative numbers ("And negative numbers basically run backwards." (T4)) – often verbalized by referring to movements along the number line. Also, transformations were expressed as situations of 'returning' or 'neutralizing' a few times. What can be observed within the respective utterances is that the learners verbally switched to deficit – or even incorrect – state descriptions when they seemed to struggle with further developing their self-created examples. The utterance "Hm maybe, if– that's [negative numbers] good when you get something back from someone, that then just– he has like minus things." (T1) exemplifies that assumption.

Discussion and Conclusion

Even though this paper can only provide a small insight into the interviews with the learners, and into what could be found in their enabled descriptions, a discussion of the research results will be attempted at this point. What can be observed with the findings of our study, namely the differentiated sub-codes of the inventory and the excerpts from the transcripts, is, that the learners seem to have a *structural conception* of negative numbers. According to Sfard (1991), at this (more advanced) stage of concept development the learners already should be able to (mentally) manipulate negative numbers as theoretical mathematical objects. However, even if the learners themselves often give examples in which *transformations* with negative numbers are being processed, they continue to try to describe *states* – which then often appear to be less suitable for the situation or even incorrect. One possible reason for this could be the lack of lexical means that express transformations. It could also be assumed that learners have not had enough opportunity to develop an *operational conception* of negative numbers – which would, as Sfard (1991) argues, be necessary for a structural conception to evolve from. Consequently, the learners seem to build their structural conception on a *deficit understanding* of negative numbers. Given that they identify negative numbers with states of 'lacking', 'non-existing' or 'negative quantities', they meet an obstacle that is both of a cognitive and linguistic nature: The non-existence (of quantities and magnitudes) is not *imaginable* and therefore not *describable*.

Despite its brevity, the analysis presented in this paper exemplified how learners' language might be 'limited' to the description of states, even when thinking of situations in which negative numbers could be used for expressing transformations. The empirical results indicate that the lexical means including deficit descriptions that are currently being used by the learners support a deficit understanding of negative numbers rather than fostering the development of sustainable conceptions. Inspired by the considerations made by Sfard (1991) and encouraged by the more recent findings of this study, we want to draw on the *operator interpretation* as a possible conceptional basis for introducing negative numbers.

This approach is not new, yet it seems to have been neglected in recent years, at least in the German schooling system. For example, from a technical mathematical point of view, Kirsch (1973) explains how negative numbers could become more cognitively accessible by referring to operators. Operators in the meaning of dynamic *state changes* or *action processes* are easier to describe and much easier to imagine than something 'less than nothing'. Learners can find them in natural processes that are invertible, such as adding or removing something or moving forward or backward – conceptions that learners already know from operating with non-negative integers, and which are also sustainable for negative numbers because they keep their mode of effect. Hence, the operator interpretation offers a chance to introduce negative numbers as descriptions of well-known performed actions rather than referring to something that is 'new', 'different' or 'lacking'. As it doesn't require a deficit description of negative numbers but rather builds on well-known mental representations and strategies, focusing on learners' development of an operational conception might be a helpful approach. Once again, referring to Davidson (1987, p. 432): "Unlike non-positive collections of material objects, non-positive actions […] not only exist but are familiar to children from infancy." Whether this approach indeed holds potential for mathematics teaching has yet to be shown. For example, further

considerations could be given to the role that appropriate lexical means – that help to understand negative numbers as expression of transformations – play in getting access to the operator interpretation as a conceptual basis for learners.

Using Maltese meaning-related vocabulary for the topic '*Equivalent Fractions*' in a bilingual Grade 6 classroom in Malta

Marie Therese Farrugia

University of Malta, Malta; marie.t.farrugia@um.edu.mt

Mathematics education in Malta is frequently conducted through translanguaging with English and Maltese. In this paper I describe a design-based research study carried out in collaboration with a Grade 6 elementary teacher. The topic in question was Equivalent Fractions *and the main thrust of the lessons was to heighten the teacher's awareness of useful Maltese vocabulary for meaning-making, to maximise student verbal participation, and to introduce the innovative idea of using Maltese for written mathematics texts. I provide excerpts of English / Maltese classroom interactions, using the illustrations to reflect on language-responsive pedagogy.*

Keywords: Meaning-related vocabulary, translanguaging pedagogy, design-based research, fractions, elementary mathematics education.

Introduction

In many classrooms in Malta, mathematics education is experienced bilingually through English and Maltese. The presence of English in the education system, and society at large, is the result of 165 years of British colonisation, which ended in 1964, while Maltese is the home language of the majority of Maltese people. In many classrooms, teachers and students communicate verbally, and negotiate mathematical meaning, through both languages, but all written mathematics is in English. In this paper, I describe a collaborative design-based study carried out with an elementary school teacher. The research question addressed was: *What Maltese vocabulary is salient for meaning-making for the curricular topic* Equivalent Fractions*?* The aim of the study was to encourage, and validate, spoken Maltese and to introduce *written* Maltese for mathematics.

The curricular topic *Fractions* and language-responsive teaching

Fractions are among the most difficult concepts that elementary children come across (Charalambous and Pitta-Pantazi, 2005). Van de Walle et al. (2020) highlight that fractions have five interpretations: *part-whole* (e.g. ¾ of a circle or ¾ of a class of 24 children); *division* (3 pizzas shared amongst 4 children); *measurement* (¾ as a number on the number line, the fraction being a measure of the whole number 1); *operator* (¾ of €20) and *ratio* (in a classroom, the ratio of boys to girls is 3:4). The focus of this paper is the *part-whole* interpretation and, more specifically, equivalent fractions. Two fractions are equivalent if they are representations for the same amount or quantity or, when considering fractions as numbers, they represent the same number. Equivalent fractions can be created by multiplying or dividing the numerator and denominator by the same number, but Van de Walle et al. (2020) stress that students need to see the connection between the concept and the procedure. Van de Walle et al. recommend that, since fraction symbolisation is difficult for young students to understand, words should precede symbols in instruction.

Several authors have written about the importance of teachers focusing implicitly on language during mathematics lessons. For example, Gibbons (2015) and Lee (2006) highlight the benefit of explicitly

focusing on mathematical vocabulary and 'ways of saying', while Melanese et al. (2011) and Moschkovich (2013) similarly advise with reference to contexts wherein students are learning through a language which is not their home language. A contemporary notion is *language-responsiveness*. Teaching mathematical content language 'responsively' is defined as "instruction that enhances language for mathematics learning" (Erath et al., 2021, p. 246). More specifically, materials and instructions should: engage students in rich discourse practices (Principle 1), establish various mathematical language routines (P2), connect language varieties and multimodal representations (P3), include students' multilingual resources (P4), use macro-scaffolding to sequence and combine language and mathematics learning opportunities (P5) and compare language pieces (form, function, etc.) to raise students' language awareness (P6). Götz and Baiker (2023) explain that language-responsive lessons cannot follow all six design principles simultaneously and my study touches mainly on principles 1, 3 and 4. Prediger (2019) advises that language-responsiveness should not be restricted to the communicative function of language, but should also take into consideration the epistemic function of language as a tool for thinking and knowledge construction. She points out that meaning-related vocabulary is likely to be a mix of both subject-specific words and 'everyday' words.

My study is not the first design-based one focusing on fractions. Two recent mixed-methods studies were carried out in Germany by Prediger and Wessel (2013) and Schüler-Meyer et al., (2019), both with the aim of aiding students' conceptual understanding. In the former study, German was used to scaffold learning for second language learners. The focus was on student explanations, and the student to teacher ratio was 2:1. In the latter study, Turkish was introduced into lessons with German / Turkish students. The focus was bilingual connections, and each teacher worked with three to five students. Both studies involved large numbers of teachers and students. While my own overall intention to support conceptual understanding is similar, my study features only qualitative data, collected in two natural classroom settings. Furthermore, my study differs in that it was carried out in a post-colonial context, wherein Maltese is an accepted language, and already used orally (to varying degrees) for mathematics, although generally in subordination to English and never for written mathematics.

Theoretical framework

My theoretical framework is underpinned by three key elements. First is the definition of translanguaging itself. The term 'translanguaging' has been used by various writers in different ways and, indeed, the interpretation of the term has changed over time (see MacSwan, 2022). In this paper, I use the perspective adopted by Cummins (2021), namely, a *Crosslinguistic Translanguaging Theory*. In this view, translanguaging is considered to involve shifts between distinct, identifiable languages, which are used according to the social context at hand. (This view contrasts with the view proposed by Ofelia García and her colleagues (e.g. García and Otheguy, 2014), wherein bi-multilinguals have one unitary language system with undifferentiated mental grammars). Second, I hold a non-deficit view of bilingualism. With respect to our contemporary world, where so many people operate through a second language, Cook (2022) challenges traditional views of language by highlighting bilingual advantage over monolingual deficit. Third, I subscribe to the belief that "translanguaging pedagogies represent an epistemic and pedagogical commitment to multilingual

learners by legitimizing and intentionally incorporating their multilingualism and multilingual identities in the classroom" (Shepard-Carey & Tian, 2023, p. 1).

Methods

Shepard-Carey and Tian (2023) believe that the exploration and development of translanguaging pedagogies is best served through researcher-teacher partnerships and collaboration. They propose a research / practice approach of "co-stance, co-design, and co-shifts" (2023, p. 6). Co-stance refers to the dynamic process of dialogue that allows both researcher and teacher to deepen their understanding of the complexity of classroom contexts; co-design refers to the iterative process of planning lessons that build on students' repertoires; and co-shift refers to moments when teacher and researcher engage in self and communal reflections. My study reflects this approach. Furthermore, the method utilised was design-based research, described by McKenney and Reeves (2019) as an approach that involves developing and implementing interventions to address problems in practice. Prediger et al., (2015) point out that design research generally has dual objectives: it focuses on a specific curricular topic while simultaneously considering a wider instructional issue. In my case, the curricular topic was *Fractions*, while the wider consideration was *the use of Maltese for meaning making in mathematics*.

The school was chosen in a purposive manner, since it had a minimal number of non-Maltese students. I wished to avoid a multilingual context which, from my experience, I knew would result the use of English as a lingua franca. Two teachers volunteered their participation. This paper focuses on the Year 6 teacher, Daniela (pseudonym). Her class comprised 18 students, aged 10 to 11 years. Daniela's home language was Maltese, but she was also fluent in English. She explained that she usually started mathematics lessons in English, but if she noticed that the students were not understanding, she repeated in Maltese. Daniela reported that the home language of all but one of the students was Maltese and that she always allowed her students to participate in Maltese, if they so wished. The Saudi Arabian student present in the class could speak Arabic, English and Maltese.

McKenney and Reeves (2019) mention key features of design-based research: It is explorative in nature, has a flexible, iterative structure, and involves ongoing evaluation and retrospection. In line with this, I started the study by conducting a one-hour interview with Daniela, during which we discussed the topic and her views on language for mathematics. I then planned and prepared six lessons. Minor amendments were made following Daniela's feedback. Daniela delivered the lessons, while I observed. Every day, we discussed the lesson for about 15 minutes, and went over the following day's lesson. Finally, another one-hour interview was held, during which we shared our overall reflections. The interviews and lessons were audio-recorded, while the lessons were also video-recorded. As I observed the lessons, I wrote down reflective thoughts for discussion with the teacher and also as a means of immediate analysis of the data being collected. I carried out daily transcription of the interviews, documenting my reflections and any points to be followed up with the teacher. Thus, the analysis and data collection were closely intertwined. For practical reasons, the finer analysis and transcription of the classroom interaction was done at a later date.

Adopting a positive view of bilingualism, I sought to encourage the teacher to use Maltese vocabulary more consciously, and more explicitly, for meaning making. I validated, and encouraged, the teacher's and students' use of Maltese and integrated Maltese text into written work, on the

assumption that this would have pedagogic benefits. The key ideas addressed – comparison of fractions of regions and quantities, equivalence and fractions on the number line – were chosen based on the mandatory syllabus. In the lesson plans, I included vocabulary – both English and Maltese – that the teacher might use. These included the Maltese term for English nouns that Grade 6 students would already be familiar with e.g. *numerator* / **numeratur**, but also expressions like *the same part of the whole* / **l-istess parti mill-ħaġa sħiħa [the same part of the whole thing]**. Thus, as pointed out by Prediger (2019), the meaning-making vocabulary was a mix of both subject-specific words and 'everyday' words. My participating students already had a few years of experience with fraction symbolisation, hence my aim was to focus on strengthening the link between symbols (and procedures) and concepts (Van de Walle et al., 2021).

The lessons were designed in a way so as to target key principles of language-responsiveness. First, verbal participation was maximised through pair work and reporting back to the class (for example, the students would work in pairs to formulate an explanation of some point for a friendly alien named Alfred) (Principle 1). Second, in line with Principle 3, both English and Maltese were associated with diagrams and symbolisation that the students were already familiar with. Furthermore, Maltese was included in the written texts of worksheets, study notes and interactive-panel projections. For example, in one worksheet, I wrote the problem: "*Alfred the Alien says that the fractions 4/12 and 12/36 are equivalent because both include the number 12 (**it-tnejn li huma fihom in-numru 12) [both of them include the number 12]**. Is he right? Explain.*" Third, Maltese was encouraged as part of verbal interaction. The topic *Fractions* was not new to the students, but Daniela acknowledged that pushing students to *explain* ideas would render the lessons more challenging (Principle 4).

Discussion of data

As Daniela delivered the lessons, she used both English and Maltese, although English was more frequent. However, as a result of my lessons plans and our discussions, Daniela now also used certain Maltese words and phrases that were anticipated to support meaning making. She admitted that some expressions 'did not come naturally' at first but that, over the days, she came to appreciate their usefulness. One example is the phrase '**jiswew l-istess**' [**they are worth the same**] with respect to 'equivalent fractions.' There was variation in the students' own use of Maltese and English, with some students choosing to use more English and some more Maltese. However, the students engaged with interest with the increased use of Maltese. When Daniela asked them (not in my presence) their opinion about the Maltese written insertions, they told her that they found this approach helpful.

I will now discuss two stretches of interaction. The first is taken from the third lesson. The expression *Equivalent Fractions* was projected on the interactive panel, and the students were asked how they would explain this expression to Alfred the alien in English.

Patrick:	Equivalent fractions are fractions that are the same/
Eddie:	(*Interrupts his partner*)/ But with different numbers.
Teacher:	Can you specify? "Different numbers" means…?
Patrick:	Like one half and three sixths. Although you think that the numbers are bigger, but, in reality, one half/

Teacher:	(*Interrupts*)/ Wait a second, wait, wait. So maybe instead of saying "different numbers" we can say "NUM..."
Patrick:	Numerators and denominators. Like one on two and three on six.
Teacher:	Like one on… one half and…? Can you give me the fraction?
Patrick:	Three sixths.

At this point, the thrust of Daniela's questions / prompts was to encourage the students to express themselves more precisely in terms of pointing to the elements of the fractions (numerator / denominator) and expressing the fraction more formally. As other students took their turn, two pairs reported the procedure for creating equivalent fractions by multiplying or dividing the numerator and denominator. Other pairs focused on the concept, using vocabulary like; *the same, always equal, equal but not same denominator and numerator, have the same amount*. After this first round of explanations, the teacher invited the students to explain the same expression to Alfred in Maltese, thus encouraging and validating their home language for mathematics. Students' explanations included expressions like: **l-istess, jfissru l-istess, għandhom l-istess ammont, għandhom valur l-istess** [**the same, they mean the same, they have the same amount, they have the same value**]. While these expressions mirrored quite closely the students' English expressions, it is interesting to note that the students picked up on Daniela's expression '**jiswew l-istess**' [**they are worth the same / they have the same value**], although here expressing it as **l-istess valur** [**the same value**]. The Maltese reference to the idea of 'same value' appeared to add further depth to the articulation of meaning. A contribution worth commenting on is Fabian's, who read out the explanation he had drafted together with Ian.

Fabian	**Mela, Alfred, il-frazzjonijiet** equiv**ilanti** [sic] **għandhom l-istess ammont, pereżempju wieħed fuq tnejn, tnejn fuq erbgħa** […] **sebgħa fuq erbatax u erbatax fuq tmienja u għoxrin.** **[So, Alfred, equivalent fractions have the same amount, for example, one on two, two on four** […] **seven on fourteen and fourteen on twenty-eight]**.
Teacher:	**Sebgħa minn erbatax**. [**Seven from / out of fourteen**]. (*Teacher looks at researcher as if to validate the expression of the fraction in Maltese*).
MTF:	**Iva. Sebgħa MINN erbatax. Tista' tgħid 'fuq', anke bl-Ingliż ngħidu** 'three on, over four', **imma proprja tgħid tlieta MINN erbgħa, jew tlieta minn KULL erbgħa.** **[Yes, seven from/out of fourteen. You CAN say 'on', even in English we say** 'three on, over four' **but really, we say three FROM / OUT OF four, or three from/out of EVERY four].**

Fabian took pride in using Maltese and here he coined a mixed-code word *equiv***ilanti** (instead of **ekwivalenti**). He asked Daniela if this word 'made sense' but, not hearing his question due to some classroom distraction, she did not respond. Fabian's word was heard and used by other students. The incorrect articulation of this word was not an issue *per se* but, after the lesson, I did draw Daniela's attention to Fabian's query, not only to validate the student's efforts but also because I believe that if we are to promote Maltese for mathematics, then the words might as well be said correctly. A more significant aspect of the above interaction was Daniela's, and my own, rephrasing of 'seven on fourteen' as **seven FROM / OUT OF fourteen** or **seven from / out of EVERY fourteen.** Here the

Maltese foregrounded the part-whole concept more explicitly than English. The excerpt also shows how bilingual connections can be made collectively, involving students, teacher and researchers.

The second excerpt is taken from the fifth lesson. The lesson started with a projection of the image of Alfred the alien on the interactive panel, together with the phrases *simplest form* and *lowest terms*. The students were asked to work in pairs to formulate an explanation of these terms, and any language could be used. Here the implicit message was that both languages are acceptable, and students could use whatever they preferred. Kyle and Amy reported their respective pair-work as follows:

Kyle: It means that a fraction keeps going down to the smallest fraction, for example, twelve on twenty-four, six all over twelve, three all over six, one half. You need to keep going down until you find the smallest fraction. I kept dividing.

Amy: We know this: 'simplest' means smallest, so when you have to turn them into the simplest form, we have to think of a [multiplication] table that fits in them. **Mbagħad għamilna**, two fourths **għamilnieh** division by two **jiġi** one half; **u** eight tenths **erġajna għamilnieh** division by two, **jiġi** four fifths.

[**Then we did**, two fourths, **we did it** division [we divided it] by two, **it comes** one half; **and** eight tenths **we once again did it** division by two, **it comes** four fifths].

Having listened to seven procedure-oriented explanations, Daniela found an opportunity to focus on *conceptual* meaning. Patrick had suggested the fractions 5/10 and 2/4 and ½, saying that they were "the same fraction with different numbers". Daniela picked up on this cue as follows:

Teacher: (*She indicates the fractions written on the panel. She inserts equal signs: 5/10 = ½ and 2/4 = ½*). So these are equal because they are equivalent fractions, just in their simplest form. So you need to also explain to me something else: that even though the numbers are different ...?

Theo: But they still have the same value.

Teacher: They still have the same value. **Jiswew indaqs. Il-parti mill-kbira, mill-ħaġa shiħa, jiswew indaqs.** Is that understood? **Dik importanti li tgħiduhulu [lil Alfred]**.

[They still have the same value. **They are worth the same. The part from the large [one], from the whole thing, they are worth the same**. Is that understood? **That's important to tell him [Alfred]**.

George: Hello Alfred. If you have a fraction of two fourths and you need to make it simplest form, it's easy! Two fourths, you can turn it into one half.

Teacher: And you need to tell him [Alfred] that the fractions are in the simplest form. They are ...?

George: The same.

Daniela's latching onto Patrick's point illustrates a commitment to language-responsiveness on her part, and the translanguaging within the same stretch created a linguistic connection that served to shift the students' attention away from procedures to a more conceptual interpretation.

Conclusion

I set out to explore what Maltese vocabulary is salient for meaning-making for the topic *Equivalent Fractions*, utilizing the notion of meaning-related vocabulary (Prediger, 2019) in a 'natural' classroom setting within the Maltese bilingual context. The teacher's increased use of purposive

translanguaging to support meaning-making, and the keen engagement with both languages by the teacher and the students, were indications that the pedagogy I designed has potential to be utilised in our bilingual classrooms.

My choices about what constituted meaning-related vocabulary were based on my professional and academic knowledge. The teacher also gave her input based on her knowledge of the subject, her experience teaching Grade 6, and her familiarity with this particular group of students. Certainly, a class teacher plays a crucial role in identifying meaning-related expressions, especially when these utilise vocabulary that is 'everyday' language. Indeed, the study highlighted that it is not always straightforward to distinguish between subject-related and everyday vocabulary. *Multiply* and *denominator* – and their Maltese counterparts – may easily be identified as subject-specific and *you keep going down* might be considered as everyday vocabulary. However, expressions like *have the same amount* and *part of the whole thing* are not so easily categorised. So, while the theoretical distinction is useful, in practice the dichotomy can be blurred. However, this blurring can help to shift our attention to the more important aspect of *meaning-making*. The study highlighted that Maltese not only served its purpose but, at times, expressed meaning in a more explicit manner than English.

I approached this study with a positive disposition toward translanguaging pedagogies. I believed that English and Maltese could be drawn on for pedagogic advantage through flexible translanguaging. While verbal translanguaging is not new in our classrooms, the use of Maltese for *written* mathematics was an innovative experiment that was well received. I believe that this method can offer a practical and helpful compromise between, on one hand, sticking to English-only written work and, on the other, a potential duplicating of all resources in both languages. Possibly, this initial experiment might find relevance in other post-colonial contexts.

The design-based approach allowed for ongoing reflection about translanguaging pedagogy for both myself and the teacher, resulting in professional growth for both. I hope to extend the study by working with other teachers. I believe that further collaborations between researchers and teachers will strengthen our efforts to establish "translanguaging pedagogies as consistent and intentional practices" (Shepard-Carey & Tian, 2023, p. 2).

The impact of multilingualism on mathematical teaching-learning situations

Marijana Gregurević and Marei Fetzer

University of Wuppertal, Germany; gregurevic@uni-wuppertal.de

In an increasingly multilingual society, the teaching of mathematics in German primary schools is particularly challenging. On the one hand, multilingualism opens up access to different linguistic perspectives, on the other hand, differences in linguistic expression and mathematical terminology can lead to difficulties in mathematical understanding. This is also confirmed by everyday experience. In this study, we investigate the effects of Croatian as a first language on the mathematical learning of primary school pupils in Germany.

Keywords: Language, multilingualism, bilingualism, primary education, Croatian.

Mathematical learning, language, and multilingualism

There is a consensus in mathematics didactics research that language plays an important role in mathematical learning processes. Vygotsky (1978) already described language as a central medium for cognitive development and learning. Since then, a lot of research has been done underlining the close connection between language learning and mathematical learning (Setati, 2005; Moschkovich et.al., 2018; Ingram et al., 2023). Lately, special attention is given to multilingual learners who have competences in their first as well as in their second language (Barwell et al, 2019) In this context, Cummins' "interdependence hypothesis" emphasises the importance of preserving the first language. Following Cummins, the loss of the first language on the one hand can have a negative impact on a child's cognitive and academic potential in the second language (Cummins, 1981). On the other hand, appropriate backing and strengthening of the first language supports academic success in the second language. Eventually, the development of language competence is not only an important learning goal, but also an important prerequisite for the learning of mathematics.

Language is not only a means of communication but also influences our thinking. In this respect, the communicative and the cognitive function of language can be distinguished (Bruner, 1974). Both are closely interwoven and influence each other. In the sense of the cognitive function, language is an important instrument for organising our thinking and structuring our knowledge. It is true that our thinking is not exclusively linguistically bound. But language and its differentiation play an essential role in the differentiation of ideas. The more differentiated linguistic means learners have to describe mathematical concepts, the more differentiated insights into these concepts they will be able to develop. In the process of developing and differentiating language skills, the exchange with others, respectively the communicative function of language, plays an essential role. Communication processes are crucial for developing new perspectives on one's own prior knowledge, they enhance not only our thematic or mathematical learning but also improve our language skills. The cognitive function of language is directly related to its communicative function (Cummins, 1981).

This aspect of (mathematical) concepts and ideas developed with relation to the individual language skills is particularly interesting in a multilingual context. If two (or more) languages are involved in

learning, it is not just a matter translating. Instead, language use is necessarily bound to a specific cognitive system which is dependent on the language structure. Different aspects of reality can therefore be emphasised due to the phrases and vocabulary given by the linguistic structure. In linguistics, this connection is described by the relativity hypothesis - also known as the Sapir-Whorf hypothesis (Whorf, 1940). It assumes that each language has a specific cognitive system that influences perception, restricting access to ideas that are not encoded within it. From a resource-oriented perspective, multilingual learners stand to benefit from drawing on multiple language systems, thereby enriching their cognitive abilities. Like communication and interaction, which enable perspective-taking and knowledge restructuring, multilingual learners can reflect on reality through two or more linguistic perspectives. Studies from secondary education prove empirically, that multilingualism can influence mathematical learning in a positive way. For example, Prediger and colleagues (2019) were able to demonstrate, that differences between Turkish and German on the topic of fractions can enhance the mathematical learning of Turkish-German bilingual students. Moreover, linguistic variation can facilitate a more nuanced comprehension of mathematical concepts (Prediger & Uribe, 2021). However, it is essential to address the differences in terms, ideas, and approaches to subject content associated with multilingualism explicitly in order to fully capitalise on this benefit. Reflection on language and concepts on a meta-level are the key to mathematical learning processes in studies in secondary mathematics classrooms (Barwell et al., 2016). Following Whorf (1940) and recognising the specific nature of the cognitive systems of different languages, it needs to be clarified to what extent the results from research relating to secondary education can be transferred to primary education or other language combinations and to what extent there are generalisable aspects. The first step towards a more comprehensive understanding of multilingual mathematical learning processes is to focus on the influence of learners' different first languages. This study follows this approach and focuses on German-Croatian bilingual primary school students from the second and third generations. As the teacher is a Croatian native speaker, microanalyses of the emerging interactions are possible with special attention to the use of Croatian as the first and shared language as well as the second language German. Data from a pilot study is introduced.

Pilot Study

For the data collection, a teaching-learning situation was designed and implemented that offers a bilingual communication occasion. German and Croatian are chosen for the setting in order to benefit from the teacher's own language skills in these two languages.

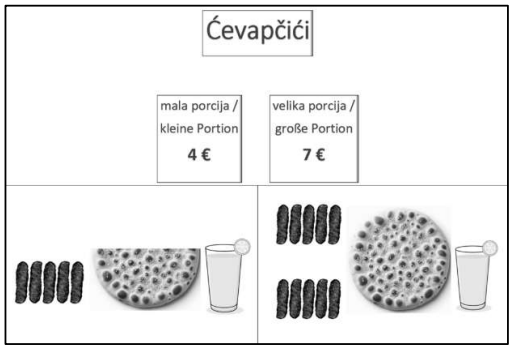

Figure 1: price board and illustration of the portions small portion 4€ / big portion 7€

A real-life context on buying well-known snacks is chosen in order to enable culturally assignment to the Croatian-speaking area and to encourage learners to use their first language when completing the task. The offered material is bilingual (see Figure 1) and the teacher leads the discussion in both languages.

As part of the teaching-learning situation, the children were given the task of explaining whether they thought it was more sensible to buy two small portions or one large portion of the ćevapčići-menu. This task enables an exploration of the mathematical topic of halving and doubling. Negotiating this topic in German or Croatian reveals a range of different formulations and grammatical structures that go hand in hand with conceptual differences. One example is given here for clarification (Table 1).

Table 1: Example German – Croatian

German	"doppelt so groß"	"halb so groß"	**Croatian**	"duplo veće"	"upola manje"
	[*double as big*]	[*half as big*]		[*double bigger*]	[*half smaller*]

If you take a closer look at the linguistic expressions, you will notice that the word "groß'" [*big*] is used in both German contexts. In Croatian, on the other hand, different words are used: "veće" [*bigger*] and "manje" [*smaller*]. These Croatian words indicate the direction in which the size of an object changes, while the German refers to the size itself. Initially, only the price board was presented. After the first justification, the picture of the "portions" including the lemonade was also shown, whereupon a further justification was initiated. Children of different ages and with different durations of school socialization in the German education system were selected. The intention was to clarify and specify challenges and resources associated with multilingualism in mathematical learning and to ascertain whether the observed effects are independent of age and duration of school socialization.

The teaching-learning situations of the pilot study were videotaped and transcribed. English is used as the reference language within the transcripts. The translations into English highlight the linguistic differences between Croatian and German, as well as the potential conceptual differences that may arise from them. For this reason, the verbalisations have been translated word by word into English. They are presented in italics. Non-verbal actions are shown in grey, reference to certain lines of a transcript are given as <5>. The names of the children have been pseudonymized.

Empirical examples

The two examples presented in this paper refer to one interview with a second and one with a fourth grader. In this way, first insights into primary mathematical learning at different learning levels concerning both, mathematical and language skills, may be introduced and compared. The data was collected during the last week of the summer holidays and the first week of lessons in Germany. As the children had been in Croatia and/or Bosnia for between three and four weeks prior to the data collection, it can be assumed that the first language was increasingly used as a means of communication immediately prior to the data collection.

Nina

Nina is the second generation in Germany. She is in the second grade. Nina's first language is Croatian and the first contact to German was at the beginning of kindergarten at the age of 3. She only speaks Croatian at home, as her parents only speak weak German.

The initial question was posed in German "Was wäre schlauer?" [*What would be smarter*?]. After glancing at the price board, Nina immediately answers in German. She decides that it would make more sense to buy the large portion because it is cheaper in total than the two small portions. When the illustration is uncovered by the teacher, Nina sticks to her conclusion. For her, the price seems to be essential for the decision. Consequently, the remaining question for her is that of a fair-minded way to share that large portion. Nina first explains in German that the large portion can certainly be shared. The teacher then asks whether Nina can also formulate her reasoning in Croatian, to which she replies in the affirmative. Figure 2 presents the corresponding transcript in a synoptic layout, allowing for direct comparison between the German and Croatian versions. To preserve this format, the transcript has been presented as a figure. Reading the transcript keep in mind that the Croatian explanation actually sequentially followed the intuitive German first try.

	German		**Croatian**
1G	Also hier ist ein halber Brot *Well, here's half bread* und hier nicht. *and here not*	1C	Znači ovdje je pola kruha, *Well, here's a half bread,* ovdje nije. *heres´s not.*
2G	Und dann können wir *And then we can* das doch halb machen. *do it half* *(draws a horizontal line through the illustration of the bread with the hand)*	2C	Pa mogu sa mojojm prijatljicom *So I can with my friend* ovako odrezati kruh *cut the bread like that* *(draws a horizontal line through the illustration of the bread with the hand)*
2aG	Und dann ja, ist ja auch praktisch. *And then yes, it's also practical.*	2aC	i onda podijelimo. *and then we share*
3G	Und dann hier ist eins für mich *And then here's one for me* *(draws a line with her hand across the top row of ćevapčići)*	3C	Ovo je za moju prijateljicu - gore *This is for my friend,- on top* *(draws a line with her hand across the top row of ćevapčići)*
4G	und das da alles für meine Freundin *and that there is all for my friend* *(moves her hand back and forth over the bottom row)*	4C	a ovo je za mene dolje *and this is for me on the bottom* *(draws a line with her hand across the bottom row of ćevapčići)*
5G	und das hier, das *and this here, that* *(draws a line with her hand horizontally through the centre of the lemonade illustration)*		
6G	das können wir doch zusammen trinken. *that we can drink together.*	6C	a ovaj sok možemo zajedno piti. *and this juice we can drink together.* *(taps the illustration of the lemonade)*

Figure 2: Transcript Nina

Nina divides the bread in half, arranges the ćevapčići into two rows, and shares the lemonade. While there are many parallels between German and Croatian expressions, some statements are even identical upon closer examination <1G-1C, 3G-4C, 4G-3C, 6G-6C>. Non-verbal actions she uses to reinforce her words are often identical <2G-2C, 3G-3C, 4G-4C). This could lead to the conclusion

that Nina mentally follows the same (narrative) path. After providing an explanation in German, she is now transferring this path into Croatian. The non-verbal actions may indicate that Nina wants to make her argument even clearer. In this way, she achieves relief on a verbal level, but still increases the chance of making her arguments explicit (Fetzer, 2011). On the other hand, however, translating word by word seems to reach its limits in lines 2G and 2C. While in German the verb "halbieren" [*to halve*] is used <2G>, the equivalent technical term in Croatian does not seem to be available, at least in this situation. Instead, Nina seems to paraphrase <2C>. Drawing the horizontal corresponds to the verbalised "halb machen" [*do it half*] <2G>. So here <2C> the non-verbal argumentation relieves her of the need to explain things verbally. These gestures substitute words when she lacks the appropriate term at least here in Croatian.

This case study indicates that the provision of multilingual material and the encouragement to formulate explanations in two languages does not necessarily have an impact on mathematical learning. The reconstruction of the case demonstrates that technical terms in the first language cannot be recalled in some instances. Consequently, a multi-perspective view resulting from different formulations of mathematical facts is precluded. The following example contrasts with the previous one, highlighting excerpts that illustrate the effects of multilingualism on mathematical learning.

Toni

Toni is the second generation in Germany. He is in the fourth grade. Toni's first language is Croatian and the first contact to German was at the beginning of nursery at the age of 1 1/2. He speaks Croatian and German at home. His parents speak German very well.

The first question was posed in Croatian and German "Što bi bilo pametnije (Croatian)? Was wäre schlauer (German)?" [*What would be smarter?*]. Toni first begins to answer in Croatian "Ja bih uzeo veliku porciju i nju popoloiviti, da ja i moj prijatelj…" [I *would take a large portion and halve it so that me and my friend…*]. When the teacher mentions that Toni can also answer in German, Toni immediately completes his answer in German "…dass ich und mein Freund die selbe Portion nur für weniger Geld haben" [*that me and my friend have the same portion for less money*].

A grammatical error seems particularly notable here. In German a hypothetical statement could be formulated as follows: "Ich würde eine große Portion nehmen und sie halbieren" [I *would take a large portion and halve it*]. The German grammatical tense "Konjunktiv II" is here made by combining the verb "würde" [*would*] and the infinitive "nehmen" [*take*] or "halbieren" [*halve]*. The Croatian Grammatical tense "Kondicional I" is made by combining the verb "bih" [would] with the past participle of the main verb "uzeo" [*taken*] or "popolovio" [*halved*]. In Croatian you would not use the infinitive in this context. Toni begins with "Ja bih uzeo veliku porciju" [I would take a large portion] and he uses the past participle of the main verb correctly. In the following coordinate clause, however, he does not follow the grammatical rules of Croatian but those of German by using the infinitive form of the verb „popoloviti" [to *halve*]. On closer analysis, in this sentence he conjugates the everyday context correctly [*I would take*], whereas the technical term [*halve*] is correctly translated in terms of meaning but follows the grammatical rules of German. This may indicate that Toni had first mentally formulated the idea of halving in German and that there was an error in the translation into Croatian. The fact that he ends the sentence much more quickly in German than he

begins it seems to confirm this assumption. Toni's arguments between Croatian and German show a number of parallels, both in verbal and non-verbal action. However, it is worth taking a closer look, especially in cases where a literal translation is not possible (Transcript Toni). For Example, the German "halb so groß(e Portion)" [*half as big (portion)*] cannot be translated into Croatian word by word (see table 1). In Croatian you would say "upola manja porcija". The German term "groß" [*big*] could not be used in the Croatian context. The Croatian adverb "upola" is composed of the terms "u" *[in]* and pola *[half]* and it means figuratively as much as *by half*, so the comparative "manja" [*smaller*] is required here. This linguistic difference becomes a topic of conversation when the teacher explicitly asks whether there is a difference between "halb so groß(e Portion)" and "upola manja (porcija)" <1> The following dialogue emerges (Transcript 1).

Transcript 1

1	Teacher:	Wenn du sagst mala porcija je upola manja od velike? *When you say the small portion is half smaller than the big one?* Gibt´s einen Unterschied zu der Aussage? *Is there a difference to the statement?* Die kleine Portion ist halb so groß wie die große? *The small portion is half as big as the big one?*
2	Student:	Ja *Yes*
3	Teacher:	Gibt´s einen Unterschied? *Is there a difference?*
4	Student:	Ja. Im Kroatischen heißt es ähm ja ähm - ich übersetzte es mal *Yes. In Croatian it says ehm, yes ehm - I'll translate it* diese Portion ist halb so klein als diese hier. *this portion is half as small as this here.*
5	Teacher:	Upola manja. *Half smaller.*
6	Student:	Ja. Und hier heißt es halb - doppelt so groß. *Yes, and here it says half - double (twice) as big.*
7	Teacher:	Und wie heißt es im Deutschen mit der Hälfte? Dieses halb? *And how is it said in German with half? This half?*
8	Student:	Die Hälfte? Das ist die Hälfte von dem. *The half? This is the half of that.*
9	Teacher:	Aber ich kann ja auch sagen, es ist halb so groß. *But I can also say, it is half as big.*
10	Student:	Das ist dann aber ein bisschen verwirrend, weil es ähm, weil es halb? *But that's a bit confusing because it ehm, because it half?* Aber so groß ist. *But it's so big.* Das wäre ein bisschen logischer, wenn es heißen würde halb so klein. *It would be a bit more logical if it said half as small.*

Toni seems to be comparing the language systems of Croatian and German here. He translates from Croatian into German and explicitly stresses that he is translating, indicating that he would not normally say "halb so klein" [*half as small*] in German <4>. Although the teacher asks how it is normally expressed in German, Toni does not use the common phrase "halb so groß" [*half as big*] <4>. Instead, he says "die Hälfte von" [*the half of*] <8>. After the teacher remarks that it can also be formulated "halb so groß" [*half as big*] <9>, Toni does not deny. He employs an interrogative tone to emphasise "weil es ähm, weil es halb?" [*beacause it ehm, because it half?*] <10>, subsequently

continuing with “Aber so groß ist” [*But it´s so big*]. The use of the adjective “groß” [*big*] in the context of the adverb “halb” (*half*) seems inappropriate to him. As a result, Toni finds a way of expressing himself that makes more sense to him. In this context the formulation “halb so klein” [*half as small*] he uses is very uncommon in German. However, the adjective “klein” [*small*] he uses would be perfect in Croatian. A possible explanation is that the differing Croatian and German formulations prompt Toni to reflect on his concept of halving, which assumes a reduction from the initial state. It can be deduced that Toni compares his concept with both language formulations and chooses the one he finds "more logical" <10>. The German phrase “halb so groß” [*half as big*] does not seem to be appropriate in this context, as “groß” [*big*] does not linguistically reflect the “becoming smaller” after halving. For Toni this fact should be reflected in the formulation so that it is also linguistically logical (according to his mathematical concept of halving). From a math didactics perspective, his concept is limited, particularly with negative numbers. Nevertheless, this example highlights the positive impact of multilingualism on math learning. Linguistic differences prompted Toni to question and restructure his understanding of halving. His generalization aligns with his knowledge level and should not be viewed as a step backwards. However, the need to reflect on different formulations and the concept of halving doesn't emerge directly from the original task. This was evident with both Nina and Toni. Toni's reflective thinking at the meta-level only occurs through interaction with the teacher. Specifically, it is the teacher's questions about differences between the German and Croatian formulations that initiates reflection. The learner is introduced to the different formulations by the teacher.

Discussion

This paper analyses the relationship between multilingualism and mathematical learning in primary schools. Theory suggests that multilingual learners have significant potential due to their access to two different language systems. To explore whether learners can benefit from this potential in practice, we designed and implemented a teaching-learning situation that allowed bilingual communication. The results of the pilot study confirm that translations and language comparisons can enable a multi-perspective approach to mathematical concepts (Prediger & Uribe, 2021). Using the example of the concept of halving, it was shown that this is already possible in primary school and can have a positive impact on mathematical learning.

Furthermore, it suggests that examining how the teacher manages the learning process could be particularly revealing. At least for the primary education it seems that this factor plays a more decisive role in helping learners to benefit from their first language than the mere provision of bilingual materials or tasks. The question therefore arises as to whether it is sufficient to sensitise teachers to the linguistic differences between the languages or whether basic knowledge of the different languages is required.

Children’s block play language and the manifestation of mathematical content

Esther Henschen[1] and Martina Teschner[1]

[1]University of Education, Ludwigsburg, Germany; henschen@ph-ludwigsburg.de

This paper explores the mathematical content present in preschool children's block play, focusing on their verbal interactions during play. Starting with Henschen’s (2020) research, the study analyses how children's language and negotiating processes are linked to mathematical concepts, particularly in geometry and aspects of spatial orientation. Using thematic analysis of video data, the study identifies categories related to mathematical content, such as size comparisons, spatial orientation, and geometric shapes. It highlights how children use everyday language to discuss and solve construction problems, revealing their understanding of mathematical relationships. The findings suggest that children's block play language reflects mathematical concepts in a way that facilitates various connections.

Keywords: Mathematical language, block play, geometric concepts, kindergarten.

Introduction

Children's block play can be considered an integral part of preschool educational settings (Ramani et al., 2014). At the same time, the importance of children's building activities for the development of mathematical skills is undisputed, not only with regard to geometric learning (Sarama & Clements, 2009). In this context, the importance of learning geometric concepts through guided play is particularly emphasised. Little attention has so far been paid to analysing children's block play concerning children’s utterances and negotiation processes. Looking at the verbal interactions and negotiation processes seems interesting, considering that language is both a means of communication and a tool for thinking (Vygotskij, 2017) and can therefore provide insight into the (mathematical) thinking of children while block play.

This paper aims to start here. Selected findings from Henschen's (2020) PhD project, in which children's block play was analysed using a thematic analysis, are presented for the first time in an English version and are extended by an interaction analysis in the sense of a mixed-methods idea. Following Henschen (2020), this paper shows how the mathematical content relates to the children's utterances during block play. While the thematic analysis focuses on the manifest content of the children's utterances, the addition of an interaction analysis, as presented in this article, enables the reconstruction of the mathematical meaning that lies behind it. In this way, it is possible to show which of these manifest mathematical contents are meaningful for the children in their negotiation processes.

Mathematical content and language in block play

An examination of different theoretical and empirical contributions shows that with regard to mathematical content, similar aspects are associated with block play. The activities of locating, measuring, and counting mentioned by Bishop (1988) can be used to categorise and classify these aspects, as Henschen (2020) carries out. For this paper, the focus is on locating, which includes

exploring and conceptualising one's spatial environment with, for example, models, words, or other means (Bishop, 1988). Many of the mathematical facets attributed to block play can in this sense be labelled as locating. So, it seems appropriate to differentiate locating into the three aspects of geometric shapes, symmetry, and spatial orientation (Henschen, 2020). Geometric shapes play an important role in children's building activities, as shown in the analyses by Ginsburg and colleagues (2004). Their analyses highlight aspects such as naming and using geometric shapes, as well as composing shapes during building activities. More specifically, they describe a young boy constructing a square based on his knowledge of geometric relationships (Ginsburg et al., 2004). Corresponding to the aspect of symmetry, the work of Fröbel (1851/1967) is interesting. He discussed the creation of aesthetic forms as part of his play gifts, which often involve symmetrical objects that children can further develop by rearranging building blocks in an orderly or symmetrical way. Among other contributions, the work of Seo and Ginsburg (2004) describes and categorises activities such as telling a location or direction under the broader concept of spatial relations. It stands to reason that spatial relations and also spatial orientation play a major role in building, for example, with building blocks.

Henschen (2020) points out that in the description of building activities used for the above classification, the authors focused more on the actions with the building material and less on the children's verbal utterances. In their analyses, Ginsburg et al. (2004) even speak of spontaneous or intuitive mathematics. In contrast, Bryant and colleagues (2024) suggest that one mechanism for how block play influences mathematical learning is mathematical language. Therefore, they focus on mathematical language use during block play. The authors differentiate between six dimensions of spatial language: "1) spatial locations (e.g., top, bottom), 2) deictic terms (e.g., here, there), 3) spatial dimensions (e.g., short, long), 4) spatial features and properties (e.g., curvy, straight), 5) shapes (e.g., circle, square), and 6) spatial orientations and transformations (e.g., turn, rotate)" (Bryant et al., 2024, p. 3). All dimensions are part of the "Spatial and Quantitative Mathematical Coding system" (Bryant et al., 2024, p. 12) developed by the authors as part of their study. Their coding then follows a quantitative approach that is based on the counting of mathematical language terms.

Mathematical content therefore appears to be present in at least two ways in children's block play. On the one hand, children spontaneously or intuitively use mathematical knowledge in their building activities. On the other hand, children use mathematical language terms while building constructions with blocks. What this focus ignores, however, is the importance of language as a means of communication and thinking (Vygotskij, 2017). In relation to block play, it can be stated that language can help children to reflect and make abstractions and communicate mathematical ideas (Bruce et al., 1992). Given these considerations, it is interesting to analyse the verbal interactions in block play situations in relation to their mathematical content. To do so, two levels can be distinguished: On the one hand, the use of certain words and phrases makes mathematical content explicitly visible on a manifest level, while on the other hand, a mathematical meaning may be present on a latent level, which only becomes manifest in the negotiation process between the interactants (Vogler, 2020).

This paper therefore addresses the following question: Which of the mathematical contents that can be described on a manifest level in block play interactions can be interpreted as meaningful in the children's negotiation processes?

Method and methodology

As this article reproduces findings of Henschen (2020), the method used there is briefly summarised here. The data was collected using videography. Small groups of children (usually 2-4 children between the ages of 4 and 6) were filmed playing with the block play materials available in the kindergarten during free play phases without the guidance of an adult and without a given task. This video data was analysed using a thematic analysis (Kuckartz, 2014). The thematic analysis procedure is shown in Figure 1 in the lower part. Firstly, scenes in which the children engaged in a controversial discussion about the building activities were selected and transcribed. These transcripts were used to develop categories that summarised the overarching themes or content-related aspects of building that were evident in the children's statements. The category names were based on the idea of "natural categories" (Kuckartz, 2014, p. 44) in an attempt to stay as close as possible to the children's expressions.

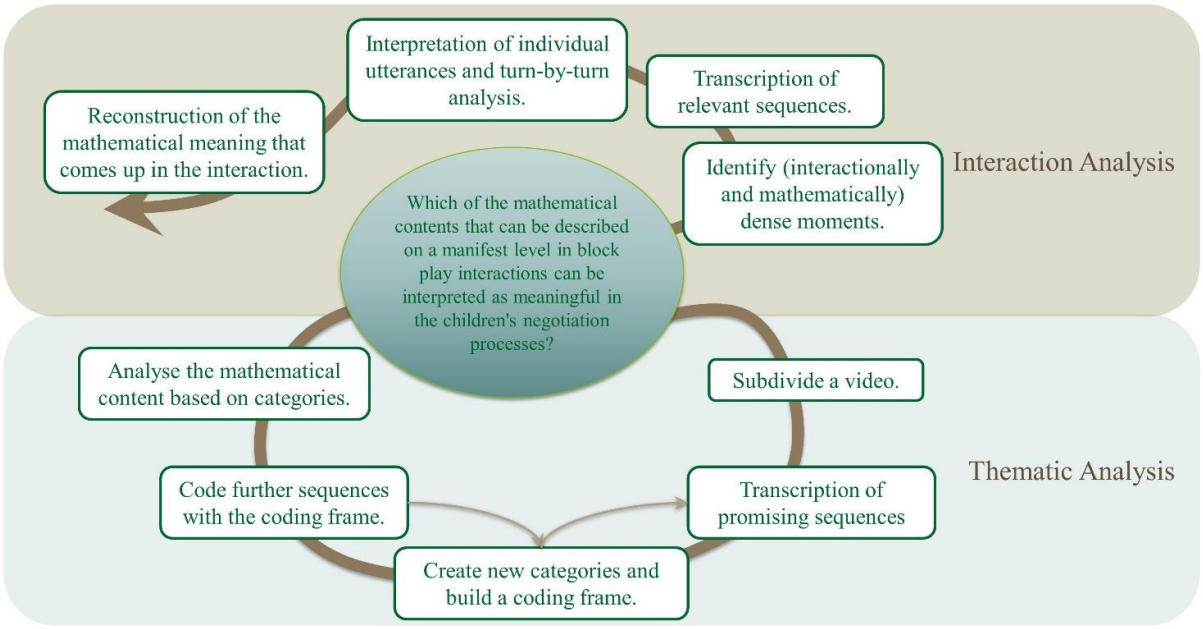

Figure 1: Method of analysis

In the empirical findings, a brief overview of some of the categories developed from the data will be given, and the differentiation and analysis of the (mathematical) content based on categories is shown on the basis of transcripts of two block play situations. These two transcribed block play situations are also adequate sequences for the interaction analysis (Figure 1, upper half), so they are taken as empirical examples for the interaction analysis. Following an interpretative paradigm, a turn-by-turn analysis is conducted to interpret the utterances of the interactants with regard to their interrelatedness (Vogler, 2020). This allows reconstructing which mathematical content appears to be meaningful in the children's negotiation process. The interplay between thematic analysis and interaction analysis

is essential for uncovering how mathematical content, which is outwardly observable, carries meaning for children within the context of their interactions, and for understanding the ways in which this meaning is constructed.

Empirical findings

With the thematic analysis, a total of six categories that can help to describe and systematise mathematical content in children's block play were developed from the data. The categories are small/large, wrong way/right way, slanted/straight, open/closed, fixed/unfixed, and equal/unequal. These categories, which are described in detail in Henschen (2020), are linked to mathematical content in different ways. Based on the scenes that are assigned to each category, various differentiations of content can be analysed and illustrated for each category. This is explained as follows for the categories wrong way/right way, open/closed (Figure 3) and slanted/straight (Figure 5). With thematic analysis it also becomes apparent that the categories and also the facets of each category are interwoven with each other. This is shown below using two empirical examples.

Figure 2: Ladder

Ron:	*points to the bottom end of the ladder*
Max:	da müssen– [we must]
Ron:	mal da ganz runter [all the way down there]
	shows the gap down to the floor (figure 2)
	dann hebts\ gell/ [then it holds\ right/]
Max:	dann müssen wir ganz runter bauen [then we must build all the way down]

With regard to the mathematical content analysed, this interaction can be best described by the following categories: wrong way/right way, open/closed, fixed/unfixed.

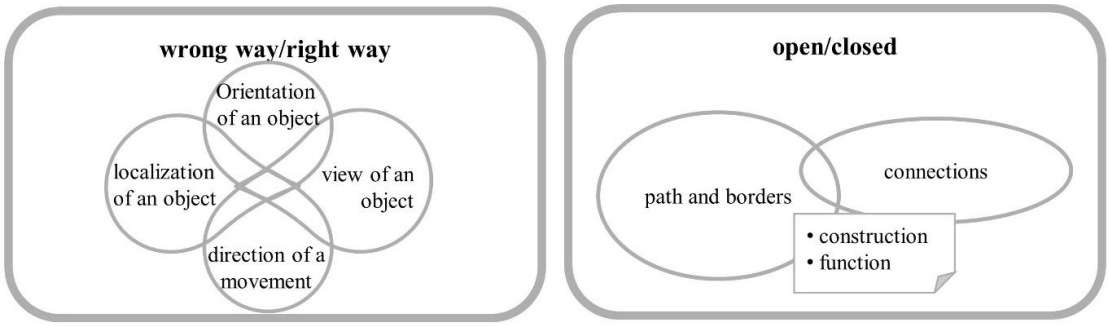

Figure 3: Illustration of the categories wrong way/right way and open/closed

Figure 3 (left side) shows the facets and connections that could be found when differentiating the category wrong way/right way with the thematic analysis. For each of the four illustrated facets, references to certain spatial relationships or concepts could be described on the basis of the children's

interactions. For the two facets of orientation of an object and direction of a movement, this is comprehensible in the above empirical example. The children use terms like “downwards” or “build all the way down,” which, on one hand, refer to the direction of a movement and, on the other hand, describe the orientation of the components that still need to be added.

The category open-closed (Figure 3, right side) references the mathematical topic of topology. As a result of the thematic analysis, a differentiation concerning the construction method and the function of the building emerges. It is, for example, about creating joints between components (connections) or ensuring a path between two locations in the building for imaginary users (path/border). In the empirical example, the statement “build all the way down” illustrates that these two aspects are often intertwined and inseparable. When the focus is on the insertion of a ladder element, it aligns with the concept of making connections. If the focus is on the incomplete connection between the end of the ladder and the floor, it fits the path/borders facet. In this empirical example, the interconnectedness of the two categories, open/closed and wrong way/right way, is striking, as can be seen in Max's statement, “then we must build all the way down”.

To determine which of the contents identified through thematic analysis hold significance in the children's negotiation processes, the empirical example referenced above is examined with a turn-by-turn analysis. In the situation, Ron and Max are building a ladder for their construction. They seem to agree that the ladder needs to be completed down to the ground. Ron first completes the sentence started by Max, “we must”, then Max repeats the whole sentence word for word and adds the verb “build”. This can be interpreted as a taken-as-shared-meaning of the idea “building all the way down”. But why do the children bring this up? Their focus seems to be on stabilising the ladder, “then it holds”. Concerning the mathematical content, it is therefore not necessarily the orientation of the components to be attached that is coming up here, but rather the idea of closing the gap, which leads to a more quantitative consideration in the further course of the block play situation with the question of how much (ladder) is still needed. This suggests that the contents, which are categorised as fixed/unfixed and open/closed, are meaningful for the children in the negotiation process.

The second example illustrated in the following transcript is about a situation in which the children build a construction from building blocks. They name it a corn maze.

Anna:	*places a stone at a right angle to the previous*
	rüber biegen [curve over]
Emma:	*continues the row with a stone straight ahead*
Anna:	rüber [over]
	continues the row with a stone straight ahead, places next stone at a right angle
	dann muss das so abbiegen [then it has to turn like this]
Max:	keine (?) [none]
	continues the row with a stone straight ahead
	so/ [thus]
Anna:	nein [no]
	places a stone at a right angle to the previous
	das muss aber so rüber [but it must turn over like this]
	continues the row with a stone straight ahead
Emma:	*places a stone at a right angle to the previous (figure 4)*
Anna:	warte da (?) so geradeaus [wait there (?) straight ahead like this]

Figure 4: A corn maze

Regarding the analysed mathematical content, this interaction can be well described by the following categories: wrong way/right way, slanted/straight, and open/closed. In relation to the category wrong way/right way (Figure 3, left side), the two facets of orientation of an object and direction of a movement can be identified in this situation. This is shown by the fact that terms such as “curve over”, “turn”, and “straight ahead” are used and corresponding construction actions are carried out that point too the orientation of an object. Simultaneously, these terms serve to indicate the direction of movement, similar to those used in a route description.

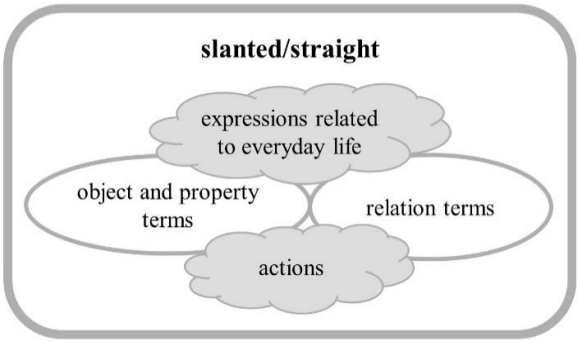

Figure 5: Illustration of the category slanted/straight

With regard to the category slanted/straight, the empirical example shows connections with relation terms. While the addition of blocks in a straight row—geometrically, one could also say at an angle of 180°—is described by the term “straight ahead”, the addition across a corner or perpendicular to the previous block is represented by modelling and pointing as well as by the everyday term “curve over”.

Here, too, it is interesting to reconstruct with turn-by-turn analysis what mathematical content seems to be meaningful in the children's negotiation process. It looks as if Max and Emma mainly carry out actions, i.e., placing bricks, while Anna seems to conduct the collective building process in addition to placing bricks herself. It can be interpreted that in this scene the process of building a (geometric) shape becomes manifest. The obvious mathematical content on the manifest level, which is summarised by the category wrong way/right way, appears meaningful to the children due to the fact that the intended shape enforces a defined arrangement of the building blocks. The fact that creating a certain shape is meaningful for the children in this situation also refers to the category slanted/straight (Figure 5).

Conclusion and Outlook

In both empirical examples, on a manifest level, at first glance, the mathematical content of spatial orientation is evident. In their negotiation processes, however, the children focus on topics that are linked to further mathematical content, such as the gap between the end of the ladder and the floor or the construction of an object in a certain geometric shape. Finally, it can be stated that the mathematical aspects summarised as locating in the theoretical framework and, in particular, the aspects' spatial locations and spatial orientations and transformations from the Spatial Mathematical Coding System of Bryant et al. (2024) can be recognised in the empirical findings presented above.

The diverse links with mathematical concepts and various connections between the mathematical contents and their facets that are evident in the block play interactions and negotiation processes of the children can be seen as a resource. It is evident that children use this resource in their interactions when they solve construction problems together (Vogler et al., 2024). One reason for this could be the effort to achieve an intersubjective understanding of the situation, as can be found among peers in block play (Henschen et al., 2024). For further mathematical learning, also in formal learning contexts, it is a relevant question how professionals can recognise and support this mathematical content, which is still approached with imprecise language by young children.

Semantic profiles in screening 6-year-olds' spatial sense and reasoning in Sweden: The impossible of not being a teacher

Andreas Ebbelind[1] and Sergej Ivanov[1]

[1]Linnaeus University, Växjö, Sweden; sergej.ivanov@lnu.se

This study explores the semantic profiles in teacher-student interactions while screening six-year-olds' spatial sense in a Swedish preschool class. The focus is on an activity where students identify and communicate spatial relationships. Using Legitimation Code Theory (LCT), the study examines changes in semantic gravity and density during interactions and the implications that the resulting semantic profiles entail for the teacher's role. While iterative shifts in the teacher's language use from context-dependent and simplified to decontextualised and highly condensed, known as semantic waves, are crucial for students' understanding and mastery of subject-specific language, these are expected to be absent in screening situations. The findings highlight the complexity of maintaining the role of screening administrator for a teacher, who might find it hard to resist the urge to transform a screening session into a learning opportunity.

Keywords: Early childhood mathematics education, LCT, screening, semantic waves.

Introduction

The foundation for students' academic success is widely acknowledged by the research community to be established at an early age (Reikerås & Dahle, 2022), while the subject content of spatial reasoning is considered a crucial part of students' development of mathematical knowledge (Clements & Sarama, 2011). Spatial reasoning skills facilitate, for example, problem-solving and creative thinking in various situations (Lowrie et al., 2019). In Sweden, six-year-olds attend preschool class, the first year of the formal education system, intended to provide a smooth transition between preschool and school. Teaching six-year-old students should "stimulate pupils' general development and learning" (National Agency for Education, 2022, p. 22), and mathematics is an integral part of the curriculum. The curriculum advocates that teaching six-year-old students should provide opportunities for students to use mathematical concepts and reasoning in contextually relevant situations, which places demands on how teachers engage in mathematical discussions with students.

Teacher interaction with students can be viewed in terms of semantic waves (Maton, 2013), reflecting iterative shifts in the teacher's language use from context-dependent and simplified to decontextualised and highly condensed. These shifts are believed to enable students to gradually master the subject-specific language use that is subsequently emphasised and assessed throughout the educational system. Therefore, examining how teachers introduce six-year-olds to one of the subject-specific language uses in more detail is essential.

To ensure individually tailored teaching and learning practice, preschool class teachers in Sweden have to use screening tools since 2019. One of those tools is entitled *Find the Mathematics* and is used to assess six-year-old's "mathematical thinking" (National Agency for Education, 2019). Its primary objective is to identify students at risk of not meeting the learning outcomes, students needing additional support, and students needing further challenges. The screening is conducted during the

autumn term, marking the beginning of the student's first year in school. It consists of four activities: patterns, number sense, measurement, and spatial sense (see Walla, 2024 for a comprehensive overview). Although the Swedish screening tool is helpful for assessment as well as teaching and learning purposes, it remains unclear to the teachers whether they should assess students' current mathematical knowledge or whether they should assess what the students learn during the screening (Walla, 2024). This might create an equity issue in screening and its results for students' further mathematical development. To follow it up, this paper delves into teacher-student interaction in one of the screening activities, *Playground*, and examines the language used in conducting this activity from the point of view of the semantic waves.

Semantic waves are ideal situations of iterative shifts in the teacher's language use from context-dependent and simplified to decontextualised and highly condensed. To describe those shifts, Maton (2013, pp. 11–12) introduced the notions of *semantic gravity* (the degree of context-dependence of meaning) and *semantic density* (the degree of condensation of meaning). Both semantic gravity (SG) and semantic density (SD) may strengthen and weaken in the ongoing classroom interaction; but a semantic wave only emerges when the language use goes from being decontextualised (SG–) and highly condensed (SD+) to being highly situated in the context (SG+) and simplified (SD–) and then necessarily back. However, strengthening and weakening of semantic gravity and semantic density do not necessarily follow this pattern and may form other *semantic profiles*, for example, a *low semantic flatline* (SG+, SD–) in which language use retains the same degree of high semantic gravity and low semantic density over the observed time (for more detail, see *Theoretical background*).

Given the ambiguity of the screening task and, to our knowledge, the lack of studies that examine semantic profiles of language use in screening situations, there is a need to shed light on how teacher-student interaction unfolds in a screening activity, focusing on six-year-olds spatial sense. Thus, this paper aims to explore semantic profiles in the teacher-student interaction in the activity *Playground,* which is a part of the Swedish screening tool *Find the Mathematics.* To achieve the aim, the following research questions are addressed:

- How does the semantic gravity of interaction between the teacher and six-year-olds change in the screening activity?
- How does the semantic density of interaction between the teacher and six-year-olds change in the screening activity?
- What does the semantic profile of the interaction reveal in regard to the teacher's role in the screening activity?

Since the screening activity, *Playground* is purported to assess six-year-olds' spatial sense, which is how they understand shape, size, position, direction, and movement internally in their minds, we need to turn our attention to *spatial reasoning*. Spatial reasoning, defined by Lowrie et al. (2019), involves spatial sense and how spatial information is represented internally and externally. Finally, spatial reasoning involves interpreting and manipulating spatial information and is comprised of the way six-year-olds communicate the information to others. It is, therefore, reasonable to investigate teacher-student interaction as a whole.

Spatial reasoning concerning six-year-old students

Spatial reasoning is conceptualised as understanding and manipulating spatial relationships between objects or shapes. It involves the mental manipulation and visualisation of objects in two or three dimensions (Duff et al., 2021) and to reason about it with others (Lowrie et al., 2019). Spatial reasoning is a fundamental cognitive skill that helps individuals make sense of the physical world, solve problems, and navigate their environment (Duff et al., 2021). Young students rely on their spatial reasoning skills to complete various daily activities. Whether they perform ordinary tasks like playing on the playground or navigating to school or more mentally demanding tasks like perspective-taking, they rely on their ability to manipulate aspects of their environment mentally.

Further, research has shown that improving spatial reasoning skills in children can support learning achievement (Lowrie et al., 2019). In recent years, the connections between spatial reasoning and mathematics ability have become particularly clear, with classroom research demonstrating that (i) spatial reasoning is straightforward to improve and (ii) improving spatial reasoning skills benefits mathematics outcomes (Lowrie et al., 2019; Mulligan et al., 2020).

In the activity *Playground*, the students are asked to imagine, from a perspective from above, what a girl should see if she stood on the ground, which is further explained in the methodology section. This activity means engaging in a cognitive process that involves mentally manipulating and rotating an object or a mental image of an object to understand how it would appear from different angles or orientations. Since the teacher-student interaction while screening provides insight into students' current level of spatial reasoning skills, there is a need for a linguistic lens to understand interactions.

Theoretical background

In mathematics educational research, there has been a social turn (Lerman, 2009) from viewing learning-as-acquisition to learning-as-participation (Sfard, 2009). In this turn to the social, interest emerged in the linguistic side (Lerman, 2009) of learning-as-participation. One theory that focuses on the linguistic side of teaching and learning, specifically on language use as a means of cumulative knowledge-building, is *Legitimation Code Theory*, *LCT* (Martin & Maton, 2013).

Stemming from Systemic Functional Linguistics, SFL, and code theory, LCT uses novel concepts such as semantic gravity and density (see *Introduction* for definitions), which are also the cornerstone of this paper. Maton (2013) introduced these concepts to enable studying knowledge-building as it unfolds in teaching and learning and pointed out the need that classroom practice "traverse[s] the semantic gap" (p. 14) that arises between students' reading of textbooks and students' high-stakes examination, generally in written form, both of which are full of decontextualised (SG–) and highly condensed (SD+) meanings. According to Maton (2013), successful classroom practice must be characterised by two *semantic shifts* in teacher-student interaction, constituting a semantic wave. First, the condensed meanings from the textbooks are unpacked in simpler ideas and placed in the context to facilitate students' internalisation of the ideas, thus strengthening the semantic gravity (SG+) and weakening the semantic density (SD–), which forms a *downward semantic shift*. An upward semantic shift should follow up on this shift, weakening the semantic gravity (SG–) and

strengthening the semantic density (SD+) so the students learn to master the kind of language use that is expected from them in the high-stakes examinations.

In the current study, which involves a screening activity of six-year-olds, there are at least two core inherent properties of the situation that are likely to impact the semantic profile of teacher-student interaction. The first one is related to the screening situation. Screening per se is not meant to develop students' knowledge but rather to assess their present mathematical knowledge level, which is hypothesised to require the teacher's language use to reveal a low flat semantic profile (i.e., SG+, SD–) and to be responsive to the students' language use. In other words, ideally, the teacher's language use is expected to retain the same semantic gravity and density throughout the screening, and at times it might mirror the students' language use if required by the communicative situation. The second inherent property is related to the age of the students. Given that LCT was initially developed to highlight cumulative knowledge-building in secondary schooling, the rationale behind what might be categorised as a highly condensed meaning (SD+) and simplified meaning (SD–) must be adjusted to fit the language use of the targeted age. These issues of language use and its semantic profiles are also related to students' spatial sense and spatial reasoning, which is addressed in the following methodological section.

Methodology

This section describes the screening activity *Playground* through a narrative example of its conduct. It includes data collection, ethical considerations, and data analysis.

Data collection

At the end of the autumn term in December 2022, a female teacher conducted the screening activity *Playground* with three groups of six-year-olds on three consecutive occasions on the same day. Each group consisted of 4 students with the gender distribution of 7 females and 5 males. The screening sessions lasted 20–26 minutes and were video-recorded.

In the initial phase of the activity, the students were instructed to solve a problem in a group and share their thoughts. The teacher showed the students a large picture of the playground and highlighted that it was drawn from a bird's-eye view (see *Figure 1*). The exact wording of the teacher cue was: "Imagine that you are flying above the playground and looking down. It would look like this. What do you see in the picture?" The teacher then proceeded to ensure that all students understood what the picture showed. In the next phase of the activity, the teacher took out the first of six picture cards showing what a girl could see in the playground and asked: "If the girl sees this [showing *Figure 2*] when she looks forward, where is she in the playground? You will have to show where she is on the large picture. Now, take a moment to think for yourself before you talk to each other." In the subsequent phase of the screening activity, the students were prompted to answer the following questions: "Why did you choose that spot? What can the girl see? How do you know that? Can the girl see the boy? Why/why not? Is there anything visible on the picture card that is not seen in the large picture?" The procedure was then repeated for the remaining five picture cards. In the final phase of the activity, the teacher asked questions about the seasons of the year. This phase was excluded from the scope of this paper since it did not concern six-year-olds' spatial reasoning.

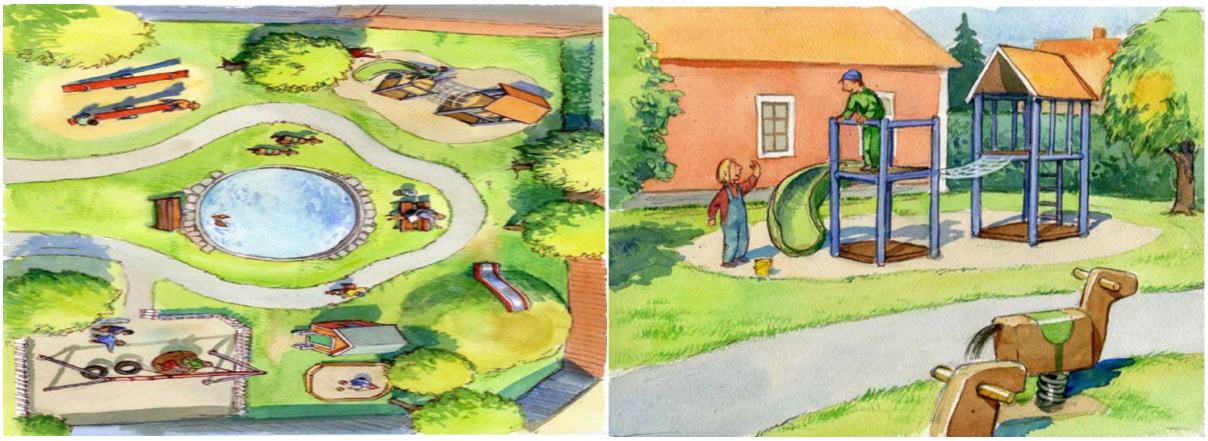

Figure 1 (left). The map of the playground; Figure 2 (right). An example of a picture card (National Agency for Education, 2019)

Ethical considerations

Before the screening activity, the students' informed consent to participation was obtained orally, while the guardians' and teacher's consent was obtained in writing. The participants were also informed that they could withdraw their consent at any time without prejudice. The students were given pseudonyms in the paper to ensure their anonymity and confidentiality. The collected data are handled through secure storage at Linnaeus University's servers, which adhere to GDPR. As such, the study conforms to the ethical regulations for research in Sweden.

Data analysis

To facilitate data analysis, the video-recorded screening sessions were uploaded to NVivo (software for conducting qualitative data analysis) and transcribed verbatim with additional information, such as gestures in the videos or omissions/modifications in the transcript, provided in square brackets. NVivo was used to analyse the video and the transcript using the codes described below. The coding continued until data saturation was achieved (Saunders et al., 2018), which occurred after ten minutes, indicating that any new data began to repeat what had already been found in the previous data.

In our coding, we used the existing codes (SD–, SD+, SG–, SG+) and introduced two new codes (SD0 and SG0); all the codes were used separately for teacher and student utterances. Introducing the new codes was necessary to capture small changes in semantic density and semantic gravity that were typical of the language used in the teacher-student interaction in the given age group. For example, an utterance was coded as SD– when only the placement of an object was expressed, while a longer utterance describing the placement of an object in relation to other objects was coded as SD0. These codes are illustrated in the following extracts: "That one… that and [pointing at the picture]" (SD–) and "The climbing frame, right, and where is it in the playground?" (SD0). Code SD+ was assigned to an utterance which, in addition to expressing the relation of an object to other objects, was also concise, thus bearing highly condensed meaning as illustrated in bold in the following: "No, because she is standing **backwards** [...] so she cannot see the sandpit".

Concerning semantic gravity, codes SG– and SG+ were assigned to the following: “Then if we see some different things that might not be visible on the big picture…” (SG–) and “[pointing at the picture]. They are very big and close...” (SG+). Code SG0 was used to categorise teacher questions when she invited another student to develop or disagree with the previous student, thus making the degree of contextualisation open to interpretation as illustrated: “Yes, what do you think, Roger?”

Results

As hypothesised, SG+ and SD– were the most frequent codes in the teacher's utterances (approximately 57 % and 71 % of all teacher codes for semantic gravity and density respectively). This suggests that the teacher strived to keep a low flat semantic profile of her language use and to assume the role of screening administrator. However, the data also revealed patterns in the teacher-student interaction, which highlighted the complexity of the task.

In a significant part of the coded screening activity (83 %), the teacher’s language use followed a mirroring pattern, that is the teacher’s subsequent utterance maintained the same degree of semantic gravity and density as the previous student’s utterance. This is illustrated in the extract below (codes are provided in the brackets).

Roger:	That one... that [points at the card]? (SG+, SD–)
Teacher:	You were thinking about that... why don't you see those two then... in this picture? (SG+, SD–)
Alva:	Because it's far away... (SG+, SD0)
Teacher:	Far away... because it's outside the picture here or this map or whatever we should call it. (SG+, SD0)

In the exchange with Roger, the mirroring was in line with the expected semantic profile (SG+, SD–), while in her mirroring follow-up of Alva’s utterance, the teacher adjusted semantic density to SD0.

The analysis of changes in semantic profiles demonstrated that semantic density fluctuated as the teacher-student interaction unfolded, as shown in the extract below.

Anton:	Windows... windows on the house. (SG+, SD–)
Teacher:	Yes, exactly... why don't we see that in the picture then? (SG+, SD–)
Anton:	Because it's from above, and that one is from the side, so we can't see it. (SG+, SD+)
Teacher:	So you can't see this one... yes... (SG+, SD–)

In this exchange Anton's language use indicates strengthening of semantic density (SD– to SD+) from one utterance to another, while the teacher language use displays the low flat semantic profile. Notably, in this case, the teacher did not mirror Anton’s strengthened semantic density and remained in the role of screening administrator, thus diminishing the risk of her impact on the other six-year-olds' language use.

However, there are a few instances in the coded data when the teacher deviated from her role as screening administrator and assumed the teacher role. One such instance is evident in the extract below.

Teacher:	OK, that's why she [the girl] stands a bit to the side. You can see the edge of the sand around the seesaw. Did you think about that? [hesitating] (SG+, SD0)
Teacher:	What do you think, Roger, or did you raise your hand? (SG0, SD–) [...]
Roger:	There... it is a bit closer. (SG+, SD–)

Teacher: Yes, but I was thinking about which direction she is looking at. Yeah... but I understand what you mean. Do you think like that, don't you? (SG0, SD0)
Roger: Yes.
Teacher: Yeah... but it's roughly the same place, and I think that fits quite well. Because then she sees... she's close to the seesaw, but she sees the other things even though they're a bit farther away. Is there something we can see that she sees here that we can't see on... on the overview map... like... [turning to] Olivia. (SG+, SD0)

In the first utterance the teacher simply mirrored the previous students' utterance (SG+, SD0) and then invited another student, Roger, to contribute (SG0, SD–). Roger appeared to immediately contextualise the meaning, thus strengthening the semantic gravity (SG+, SD–). However, the next two teacher utterances were characterised by strengthening of semantic density of the interaction (SD– to SD0) as she deviated from her role as screening administrator and assumed the teacher role.

Discussion

When looking at the semantic profiles of the interaction and what they reveal concerning the teacher's role in the screening activity, we can conclude that though it is not the aim of the situation, students explore their shared knowledge and create learning opportunities. As such, the teacher has a complex task in sustaining the role of screening administrator. While the teacher in this study mainly keeps the low semantic profile to assess six-year-olds' understanding and does not engage in teaching when learning opportunities arise, some sections show complexity, as presented in the result. The deviation from the low semantic profile is sometimes evident in (1) mirroring when the teacher is likely to conform to Grice's (1989) maxim of relation of efficient communication; (2) situations when she cannot resist the urge to transform a screening session into a learning opportunity thus assuming the teacher role. Therefore, it remains unclear whether teachers assess students' current mathematical knowledge or whether they assess what the students discern and learn during the screening. For students at risk, this means that they might fly under the radar and be deprived of adequate support at an early stage, which is precarious not only for honing their spatial reasoning skills but also for overall school success.

Investigating pre-service mathematics teachers' requests for information in one-to-one tutoring

Sara Julsgård

Linköping University, Department of Mathematics, Linköping, Sweden; sara.julsgard@liu.se

This paper reports on a study of the requests for information posed by pre-service teachers practicing one-to-one tutoring of university preparatory mathematics students. The objective was to capture the topics of requests and pre-service teachers' stated rationales for posing them. Data was collected using audio recordings of one-to-one tutoring in a whole class lesson setting along with individual interviews, and analysed using inductive and deductive coding. The findings reveal requests centred on the task, mathematics, the student's knowledge or experiences, and the textbook. Rationales behind requests include orientation of the student's knowledge, encouragement of recalling prior knowledge, and guidance of delimited procedures. This study offers a topic perspective on teacher-student talk and provides additional insight into this complex yet important practice.

Keywords: Classroom communication, preservice teachers, tutoring, questioning techniques.

Introduction

It is acknowledged from decades of research that teacher-student talk has a significant influence on students' mathematical learning outcomes (Brodie, 2011). However, pre-service teachers are faced with challenges when learning how to communicate effectively in the mathematics classroom. This has been exemplified by Gaspard and Gainsburg (2020), with results showing discrepancies between pre-service teachers' knowledge about successful questioning practices and their performed practices. To develop pre-service mathematics teachers' skills in classroom interaction, it is important to study their practice of and rationales for requesting student input in mathematics teaching.

Mathematics teachers' verbal communication has largely been studied in whole class settings. This study is an attempt to extend this knowledge base of teacher-student interaction to one-to-one tutoring conversations. These conversations are particularly interesting for interaction and communication research in mathematics education, since they are usually initiated by the student, whose issue frame the conversation. Additionally, unlike whole-class teaching, teachers cannot plan as much for what to say or how to lead the conversation forward. This makes the rationale behind the teacher's communicative moves an interesting object of study, which this paper seeks to address.

In various ways, mathematics education research has identified and classified teachers' requesting information from students in classroom conversations (Boaler & Brodie, 2004; Drageset, 2014; Mehan, 1979; Nathan & Kim, 2009; Sinclair & Coulthard, 1975). These studies have produced knowledge about the structure of question-response interactions, the usage of "higher order" versus "lower order" questions, and the various ways by which teachers ask for student input in classroom conversation. However, one question remains, that is, what are the teachers asking about? This study attempts to contribute to efforts toward a more comprehensive understanding of teacher-student communication in mathematics classrooms by addressing this issue.

The aim of this study is therefore to investigate pre-service teachers' (PSTs') requests for information in mathematics one-to-one tutoring in a way that reveals topics of the requests and rationales behind them. Hence, the study is guided by the following research questions:

RQ1: What do PSTs request information about during one-to-one tutoring in mathematics?

RQ2: What rationales do PSTs provide for their use of requests for information from students?

Background

Seminal literature on classroom discourse (Mehan, 1979; Sinclair & Coulthard, 1975) made an extensive work in classifying the structure of classroom talk between teacher and students. Sinclair and Coulthard (1975) identified three major speech acts performed by the teacher in the classroom: *elicitation* (request of linguistic response, realised by a question), *directive* (request of non-linguistic response) and *informative* (give information or opinion). In later work, Nathan and Kim (2009) added to the elicitation category by also including pauses and provocative statements made by the teacher. The present paper is limited to the study of requests for information. This demarcation includes more requests than the syntactic questions of Sinclair and Coulthard's (1975) elicitation category, while excluding other, more subtle, ways of inviting students to participate in the conversation.

The notion of speech *acts* used by both Mehan (1979) and Sinclair and Coulthard (1975) reveals the assumption that *saying something means doing something*. An act is defined as the smallest unit of analysis of discourse, and may be described as the functional equivalent to the grammatical clause (Mehan, 1979; Sinclair & Coulthard, 1975). Seeking to identify PTSs' requesting in tutoring conversations, the same basic assumption is essential to this paper. One or several acts are made within a *turn*, which Mehan (1979) defines as the period in a conversation during which a single teacher or student speaks, before giving the word to or being interrupted by someone else.

Previous literature on requests, elicitations or questions posed by the teacher in mathematics teaching have resulted in various classification systems. In a literature review of research on mathematics teachers' use of questions, DeJarnette et al. (2020) conclude that classifications are often based on what type of responses the different questions elicit. One common approach is to classify questions by the cognitive demand they place on students for responding, ranging from lower to higher order (e.g. Nathan & Kim, 2009). The same approach has been used when analysing the questioning practices of PSTs in one-to-one mathematics tutoring (e.g., DeJarnette & Hord, 2022; Kilic, 2018). These studies have shown that PSTs usually use lower order questioning that requires short answers, but also that participation in training related to posing mathematical questions can increase the usage of higher order questions. There are also studies identifying teacher questions according to intentions with asking them, as interpreted by the researcher (e.g. Boaler & Brodie, 2004; Drageset, 2014). As a third approach, Gaspard and Gainsburg (2020) classified PSTs' questions in whole class teaching into the main categories predictable and unpredictable questions, referring to if the response anticipated from the students was predictable by the PST or not. The authors also interviewed the PSTs for their rationales for asking different kinds of questions over time. Results include an increasing avoidance of unpredictable questions motivated by their invocation of negative reactions among the students (Gaspard & Gainsburg, 2020).

The current study does not attempt to classify requests according to the cognitive demands placed on students when answering them, the teacher's intention with asking them (as interpreted by the researcher), or whether or not the answer is predictable by the teacher. Instead, the aim is to describe the topics of the requests, along with rationales for posing them as stated by the PSTs. The way in which the study was conducted in order to achieve this aim is outlined in the following section.

Method

Four PSTs in their third or fourth year of study were invited and accepted to assist 35 students enrolled in university preparatory courses during two mathematics lessons. Individual interviews with the PSTs were held after each lesson. Both PSTs and students received written and oral information about the study, and written consent was obtained. Data collection and analysis in response to each research question was conducted in two separate stages, and hence are presented separately below.

To address RQ1, audio recordings of one-to-one tutoring conversations were collected and thereafter analysed using inductive coding. In this paper, one-to-one tutoring (tutoring for short) refers to in-class personalised teaching occurring in a conversation including one tutor and one or a few students. The tutoring conversation aims to guide the student(s) towards understanding of the mathematical content and solution of specific textbook problems. During the lessons in the current study, the students were supposed to work individually or in pairs on tasks from their mathematics textbook. The subject matter of the two lessons were integrals and trigonometry, respectively. However, students also worked on tasks concerning functions, logarithms, equation solving, and differentiation.

The audio recordings were transcribed verbatim. All participants were anonymized in conjunction with the transcription process, assigned pseudonyms (PSTs) or numbers (students). Transcription served as the first phase of analysis, familiarising the researcher with the material, while the subsequent step identified the requests. In each conversation, the PST's verbal contributions were examined. The objective was to identify turns or sub-turns constituting acts of information request. This study uses the concept of turn similarly to Mehan (1979), and acts similarly to Sinclair and Coulthard (1975). Moreover, this study considers request for information to be those acts made by the PST where he or she, in the syntax form of a question or not, asks for student input. The input is requested to be informative, not confirmative, and a linguistic response is expected. Table 1 illustrates the process of identification of information requests. These acts might often appear as questions, but not always – and not all questions were identified as requests for information. Excluded acts were confirmations, directives, explanations, corrections, encouragements, and "hidden telling" (e.g. explanations ending with "right?", or "isn't it?", requesting a confirmation from the student). This first identification yielded 173 PST requests relevant to this study.

Aiming to capture the topic of each request, the third phase of analysis used inductive coding (Braun & Clarke, 2006), focusing on *what* the request centred on, and is illustrated in Table 1. During coding, the context of each request was considered, e.g. the problem the student was working on or the most recent talk. When necessary, the audio files supplemented transcription to facilitate the analysis, providing important information on verbal emphases. Thereafter, codes were formed into broader categories, considering similarities and differences across codes.

Table 1: Illustration of identification and coding of requests for information

Turn	David: *And that equals…? Yes! And, have you used the pq-formula before?*		
Identification of requests	*And that equals…?*	*Yes!*	*And, have you used the pq-formula before?*
	Request 1	Not request	Request 2
Code (topic of request)	What it equals	-	The student's prior experiences

In the one turn presented in Table 1, David performs two different requests with a confirmation in between. The question marks added during transcription, as well as the actual words being pronounced by the PST, provided guidance in the process of identifying requests for information. The confirmation ("Yes!") in the middle of the turn, acknowledging the student's writing in their notebook, along with a brief look at the content of the requesting parts of the turn informed the division of it into two different requests for information. The first request takes the form of an incomplete sentence ending with a raise in intonation, which asks for the result of a multiplication. This information was provided by the context of this turn, i.e. the teacher and student talk preceding this one. This context, along with the explicit use of the word "equals", motivated the code *what it equals*. In the end of the turn, the PST asks for information about the student's possible prior usage of a certain formula. This was coded as requesting information about *the student's prior experiences*.

In order to answer RQ2 and gain insight into the PSTs' rationale behind requests for information in mathematics tutoring, individual interviews were conducted immediately after the lessons. These audio recorded interviews focused on the PST's thoughts on, approaches to, and strategies in one-to-one tutoring. Conducted semi-structurally (Kallio et al., 2016), the PST was first asked to share their recent experience of tutoring in the recorded lessons. Following this, the main question of the interview was "In general, how do you think when you are tutoring students in mathematics?". Further questions varied based on each PST's responses, including examples like "How do you decide when to ask questions and when to show a procedure?", "How do you adjust your communication to individual students?" and "What difference do you think it makes between asking a question you know the answer to and one you don't?".

The interviews were transcribed verbatim and thereafter analysed by identifying parts where the PSTs talked about requests for information in tutoring. This analysis was conducted deductively, based on the codes and categories found in response to RQ1, presented in the result section. Relevant parts of the interview, often constituting PST reasoning in a few sentences, were assigned a suitable category from the RQ1 results. Next, a description of the rationales for each request category was produced, and representative examples were identified. Categories of requests and rationales for them will be presented and exemplified in the following section.

Results

The findings of this study are presented in relation to the two research questions respectively.

RQ1: What do PSTs request information about during one-to-one tutoring in mathematics?

The analysis revealed four categories of information that the PSTs requested during one-to-one tutoring, centring on different elements of the tutoring situation. The requests were task-centred (n = 24), mathematics-centred (n = 90), student-centred (n = 43) and textbook-centred (n = 16). The first two categories were found in tutoring conversations of all four of the PSTs, whilst the two latter were found among three out of four PSTs.

Task-centred requests concern task information and the student's work or thoughts on the task that is currently being worked on. The PSTs ask for what is known or what to seek in the specific task. When requesting information about the student's work or thoughts on the task, the PSTs ask for a description of the work performed by the student so far or how the student think it is appropriate to move forward in the solution. A generic example of this category is "What have you done so far [on the task]?".

Mathematics-centred requests are broader in terms of application compared to the requests centred on the task. They often stem from a task being worked on at the moment but focus on mathematics in general. The PSTs ask for concept explanations, procedure steps, or mathematical relationships. The straightforward question of "what it equals" is frequent in this category. Examples are

Christopher: I know we're supposed to take e to the power of ln 3, and what do I mean by 'to the power of'?

Bella: And what value does it equal then? If we put in 90 degrees?

David: When can the Pythagorean theorem be used?

In the first example, Christopher pauses his explanation of procedure to direct the student's focus to the concept of "to the power of". He requests general rather than task specific information about the meaning of this concept, from the student. The same goes for Bella's request on the value of sin 90° and David who asks for a general prerequisite for using the Pythagorean theorem.

The third category, *student-centred requests*, ask for information about the student in relation to the mathematical context. These requests concern the student's feeling or opinion about a certain solution ("Do you find it weird?" - Christopher), as well as questions explicitly asking if the student understands. Other requests in this category concern the student's work on other tasks, like questions on if, or how, the student has solved problems the PST considers relevant to the one at hand. There are also requests belonging to this category in which the PST asks explicitly for student's prior knowledge or if the student recognises something being shown or told. Some examples are

Annie: Do you recognize this from school?

Christopher: What do you know about calculating the area of a surface?

Requests in this category centres on the student while still asking about mathematics. This emphasis on the student can often be detected by the formulation of "do *you*"/"did *you*" in the request, and distinguishes student-centred requests from the mathematics-centred ones. In mathematics-centred

requests, the request is also directed to the student, which is the one expected to produce a response, but it is the mathematics that is at the centre of the request.

The fourth and last category of requests is *textbook-centred requests*, focusing on the textbook used during the lesson. The PSTs ask for where they find formulas in the book or what the book's solution key says for correct answer. This is exemplified by David below.

David: How did they [the authors of the book] do in the answer?

The use of "they" as referring to the authors of the textbook makes this example textbook-centred.

RQ2: What rationales do PSTs provide for their use of requests for information from students?

In the interviews, the PSTs offered several reasons for the requests being posed during the lesson. Here, those rationales will be presented in relation to the four categories of requests for information.

Task-centred requests were used by all four of the PSTs. Annie, Bella and David all motivate this kind of request being posed in the beginning of the conversation as a way of finding out what kind of assistance the student needs. Asking for what is known or what to seek in a certain mathematics task is described by Bella as a kind of summarising in order to progress on the task.

Bella: I don't like to give them the answer, I'd like to make them think for themselves. And to summarise what we've got, what the task description tells you, and what you know yourself.

In this example, "what we've got" and what the text in the task tells you are information provided by the textbook but requested from the student by Bella. Similarly, David describes how he could proceed from the information gained from task-centred requests by asking the student about a mathematical procedure. This refers to a *mathematics-centred requests*, which were identified among all four of the PSTs. David calls the guidance of a limited procedure a "smaller issue" to face, compared with if the student does not know how to approach the task at all.

The third category of requests, *student-centred*, was used by Annie, Christopher and David. Christopher puts a lot of thought into how he requests and gains information on students' knowledge. In the interview he talks about how he prefers to let the students tell what they know from before.

Christopher: Because they often wonder, I mean, they don't know what they don't know. And if you can find out what they don't know, there's no need to help them all the way.

Christopher describes that when he asks about students' prior knowledge, he tries to avoid questions he already knows the answer to. For example, he would rather ask "What do you know about ln?" (student-centred request) than "What does ln e equal?" (mathematics-centred request). He says that he tries to steer the conversation towards their knowledge, posing a request for which the answer lies in the power of the student. This is rationalised on the basis that there is no clear right or wrong in the student's answer "nothing" to the question of "What do you know about ln?", but that it does provide the PST with information about the student's prior knowledge. Another reflection concerns the closely related matter of the type of requests for which Christopher himself knows the answer to.

Christopher: Why would I ask for something I know the answer to myself? You would never do that otherwise. And it's like, well the teacher has all the answers.

Textbook-centred requests were used by Bella, Christopher and David. In his interview, David refers to the book as a helping hand when he's unsure of something and afraid to admit it to the student. He states that he finds it easier to say he does not remember the formula and look it up in the textbook than to say he doesn't know how to solve the problem.

Discussion

The findings of this study consist of categories of requests for information posed by PSTs in mathematics tutoring, as well as PSTs stated reasons for requesting that information. In summary, the PSTs' requests are centred on the *task*, on *mathematics*, on the *student* and on the *textbook*. Rationales for different kinds of requests include mapping of the student's former work or knowledge, encouragement of the student's independent thinking in place of teacher telling, and provision of guidance for oneself. Categories were formed based on the topic of the request, providing additional insight into classroom interaction in the context of one-to-one tutoring. Along with the description of rationales behind requests, this paper contributes to our understanding of mathematics teachers' questioning by nuancing as well as explaining the topics of the requests being posed.

The categories of requests were found to be unevenly distributed, with mathematics-centred requests being the most prominent (n = 90) and textbook-centred requests the least (n = 16). Considering one rationale for textbook-centred requests being mathematical uncertainty of the PST, this result is not surprising. The findings on rationales for requests relate to previous literature in several ways. For example, Christopher condemns questions that he knows the answer to, such as closed questions asking for mathematical facts. These kinds of questions reflect Gaspard and Gainsburg's (2020) notion of predictable questions. The interview transcripts show how Christopher's rationales for asking student-centred questions instead of mathematics-centred questions builds upon a view of predictable questions as something artificial, while the PSTs in Gaspard and Gainsburg (2020) rationalise the use of predictable questions by reactions from students they have taught. However, DeJarnette et al. (2020) state that teachers often ask questions with a specific response in mind. With data on PSTs' rationales for requesting certain types of information from students, it seems close at hand to compare those to the intention-based classification systems of Boaler and Brodie (2004) and Drageset (2014). In a future study, the relation between rationales behind requests in this type of study and the categories from previous mentioned literature could be analysed.

Regarding data collection methods, the interview was chosen for answering RQ2 on PSTs' rationales behind requests because understanding the rationale behind actions requires asking the actors themselves. Since the interviewer had not yet accessed the audio recordings or conducted an analysis, preparing specific questions about the requests actually posed during tutoring was not possible. This limitation might have reduced the number of rationales identified for each category. However, the narrow time gap between lesson and interview is a strength as it ensures fresh recall of the experience.

The recorded lessons constituted a real-world setting for the students considering teaching method, textbook, and tasks used. What differed was that in addition to the students' ordinary teacher, PSTs participated as tutors, meeting the students for the first time. The PSTs had limited prior knowledge of the students' mathematical performance, requiring them to gather essential information during these lessons. This means that the information that the PSTs considered necessary for one-to-one

tutoring is included in the collected dataset and therefore accessible for study. In addition to the findings on requests for information, however, future studies using a similar approach could address teacher acts of giving information to or requesting action from the students.

Linguistic demands and more: A framework for analysing mathematics lessons

We present a framework developed as a tool for analysing rich episodes of mathematics lessons in ways that reflect this richness rather than summarise it through coding. Our project supports language-responsive teaching. This framework was developed to address our concerns that through code-based analysis of lessons we were losing too much of the complexity, particularly relating to mathematical connections and aspects of the interactional context that build, evolve, and adapt during an episode, task or lesson. The framework involves identifying structure within lesson episodes, based on shifts in mathematical focus, and analysing how key dimensions of language-responsive mathematics teaching are at work within this structure. We draw on data from one analysed lesson episode to illustrate the use and potential of the framework, but also to underscore some of the challenges and reflections that the framework has brought to our work within the project.

Keywords: Language-responsive teaching, mathematics classroom discourse, noticing.

Introduction

In 2022, in the context of a broader team including secondary-school mathematics teachers and other researchers and teacher educators, we started a project aimed at examining and discussing language-responsive ways of developing mathematics teaching. We have faced several challenges since then, one of which has been the thinking and use of a framework that allowed us to "see" and investigate some of the features of the mathematics lessons conducted by the teachers engaged in the developmental activities of the project. Videotaped lesson data is always incredibly rich in many respects and decisions need to be made for the prioritisation and analysis of some features over others. Decisions such as splitting up lessons for the analysis and how to do the splitting, for example, are not trivial. As posed by Adler (2017): "A major task for any lesson analysis is how to chunk or divide the lesson into analytic units." (p. 130). Classroom research in mathematics education with a focus on language and communication has provided a range of alternatives for breaking down lessons. Adler (2017) suggests identifying the object of learning and creating related episodes; O'Halloran (2004) interprets mathematics lessons as sequences of curricular content microgenres; and Clarke (2001) proposes the structure consisting of *Lesson*, *Activity*, *Episodes*, *Negotiative event*, *Turn and Utterances.* What comes from the study of the lesson data can be hard to put together again to produce some understanding of how the teaching and learning developed, and more so if the criteria for chunking the lessons and analysing each separate lesson piece are not consistently shared and applied.

In this paper we present a framework that was elaborated as a tool for the analysis of mathematics lessons with experienced teachers and learners of diverse linguistic repertoires. Support for these teachers was planned through participation in a professional development program on language-responsive mathematics teaching, which involved the collaborative design of mathematical tasks on

linear equations, angle properties and probability and the discussion of instances of teaching moves, amongst other key moments of practice. We draw on data from one of the videoed lessons to illustrate the use and potential of the framework, but also to underscore some of the challenges and reflections that the framework has brought to our work within the project.

Background

The authors are members of a research team working on the above-mentioned project on mathematics teaching in linguistically diverse classrooms in England, aiming to support language, communication and mathematics together (for further details of the project see Ingram and Lee, 2023). We view language and communication in mathematics lessons as consisting of words, images, diagrams, and other ways of communicating about mathematical objects, ideas, and practices. As described in Ingram et al. (2024), members of the team have experience with diverse interpretive approaches for researching language and communication in mathematics classrooms, including ethnomethodology, sociocultural theory and systemic functional linguistics. Our collaboration is mediated by this range of theoretical approaches and the belief that the understanding of lesson data can benefit from the adoption of a complementary perspective.

Design of the framework

Our intention was to develop a framework for analysing rich episodes of mathematics lessons that we have identified in our project data, in ways that reflect this richness rather than summarise it through coding. The framework we present (see Figure 2 for an example in use) was developed by the project team. It aims to provide a structure to support analysis of lesson discourse within lesson episodes for the purposes of following the mathematical story of the lesson. We identify episodes as sections of a lesson involving one type of activity in work on a task, e.g., a discussion or students working on a task. The framework uses as a unit of analysis the sub-parts of such an episode, which we call *stanzas*. A stanza could be as small as an utterance or span several minutes of a lesson. We recognise changes between stanzas as a shift in focus, as agreed by more than one member of the team, and adopted the term *stanza* because it has resonances of a smaller part of a whole and having a particular focus.

We name stanzas (column 1, Figure 2) by what we identify as the theme of the interaction in the stanza and give a qualitative characterisation of the mathematics in focus (column 2). Our intention for these columns is to help keep the mathematics foregrounded: how the interaction relates to this mathematics and how this relates to the story of the whole episode. This includes how the teacher or students return to a focus, for example in a developing argument, which we propose to indicate by overlaying arrows on the completed table. The four remaining columns involve analysis of key dimensions of language-responsive teaching (see below), which are a focus of the wider project. These four dimensions were developed by the project team based on prior work identifying design principles and teacher moves that enhance language for mathematics learning (Erath et al., 2021).

Our analysis of lesson episodes focuses on what we noticed during the stanzas, where what we notice individually is influenced both by the theoretical background we each work with and by the noticing of others in the analysis discussions, and may draw on one or more of these dimensions of language-responsive teaching. By focusing on what we noticed in the stanzas in relation to these dimensions, we aim to develop our understanding of the nature of language in classroom discourse and its role in students' learning.

Dimension 1: Linguistic demands of the mathematics. This dimension draws attention to linguistic demands by noting the language teachers or students say or write in relation to key concepts of the lesson, as this reflects the opportunities students have to hear, read, write or speak this language and how language use is modelled (Prediger, 2019). For example, choosing to name or label objects, relationships or processes can support communication about these and can emphasise their importance. Furthermore, choices of names or labels can foreground certain meanings in a particular context (Mason, 2002).

Dimension 2: Student reasoning, explanations and argumentation. Reasoning, explanations and argumentation in mathematics have distinctive features that differ from everyday language or other subjects (Erath et al., 2021; Schleppegrell, 2007). This dimension captures students' explanations, how they share their reasoning or build arguments, and what aspects of these are focused on, developed or evaluated. We note here that explanations or arguments that draw false conclusions may nonetheless contain mathematical features, such as conjectures, connections to previous mathematical tasks or use of mathematical language.

Dimension 3: Listening and feedback. This dimension includes how feedback on explanations draws attention to the mathematics, offers opportunities for students to listen to each other or be supported in this and teachers actively listening for mathematical features of what students say even when it is not obviously mathematical. Listening can serve different roles in mathematics lessons, for example, to evaluate or interpret students' responses, or to make connections with other ideas. Distinctions between these can be indicated by the response that follows.

Dimension 4: Making connections. Making connections is a key part of teaching and learning mathematics, but there are many different types of connection that could be made, for example between ideas, tasks, methods, or processes. In our study we also consider connections that relate to communicating mathematics, including between representations, between families of words and between informal and more technical ways of describing mathematics.

We note that the dimensions are ordered for the purposes of arranging them in the framework table (Figure 2), but we consider them to be intertwined and may occur throughout a stanza. In particular, like Adler and Ronda (2015), we caution that this ordering does not suggest a teaching sequence. This is one design reason for not locating *Listening and feedback* in the final column, which might suggest that it happens 'last' in classroom interaction (as noted by the teachers in the project).

The framework described above is therefore designed to support noticing and a focused analysis of each dimension separately and also consider how they are at work within each stanza and over the course of the episode, including whether and when some dimensions move out of focus.

Method

In the first stage of using the framework, two members of the project team used it to analyse one lesson episode together, then another episode separately. One of these team members and another team member then analysed a further episode separately to assess the potential for using the framework reliably by different researchers. This raised anticipated issues of grain size for the stanzas and time for use. As a group we then analysed two further lesson episodes from different topics, in person and then online (see below for details of episode selection). Our choice to collaborate at this stage was based on our goal of understanding more about the potential of working with the

framework, rather than reliability of coding of our project data. Collaborating enabled us to surface and debate issues the framework raised for us, through which we drew on and examined how our different backgrounds in analysing classroom language and communication may have affected what we noticed in the data through differently developed sensitivities (Mason, 2002) and what we chose to report. For example, one author noticed pauses and intonation and others noted slight shifts in word choices and grammar. These differences raised questions about what level of detail to report in the framework while keeping the mathematics foregrounded.

Episodes were selected for analysis through a two-stage process that is part of the wider project work. In the first stage, lesson episodes were identified by considering the types of activity around a task, for example students working on the task or a discussion. In the second stage, a reduced version of the Global Teaching InSights coding scheme (OECD, 2020) was used to identify episodes that scored more highly in terms of the quantity and quality of interaction between the teacher and the students. We watched the video of the episodes multiple times during analysis, re-watching short sections to confirm our *accounts of* (Mason, 2002) or as our discussion drew attention to different features.

Results: Illustration of our use of the framework to analyse a lesson episode

We now illustrate our use of the framework using data from our analysis of a 5-minute episode from a lesson on angles in parallel lines for students aged 12-13 in England. For practical reasons our analysis took place in a recorded online meeting (approximately 1 hour 40 minutes) after previous work in person on other episodes. The episode involves a whole-class discussion that followed up on a task in which students were shown the diagram in Figure 1 and asked to discuss and "write down as many statements or equations about these angles as possible". In the discussion the teacher selected relationships that students had identified, wrote them on the board and asked for reasons for them.

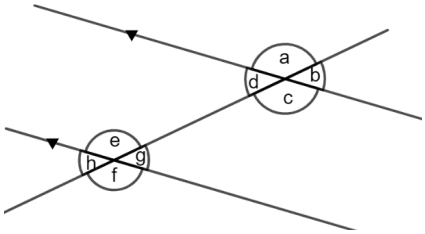

Figure 1: Parallel lines task (reproduced from lesson video)

Figure 2 illustrates our shared analysis of the first three of five stanzas in the episode, presented here in the form produced during our shared analysis session. We now describe some of our deliberations and choices made in this analysis. For reasons of space, we do not describe all details for each stanza.

In our first two meetings, we had first identified a stanza and then analysed each dimension before continuing to identify further stanzas. In contrast, in our analysis of this episode we first focused on identifying stanzas, and then analysed across the dimensions, working stanza by stanza. One challenge in our analysis was the level of detail to include in cells. Figure 2 illustrates our choices, which took into account the goals of our analysis and therefore combine verbatim quotes and summary comments.

In our shared analysis, we quickly reached agreement on the shifts in focus that defined boundaries between stanzas and the core mathematical ideas or activities within the stanzas. For example, we interpreted the two geometric results in stanza 1 as forming one stanza together, rather than separate

Stanza	Core mathematical ideas and activities	Linguistic demands of the mathematics	Student reasoning, explanations and argumentation	Listening and feedback	Making connections
1. Angles prior knowledge (0.00–1.06)	Sum of angles round point and on straight line. Using this as a basis for relationship between angles.	Angles around a point Angles on a straight line (preposition) Degrees, Equals, Equation, point Reason (why, and what you write after the answer), what a reason is in mathematics	Modified from angles in a 'complete circle' Students completing missing words in mathematical statements started by the teacher	Accepting answers as correct but requesting rephrasing and structuring statements into conventional forms Referencing routine of how to give a reason when making an argument	Students communicating using written notation, copied by teacher, but speaking the notation, e.g. equals not = Connecting to prior knowledge by asking for reasons for equations Complete circle given as reason for the equation
2. Straightness of line (1.06–1:28)	Raising assumption that lines are straight in the diagram	Straight, line, straight line Not necessarily, Assuming Parallel lines cut by…			Connecting representations (tracing along line) This diagram being a representation that tells them a line is straight (basis of assumption)
3. Comparing angles (1.28–3:30)	a>d is inequality, a=c is equation. When is it sometimes true, or always true?	Is greater than Equation, Expression, Inequality If… would …always Still the same Opposite angles True Cut line (naming transversal) Same, different Same place' to describe angles on new line In this scenario, case	Is the relationship always true or only sometimes true?	Validates appropriate mathematical responses, repeats appropriate answers	Inequalities are a type of expression, but it's not an equation Speaking 'greater than' connecting with symbol Using dynamic language to explore the static diagram.

Figure 2: Example of the framework in use

stanzas, because they both involve the core mathematical activity of students using prior knowledge in an explanation of a relationship they had identified between angles. We identified the move from stanza 1 to stanza 2 by the teacher drawing attention to an assumption that the transversal line was straight in response a student's use of *straight line* in their explanation in stanza 1. The shift in focus that marks a move from stanza 2 to stanza 3 was indicated by introducing the inequality relationship $a > d$, which holds for the given diagram, and using this as a starting point for the core mathematical activity of contrasting a relationship that is sometimes true with one that is always true, e.g. $a = c$.

In stanza 1 we identified *Linguistic demands* that included statements involving prepositions, such as *angles around a point* and specialised vocabulary such as *degrees*, *equation* and *point*. We included the teacher's clarification that a *reason* is what should be written after stating the relationship. We interpreted this as a linguistic demand because it set out what a reason looks like in mathematics, and because in England there is an expected form for these reasons in geometric arguments. There was an explicit interplay between the dimensions *Student reasoning, explanations and argumentation* and *Listening and feedback* in stanza 1, as *Listening and feedback* was characterised by restructuring students' arguments. For example, the teacher accepted "because it's a complete circle" as a correct reason but then requested "Angles around a WHAT equals 360?" In this way, the teacher's feedback also referenced a routine from general mathematical practice of giving reasons.

Connections that we considered to be made in stanza 1 include students connecting to prior knowledge of geometric results as reasons for their equations. The teacher also connected words with the symbols students used to communicate relationships, for example by speaking "=" as "equals". We discussed whether stanza 1 involved connecting algebraic representations with the diagram. Some students are likely to have made such connections before this episode by forming equations to express relationships between angles in the diagram, but we decided that this connection was not made during stanza 1 itself because neither the teacher nor the students connected the equations with the diagram in speech or through other means such as gestures (Alibali et al., 2014), which, by contrast, the teacher did in stanza 2. This discussion highlights the challenges of using the framework for individual episodes: connections made available previously may later be left tacit and we may only be able to record connections that are articulated in the episode.

Stanza 2 focuses on the assumption that the transversal line is straight (which we consider to develop the statement introducing angles on a straight line in stanza 1 and indicate by a connecting arrow in Figure 2). In stanza 2 we did not identify any student speech, so there are no examples of *Student reasoning* or *Listening and feedback*. *Linguistic demands* include classifying lines, e.g. *straight line*, *parallel lines*, and phrases associated with assumptions, e.g. *not necessarily*, which are important for precise communication within mathematical arguments as well as being everyday expressions. One focus of our discussion was the teacher's use of the diagram to make connections. First, she connected speech with the diagram by asking "How do I know this line is straight?" while tracing along the transversal line. She also connected the assumption that the line is straight with what students could "see from the diagram". We noted that use of the diagram therefore extends beyond a point of reference: its visual properties are used as a basis for a claim for properties of a line. This contrasts with properties made explicit through notation, such as arrows on parallel lines, or stated in the task.

In stanza 3 the mathematical focus is the inequality "$a > d$" and whether it is always true, which the teacher contrasts with the relationship $a = c$ which is always true. In addition to specialised terms,

and giving the name *cut line* to afford communication about the transversal, *Linguistic demands* here particularly include conditional statements such as "If I moved this cut line, would a always be greater than d?" One particular type of connection that we interpret the teacher making is between the related specialised terms *equation*, *inequality* and *expression* as she identifies the *inequality* as a type of *expression* and contrasts *inequality* with *equation*. A further type of connection is between the static diagram and a range of possibilities that it could represent. The teacher makes these connections through dynamic and temporal language, e.g. *moved*, *always*, *still the same*, and drawing an alternative transversal for which $a < d$ could be interpreted visually from the relative size of the angles in the diagram and connecting this with an algebraic representation. As a form of *Listening and feedback*, we considered the teacher's repetition of mathematically appropriate student statements such as "They are the same" to validate these responses. Although opportunities for *Student reasoning, explanation and argumentation* were framed by the teacher questioning whether the result $a > d$ was always or only sometimes true, we did not identify examples of students explaining why this was the case, or being pushed to explain this.

In summary, these descriptions of our analysis of stanzas 1-3 illustrate how our use of the framework supports us to draw out details of how the teacher and students sustain or change the mathematical focus of discussions. For example, we identified a range of topic-specific and mathematical linguistic demands that differed between stanzas, support for more general mathematical practices such as giving reasons and considering whether relationships hold always or only sometimes. We also identified differences in attention to how students make their arguments through the teacher's listening and feedback and the variety of connections articulated in these short sections of discourse.

Conclusion

Data analysis requires the summarisation of data, which reduces the complexity of the situation. The act of videoing or observing a lesson also necessarily results in data reduction. However, classroom interactions are complex, multifaceted and dynamic in ways that intertwine pedagogic decisions, the mathematical content and the interactional context. We lose so much information when we reduce classroom data to a set of codes. This framework was developed to address a concern that we were losing too much in the earlier coding, particularly connections, themes and aspects of the interactional context that build, evolve and adapt during an episode, task or lesson, or even across lessons. Furthermore, many of the coding systems we considered seemed to lose sight of the way in which interactions are intertwined with the mathematical content because they focus on particular pedagogic teacher moves or structures of interaction, rather than how these moves or structures might be influenced by or influence the mathematics in focus. Other systems, such as Adler's MDI framework (Adler & Ronda, 2015), consider these relationships across lessons rather than at the level of interaction. We have illustrated here how the framework has supported our analysis of lesson episodes in our project and now raise the question of whether it could be used beyond our project to capture quality in language-responsive teaching.

Acknowledgment

The project has been partly funded by the Nuffield Foundation, but the views expressed are those of the authors and not necessarily the Foundation. Visit www.nuffieldfoundation.org.

We thank Jill Adler for her contribution to the design of the framework and discussions about its use.

German upper-secondary students' use of discourse practices and lexical means related to the scalar product

Olga Lomas and Lena Wessel

Paderborn University, Faculty of Mathematics, Paderborn, Germany;

olga.lomas@uni-paderborn.de

This study examines the role of language in upper-secondary mathematics education in Germany, emphasising the interplay between language, learners' conceptions, and concept formation, particularly regarding the scalar product. The research introduces a further differentiation of the refined model of representations and registers into verbal arrow geometry, verbal vector algebra, and elementary geometry levels. A teaching-learning arrangement was designed to observe which discourse practices and lexical means within these verbal levels students use in learning processes towards understanding the scalar product. The findings suggest a geometry-specific refinement of conceptually rich explanatory forms.

Keywords: Discourse practices, lexical means, scalar product, conceptual understanding.

Context of the study in Germany

In Germany, empirical studies on language in mathematics education predominantly focus on primary and lower secondary education. Language phenomena related to topics in upper secondary education, such as stochastics, analysis, and analytical geometry, have received less research attention so far (exception: Prediger & Sahin-Gür, 2020; Armbrust, 2022). Analytical geometry, one of the major topics in the upper secondary curriculum in Germany, involves algebraizing geometry using vectors. However, research on learners' conceptual development in geometry-specific areas is lacking (Sträßer, 2015, p. 9), although a few recent studies are addressing this gap (Büttner & Erath, 2023 on trigonometry). The interdependence between language, learners' concepts, and concept formation (Vollrath, 1984; Wessel, 2020) highlights the importance of these relationships in mathematical learning. This interdependence suggests a similar need for greater focus on language use and conceptual understanding within the field of analytical geometry. In German schools, analytical geometry is often reduced to procedures, with concepts such as the scalar product being treated as a formula tool. Regarding the scalar product, students often struggle to interpret it geometrically when it is not equal to zero (Frohn, 2020), which suggests a lack of conceptual understanding.

Theoretical background on conceptual understanding, representations and discourse practices

Hiebert and Carpenter (1992) define *understanding* "in terms of the way information is represented and structured. […] mathematics is understood if its mental representation is part of a network of representations" (p. 67). The authors highlight the importance of connecting concepts, facts, and procedures across past and present learning contents (Hiebert & Carpenter, 1992). This idea is also found in the work of Vollrath (1984) with regard on concept formation: a mathematical concept is understood when its *scope* and *content* is clear, and it is embedded in a conceptual *network*. In the cognitive-psychological model of understanding proposed by Drollinger-Vetter (2011), a conceptual

network is further specified. In her model, concepts are deconstructed into their associated representations, which are supported by underlying concept elements that describe partial aspects of the main concept and must be linked and understood. Some concept elements for the scalar product are, e.g., lengths, angles, and vectors, because they represent previously learned content and are integral to the concept itself, which need to be connected for a deeper understanding. On the one hand, learners build their understanding of a concept by consciously compacting several concept elements into the actual concept. On the other hand, conceptual understanding is developed when compacted concepts are unfolded into their underlying elements (Post & Prediger, 2022).

Integrating meaning-related vocabulary, representations, and discourse practices for developing conceptual understanding of the scalar product

The processes of *compacting* and *unfolding* aim to foster learners' conceptual understanding, which in turn requires the use of meaning-related lexical means (Wessel, 2020). While research shows the relevance of these lexical means, the relevant meaning-related vocabulary must still be identified for each mathematical topic. Regarding analytical geometry, research suggests a differentiation of *vector language*, *arrow language*, and *point language* (Artmann & Törner, 1983). The authors show that in proofs and propositions, vector language is predominantly used while in means of illustration and motivation, which support conceptual understanding, arrow and point language dominate (Artmann & Törner, 1983). This study combines arrow and point language under the language of *arrow geometry*, recognizing them as key components of meaning-related vocabulary in analytical geometry.

Given the abstract and primarily relational nature of mathematical objects, understanding a concept in all its facets needs activities of relating concept elements and representations (Drollinger-Vetter, 2011). By connecting *verbal*, *symbolic, graphical* and *concrete* representations, learners develop the mental constructs and relationships that a mathematical concept entails (Duval, 2006). Wessel (2020) developed a *refined model of representations and registers* by further unfolding the verbal representation level into *verbal technical*, *verbal academic*, *verbal everyday* registers. While graphical representations play a significant role in analytical geometry, especially given the focus on language in describing them, this discussion will not delve into the other representational levels (graphical, symbolic-numeric, symbolic-algebraic, and concrete). For the concept *scalar product*, the *verbal academic register* particularly includes lexical means of *verbal arrow geometry*, *verbal elementary geometry,* and *verbal vector algebra*. Arrow geometry involves interpreting vectors as arrows in both graphical and verbal forms. In contrast, vector algebra focuses on formal, abstract descriptions through symbolic and verbal representations. Elementary geometry comprises the foundational elements learned in lower secondary education, present across all representational forms. For example, the relationship between orthogonality and the scalar product can be expressed using formal (verbal vector algebra level) or meaning-related vocabulary (verbal arrow geometry level and verbal elementary geometry level):

- *Example 1* (formal)*:* If two vectors $\vec{a}$ and $\vec{b}$ are orthogonal, their scalar product is zero.
- *Example 2* (meaning-related)*:* The two arrows with a common starting point represent two vectors and form a right angle. In this case, the scalar product is zero.

Even more importantly than the lexical level, activating students in rich discursive practices such as *explaining* is needed for fostering conceptual understanding (Erath et al., 2021). *Explaining* complements *understanding.* Klein (2009) differentiates three types: *explaining-what* (meanings of terms and constitutive properties), *explaining-how* (sequences of actions and constructions), and *explaining-why* (justifications of connections and relationships). They are referred to as *explanatory forms* in the following. In relation to the different explanatory forms in mathematics education, Erath (2017) highlights that oral explanations of meanings and justifications in class 5 mathematics lessons occur less frequently, while procedural explanations, particularly explaining-how (e.g., the steps in a specific calculation) seem to take centre stage.

Research question

Regarding analytical geometry, there is a lack of empirical research on how learners handle these explanatory forms and which lexical means they actually use in these processes. Also, processes of relating representations of elementary geometry, arrow geometry, and vector algebra, are not yet empirically investigated and the potential and hindrances of the interplay of representations, explanatory forms, and specific lexical means in analytical geometry remain mostly unclear. This leads to the central research question: *How do upper-secondary students handle specific explanatory forms related to the scalar product, and which lexical means do they use?*

Methods and research design

The overarching project which aims at designing a language-responsive teaching-learning arrangement towards the *scalar product* follows a didactical design research with its topic-specific features and iterative cycles. The teaching-learning arrangement was designed following a structured specification of the learning content and incorporating the design principles *relating different representations* and *engaging students in rich discourse practices*, which have proven to be fruitful in other studies on language-responsive approaches (Erath et al., 2021).

Design of the teaching-learning arrangement

The designed teaching-learning arrangement consists of five stages and includes various tasks for learners to complete. The scalar product is first introduced through an angle problem in an irregular hexagon, then distinguished from other products. Subsequently, both the arithmetic formula $\vec{a} * \vec{b} = a_1 b_1 + a_2 b_2$ and the cosine formula $\vec{a} * \vec{b} = |\vec{a}| \cdot |\vec{b}| \cdot \cos\alpha$ are presented and demonstrated to be equivalent using concrete vector examples. Next, the effect of positional relationships of arrows with a common starting point for two vectors on the scalar product is explored (see Figure 1 for segment of the task).

Exploring characteristics of the scalar product

a) $\vec{a} = \binom{4}{1}, \vec{b} = \binom{3}{5}, \alpha = 45°$ **b)** $\vec{a} = \binom{5}{2}, \vec{b} = \binom{-2}{5}, \alpha = 90°$ **c)** $\vec{a} = \binom{4}{4}, \vec{b} = \binom{3}{3}, \alpha = 0°$

Use GeoGebra to geometrically represent the vectors and angles from each task.

- What do you notice about the scalar product? Make notes.
- Explain why your observations are valid by examining the magnitude of the cosine on the unit circle.

Figure 1: Segment of stage 3 in the learning pathway

Initially, learners relate the symbolic-numeric representation to its graphical counterpart and then articulate the observed relationships in a written explanation. The fourth step focuses on the equality of scalar products, especially when the scalar product equals the product of vector magnitudes. Figure 2 illustrates the derivation task through the decomposition of vector $\vec{b}$ into two parts.

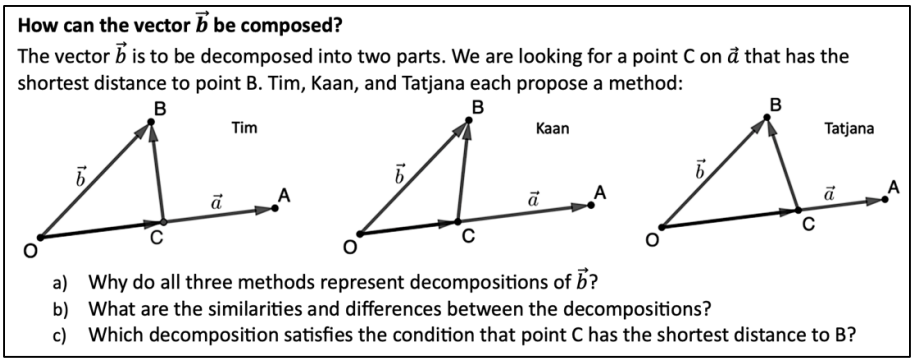

Figure 2: Segment of stage 4 in the learning pathway

Like previous tasks, learners are required to connect their verbal descriptions with the graphical representations. Next, vector $\vec{b}$ is further defined as having an orthogonal component $\vec{b}_{\perp}$ and parallel component $\vec{b}_{\parallel}$ forming the basis for deriving the relationship $\vec{a} * \vec{b} = |\vec{a}| \cdot |\vec{b}_{\parallel}|$. This prepares learners to interpret the scalar product as the area of a rectangle in the final stage of the learning pathway.

Data collection and data analysis

The teaching-learning arrangement was tested in a classroom setting ($N = 25$) over six 45-minute lessons. All plenary discussions, as well as two focus groups (each with three participants) were recorded during the lessons, and all learners' written work was collected. The video material was transcribed and analysed using Mayring's (2015) combined deductive and inductive approach. The analysis involved three steps:

(1) *Theoretical inventory of language demands:* Language requirements were inventoried according to elementary geometry, arrow geometry and vector algebra, with further specification of *explaining* and the construction of examples. For instance, an *explaining-why* example in arrow geometry could be: The scalar product is zero because the two arrows of the vectors are orthogonal to each other.

(2) *Coding (further) discursive practices and lexical means:* Terms like *segment*, *perpendicular*, and *parallel* were assigned to lexical means of elementary geometry; *arrows* and *decomposition* to arrow geometry; and *vector* and *linearly dependent* to vector algebra. Additionally, deictic means and individual terms used by students like *these things* and *overlapping* were also coded. To avoid redundancy familiar concepts like *angle* from lower secondary education were assigned to elementary geometry.

(3) *Analysis of interplay:* The relationship between task, discourse practice, and lexical means was examined to identify peculiarities, similarities, and differences.

Empirical insights into students' explanations regarding the scalar product

In the following, cases are presented in which an inductive refinement of specific explanatory forms emerged during data analysis. These include *explaining-how to visualize a geometric construction* as an important conceptual specification of *explaining*, *deictic means* and *individual terms as support for explaining-why* in the context of arrow geometry, and *describing graphical representations as scaffold for explaining-why.*

Explaining-how as a potentially conceptual specification

In relation to explaining within the context of (arrow) geometry, students tend to explain how to visualize a (given) situation geometrically. An example of this can be seen in the transcript excerpt from Emma and Tina. During the plenary session, vector addition which forms the basis for decomposing a vector into two parts (see task from Figure 2) was to be explained to everyone, while Emma was speaking quietly to her neighbour, Sarah. The teacher labelled the parallel and orthogonal parts from Tim's decomposition as $\vec{c}$ and $\vec{d}$ in the sketch and asked who could explain what vector addition is

Emma:	[*Talking to Sarah:*] I think she [*the teacher*] means that two new vectors are created by this path [*points to the adjacent arrows, which are parallel and orthogonal to the arrow of* $\vec{a}$]. Instead of using vector b, you kind of use two, you know? […]
Teacher:	[*Have Tina go next*]
Tina:	You add vector c and d […]. And that then creates b.

Emma explains to Sarah how vector addition can be visualised using two adjacent arrows "instead of using vector b". Emma argues on a conceptual level within arrow geometry, imagining vector addition as a *path*, which represents her individual use of lexical means. She stays close to the graphical representation of the concept referring to the arrows. Explaining-how to visualize a situation geometrically was found more often in the data. Putting a (given) graphical geometrical relationship into words seems conceptually fruitful. Tina, on the other hand, explains how to perform vector addition, using lexical means from vector algebra. Such rather procedural explanations were also found in the data, but it appears that *explaining-how* extends beyond mere procedures and is a conceptually rich discourse practice, particularly in geometrical contexts.

Individual and *deictic means* as support in explaining-why

An analysis of students' explaining-why statements reveals a frequent reliance on graphical representations for justifications. In the following transcript, Nina and Jana first exchange ideas on how to explain why all options suggested by the three fictional characters qualify as vector decompositions (see task a) from Figure 2).

Nina:	[…] Yes, because everyone draws a different stroke. So/ … You know? Here, this one draws a stroke there [*points to the part of the decomposed vector that is orthogonal to* $\vec{a}$ *in Tim's decomposition*]. This here.
Jana:	Yes, because you always get to the vector through two strokes. Sorry. I mean to the point.

The explanations by Nina and Jana refer to the graphical representation of the three situations presented to them in the task. In the negotiation process between Nina and Jana, it is evident that they use both deictic means like "Here, this one draws a stroke there. This there" and individual lexical

means such as "one draws a stroke there". It appears that the proximity to the graphical representation and the use of deictic means support their explanation process. Since Nina and Jana struggle with explaining-why, they initially rely on individual meaning-related lexical means within everyday language in their oral explanations to each other to bridge linguistic difficulties. Similar simplifications are also found in the data, particularly in relation to *explaining-why*, where students often rely on graphical explanations drawing on arrow geometry.

Describing **as scaffold for** ***explaining-why***

Looking at the transcript of Nina and Jana above, it becomes evident that describing and explaining are closely connected, as Nina, for example describes similarities in the individual decomposition by stating "Yes, because everyone draws a different stroke [*explaining-why*] […] Here, this one draws a stroke there. This there. [*describing*]". This phenomenon is not unique to the case of Nina and Jana. The data analysis suggests a close connection between *describing* and *explaining-why*. A further example can be found in the excerpt from Emma. She relates to the task in which the learners were asked to explore the properties of the scalar product (see Figure 1), particularly the relationship between types of angles and the magnitude of the product.

> Emma: Yeah, exactly, that they are, like, similarly aligned and that it's, well, an acute angle [*writes on her worksheet*]. And I also wrote down that they are not orthogonal or perpendicular to each other, so, yeah, that's why the scalar product is still greater than zero.

Emma refers to the first part of the task, where observations were to be noted. She does not focus on the section explicitly requiring a why-explanation using the cosine on the unit circle. Instead, Emma describes the positions of the arrows of $\vec{a}$ and $\vec{b}$ to her classmate by initially talking about the directions of the arrows and the included angle. In the next part of her statement, she draws on the previously learned relationship between orthogonality and the scalar product as a resource. While doing so, Emma adopts both terms *perpendicular to each other* and *orthogonal*, which likely represent synonyms for her. Only after her description does Emma, on her own initiative, add an explaining-why statement by providing the reasoning that the scalar product in this case is greater than zero. In the descriptive part of her statement, Emma uses lexical means from arrow geometry in combination with graphical representations and only when explaining does she switch to previously learned lexical means from vector algebra. It appears from the data that for the other learners who completed the tasks, describing first and then providing an explanation seems easier than producing explanations right away. A look into German linguistic didactics confirms this assumption, as Feilke and Rezat (2021) state that explaining aims to make concepts understandable, and descriptions are helpful as part of the explanation process.

Conclusion

The transcript analysis highlights the need for theorizing and applying the model of registers and representations by Wessel (2020) within analytical geometry. The study offers a preliminary categorization of verbal elementary geometry, verbal arrow geometry, and verbal vector algebra as relevant categories for distinguishing between formal and meaning-related vocabulary.

First, the findings indicate that students frequently combine explaining-why statements with descriptive lexical means, suggesting a natural progression from description to explanation, where initial descriptions help ground the more abstract justifications that follow. Second, students engage in explaining-how regarding geometric concepts, such as imagining or visualizing geometrical relationships related to the scalar product. This explanatory form potentially aids both in developing procedural fluency in the context of vector algebra and in supporting conceptual understanding in the context of arrow geometry, as students articulate and refine their thoughts on the application of geometric principles. In this context, *explaining-how* is understood as explaining how mathematical objects can be visualised. Finally, the data demonstrate that students use a wide range of lexical means, drawing from elementary geometry, arrow geometry, and vector algebra. Their diverse use of individual lexical means highlights the multifaceted nature of their understanding, suggesting that different representational levels and registers are dynamically integrated into their learning processes. These insights underscore the need for careful consideration in designing teaching-learning arrangements and selecting discourse practices, especially for representation-rich concepts as the scalar product.

Language-responsive support for connecting understanding division and fraction division: A design research case study

Jessica Mähnert and Kirstin Erath

Martin Luther University Halle-Wittenberg, Germany; jessica.maehnert@mathematik.uni-halle.de

The division of fractions is often regarded as one of the most procedural and least comprehensible topics in school. The study presented in this paper gives insights into a design research project aiming to provide learning opportunities for developing a conceptual understanding of fraction division. The study introduces a language-responsive teaching-learning arrangement designed to enhance students' conceptual understanding, where the division of natural numbers is used as a starting point. Short snapshots from a case study illustrate how students interact with the tasks and what potential and opportunities can be observed.

Keywords: Fraction division, relating registers, discursive, design research, conceptual understanding.

Introduction

Academic language can be challenging for many students due to language's cognitive and epistemic function (Schleppegrell, 2004). These challenges are highly relevant for learning mathematics. Consequently, research in mathematics education works towards developing and investigating learning arrangements that effectively combine the learning of mathematics with language learning, as highlighted in Prediger and Wessel (2013) and Pöhler and Prediger (2015). The presented paper focuses on fraction division, known to be one of the most challenging concepts in middle school mathematics. Since students often struggle with interpreting the division of fractions (Malle & Huber, 2004), a teaching and learning arrangement was created to develop a deeper conceptual understanding of fraction division. To enhance the ability of describing fraction division and explaining formal tasks and patterns, language-responsive instructional approaches may be effective (summarized in Erath et al., 2021). Since there is a gap in the interpretation of the arithmetic operations, an understanding should be built by reflecting on and expressing ideas as well as using different representations. In the first cycle of a design research project, we discovered that students used both meaning-related and formal-related language to solve division tasks (Mähnert & Erath, 2024). However, students not only used these two language varieties, which are important to enhance mathematical understanding, but they also solved division problems in different ways (e.g. inverse operation, part-whole concept, equivalence of fractions, and repeated addition). Consequently, as we move into the second cycle of this project, we are now exploring how learners develop multiple and linked ideas of the concept of fraction division. Therefore, we focus on linking different representations and encouraging students to articulate their mathematical ideas.

Theoretical background: Design principles and the division concept

Research has shown (Prediger et al., 2022) that academic language proficiency has a significant impact on mathematics achievement, and that language challenges can affect monolingual students too. To overcome these challenges and support conceptual understanding, it is effective to teach

mathematics language responsively, defined as "instruction that enhances language for mathematics learning" (Erath et al., 2021, p. 246). This approach integrates content and language to provide targeted learning opportunities for the academic language needed to articulate mathematical concepts. Previous design research studies already explored instructional approaches integrating content and language to support students (e.g., on fractions Prediger & Wessel, 2013, and percentages Pöhler & Prediger, 2015). However, similar approaches have yet to be explored specifically for dividing fractions. This highlights the need for designing learning resources that enhance students' understanding of fraction division. Our research aims to fill this gap by investigating language-responsive instruction for dividing fractions. For such instructional approaches that enhance language for mathematical learning, six central design principles were extracted from the literature (summarized in Erath et al., 2021) P1: engage students in rich discourse practices, P2: establish various mathematical language routines, P3: connect language varieties and multimodal representations, P4: include students' multilingual resources, P5: use macro-scaffolding to sequence and combine language and mathematics learning, P6: compare language pieces (form, functions, etc.) to raise students' language awareness. Integrating all six design principles for language-responsive instruction may not be practical. Therefore, prioritization should depend on the specific mathematical content and the language skills of the students. Before discussing the advantageous design principles for our mathematical content, it is important to first discuss the concept of division.

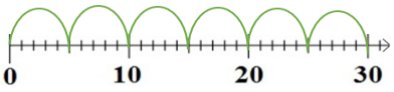
In Germany, primary school students learn about whole number division, understanding it as partitive division (e.g., What is the fifth part of 25?) and measurement division (e.g., How many times does 5 fit into 25?). During the first cycle, students used various ways to solve division tasks in the measurement context, which seems to be a good starting point for discussion (Mähnert & Erath, 2024). As a result, the measurement context is incorporated into the second cycle, focusing on linking the division of natural numbers. Before detailing its implementation in teaching, the concept of understanding is addressed.

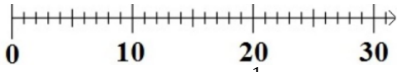
Understanding is not a static property or state, but a dynamic process of development. Carpenter and Lehrer suggest studying the "mental activity that contributes to the development of understanding" rather than "static attribute[s] of an individual's knowledge" (1999, p. 20). They propose five forms of mental activity from which mathematical understanding emerges: (a) constructing relationships, (b) extending and applying mathematical knowledge, (c) reflecting about experiences, (d) articulating what one knows, and (e) making mathematical knowledge one's own. According to them, understanding involves various mental activities and not all students learn or demonstrate understanding in the same way. Ideas must be connected to other ideas, but these connections can vary.

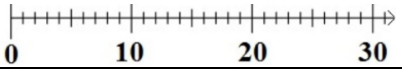
Therefore, in the teaching-learning arrangement, the concept of division of natural numbers is addressed and then extended to the new number range of fractions in order to connect ideas. Similarly, reflecting on and expressing ideas is crucial for understanding, and each person's journey to understanding is unique. This underscores the importance of creating a teaching-learning arrangement that fosters opportunities for students to articulate their thoughts and ideas. To realize this, design principle P1 was implemented, because conceptual understanding can be achieved when students are engaged in rich discourse practices such as arguing and explaining meaning because this creates

opportunities for language and mathematics learning (Erath et al., 2021). Emphasizing formal definitions and expressions early in the learning process may lead students to focus on superficial descriptions and procedures. So, it is important to engage in more elaborate discourse practices like arguing or explaining that would be needed for productive work in later steps of the knowledge construction process (Erath et al., 2021). Additionally, research has shown (Duval, 2006) that the cognitive development of mathematical concepts is closely linked to the ability to connect concepts in different representations. As a result, design principle P3 was implemented, meaning that activities in mathematics classes involving the connection between different representations were integrated to enhance conceptual understanding. It is recommended to utilize various graphical representations and connect different forms of representations, such as contextual, verbal, and graphical, to enhance learning. The instructional approach of relating representations (symbolic, numerical, verbal, and graphic) and registers (everyday, academic and subject-specific technical language) and its effects have been theorized, empirically investigated, and practically implemented in mathematics (Prediger & Wessel, 2013). It was shown that the activities of relating registers and representations provide the discursive opportunities to explain and argue, hence to construct meanings. Our study focuses on connecting representations and language varieties for division fractions and linking them to division with natural numbers. By combining design principles P1 and P3, we aim to create learning opportunities at both conceptual and discursive levels. The study addresses the following research questions: *How can the designed teaching-learning arrangement with the design principles "engage students in rich discourse practices" and "connect language varieties and multimodal representations" support students' learning processes? What language challenges and opportunities can be identified?*

Case study on explaining the concept of division and fraction division







Method: Design Research

Design research (Gravemeijer & Cobb, 2006) was chosen as a methodology to focus on learning as a process in which students are actively engaged in making sense of mathematical ideas. It involves an iterative interaction between designing teaching-learning arrangements, conducting design experiments, and analysing the teaching and/ or learning processes. There are two main goals: creating effective learning opportunities and gaining practical insights into the learning processes related to the content. This paper presents insights from the second cycle of design experiments.

Design of the teaching-learning arrangement

The second cycle emphasizes understanding division in the measurement context. In our case, we are considering the learners' prior knowledge regarding the division of natural numbers. Initially, students are prompted to share their associations with division (see Table 1, Task 1). We then reinforce the basic concept of division with natural numbers using the number line (see Table 1, Task 2), before moving on to division involving fractions (see Table 1, Task 4). Table 1 demonstrates how the design principles P1 and P3 are implemented through these tasks.

Table 1: Example tasks realizing the refined design principles P1 or P3

Design principles	Examples of tasks on division and fraction division
P1: engage students in rich discourse practices (here, explaining division and its connection to the procedure) **P3: connect language varieties and multimodal representations** (here, from symbolic to verbal)	**Task 1 – Associations with division and fraction division** a) What do you associate with the task 25:5? Explain. b) What do you associate with the task $1:\frac{1}{2}$? Explain.
P1: engage students in rich discourse practices (here, explaining the connection between multiplication and division with meaning-related phrases) **P3: connect language varieties and multimodal representations** (here, from graphic to symbolic)	**Task 2 – Jumps on the number line** a) Write down a suitable division task and multiplication task. Then, explain the connection between the division task and the multiplication task. Explain using the picture. 
P1: engage students in rich discourse practices (here, students explain their drawings in Task 4c)) **P3: connect language varieties and multimodal representations** (here, from verbal and symbolic to graphic)	**Task 4 – Represent division on the number line** a) How many times does 4 fit into 24? Draw the jumping arc in the picture that corresponds to the task 24:4.  c) How many times does $\frac{1}{2}$ fit into a whole? Could you draw the jumping arc in the picture that corresponds to the task $1:\frac{1}{2}$? Explain how you would draw the jumping arcs. 

Methods of data collection

Our research involved 10 sixth-grade students from two different schools in a city in central Germany. These students had previous experience in working with arithmetic operations involving fractions. They worked in pairs for 180 minutes using the provided learning materials. The first author or a colleague attended all sessions and intervened in the learning process to a minimum. The sessions were videotaped and student's written materials were collected. The overall project aims to design a content- and language integrated teaching design on dividing fractions that combines conceptual understanding with subject- and language-integrated support for learners. The brief illustrative excerpts presented here are intended to provide insights into the individual learning pathway of the learners along the hypothetical learning trajectory. They especially show the role of graphical representations and the discourse practice of explaining. For this, documents and short transcripts of the videotaped episodes of the learning process were contrasted. The representation of the analysis is more illustrative, focusing on the specific task sequences rather than serving as a methodologically rigid tracing of individual learners' individual learning processes across the entire learning pathways. So, the analysis in this paper could take only a local perspective for answering the research question.

The case of Lia and Alina: Challenges and learning opportunities when explaining division and fraction division

This section presents selected snapshots as the first results of an ongoing data analysis. We focus on the case of Lia and Alina, two 12-year-old girls in grade 6 who worked together. Selection criteria was that they showed a high potential for eliciting discourse practices in a first rough analysis of the video material. In the transcripts. ./../... marks a 1/2/3sec. pause.

Snapshots of students' associations with division (Table 1, Task 1)

At the beginning, students were asked what they associated with task $25:5$ to explore the prior experiences they brought from primary school and connections to measurement or partitive division. Alina stated that the result is 5, and Lia agreed.

6	Alina:	So actually, the first thing I see is five, because 25 divided by five is five. Right? Yes.
7	Lia:	Yes.
8	Interviewer:	Can you explain a bit how you know that's five?
9	Alina:	Well, because the 5 fits in the 25 five times. And then you know that if you divide 25 by 5, you have to look how many times the five fits in and that's five times, so I know that 25 divided by 5 is 5.

Alina discusses the result of the task (line 6), but it is unclear if she or Lia fully understand what "25 divided by 5" means. The interviewer's invitation to explain their thinking (line 8) leads to insights. Alina shows her conceptual understanding of measurement by explaining that dividing 25 by 5 means figuring out how many times 5 fit into 25 (line 9). Her language structures indicate her understanding, using phrases like "have to look how many times" and "fit in five times". She also uses "divided by" meaningfully because she refers to its contextual meaning. Next, the students are asked about their associations with the task $1:\frac{1}{2}$, which involves a fraction.

15	Lia:	So, it's also a division task, um, because that's like 1/2 and to make a whole, you need two halves. Yes, so it fits in there twice.
16	Alina:	So, when I saw that, the first thing I had in my head was 0.5, because that's kind of in my head, I don't know, and then I just looked at how a normal division task would be, so 1 divided by 0.5 equals 2.

The students revisit the measurement concept, highlighted by Lia's utterance in line 15, where she explains that $\frac{1}{2}$ fit into a whole two times. This explanation could also reflect the idea of division as the inverse of multiplication, as Lia implies that two halves are needed to obtain a whole, implying that multiplying $\frac{1}{2}$ by 2 results in a whole. Consequently, the context of measurement presents an opportunity to discuss the inverse operation, fostering a deeper understanding and connection of concepts. Furthermore, Alina initially describes having 0.5 in mind and then proceeds with the standard division process, thus establishing a connection between fractions, decimals, and division. Therefore, the combination of representations and the discourse practice of explaining gives insights into the students' understanding of division and reasoning process.

Snapshots of solving division problems with natural numbers (Table 1, Task 2)

The following snapshot refers to a task completed after the initial questions (see Table 1, Task 2) illustrating the relationship between multiplication and division through a graphical representation.

This activity focuses on connecting the graphical and symbolic representation, encouraging students to use language that is related to the meaning of multiplication and division. Initially, students were unsure whether the multiplication task was $6 \cdot 5$ or $5 \cdot 6$, but they finally agreed on the correct answer and changed their initial response. The teacher asked about their reasoning for this change.

92	Interviewer:	Now you have changed the results. Could you explain why you changed it?
93	Alina:	Because we thought, well, if it were five now, then you would mean that there are always five steps and we just think that this rather describes .. so we don't know, but that there are just six .. um that you just need six times the five steps to reach 30 … but actually I don't think it matters, you could also use five times six and then you could … then you would mean something different in principle, but basically neither is wrong.

The linear representation of the number line illustrates both the product and the factors. In line 93, Alina first mentions the five steps, signifying that there are consistently five steps in the graphical representation. She then states "you just need six times the five steps to reach 30", thereby defining the mathematical operation of multiplication. This clarifies that five (jump size) serves as a multiplicand and the six steps (number of jumps) serve as the multiplier. The snapshot highlights the potential benefits of linking language varieties and multimodal representations with the discourse practice of explaining, which helps students to visualize and conceptualize the abstract operation of multiplication in a concrete way. Alina demonstrated her understanding, explaining that the order of numbers does not affect the result. By saying "five times six and then you could (…) then you would mean something different in principle, but basically neither is wrong" (line 93) it can be assumed that only one multiplication task corresponds to the given picture. Her use of the number line and her reflection on the phrases "six times the five steps" and "five times six" indicates that she succeeded in unfolding the concept. Therefore, the combination of graphical and symbolic representations, along with the discourse practice of explaining and the precision of students' language, is crucial for understanding multiplication concepts. However, this can be a challenge for other students. The question arises: how do students handle the situation when they are not dealing with natural numbers, but also incorporating fractions into such tasks? The following snapshot addresses this.

Snapshots of solving division problems with fractions (Table 1, Task 4)

In Task 4, students are required to represent division tasks by drawing jumping arcs on a number line. While part 4a) is straightforward, part 4c) becomes more complex due to the scale of the number line. The consistent graphical representation of the number line remains to encourage students to engage in explanations and discussions. In Task 4c), it is crucial for the students to recognize that they must adjust either the division or the range of the number line. Drawing the jumping arcs in the previous tasks functioned effectively without further discussion. The following snapshot shows a conversation about the definition of a whole in Task 4c).

151	Alina:	I think it's the same task only in reverse and we know twice that ½ fits into a whole. But what is meant by a whole? 30 or 10?
152	Lia:	10
153	Teacher:	What would you guess?
154	Alina and Lia:	10.
155	Alina:	But 30 is also possible. Then there are thirty wholes.
156	Lia:	But 1/2 it is 0.5
157	Alina:	But then it's 1. … No, it could also be 10. It could also be 10.

158	Lia:	Yes, exactly. It could also be 20.
159	Alina:	With twenty it would be 0.10. Nope.
160	Lia:	Yes, of course.
161	Alina:	Eh? With twenty, it would simply be 10.
162	Lia:	So it's ten.
163	Alina:	Yes. 0.5
164	Teacher	What was the reasoning behind the last one?
165	Alina	Because 0.5 times two is 10. But if it were up to 20, for example, then it would be 10 times 2 and then 10 would be half and not 0.5. Although no. 0.5 can also be twenty. That's always half. No, 0.5 is half of a whole.

The students are uncertain whether a whole can be 10, 20, or 30, (lines 154, 155, 158) despite recognizing that $\frac{1}{2}$ fit into a whole twice (line 151). They perceive 0.5 as a flexible value and struggle to apply it as a fixed value representing half of one whole. The confusion may arise from the flexible usage of the terms "a whole" and "a half" in everyday German language. After the students have chosen to answer 10, the teacher asks if they can justify this (line 164). Alina starts by saying that 0.5 multiplied by 2 is 10. Then she tries to argue with a counter-example using 20 to explain that 10 multiplied by 2 equals 20 and therefore 10 is half of 20. While 0.5 as a number is always half of 1, half of another number is simply that number divided by 2. Moreover, they faced difficulties with arithmetic operations. Alina argued that they chose 10 because 0.5 multiplied by 2 equals 10, and did not consider 20 as a whole because "then 10 would be half and not 0.5". The explanations that were given at the beginning of the learning environment (see Table 1, Task 1) for the same task and which took up the conceptual understanding of the measurement in the area of natural numbers could not be incorporated at this point. In the end, the students do not answer the question and the teacher intervenes and explains the task to them. To summarize, the students face challenges when transitioning from verbal to graphical representations, as they have not yet developed a clear understanding of the concepts of wholes and fractions. Although the number line was used the same way in all tasks, it is evident here that the graphical representation alone is insufficient to overcome these misunderstandings. More activities are needed to deepen the work with the number line and help students to grasp the concept of fractions and wholes more clearly.

Conclusion and Outlook

To address the research questions, the learning pathway of Alina and Lia provides insights into the role of language and the development of mathematical understanding of fraction division. While both students demonstrate a strong grasp of division as measurement, they struggle to apply this concept to fractions. In Task 2, Alina reflects on varied phrases "six times the five steps" and "five times the six" to interpret the multiplication task within a graphical representation. This underscores the role of language in developing conceptual understanding, as Alina uses and reflects language that pertains to the meaning of multiplication. While Lia and Alina demonstrate a strong understanding of division as measurement with natural numbers, it becomes more complex with fractions, particularly in defining the whole. These insights highlight the increasing complexity of the conceptual idea of measurement and the need to emphasize phrases related to division more effectively. We think that building upon language varieties acquired in primary school for division can offer appropriate support in deepening students' conceptual understanding. In answering the research question, the design principles "engage students in rich discourse practices" (P1) and "connect language varieties and

multimodal representations" (P3) proved their potential for developing and deepening an understanding of division and fraction division (see Task 2). In summary, the individual learning pathway of the two students shows that linking division and fraction division opens up the potential for building conceptual understanding. However, more research is needed, also to identify supportive linguistic means and phrases. Also, in this project, more data will be analysed to contribute to a better understanding of language learning and conceptual understanding for the case of fraction division.

The connection between task design and how algebraic variables and constants are described

Tamsin Meaney[1], Silke Lekaus[1] and Eugenia Ferrari[2]

[1]Western Norway University of Applied Sciences, Bergen, Norway; tme@hvl.no

[2]The Royal Norwegian Naval Academy, Bergen, Norway

In designing mathematical tasks that utilise language(s) as a resource, there is a need to identify which aspects of language are most likely to contribute to developing important mathematical concepts, such as algebraic variables and constants. The aim of this study is to identify how questions in a task about patterns contributed to preservice teachers, as fluent users of the mathematics register, describing variables and constants in specific ways when discussing their solutions. The analysis suggests how the task question could be revised to prompt the use of algebraic rather than arithmetic thinking.

Keywords: Algebra, language as a resource, task design.

Introduction

In an ongoing international project, we have been exploring how to develop mathematical tasks that utilise the epistemic potential of multiple languages to provide "mutually supporting perspectives on a mathematical concept" (Schüler-Meyer et al., 2023, p. 102). However, pursuing this aim has identified many tensions, including that "the use of technical language and how to structure mathematical argumentation seemed to affect how the students interpreted and responded to the requirements of the task" (Ferrari et al., 2023, p. 1589). Thus, rather than continuing to develop new tasks to trial in multilingual classrooms, it became essential to better understand how task questions could contribute to specific aspects of mathematical language being used. In this study we focus on how questions in a task about patterns elicited different ways of describing variables and constants from preservice teachers, who were assumed to be fluent in the mathematics register in Norwegian.

The focus on algebra was chosen because difficulties had been identified in shifting thinking from arithmetic operations with specific numbers to abstract generalisations (Ferretti et al., 2022). This shift is not immediately recognisable in the products of the thinking. For example, Radford (2014) stated that deducing a formula for patterns could require algebraic thinking whereas guessing a formula and trying it out until it worked for a range of specific quantities would indicate arithmetic thinking. It is likely that the language used to describe the deducing would be different to that used for guessing. Therefore, patterns seemed an appropriate mathematical topic for considering how task questions might affect whether algebraic thinking was required and how it was described.

In the table and chairs task, used from the early stages of the project (Schüler-Meyer et al., 2023; Ferrari et al., 2023), the focus was on multilingual students developing rules for patterns in everyday language. To do this requires an understanding of both variables and constants and can be considered a form of functional thinking, an aspect of algebraic thinking, which "involves generalizing relationships between covarying quantities and representing and reasoning with those relationships through natural language, algebraic (symbolic) notation, tables, and graphs" (Blanton et al., 2015, p.

43). Like Radford's (2014) focus on deduction, reasoning about the covarying quantities can affect and be affected by the ways that language is used.

In this study, we aim to identify how variables and constants are described in responses to specific task questions. The tasks were completed by preservice teachers for grades 5–10 in pairs. We presumed that they could complete the tasks appropriately and would have a rich repertoire of mathematical representations and linguistic expressions for describing variables and constants. The research question is: How do task questions contribute to preservice teachers using specific ways of describing variables and constants when orally determining rules for patterns?

Theoretical framing

To respond appropriately to the research question, it was necessary to identify the different ways that variables and constants could be described. Researchers have investigated students' conceptions of letter symbols in mathematics for decades. Küchemann (1978) distinguished between six levels of understanding, where the most complex was "letter as variable", with the requirement that the student had "an awareness that there is some kind of relationship between the letters, as their value changes in a systematic manner" (p. 25). Yet, this covarying property of variables in relationship with each other may not always be in students' minds when working with patterns. Bardini et al. (2005) found that students described a toothpick pattern with the formula $n = 2x + 1$, where x symbolized the number of the figure and n the corresponding number of toothpicks. However, they seemed to treat x as a "temporarily indeterminate number" and n as a "potentially determinate number" that would eventually be assigned a value.

Ely and Adams (2012) also identified issues, describing letter symbols as "unknowns", "variables", "placeholders" and "generalised numbers" and provided examples of how they could appear in what they referred to as typical algebra lessons. The term "unknown" was used to describe fixed amounts that were yet to be determined. Ely and Adams (2012) gave the following problem in which, "the unknown is 'some amount', and the equation is tacit: 'Jack has some amount of apples and then gives 4 of them away. If he now has 3, then how many apples did he start with?'" (p. 21). Variables describe two indeterminate amounts, both of which could assume "any of a (large) set of values" (p. 21) which are always in relationship to each other, and so are covarying. Whereas Blanton et al. (2015) focused on the covarying relationship in describing functional thinking, Ely and Adams (2012) were more focused on the indeterminate amounts, in a similar way to Küchemann (1978). Nevertheless, reasoning about variables includes considering the arithmetic operations which contribute to the covariation. A placeholder is "a letter standing for a number that will be provided in a particular problem or context" (Ely & Adams, 2012, p. 21). Thus, coefficients and constants in equations can be considered placeholders, in that they have specific values in particular examples of that equation. For students trying to make sense of generic equations, such as "y=mx+b", then "m" and "b" can appear to be variables because they can stand for a range of different numbers. However, because they have a specific value in a particular example of this equation and do not vary in relationship to each other, they are different to variables. Determining a pattern requires reasoning about the specific amounts that could fill the coefficient and/or the constant and so can also be considered part of functional thinking. Placeholders could also be what students, in Bardini et al.'s (2005) study, had

considered to be variables when they took on the role of being potentially determinate numbers. The final distinction that Ely and Adams (2012) made was about generalised numbers in which the intention was not to find a specific result but to keep the discussion at the level of general amounts. They gave an example of "a(b + c) = ab + ac" (p. 22). In identifying the specific aspects of patterns, it may be that simplifying the pattern to its most elegant form could involve generalised numbers.

Our focus is not on how letter symbols are used but on how variables and constants in patterns are discussed in everyday language. The distinctions of Ely and Adams (2012) were a starting point for identifying algebraic thinking. Radford's (2014) description of guessing the formula for a pattern and testing it with different numbers can be related to Ely and Adams' (2012) unknowns, which suggests unknowns are more likely connected to arithmetic rather than algebraic thinking. In contrast, being able to reason about a pattern by determining the relationship between the covarying indeterminate amounts would align with Radford's (2014) algebraic thinking. Therefore, identifying how variables and constants were described in responses to specific task questions could provide insights into how to improve algebraic thinking.

Data collection

To determine how the task questions contributed to variables and constants being described in different ways, we analysed the discussions of second-year preservice teachers for grades 5–10. We considered that this group would have an appropriate linguistic repertoire for interpreting and forming patterns, rather than still gaining aspects of it which could be the case with school students. The preservice teachers were participating in a problem-solving course and completing mathematical problems was a normal part of the lesson.

The first and third authors used one workshop in September 2023 to record pairs of preservice teachers working through the task, along with the plenary sessions. In this article, transcripts of the work of five pairs, who gave permission to be recorded, were analysed. The responses to tasks that included comparing other languages are not analysed in this paper.

An earlier version of the task is in Meaney (2024). In the results and discussion section, we provide details of the questions, especially when they deviated from the version in Meaney (2024). In Figure 1, we provide the illustrations for the three patterns that were the focus of the tasks. After working with these, the PSTs were asked to design another pattern with a different table shape.

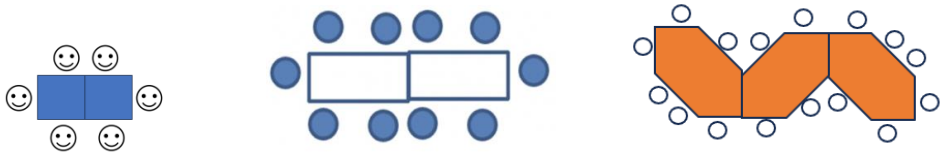

Figure 1: Patterns of tables and chairs used in the task

Data analysis

We began by reading the transcripts carefully, noting where and how the preservice teachers interpreted or described patterns, including variables and/or constants. Table 1 sets out our revised set of categories, adapted from Ely and Adams (2012), to accommodate the mostly natural language,

used by the preservice teachers. To these categories, we added a fifth one to describe how the preservice teachers discussed variables and constants when referring to the structure of patterns, suggesting they were engaged in a meta-level discussion.

Table 1: Categories of aspects of patterns

Category	Description	Language characteristics	Example from the data
Unknown	Amounts that were to be determined.	Use of specific amounts to test the validity of a formula for a pattern.	Eight. What was it here? Twelve? (counts) … Eight, twelve, sixteen.
Variable	Indeterminate covarying amounts	Focus on the relationship between two variables (one or more could be implicit).	The number of tables times two plus two equals the number of people who can sit at the table.
Placeholder	Coefficients or constants.	Focus is on the amounts that should be multiplied or added to the variables.	It will probably be, actually, since it is six, it will then be 6a. But instead of having plus 2, we get ... minus two? But then there will be plus two again, so it will only be 6a.
Generalised number	Focus on simplifying formula.	Identification of unnecessary aspects in the formula.	X one plus two. There's no point in taking times one, then. It is very unnecessary. Tables plus two.
Structure	Meta-level discussion about the structure of a pattern.	Focus on the features, rather than the specifics of the patterns.	Yes, it's the same rule, you just have to change how much it increases by and how much are constants.

Once the different ways of describing variables and constants were classified, we then identified the task questions that seemed to provoke these categories. Although it is not possible to determine a causal relationship between question and ways of describing variables and constants in the responses, the analysis provides insights for further exploration and task adaption.

Results and Discussion

In this section, we present examples from each category and then discuss the task questions which seemed to elicit them.

Unknown

The first task question gave six rules for determining the number of chairs when square tables were placed side by side (see Figure 1) and asked to determine if any represented the pattern. Two of these rules were "Each table you add, gives space for two more people" and "If you multiply the number of tables by two and add two, you get the number of people that can sit down for dinner". This

question seemed to prompt the five pairs to test each rule with specific numbers. Sometimes, they began the calculation with "if" to indicate that there were other choices, rather than just one number.

Pair1PS1: Ja, hvis du har tre bord, så ganger du det med to, da får du seks. Det er jo de seks som sitter på sida her, og så plusser du på de to som sitter på endene til slutt.
Yes, if you have three tables, you multiply that by two, then you get six. It's the six that sits on the side here, and then you add the two that sit on the ends at the end.

The preservice teachers' main focus was not on finding a specific unknown amount, as was the case with Ely and Adams' (2012) original definition of unknown. Instead, the outcomes of the calculations were used to determine the veracity of the rules. The similarities for testing different values for the unknown suggests that arithmetic rather than algebraic thinking was being utilised, similar to Ferretti et al.'s (2022) distinction. Therefore, asking the preservice teachers to evaluate a set of rules, did not on its own seem to result in algebraic reasoning.

As well, in the discussions, very few preservice teachers indicated whether they were talking about tables or chairs. Sometimes, this resulted in the preservice teachers misinterpreting the rule, which is a common issue noted in earlier research (Ely & Adams, 2012). This suggests that the question not only did not contribute to algebraic thinking but also restricted possibilities for determining the relationship between the two variables.

Placeholder

Talk about placeholders appeared when preservice teacher determined the specific coefficients for multiplying the number of tables and the constants, the chairs at the end of the rows of tables, for each pattern. A rule given in the first question about the square-table pattern was, "You take the number of chairs at each table and times it with the number of tables". In discussing this rule, the preservice teachers seemed to focus on the coefficient, as they felt this was not clearly expressed.

Pair4PS1: To av bordene vil jo ha tre. Resten har to.
Two of the tables will have three. The rest has two.

In this excerpt, three refers to the number of chairs at the tables at each end. The rule's imprecision led to this pair abandoning the discussion. In contrast, the same rule seemed to contribute to Pair 5 focussing of determining the constant. Pair5PS1 suggested an alternative rule, "du tar to stoler ved hvert bord, ganger det med antall bord og så plusser på to" (*you take two chairs at each table and times it with the number of tables, and then you add two*"). This alternative rule clarified what the coefficient and constant were for the square-table pattern.

In the task about the rectangular-table pattern, a table was provided to support the preservice teachers to determine the increase in the number of chairs between consecutive figures. This triggered talk about the placeholders, representing the coefficients of the number of tables and the specific constants at the end of the rows of tables. The coefficient as a fixed quantity was also described by preservice teacher 1 in Pair 5 as a specific amount, "antall bord ganger fire pluss to (…) fordi det er jo ikke plutselig at etter fire bord, så er det tre stoler per side" *(number of tables times four plus two (…) because it is not that suddenly after four tables, there are three chairs per side).*

For the hexagonal-table pattern, the question was "If the table shapes were different, how would the rule change? Use the pattern below to help you explain how the rule could change". The complexity

of the pattern seemed to support the preservice teachers to focus simultaneously on the coefficients and the constants in the rules, as these were not immediately obvious. The example below was typical in that they began by identifying the difference between consecutive figures, to determine the increase, but also identifying the additional chairs at the ends whose sum determined the constant:

Pair2PS2: Ja, her legger du bare til fire. Her legger du også bare til fire, da.
Yes, here you just add four. Here you also only add four, then.
Pair2PS1: [peker på ark] Og så tenker du at disse her bare er på utsida, og disse to er på utsida. Så da er det fire her og. Så det er da fire her også, og fire her også.
[points to sheets] And then you think that these here are only on the outside, and these two are on the outside. So, there are four here and. So, there are four here as well, and four here as well.
Pair2PS2: Ja. Eh ... åtte blir det ... X ganger ...
Yes. Uh ... eight that will be ... X times ...
[Pause i 10 sekunder] [Pause for 10 seconds]
Pair2PS1: X ganger fire pluss fire.
X times four plus four.

Likewise, the question about drawing a pattern with a different shape of table and determining a rule for it, had the potential to support reflection on both the coefficients and the constants, as illustrated by Pair 1 who described a pattern with triangular tables:

Pair1PS1: Det øker med én hver gang.
It increases by one every time
Pair1PS2: Øker med én ja? Men da er det ... bord ganger én pluss to. Det blir det egentlig.
Increases by one, yes? But then it's ... tables times one plus two. It really will be.
Pair1PS1: Ja. Det gjør det egentlig. Bord ganger én pluss to. (Begge ler) Det er bare å plusse to på antall bord. Ja, den er fin.
Yes. It actually does. Table times one plus two. (Both laugh) Just add two to the number of tables. Yes, it's nice.

In these cases, the focus was on the general properties of the pattern, rather than testing its validity, as had been the case when amounts took on the role of unknowns. This seems to align with the points made by Ferretti et al. (2022) who highlighted the importance of students being able to make sense of working algebraically by connecting back to arithmetical operations.

Variable

The questions about the rules for rectangular- and hexagonal-table patterns (see Figure 1) seemed to support the preservice teachers to focus on the relationship between the number of chairs and the number of tables. For Pair 2 in the excerpt in the previous section about the placeholder, the figures on the task sheet supported them to clarify whether they were talking about the tables or the chairs in the pattern, which then helped them to clarify what "X" referred to. This supported the relationship between them, as suggested by Blanton et al. (2015), being considered important, rather than the individual indeterminant amounts.

Pair 5 gave a general description of the linear pattern at the end of the discussion, in which they had used letter symbols to express the constant and the variables.

Pair5PT1: Det blir jo da A som er antall bord ganger x som er ukjent antall stoler som det øker med til vanlig pluss y som er et konstant tall på det ytterste (…) er lik B som er antall personer som sitter rundt bordene. Så A*x+y=B."

> *It will be A which is the number of tables times x which is the unknown number of chairs it usually increases with, plus y which is a constant number at the end (…) is equal B which is the number of persons who sit around the table.")*

Here, the role of each letter was clearly specified, but the choice of the letters (x,y for placeholders) and A, B for variables was unconventional.

Generalised number

There were very few examples where formulas were simplified and these occurred when two pairs independently determined a rule for a pattern about using triangular tables which they had generated. In Table 1, there is an example where Pair 1 simplified the rule. However, these possibilities did not arise because they were prompted by a question, but because the pairs had chosen particular patterns. In having students interpret formulas, it could be possible to include a question that supported them to reflect on the precision of the language, but such task questions would need to be trialled.

Structure

The new category which we added to those of Ely and Adams (2014) was that of structure, which occurred when the preservice teachers talked generally about the pattern formula. Interpreting the given rules for the square table pattern seemed to lead Pairs 3, 4 and 5 to discuss the general structure of the rules, after discovering that they were all valid. Preservice teacher 2 in Pair 3 stated, "Jeg tror det er det samme, bare skrevet på en annen måte, som en av disse her [refererer til de andre reglene]. (*I think it's the same, just written in a different way, like one of these here*)". Although the preservice teachers noticed the similarities, many did not provide details about what was similar.

The other situation in which the structure was discussed was towards the end of the task, after the preservice teachers had produced a rule for the hexagonal-table pattern or made a pattern using a shape of their choice. The example in Table 1 comes from Pair 5. However, such explicit discussions did not seem to be prompted by specific task questions. It may be that a question that focuses more on the similarities and differences between the rules could contribute to students having a structural discussion and leading to understanding about the generalisability of algebraic thinking, which is considered valuable for students' learning (Ferretti et al., 2022).

Conclusion

This study provides some insights into how task questions might contribute to different ways of describing variables and constants in rules for patterns, particularly when using everyday language. Knowing how fluent users of the mathematics register, who are competent in algebra, are prompted to use particular ways to describe variables and constants may support the development of algebra tasks for school students that utilise language as a resource (Schüler-Meyer et al., 2023) and overcome one tension identified in using a previous version of the task with school students (Ferrari et al., 2023).

Questions that required verification of the validity of rules may result in variables and constants being treated as unknowns, as specific amounts are needed to check the veracity of the rules. However, it seems that if the questions prompted a comparison of similarities and differences between rules of the same and different patterns, then variables and constants could be discussed in other ways, which could facilitate algebraic thinking. With this information, it is possible to redesign the task so that the

epistemic potential of language can be maximised (Schüler-Meyer et al., 2023). It also provides opportunities for looking at how other languages might express variables and constants.

Noticing aspects of the mathematical discourse in a developmental context on teaching angles

Juan Gabriel Rave-Agudelo and Núria Planas

Universitat Autònoma de Barcelona, Catalonia, Spain; JuanGabriel.Rave@uab.cat

In this report, we examine the noticing of a group of secondary-school mathematics teachers of aspects of the mathematical discourse during the collaborative discussion of a task on teaching angles. Our framework integrates aspects of the mathematical discourse in content-specific teaching that are responsive to students' common challenges in learning angles, as a focus of mathematics teachers' noticing. The data were collected during a one-day workshop. Using hybrid methods of deductive and inductive analysis, we examine what teachers identify, interpret, and decide regarding mathematical vocabulary, mathematical explanations, and graphical examples for teaching angles. A result is that the teachers in the group engaged in noticing mathematical-linguistic explanations with multimodal examples for teaching angles with meaning in dynamic contexts and in relation to non-metric properties.

Keywords: Collaborative discussion, mathematical discourse in teaching, teachers' noticing, teaching angles.

Introduction

In this report, we present a study initiated as part of a research and developmental project with secondary-school mathematics teachers on the mathematical discourse in content-specific teaching. One of the project strategies was the participation of the teachers and of the researchers as facilitators in one-day workshops to discuss professional tasks on aspects of the mathematical discourse in teaching. In Planas and Alfonso (2023), for example, the noticing of two groups of participant teachers was analysed, with a focus on mathematical-linguistic practices of naming and explaining, alongside other foci spontaneously introduced by the teachers. The design and implementation of the workshop in the current study include tasks with written prompts aimed at identifying, interpreting, and deciding on mathematical vocabulary, mathematical explanations, and graphical examples in fictional situations of teaching angles. A notion of supporting students' common challenges in content-specific learning by using aspects of the mathematical discourse in teaching is at the basis of the task design (for details, see Rave-Agudelo & Planas, 2022; 2023). Our study is therefore situated at the intersection of research on mathematics teachers' noticing (van Es & Sherin, 2002; Jacobs et al., 2010) and research on mathematical language and discourse in teaching (Morgan, 2013; Planas, 2021). The study of mathematics teachers' noticing is a relevant line of research, as it is a fundamental aspect of the teaching profession (König et al., 2022). It is also important to ensure that mathematical language and discourse have a place in teacher professional development programmes on mathematics teaching (Planas, 2021). We aimed at examining responses to the following research question: *What does a group of secondary-school mathematics teachers notice regarding aspects of the mathematical discourse when discussing tasks on teaching angles?*

Theoretical framework

Our framework integrates three components: aspects of the mathematical discourse in content-specific teaching, students' common challenges in content-specific mathematics learning, and mathematics teachers' noticing.

The presence of mathematical vocabulary, mathematical explanations, and graphical examples in teaching has the potential to communicate and facilitate the communication of mathematical meanings (Planas, 2021). In our study, these aspects are inspired by the *Mathematics Discourse in Instruction* (MDI) framework (Adler, 2021), particularly regarding the mathematical-linguistic practices of naming and explaining, and the mathematical-graphical practice of exemplifying. We understand *mathematical vocabulary* in relation to mathematical naming, as the set of words or phrases from the mathematical discourse used to name objects, symbols, properties, actions, procedures, and practices in mathematics (Adler, 2021). This vocabulary serves to answer questions such as: *What is this?* (Planas & Alfonso, 2023), *What is it called?* or *What are we talking about?* We understand *mathematical explanations* in relation to mathematical explaining, as sentences incorporating mathematical vocabulary that build mathematical meaning by establishing relationships between objects, symbols, properties, actions, procedures, and practices in mathematics to facilitate students' thinking. These explanations address questions such as: *What is said about something? How does it happen? How is it done?* or *Why is this?* (Planas & Alfonso, 2023). This understanding of mathematical explanation aligns with Leinhardt's (2001) notion of *instructional explanation*, in which the disciplinary nature of the mathematical content is linked to teaching practices that support students' thinking. We understand *graphical examples* in relation to mathematical exemplifying, as graphical representations (pictures, illustrations, photographs, diagrams, etc.) of mathematical examples. A mathematical example is a particular case within a broader equivalence class (idea, concept, technique, ... in mathematics) that supports reasoning and generalisation (Watson & Mason, 2002). A graphical representation is thus a visual mode of communication that conveys complex objects, structures, and processes holistically by integrating visual elements and interpretation rules (Winn, 1987).

A starting point for our investigation is the lack of consensus in defining the concept of angle and its implications for teaching and learning. For our study, common challenges in learning angles were identified in the literature on mathematics education (Rave-Agudelo & Planas, 2022). The studies selected highlighted two common challenges in learning angles that can occur simultaneously: the tendency to communicate meaning about angles in static contexts, without considering dynamic contexts (Mitchelmore & White, 2000), and the tendency to confuse the numerical value of angle amplitude with the angle itself, while overlooking non-metric properties (Tanguay & Venant, 2016).

Regarding mathematics teachers' noticing, van Es and Sherin (2002) conceptualise it by considering the identification of specific aspects of classroom interactions, the connection between these aspects and broad principles of teaching and learning, and the use of contextual knowledge to reason about these interactions. In this initial phase of the study, we adopt the conceptualisation proposed by Jacobs et al. (2010), which involves processes of identifying, interpreting, and deciding on relevant aspects of teaching and learning based on pre-established criteria. While other studies within the broader

project have shown that teachers notice additional aspects beyond those considered in the design of professional development workshops (Planas & Alfonso, 2023), the characterization and description of these processes constitute a crucial step in understanding the complexity of mathematics teachers' noticing. In order to study mathematics teachers' noticing focused on aspects of mathematical discourse in the teaching angles, we adapted Jacobs et al.'s (2010) processes as follows: (i) *Identifying* mathematical vocabulary, mathematical explanations and/or graphical examples of angles in teaching accounts; (ii) *Interpreting* the potential impact of the identified aspects of the mathematical discourse on supporting students with common challenges in their learning of angles; (iii) *Deciding* on proposals of mathematical explanations with mathematical vocabulary and/or graphical examples of angles with the potential to support the students' learning.

Methods

The empirical context of this study was a one-day workshop on aspects of the mathematical discourse in teaching angles. The first author was the teacher educator. Five secondary-school mathematics teachers participated in this workshop. Two participants had a degree in mathematics, and the other three had a degree in engineering. Their professional experience in teaching mathematics ranged from six months to 25 years. They all reported that they had not previously participated in development programmes on aspects of the mathematical discourse in teaching.

In Rave-Agudelo and Planas (2023), we report on the workshop design and the structure, following three stages. The first stage consisted of the presentation and group discussion of two introductory documents. The first document presented and illustrated two students' common challenges in learning angles. The second document illustrated mathematical vocabulary, mathematical explanations and graphical examples for teaching angles. The group discussion of these documents helped introduce the teachers to relevant aspects from the literature on teaching and learning angles. This group discussion also facilitated presentations of the teachers' professional experiences. The second stage involved the teachers' individual responses to two tasks related to teaching angles. Each task provided a fictional account of teaching with three prompting questions. These prompts were invitations to identify, interpret, and decide on mathematical vocabulary, mathematical explanations, and graphical examples to support students' learning. The third stage consisted of a group discussion of the tasks. The teacher educator started the discussion by asking for responses to each of the task prompts. The teachers participated by sharing their answers and focusing on aspects of the mathematical discourse in the tasks that they saw as related to the common challenges in learning. The teacher educator tried not to interrupt the discussion.

In this report, we consider the group discussion of the first task. This task presented a fictional situation in which a student asked the teacher for a mathematical explanation after reading a definition of angle and its classification in a mathematics textbook. In the textbook, the mathematical vocabulary and the mathematical explanations focused on communicating the meaning of angles in static contexts. The graphical examples focused on communicating the metric property. The student's utterance was as follows: '*If an angle is the portion of the plane between two straight lines, why do we take a different portion in the reflex angle? The outer one*'. The everyday meaning of the word

"between" differs from its mathematical meaning, particularly in the phrase "the plane between two straight lines". Figure 1 shows an English version of an extract from the task.

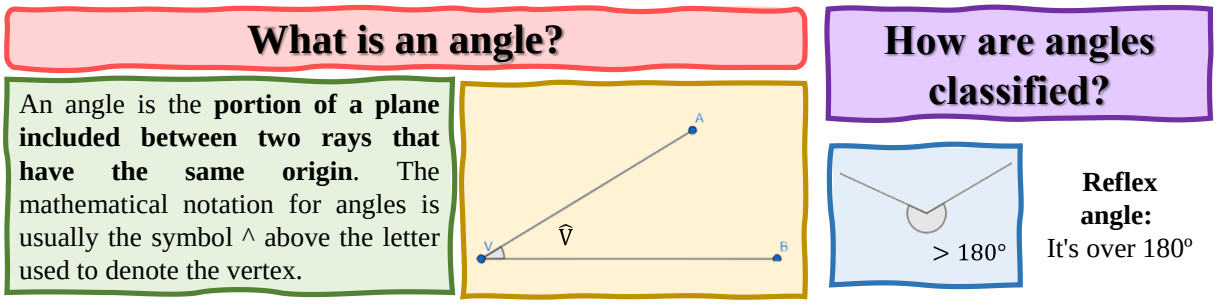

Figure 1: English version of an extract of the task

The prompts provided in the tasks were: (1) What mathematical vocabulary, mathematical explanations, and graphical examples are communicated to the student during teaching? (2) What effects might these aspects of the mathematical discourse have on the students' learning of the concept of angle? (3) What mathematical explanations with mathematical vocabulary and graphical examples, could serve in teaching that is responsive to this student's learning?

The workshop was audio-recorded and transcribed by the first author. The transcript of the group discussion for the first task was divided into three segments, each associated with one prompt. The analysis was then focused on examining evidence of identifying, interpreting, and deciding processes as constituent elements of mathematics teacher' noticing. In this process, we used hybrid methods of deductive and inductive coding analysis (Nowell et al., 2017). A preliminary analysis of the teachers' written responses formed the basis for creating initial codes. The turns in the group discussion were coded deductively, when possible, and this procedure led to the induction of additional codes. The coding was thematically oriented and included processes of noticing (identifying, interpreting, deciding), aspects of the mathematical discourse (mathematical vocabulary, mathematical explanations, graphical examples) and emergent related features. There were variations in the coding process across the task prompts for questions 2 and 3. For the second prompt, for example, the potential effect of the relationship to the students' common challenges in learning and to other aspects of the teachers' professional experience were included. For the third prompt, the potential response to the common challenges in learning and to the other aspects of teaching and learning were added to the created codes. Together with the teachers' turns in the group discussion, the episodes served as a primary unit of analysis. Episodes were created by selecting sets of turns where the teachers' noticing and the aspect of the mathematical discourse in focus were consistent, despite nuances and differences in the features discussed. Although the coding was overall guided by the framework, we remained interpretative and inductive in the analysis of the episodes. For the sake of rigour, we discussed the coding of the turns and the interpretation of the episodes. We present the episodes in an English version.

Analysis and findings

In this section, we present evidence of the participant teachers' noticing of aspects of the mathematical discourse in the teaching of angles.

Identifying aspects of the mathematical discourse in teaching angles

The teachers discussed responses to the first prompt concerning the identification of aspects of the mathematical discourse, but they did not address the identification of mathematical explanations. The extract below illustrates the identification of mathematical vocabulary and graphical examples of angles. In the first part of the discussion, the teacher educator repeated the first prompt, and the teachers identified mathematical vocabulary related to angles. In [2], Senú mentioned the Catalan words for "vertex" and "amplitude". In [3], Tule referred to "plane" and "ray", which Senú repeated in [4]. In [5], Chibcha mentioned "lines" and "origin". In [6], Senú noted that the teacher in the task spent time discussing the classification of angles. In the second part of the discussion, the teacher educator asked about the presence of mathematical explanations and graphical examples, and the teachers focused on graphical examples. In [8], Tule mentioned that there were no graphical examples, but in [9], Nutabe referred to the shapes of angles in his written and graphical response to the task. In [10], Katío referred to the measurements in the graphical examples related to the classification of the angles. In [11], Tule distinguished between graphical representations and graphical examples, associating graphical representations with abstract contexts and graphical examples with real-world contexts. The episode thus illustrates the identification of mathematical vocabulary and multimodal examples (both graphical and real-world context) related to angles.

1	Educator:	What mathematical vocabulary, mathematical explanations, and graphical examples are communicated to the student during teaching?
2	Senú:	She provides many definitions. She talks about the vertex, the angle, and the amplitude…
3	Tule:	About the plane, the ray.
4	Senú:	About the ray…
5	Chibcha:	Straight lines, origin.
6	Senú:	And then she spends a lot of time sorting the angles according to their measure, right?
7	Educator:	What do you think about mathematical explanations and graphical examples?
8	Tule:	There are not any graphical examples, are there?
9	Nutabe:	I have drawn the shape of angles.
10	Katío:	Including the measurements.
11	Tule:	Yes, I mean, these are graphical representations, but when I hear the word example, I think back to when I was a child. I suppose… I need to relate it to something familiar, something tangible that I can physically interact with, right? I mean, for me, those are more than examples; they are graphical representations. But when I think of examples, I picture things like the hands of the clock or the handle of a door...

Interpreting the potential impact of the identified aspects of the mathematical discourse

The teachers interpreted the effects of the identified aspects of the mathematical discourse in relation to common learning challenges, as well as their professional knowledge and teaching experience. In [18], the teacher educator asked for a response to the second prompt. In [19], Senú associated the identified aspects with the communication of meanings for angles in static contexts, without mentioning turns and movements. In [20] and [22], Tule pointed out that "turning" is a missing term that does not appear in the task. In [21], Chibcha, the most experienced teacher, mentioned that the mathematical explanations in the textbook are contradictory. She noticed that these explanations fail

to support the distinction between static contexts, where the angle is described as a region of the plane, and dynamic contexts, where the vertex is emphasised as the centre of rotation. This episode illustrates the interpretation of the potential impact of the mathematical discourse on learning, in relation to the introductory documents discussed in the workshop, to professional knowledge, and to teaching experience.

18	Educator:	Could these things be connected to the common challenges we have been working on? Could you explain how they are connected?
19	Senú:	Yes, sure. She teaches..., in other words, she teaches it in a totally static way, doesn't she? The angle is not presented as a turn; instead, an angle is this, and it is classified in this way, but they don't see that it can be associated with movement.
20	Tule:	The turn is absolutely absent; it does not appear anywhere.
21	Chibcha:	But, you see, it does... That is, in the first explanation, it is the portion of the plane, and in the second, the vertex is part of the angle. Also, she contradicts herself, because the vertex is the centre of the turn, not the ray, but the centre of the turn is important for the angle.
22	Tule:	The turn is absent at any moment.

Deciding on mathematical explanations with multimodal examples

The teachers decided on mathematical explanations with related examples using different modes of communication. The structure of the prompt and the dynamics of the workshop facilitated decision-making regarding these modal aspects of the mathematical discourse in an integrated manner. In [28], the teacher educator asked for an answer, that is, a decision that resolved the doubt raised by the student in the task. In [29], Senú read the explanation in his written answer and stated that moving a ray to one side is not the same as moving it to the other side, which implies a turn. In [30], the educator asked for a graphical example, and in [31], Senú made a hand gesture. In [32], the educator asked if he would present the example with hand gestures, to which Senú responded affirmatively in [33]. In [34], Nutabe presented an example previously discussed that had meaning in static contexts. In [35], Tule presented an example linked to the movement of a clock hand to explain the angle as a rotation and the direction of the rotation. In this episode, mathematical explanations and examples responded to common learning challenges by focusing on communicating dynamic contexts and non-metric properties. Furthermore, the way in which the teachers present an explanation with examples reflects some group decision-making. Although the teachers use words from the mathematical discourse when presenting mathematical explanations, this did not seem to be the focus of their discussion. They also made suggestions that were not related to learning challenges but to other aspects, such as emotions in [34]. Another relevant aspect was the use of examples in modes of communication other than graphical representations, such as hand gestures and manipulatives, suggesting that teachers considered visual representations as complementary to linguistic explanations.

28	Educator:	Can you provide a concrete answer for this student?
29	Senú:	What I wrote is that… I mean, when you go from one ray to the other ray, doing this is not the same as doing that; it is different, hence associated with a turn.
30	Educator:	And how would you present the graphical example?
31	Senú:	Like this, isn't it?
32	Educator:	With hands? With gestures?
33	Senú:	With hand gestures, yes.
34	Nutabe:	I liked the example of the pizza; I think they appeals to emotions, and...

35	Tule:	In addition to the pizza, I used the example of the clock hands. I put one in a different colour, and we played as if we had a time machine. Let's move time forward or backward. Then they see that if you do it on one side, you can do it on the other side too. I am not sure.

Discussion and conclusions

The group discussion of the task demonstrates processes of noticing in collaboration amongst the teachers, focused on aspects of the mathematical discourse in the teaching angles. We suggest that structuring the task around prompts aimed at identifying, interpreting, and deciding facilitated the analysis of data and mediated the production of findings in our approach to understanding *What does a group of secondary-school mathematics teachers notice regarding aspects of the mathematical discourse when discussing tasks on teaching angles?* The teachers identified several aspects of the mathematical discourse in the fictional teaching account. The absence of mathematical explanations in the process of identification can be linked to the complexity of what is meant by mathematical explanation. However, it can also be attributed to the design of prompts that did not sufficiently encourage the teachers to identify explanations as an aspect to be discussed in the workshop. Instead, they may have been involved in other processes of noticing related to mathematics teaching and to mathematical discourse in teaching that we did not capture in our study. Although the processes of interpretation are not related to each of the aspects of the mathematical discourse prompted in the task, the teachers interpreted the potential effects of these discourse aspects on the common learning challenges presented to them, incorporating their professional knowledge and experiences. The group discussion of the introductory documents led to the recognition of common challenges in learning angles. The processes of decision-making included mathematical explanations and multimodal examples that are responsive to common challenges in learning angles. Finally, as stated in our framework, by considering mathematics teachers' noticing through identifying, interpreting, and deciding, we are only beginning to understand the complexity and learning richness of the noticing that can occur during a developmental workshop.

Teacher responsiveness and didactical decision-making in a multilingual mathematics classroom

Shintia Revina and Alexander Schüler-Meyer

TU Eindhoven, Eindhoven School of Education, The Netherlands; a.k.schuelermeyer@tue.nl

Developing multilanguage-responsive teaching requires teachers to meet the situational demands of harnessing students' multiple languages for learning mathematics. To better support teachers to develop this expertise, it is crucial to understand what prompt them to deploy certain teaching practices in response to students' multilingual contributions. This paper shows how a case teacher's multilanguage-responsive practices link to his perception of situational demands in a multilingual classroom. The study uses the teacher's own video-recorded lesson and conducts a video-stimulated reflection interview that allows the teacher to justify his in-lesson practices. The results present two critical students' contributions and the teacher's responsive decision-making following these contributions – that illustrate how he realizes the demands of multilanguage-responsive teaching.

Keywords: Teacher responsiveness, didactical decision making, multilingual classrooms.

Introduction

Harnessing the epistemic benefits of multiple languages for facilitating conceptual understanding of mathematics (Uribe & Prediger, 2021) requires teachers to master specific situational demands. We call this multilanguage-responsive teaching. It encompasses the teaching practices through which teachers create opportunities for "students' multiple languages to become a resource for conceptual understanding" (Schüler-Meyer et al., in press, p. 6). Multilanguage-responsive teaching has many benefits, ranging from encouraging students to use all their language repertoires for increased participation and agency (Barwell et al., 2016; Norén, 2015), to benefits for enhancing students' mathematical thinking and learning (Uribe & Prediger, 2021). Yet, despite these benefits, we hardly understand how teachers develop multilanguage-responsive teaching practices. To address this issue, we engaged expert teachers in activities to trial specifically designed tasks which have the potential to harness students' multiple languages for conceptual insight, through the principle of contrasting and comparing languages (Schüler-Meyer et al., 2023; Revina & Schüler-Meyer, 2023).

In this paper, we investigate what prompt teachers to deploy certain teaching practices in a multilingual classroom. We focus on analysing how one case teacher Sven picks up students' multilingual contributions and how he responds to the students' utterances. Furthermore, through a post-lesson reflection, we investigate Sven's decision making for specific practices. In this study, we are guided by the following question: "How does a teacher's multilanguage-responsive teaching practices link to his perception of situational demands in a multilingual classroom?"

Responding to situational demands in multilanguage-responsive teaching

Multilanguage-responsive teaching extends approaches of language-responsive teaching aiming at enhancing students' language for enhancing mathematical understanding (Prediger, 2019) by also harnessing multiple languages as resources for mathematics learning. Accordingly, we have adapted demands of language-responsive teaching from prior research on its situational demands (Prediger,

2019) for multilanguage-responsive teaching of mathematics (Schüler-Meyer et al., in press). For this paper, we discuss three relevant situational demands as follows:

- ELICITING LANGUAGES in multilanguage-responsive mathematics teaching is aimed at turning students' languages into an epistemic resource in the mathematics classroom (Barwell, 2020). Eliciting languages should not only engage students in translanguaging but should also create the environments for harnessing the epistemic potential of language reflections.
- SUPPORTING LANGUAGE AND LANGUAGE REFLECTION refers to supporting students in producing utterances in their home languages and supporting the reflection about similarities and differences in how different languages express mathematical concepts.
- IDENTIFYING MATHEMATICALLY RELEVANT LANGUAGE ASPECTS is concerned with recognizing meaning potentials from conceptual connotations expressed in students' languages. Here, teachers must identify what is mathematically important with respect to students (home) language and what is peripheral, for this, topic-specific meaning-related phrases are more powerful than formal technical phrases (Prediger & Uribe, 2021).

For developing teachers' multilanguage-responsive practices for mastering these situational demands, we consider Mason's (2016) perspective on teacher responsiveness: How teachers respond to students' concerns and states significantly impacts both individual student learning and the overall class dynamic. In the context of multilanguage-responsive teaching, this means that teachers' practices in eliciting and incorporating multiple languages influence students' contributions in translanguaging activities. These contributions, then, enable teachers to understand how students interpret concepts in their language(s) and how this interpretation can enhance the class's understanding.

Teachers' responsive practices are shaped through a process of professional judgement: perceiving students' thoughts and ideas, interpreting those thoughts, and making informed instructional decisions to advance students' understanding (Jacobs et al., 2010). In a multilingual classroom, this process involves perceiving and interpreting students' contributions in multiple languages with respect to the demand of enhancing students' mathematical understanding. In other words, teachers need to realize the demands of eliciting language so students' contributions in multiple languages can be exploited. Noticing and interpreting valuable contributions that can create opportunities to harness the potential of students' utterances for meaning making, yet it involves the demands of identifying mathematically relevant language aspects. Ultimately, for making informed instructional decisions to advance students' learning, teachers face the demands of supporting the reflection about how different languages express a mathematical concept and, particularly, how the different connotations can enhance students' understanding of the concept. As teachers often struggle to enact the decision-making phase during the lesson, Mason (2011) suggests providing teachers with opportunities to reflect about the decision making retrospectively, which can help teachers developing a heightened sensitivity, enabling them to adapt their responses rather than relying on habitual reactions.

Methods

The case teacher in the present study, pseudonymised as Sven, is among the teachers who involved in the development of PD activities for multilanguage-responsive teaching. Sven teaches a Year 4 secondary classroom in an international school in the Netherlands, with English as the language of

instruction. He is a native Swedish and fluent English speaker. He has more than 10 years of experience in teaching students with multilingual background. Nearly all of Sven's students were born outside the Netherlands or have had their formal education abroad either in their country of origin or elsewhere, other than the Netherlands. The languages present in the classroom are including Chinese, Hindi, Urdu, Arabic, Turkish, Italian, German, and Dutch.

The lesson we observed in Sven's classroom is on the topic of 'completing a square' method to solve quadratic equations. The completing a square task requires students to identify how 'completing a square' methods is expressed in their home language and reflect upon the meaning – whether the meaning of the expression can be helpful to understand the steps in completing the square method. The task provides students with some examples of how the phrase 'completing a square method' is expressed in other languages, such as in Polish 'do pełnego kwadratu' (to make full square), and later highlights the geometric and algebraic interpretations of completing a square method. The task follows the principle of contrasting and comparing languages (Schüler-Meyer et al., 2023). The observed lesson is Sven's second teaching experiment in the project, and the duration is 50 minutes.

We videorecorded Sven's 'completing a square' lesson and conducted a stimulated-recall reflection interview following the lesson. Video-stimulated recall or reflection interviewing is deemed as appropriate since it allows the subject (Sven as the teacher) to view a video sequence of his teaching practices and is then invited to reflect on his decision-making processes during the recorded event. While the lesson duration is 50 minutes, for the purpose of the video-stimulated reflection interview, we ask Sven to reflect upon the 10 minutes of plenary session at the end of the lesson where comparing and contrasting languages takes place. During the interview, Sven is instructed to stop the video when he wants to remark on a specific situational demand he experienced. The interview evolves around Sven's responsive practices by which he follows up on students' contributions. The lesson and the interview are transcribed and analysed qualitatively.

Results

We present two student contributions to which Sven responded and unfold the potentials for realizing situational demands of harnessing these contributions for promoting deeper understanding of completing a square method in solving quadratic equation. This is followed by an analysis of Sven's practices in terms of how they meet these situational demands and his reflection on them.

Students' contribution 1: Two meanings of 'square' in some languages – as a geometrical shape and as the power of two

During the watching time of video-stimulated interview, Sven pauses the lesson video following the opening of the lesson when he starts the plenary session as below:

> Sven: If I translate completing the square into Swedish, it is *kvadrat komplettering. Kvadrat* [*Swedish words*] means square, both in a geometric sense and the exponent of two. […] If I would translate it [*the Swedish words*] back into English, it would mean completing the square. It has the same meaning. Swedish and English is actually very close. The build-up of sentences and many words have a direct translation. So, Swedish would be a bit a boring example of this. It means basically the same thing as it does in English. We use square for the geometric figure, square, but also for the exponent. Two squared means two to the power of two. But we have found at least one, so far, different meaning for completing the square. [*Sven points*

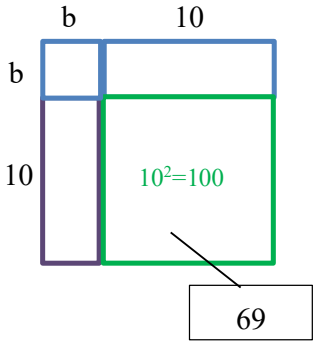
to a student] Would you like to share that with the whole class? What it means in your language?

In the above episode, Sven starts with a reflection from his own language, Swedish, and shares that the expression for completing a square in Swedish provides him with a reference to both geometric and algebraic meaning. He highlights that he found a different meaning for completing the square, most probably from the time he walks around the class. The first author follows up Sven's remarked practice by asking him to describe what he observed in the paused moment. He describes that he receives an unexpected contribution from a Chinese and a Hindi student before the plenary session begins. Below is an episode from the interview.

Researcher: So, please explain why you think this moment in the lesson is critical.
Sven: In my language, Swedish, it is not that interesting to think about [*translating*] 'completing the square' because it means the same thing as in English. The direct translation is the same. When I walked around the class, I get some feedback from my students. I didn't realize there were so big differences in other languages, such that in Hindi or Chinese. They are very different from the English. That there are different words for the geometric square and the power of two.
Researcher: That part you didn't realize?
Sven: No, I didn't reflect before. So that was new to me as well. That's one of those interesting parts of this.
Researcher: And do you think brought this up [the two meanings of 'square'] to the whole class can potentially open up a discussion? What kind of discussion?
Sven: To explore from different language perspectives. Because as we found out completing the square is translated differently in different languages – could carry more algebraic or more geometric meaning. And that could be interesting to look at, I'm not sure if it helps students' understanding. Difficult to measure but it is at least an interesting point of view to look at.

The episode shows how Sven sees the potential of exploiting students' multiple languages for opening a discussion about what it means by 'completing a square' and how it may help to understand the method both geometrically and algebraically. He notices that in English, the phrase 'completing a square' may bring some confusions, as the word 'square' has dual meanings, as a geometrical shape and as the exponent. He recognizes that contributions from a Chinese- and Hindi-speaking students, that he is unaware of, may offer valuable insights to students learning of the topic. In regard to the situational demands, the episodes illustrate how Sven frames the demands of IDENTIFYING MATHEMATICALLY RELEVANT LANGUAGE aspects, and it is evident that he recognizes the potentials of SUPPORTING LANGUAGE REFLECTION for facilitating students' understanding.

In terms of didactical decision making, Sven follows up the potential of exploiting the meaning of 'square' and 'completing the square' in Chinese and Hindi by providing an example on how he thinks about the problem – doing a back-to-back translation, and then by asking a student to share her thoughts in a plenary session. Sven's actions reflect the three steps for utilizing students' ideas to inform his teaching (Jacobs et al., 2010). In this case, he perceives the students' contribution of two different meanings of the word 'square' in languages other than English (the language of instruction) which may affect how 'completing a square' is interpreted differently. Sven attempts to discuss the meaning of completing an incomplete geometrical squared shape or completing an algebraic form to the power of two, and perhaps to connect the two. Nevertheless, his idea remains superficial which suggests that he struggles to recognize the potentials for meaning making in students' utterances.



Sven's responsiveness is limited by the unexpected nature of the students' ideas, requiring him to make in the moment adaptions to his teaching practices. In the following episodes, Sven responds to a student's contributions and describes how his perspectives about the situational demands in multilanguage-responsive teaching influence his responsive decision making.

Students' contribution 2: 'Matching the power' may explain the algebraic steps in 'completing a square' method

The interview is continued with the first author and Sven resume the video lesson. Sven pauses the video following the below episode in the lesson.

Sven:	Would you like to share that with the whole class? What it means in your language?
Lin:	Like the name of the method for completing the square, if you translate it to Chinese and translate it back, then it is matching the power. [*Lin wrote on her worksheet:"配方法/ pèi fāngfǎ (matching the power of two)*"]
Sven:	OK. Matching the power. Because you have two different words, for the geometric square and the algebraic expression square [*power of two*]?
Lin:	Yes
Sven:	So, there are two different words in Chinese, two different meanings. […] So, matching the square. In Chinese, the geometric square has different words [*from the algebraic expression square*]. So, if we forget about this figure here [*points to the square drawn on the board/ shown in Figure 1*], but looking at these equations instead, how can we relate to matching the square? Or matching the power. The power here is two. So, I am writing an expression with power of 2. Here is the "green part" [*he highlights* 10^2 *in green*] that I have to do to match these two processes.
Lin:	Yes, like we are trying to find for example $(b + 10)$ square. We are trying to match like the 10 square part of that in $(b + 10)$ square.
Sven:	Yes exactly, I think that is a very algebraic way, we're not looking at any geometric parts here, just algebra. But that's exactly what we're doing right. We're trying to match this equation to this equation [*points to the two equations shown in Figure 1*]. We write it in another form, with a power. Thank you.

The episode shows that Sven intentionally encourages Lin, the Chinese speaking student, to share the expression of 'matching the power', the translation for 'completing a square' in Chinese. Sven uses the visual representation and equations that he provides on the whiteboard, so Lin can reflect on her thought when put the meaning into the 'matching the power'. Lin elaborates her answers and shows what she meant by 'matching' when matching the power in the equations and points to specific part of the equation (and the drawing). In this episode, Sven seems to master the demands of eliciting language and supporting language reflection by connecting registers and representations. Sven's practice of eliciting language has set a crucial step for his students to make sense of what 'completing a square' entails, but still, some potentials remain unexplored, e.g. elaborating in class how Lin's idea could inform the procedure for completing the square. During the interview, Sven shares more about his interpretation of the situational demand in this episode.

Two expressions that teachers wrote on the board:

$$b^2 + 20b = 69$$

$$(b + 10)^2 - 10^2 = 69$$

Figure 1: The geometric figure and algebraic expressions written on the board by the teacher

Researcher: Do you think that the language of 'matching the power' is powerful to discuss about the algebraic meaning? Better than completing the square?

Sven: Yes. It explains more, I think so.

Researcher: In relation to that, why then you decided to focus on the two equations after hearing that the student says, 'matching the power'. Is it like you think, "oh the student is talking about the algebra?"

Sven: Yes. Yes, it is definitely the algebraic interpretation. Yes, because then we see, the point is that they have to write an expression to the power of two so that they can have, take the square root of that expressions with the variable inside the brackets. So that we make that variable as the subject when solving the equation. So, this is a step we have to take, we have to rewrite $b^2 + 20b$ into an expression with variable square, and not the form we started with. So, yes, we have to rewrite it in another form, they have to match. The way she is talking about is the algebraic way. I focus on that because that is the step that we have to take to solve the equation.

Researcher: And, what is your intention when providing the visual representation on the whiteboard [*see Figure 1*]?

Sven: Because I think it helps them to understand what is happening. That b^2 is the area of a square with a side b. So, by putting the algebraic method and the geometric method side by side they see the connection, and they can visualize what is happening. […] That we are actually comparing the area of these squares and rectangles, that we are adding them. So, I think it is easier for the students to understand what the algebra represents.

Researcher: Alright. Do you want to add more comments?

Sven: Well, [*in future lesson*] I would want to try to emphasize their different meanings more, connect it more to the respective ways of looking at it. […] Creating a geometric figure from the algebraic expression. And go all the way, solve the equation. So don't stop at rewriting toward another form. Why are we doing this? They are probably thinking why are we doing this? What is this for? It is to solve algebraic equations. […] And then, start with simple quadratic equations, just to solve $x^2 = 25$ or $x^2 + x = 0$. The simple quadratic equations, start with those. Then move on to the complex quadratic equations where they have to use this method.

The interview highlights that Sven remarks Lin's contribution of 'matching the power' that can be valuable to explain the manipulation algebraic steps in completing the square method to solve a quadratic equation. Following Lin's contribution, Sven interprets what Lin tries to say about 'what to match'. Sven is aware that the expression 'completing a square' is not explicit regarding the procedure to rewrite a given quadratic equation, for instance, $b^2 + 20b = 69$ into a perfect square form, whereas the expression 'matching the power' allows an interpretation to do so. Following Sven's noticing and interpretation of Lin's contribution, he decides to ask for Lin's clarification or

elaboration on what she means by 'matching' in 'matching the power' and how she can relate the two equations he puts in Figure 1 to the idea behind 'matching the power'. It is interesting that Lin can specify that she matches "… the 10^2 part of that in $(b + 10)^2$".

Sven associates Lin's utterance of "matching the power" with the idea of transforming the quadratic expression into a binomial form. In his retrospective, Sven shows his understanding of realizing the demands of supporting language and language reflections by connecting the visual and symbolic representations (shown in Figure 1) which aims to allow students to make connections when trying to understand the algebraic procedures in solving the quadratic equation. Moreover, Sven suggests that alternatively, he would want to start with a simple equation, offering opportunity for students to connect the algebraic and the geometric meanings, and to explore the algebraic manipulation steps in solving quadratic equation more explicitly.

Discussion and conclusion

This paper reports how a teacher realizes the situational demands of multilanguage-responsive teaching by investigating how he responds to two critical contributions from his multilingual students and utilizes the contributions to inform his in-lesson decision making. In his reflections, the teacher highlights some limitation of his current practices and therefore devises some alternative approaches that could have been beneficial to support students' deeper understanding. Nevertheless, as we have discussed elsewhere (Revina & Schüler-Meyer, 2024), it seems demanding for teachers to utilize students' contributions in multiple languages in consistent way. While previous critical inquiries into multilanguage-responsive teaching seem to have enabled teachers to elicit multiple languages in the shown cases, more work needs to be done to better understand how teachers can be supported to continuously develop their capacity to enact responsive instruction (Kavanagh et al., 2020) that utilizes students' multilingual contributions in the classrooms, for promoting mathematical understanding in class. Future work needs to be done to design specific and targeted professional development opportunities for that purpose.

Fostering mathematical explanations through LLM-based tasks

Hanna Eckhardt and Daniel Thurm

University of Siegen, Faculty IV, Siegen, Germany; eckhardt@mathematik.uni-siegen.de

Keywords: Artificial intelligence, large language model, explaining, digital escape game.

Introduction and Theoretical Background

Explaining is "[…] an interactive and discursive activity" (Heller, 2016, p. 254) and widely recognized as a crucial learning strategy for enhancing students' outcomes (Dunlosky et al., 2013). In particular, explanations provided by students themselves contribute to the development of deeper understanding (Bisra et al., 2018). Consequently, explaining is frequently observed in classroom discourse. However, active student participation in these discursive activities varies considerably. Factors such as large class sizes, which reduce individual speaking opportunities, and limited discursive competence among students pose significant challenges.

Research Goals

We aim to develop and research tasks that engage students in explanation processes about mathematical concepts by leveraging artificial intelligence (AI), specifically large language models (LLMs) like "ChatGPT". LLMs simulate human-like interactions, allowing questions and statements to be communicated in a natural and conversational manner. The advantage of LLMs in this context is their ability to be preconfigured for specific tasks or purposes through customized GPTs.

In advance, the LLM was configured to act like a learner with difficulties in solving a mathematical task and to ask students, who assume the role of explainers, for assistance. Rather than providing explanations directly, the LLM is designed to initiate deeper levels of explanation from the students by posing understanding-oriented follow-up questions. Moreover, the LLM was configured to reference visualizations embedded in the task, for example, by representing fractions not only in their numerical form but also as parts of a whole in a circle diagram. By doing so, it encouraged learners to engage with different representations in their explanations. In this way, the LLM is overall designed to stimulate rich discourses on mathematical topics with the provision of little help and the omission of own explanations.

Building on the concept of situated learning, we situate the explanation process within a digital mathematical escape game, creating a motivating, immersive, and goal-oriented context (Jiménez et al., 2020). In this environment, students interact with a LLM, which appears as a game character. This design-based research project explores two key questions:

(1) What are relevant design principles for the LLM that enhance the explanation process?

(2) Which mathematical discourse processes are stimulated through interactions between learners and LLM, and how do these interactions influence the quality of students' explanations?

First Results and Outlook

We conducted a first pilot with a self-developed escape game called "The Scavenger Hunt," in which students visit a museum and search for hidden clues. During the game, they encounter Justin (a

configured LLM), who asks for their help on a specific mathematical task he is struggling with. The setting was structured for students to work in pairs, allowing them to collaborate with each other while also interacting with the game character. The learners communicated with Justin via speech-to-text and received his responses in written form. The pilot project was conducted with six pairs of students each from the 6th grade focusing on fraction arithmetic and the 8th grade focusing on linear functions. We collected video recordings of the learning environment as well as screencasts and chat logs. The data is methodologically analyzed using qualitative content analysis.

The situating of the task worked well, as students quickly adapted to the game scenario and engaged with Justin as though interacting with a real human friend. In many cases, interactions with Justin, especially his follow-up questions that consistently pressed for deeper explanations (for example "Why is that…?") encouraged students to discuss their explanatory responses and prompted them to think more deeply about the mathematical topic and their initial explanation, which was typically superficial. As a result, they provided more thorough explanations, and, in some cases, identified additional connections within the task.

However, despite the task focusing on mathematical topics that had been previously covered in class, some students struggled with the explanation process due to considerable knowledge gaps. In these instances, it became evident that a complete omission of explanations by the LLM as a design principle does not work as effectively: Justin's questions aimed at eliciting deeper explanations failed to elicit progress, as the students lacked the necessary vocabulary and comprehension to respond effectively. Moving forward, we plan to explore how the LLM game character can offer subtle scaffolding during the explanation process. For instance, Justin could present suggestions or ideas himself, giving students a pathway to continue their explanations.

Teaching AI about epistemic logic puzzles: Directing attention

Ingólfur Gíslason

University of Iceland, School of Education, Reykjavík, Iceland; ingolfug@hi.is

Keywords: Interaction, preservice teachers, AI, attention, epistemic logic.

Attention, babbling, gargling, and epistemic logic

Mason (2008) explains that teaching is about *directing learner attention* and scaffolding and fading support so that they eventually attend in mathematically productive ways on their own. Mason (2017) contrasts the notions of *babbling* and *gargling* to describe mathematics learners' unsuccessful explanations. Babbling refers to inexpert efforts to express thought. In contrast, gargling refers to learners "throwing technical terms into assignments in the hope that the teacher will recognise them and award marks for them" (Mason, 2017, p. 7). A gargling student is not trying to *mean* anything.

I assigned preservice teachers (PSTs) the homework task of presenting a challenging mathematics problem to the ChatGPT chatbot, leading it to a solution, and, reflecting on the interaction, comparing it with interacting with human students. The rationale is that a session with a chatbot can support preparing for interacting with human students as ChatGPT might make similar mistakes to students in the classroom, including babbling and gargling, and need directing of their (artificial) attention.

One conversation was on an *epistemic logic puzzle*. Epistemic logic puzzles involve reasoning about knowledge, including one's knowledge or the knowledge of other people, especially knowledge of knowledge or knowledge of the lack of knowledge (Hamkins, 2019). The puzzle reads as follows: "At a party, you hear a guest asking about the ages of the host's three children. The host tells the guest that the product of the children's ages is 72, but the sum of their ages is the same as the guest's house number. The guest knows their house number, but after thinking for a while, they ask the host for more information to determine the ages. The host says that their oldest child likes strawberry ice cream. The guest could then determine the ages of the children. Although you do not know the guest's house number, you have received enough information. Assume that age is always given in whole years. How old is the oldest child?" The puzzle requires unusual attention to epistemic clues.

The conversation

In the following, I present segments of the 13 turn-pair interaction between the PST and ChatGPT to explore similarities with human-to-human teaching situations, specifically on directing attention, babbling, and gargling. In the first attempt, it created a list of several (but not all) possibilities to get 72 by multiplying three numbers. Later, in the same turn, it concluded its first solution attempt.

ChatGPT: […] If the sum were 14, there is only one possibility: 2 + 2 + 9. The host's oldest child must be 9 years old because it is the only age that appears in only one combination. Therefore, the answer is that the host's oldest child is 9 years old.

PST: Try to think about the fact that the guest needed another hint, that tells us that although the guest knows the house number, they still needed another hint.

An aspect of ChatGPT's response can be interpreted as babbling if we think that the generation of possibilities of multiplying and considering sums constitutes an engagement with the meaning of the task. But "it is the only age that appears in only one combination" is only superficially related to the

task and could be interpreted as gargling. The PST response seems to be intended to direct attention to a specific (essential) detail, namely the role of the epistemic information in the puzzle. After three more turn pairs, ChatGPT produced a complete and correct list of possibilities, saying that the children are either 3, 3, and 8, or 2, 6, and 6 years old because those numbers uniquely give the same sum. Then, ChatGPT seems to gargle about the age relations of twins and their siblings:

ChatGPT: If the twins are the oldest children, then we know that one twin is older than the other, but we do not know which. However, if the child who is not a twin is the youngest, then the older twin must be the one who likes strawberry ice cream. This is because the host would not have referred to the younger twin as the oldest child if there is an older twin. Therefore, we can conclude in this case that the oldest child is the older twin, and the other twin and the non-twin child are both six years old.

PST: What if I tell you that we always consider twins to be of the same age?

The PST directs the attention to a feature of the task without directly stating what is wrong with the answer. In the tenth round, the teacher candidate summarizes for the artificial student that the possibilities are 3, 3, and 8, and 2, 6, and 6, and directs attention again to the critical clue:

PST: We know from the clue about the ice cream that one child is the oldest, so in which possibility is there definitely an oldest child?

This is already on the verge of being a case of funneling. At last, the PST asks a funneling question:

PST: I think you are overthinking this, how old is the oldest child if there are three children who are 3, 3, and 8 years old?

After this, ChatGPT gave, as a final turn, a reasonably good account of the solution as a whole when asked to do so.

Conclusion

Some of ChatGPT's difficulties in solving the task differed significantly from those of a human student. A human would not need multiple turns to accept that twins are considered the same age or to realize that the clue implies one child must be older than the other two. On the other hand, many human students benefit from having their attention directed to points such as the guest needing another clue to deduce the children's ages. In the conversation with ChatGPT, the PST practiced directing students' attention and getting them to revise their answers while increasing their awareness of babbling and gargling.

TWG 10: Diversity and Mathematics Education: Social, Cultural and Political Challenges

Report to TWG10: Social, Cultural and Political Aspects of Mathematics Education

Timo Dexel[1], Laura Black[,2], Mariam Makramalla[3], Juuso Henrik Nieminen[4], Sabrina Salazar[5] and Daniela Steflitsch[6]

Scope and Focus

Thematic Working Group 10 (TWG 10) has its roots in the *language diversity group/teaching and learning in the multilingual classroom* and progressively transformed to include broader settings, political perspectives, theoretical perspectives. It centres discussions of mathematics education within the realms of the cultural, the social and the political. TWG10 builds on the premise that mathematics education is always more than an encounter between an individual and a mathematical object in a classroom setting. Instead, it views such encounters as shaped and produced by wider cultural and societal contexts that are inherently social and political. At the same time, such encounters are also viewed as contributing and constituting the contexts in which they are embedded in ways that reproduce, challenge or disrupt power relations. TWG10 is characterized by an effort to reflect its own double-role in analysing, shaping and reconfiguring mathematics education practices. The group is specifically interested in research that investigates how diversity and difference affect the possibilities, opportunities, obstacles, privileges and disadvantages associated with mathematics education. This includes issues of gender, race and ethnicity, language, socio-economic status, social class, disability, inclusion/exclusion, life opportunities, aspirations, worldviews and ideologies, school systems, governance structures, space, and settings. Additionally, diversity and difference may occur in relation to who is doing the research and who is being researched, posing methodological issues of an ethical, ontological and aesthetic nature. Diversity and difference are therefore perceived in a broad sense and refer to various ways of doing mathematics education research within the realms of the cultural, the social and the political. As all these multiple diversities and differences intersect, a reflective approach is expected in reporting on implications of any research.

Organization of TWG10's work at CERME14

In the run-up to the conference 25 papers and 5 posters were submitted. 23 papers and one poster were accepted and discussed at the conference, leading to 21 contributions that were included in the proceedings. As at previous CERMEs, the group adopted the principle of *peer presentation*, namely that authors do not present their own paper, but give a short (5 minutes) presentation of a paper submitted by another participant in TWG10. This peer presentation included a description of the

paper's main ideas (as read by the presenter) and the formulation of questions from the presenter's own perspective. This was followed by a 5 minute response from the author(s) and then questions and discussion within the whole TWG. However, the experience of the last conference (CERME13) showed that some authors want to present their own paper for various reasons. We were also discussing, that the separation could create distance between voice of the researcher and their work or denying researchers the opportunity to have their voice heard. For this reason, this time gave the opportunity to deliver one's own presentation, which was at least partially used. The poster was discussed alongside the presentations in order to make it visible to the whole group.

The Papers

In this section, we briefly describe the papers sorted by main topics, starting with papers on the *designing of tasks, reflecting books & curriculum*: *Norén and Wallin* discussed the challenges for second language learners to solve mathematical word problems and how material entanglements play out around mathematical word problems when students talk about them. The paper by *Da Cruz et al.* focused mathematics textbooks in Brazil and Canada, comparing linguistic, cultural, and sociopolitical factors. The study highlights textbooks as pedagogical and cultural artifacts, suggesting that national guidelines may benefit from balanced approaches that include local perspectives. *Jablonka and Nazir* also used a comparative approach but not in analyzing books or tasks, but curriculums. Using Basil Bernstein's notion of framing the Berlin Mathematics Curriculum (Germany) and the Turkish Mathematics Curriculum were discussed. When it comes to curriculums, universal design for learning becomes a more and more common approach, though there is little known about the concept. That is why *Bray, McKenna and Oldham* provide a scoping review that reveals limited but promising research, highlighting a need for further studies to explore UDL as a framework for inclusive and equitable mathematics classrooms. Another paper in this section is about designing a Professional Learning Task (PLT) within the context of preparing mathematics instructors in higher education, focusing on an innovative curriculum that uses technology as a leverage for promoting social justice. *Salazar and da Silva Schneider* discuss elements that integrate mathematical knowledge with its teaching and that aim to challenge mechanisms of oppression affecting traditionally marginalized students in mathematics courses.

Another important topic emerged on *political and environmental crisis*. *López-Serentill et al*. join the analysis of curriculum conceptions and research how sustainability competences have been integrated into the current primary education curriculum in Spain by using the GreenComp European sustainability competence framework. Not only the environmental crisis but other conflicts over inequality are topics for mathematics education. That is why *Neuenfeldt and Dexel* suggest a framework of 'arenas of conflicts over inequality' and transfer it to mathematics educational research. *Fosse and Hauge* present a project on sustainability conducted by pre-service mathematics teachers. Different aspects of the clothing industry within the the subjects of social studies, natural science and mathematics were discussed by the participants and linked to questions of empowerment and disempowerment. A similar project with Norwegian and South African researchers on clean water was carried out and thoroughly researched with reference to video data by *Foyn et al.* The authors report in a very self-reflective way on the difficulties of changing and influencing the positioning of students within such projects.

Empowerment also plays a role in the next notable topic of our working group, the research of student diversity. Drawing on the concept of mathematical empowerment, *Billigen and Söbbeke* analyze the extent to which social participation can be developed in a mathematical negotiation process using a case study. *Wagner et al.* describe the effort to surface experiences and conceptualisations of those experiences drawn from interactions with newly migrated and Indigenous mathematics students. They identify challenges in surfacing student experiences, and in naming their conceptualisation of those experiences as storylines. *Wang and Kollosche* categorise subjective relevance of mathematics students in deriving dimensions of relevance from theory and supplement them with examples from empirical research. *Österling et al.* present a survey study of the mathematics capital of first-semester mathematics students in Swedish universities, using a cluster analysis that shows how mathematics capital is distributed among three clusters of students, distinguished mainly by parents' or significant others' relation to STEM.

One of the most prominent topics at our sessions on student diversity evolves around different conceptions of *gender* and mathematics education. In a quantitative study *Tscholl* examines whether a gender gap in mathematical self-concept can be found among first-year STEM students at the University of Innsbruck and if the accuracy of mathematical self-perception relative to performance differs by gender. She comes to the conclusion that gender-specific filter mechanisms appear to persist when entering STEM degree programs. *Aquilina* takes a closer look at the Italian INVALSI tests aiming to explain how a higher gender gap is constructed. For that reason, she analyzes 657 students answers to the 'Tennis-Tournament'-task. Her results suggest that gender disparities may stem more from situated than from mathematical knowledge. Another approach to determine the relationship between gender and mathematics is made by Brieger, who analyses in detail interviews with mathematicians who describe their mathematics lessons in school and corresponding interpretations by others. In the study female mathematicians describe themselves using mostly masculine-associated wording and women's memories of mathematics lessons in school were being framed in the contexts of competitions and strong will to succeed. The poster in this session by *De Rocco et al.* addressed how mathematics teachers perceive gender difference within a prison school.

As *Teachers* of course play a very important role when it comes to social and political aspects of mathematics education there were different papers prioritizing this group. *Beccuti and Polo* discuss discourses on mathematics and mathematical ability of support teachers in Italy in context of broader systemic issues connected to the support of the teaching and learning of mathematics in Italy. *Guillemette* describes a participatory research project implemented with in-service secondary school mathematics teachers in Montreal, Canada. In the dialogues about mathematics cultural and historical emerge three main thematic topics: Otherness, Hospitality and Reflexivity. In a synopsis of three research projects about socially just approaches to mathematics, *Wright* emphasizes the aspects relational pedagogy, relational authority and relational agency in context of learning and teaching. The paper by *Kitchen et al.* focusses on the development of teacher leaders in hierarchical schools and school systems. They use a socio-political theoretical perspective to explore the opportunities that minoritized teachers have in engaging as teacher leaders in mathematics in their schools and school system, showing that that a ceiling exists for them that limited their growth as leaders.

Next steps

Keeping a critical approach towards 'rigour' during the review process

The number of submissions to CERME has increased quite rapidly during the recent years, which is why the conference organisers have understandably needed to implement measures to ensure as many colleagues as possible could attend the conference. Amid this context, the acceptance rate for CERME papers necessarily gets lower. The question then arises: how could we make informed and fair decisions about submissions to TWG10 in the future? In other words, how can we remain critical and transparent about what sort of work gets rejected from our TWG – especially as such cases are likely to increase?

As with any topic in our TWG, we must also consider the peer review exercise in CERME not as a neutral mechanism, but as a socio-political practice that in many ways represents and renews power relations. What gets accepted and what gets rejected in our TWG is a thorny issue from this point of view. We presume that the upcoming years will need to engage the TWG10 community in tricky conversations about what 'rigour' means within the scope of our TWG. We cannot simply utilise definitions that work elsewhere; ones that emphasise particular worldviews and paradigms beyond our socio-political one. It is likely that CERME will aim to make the peer review process more standardised in the future, and while there is an important message behind such approaches in ensuring all colleagues are treated equally, our TWG may also need to make editorial decisions that help increase the visibility of non-dominant forms of research and research in non-dominant communities'. Representative examples of this might be studies drawing on an activist stance (such as disability studies), or studies drawing on Indigenous approaches (see e.g., the work of Beccutti and Wagner et al. in this year's contributions).

One of the criteria for CERME papers is the fit between the paper and the TWG. We anticipate this criterion will become increasingly important in the future. Many excellent research papers might be excluded from TWG10 if they lack critical perspectives, for example, if they do not adequately contextualise the issues at hand. Yet again, the divisions between what counts as 'critical enough' for our TWG are not simple but most likely require some thorny dialogues. It seems likely that controversial topics will become more frequent in the future, given the many political and social challenges unfolding in different parts of the world.

In discussing these challenges, we believe our responsibility is to keep TWG10 as a space for difficult and important socio-political conversations. Ultimately, the task is about creating space for discussion that is respectful, thoughtful and open to diverse opinions and which welcomes non-dominant scholars and those active in the struggle of the oppressed against oppression. This requires explicitly recognising academic freedom as politically non-neutral whilst upholding ethical responsibility in the struggle for social justice. TWG10 has to remain open to a plurality of perspectives, but it also has to ensure that contributions are transparent, critically contextualised, and aligned with the group's socio-political focus. These tensions are not easy to navigate, but they are central to the ongoing work of TWG10.

Beyond performance in mathematics results: gendered patterns and contextual knowledge in the "Tennis tournament" item

Ginevra Aquilina

Department of Mathematics, University of Pisa, Italy; ginevra.aquilina@phd.unipi.it

Standardized assessments in mathematics consistently reveal a so-called gender gap in favor of boys in Italy. The broader study seeks to acknowledge the complexity of this often-oversimplified phenomenon by shifting the focus from quantitative data – the results of standardized assessments – to a qualitative analysis of students' descriptions of their solution processes. This paper examines a grade-8 item from the Italian standardized assessment (INVALSI test) – the "Tennis Tournament" item. The grounded analysis of 657 students' protocols highlighted the gendering of students' solution patterns and the critical role of contextual knowledge in answering correctly. These findings are particularly relevant to the "gender gap discourse", given the widespread belief in the objectivity of standardized test results. Only by focusing on the processes behind students' answers can we meaningfully interpret the data and challenge both the gender gap and its prevailing narrative.

Keywords: Gender gap, mathematics, standardized assessments, contextual knowledge.

Introduction and theoretical background

Over the past decades, national and international standardized tests have gained significant prominence in evaluating educational systems, influencing public opinion, and shaping policies. A recurring outcome of these assessments is the so-called gender gap in mathematics performance observed across most countries. The 2022 PISA (Programme for International Student Assessment) report, which focused on mathematics, highlights that this performance gap remained unchanged over the past decade in 53 of the 64 participating countries or economies with comparable data, including Italy (OECD, 2023). While the average mathematics test scores in Italy aligned with the OECD average, Italy recorded the largest gender gap in favor of boys, with a 21-score point difference compared to the OECD average of 9 points. Globally, boys outperformed girls in mathematics in 40 countries/economies, whereas girls outperformed boys in 17. This international variability underscores the importance of questioning simplistic interpretations of the so-called gender gap and considering the critical role of sociocultural factors in shaping mathematical learning outcomes.

In the Italian context, the INVALSI (Italian National Institute for the Evaluation of the Education and Training System) annually assesses students' competencies in Italian, mathematics, and English across various school grades (2, 5, 8, 10, and 13). Historical data reveal that girls consistently outperform boys in linguistic tests, while a stable and pronounced gender gap in favor of boys persists in mathematics performances (Giberti, 2019). According to the 2023 INVALSI report, male students in the "type" group – an INVALSI category defined by specific socio-demographic characteristics – score between 4.6 and 7.4 percentage points higher than females across school grades, accounting for approximately 50% of the yearly average learning.

The results of standardized assessments are just one indicator of the inherently complex phenomena of educational gaps, yet they are particularly significant because they enable diachronic and

geographical comparisons and because they strongly influence public opinion. Consequently, many studies have attempted to explain the determinants of the gender gap in mathematics through analyses of the overall results of standardized tests. However, Giberti (2019) highlighted a lack of didactical interpretations in the use of such data, which are often analyzed purely statistically. Together with colleagues, she conducted item-level analyses to identify specific characteristics of test items – such as typology, formulation, and context – that could influence the gender gap (Bolondi et al., 2018; Ferretti & Giberti, 2021). Their findings suggest that the "didactic contract" may exert a stronger influence on girls, potentially explaining their response patterns on specific INVALSI items.

I argue that moving beyond the quantitative data from standardized assessments is essential to interpreting the so-called gender gap in final scores and understanding the underlying dynamics. As Di Martino and Baccaglini-Frank (2017) observe:

> Standardized assessments are interested in describing quantitative macro-phenomena rather than in understanding them, also at a micro level. To gain such understanding, using Crespo's words (2000), it is necessary to acquire an interpretative orientation, collecting students' ideas with the purpose of accessing rather than assessing students' mathematical understanding (p. 1).

Cooper and Dunne (1999) supported the need for an interpretative approach, focusing on the analysis of the problem contexts that often reflect implicit class and gender biases. While aiming to enhance relevance and understanding, contextualized tasks frequently rely on cultural capital and prior experiences that are unequally distributed among students, potentially disadvantaging girls and students from lower socioeconomic backgrounds. Similarly, Boaler (2003) highlights how pseudo-realistic word problems can embed biases that influence student performance, impacting particularly on girls, who seem to engage more deeply with contextual variables. Boaler and Sengupta-Irving's (2006) relational approach to learning further stresses that problem-solving cannot be disentangled from the environments and interactions that shape how students engage with tasks. These perspectives reinforce that the context in which mathematical reasoning is assessed is never neutral: it carries implicit messages about whose knowledge and experiences are valued.

These findings stress the need for developing qualitative analysis to meaningfully interpret the so-called gender gap phenomenon and to inform more equitable discussions about mathematics assessment. Questioning the phenomenon and understanding the dynamics behind the performance gap are the first steps toward imagining effective actions to counteract it.

Research aims

In this frame, I am conducting a comprehensive study focused on the qualitative analysis of students' descriptions of their solution processes. The overarching aim of the broader study is to unpack quantitative data to question both the so-called gender gap in mathematics and its underlying narratives. Building on the interpretative orientation advocated by Di Martino and Baccaglini-Frank (2017), I aim to analyze students' problem-solving patterns on INVALSI items that revealed a significant gender gap in the Italian standardized assessment. By doing so, I seek to uncover the underlying dynamics of response construction, moving beyond a surface-level assessment of outcomes. Specifically, the guiding question is: How are gender differences in results reflected by

the gendering of students' solution patterns? Furthermore, I am interested in interpreting the factors affecting these different patterns, particularly their relationship with mathematical competence, as well as other kinds of factors, such as contextual or sociocultural influences.

Once having outlined the methodology adopted in the broader study, this contribution focuses on the results of the analysis of the responses to the "Tennis tournament" item. The goal is twofold: to share the grounded and interpretative approach that guides the study as a whole and to discuss how this case study sheds light on the interplay between the so-called gender gap in the results, the gendered patterns of responses, and contextual factors in standardized assessments.

Research methodology

To select the items for the new data collection, I considered the whole sample of public INVALSI items for grades 2 and 5 (between 2009 and 2022) and for grade 8 (between 2009 and 2017). Then, I conducted a quantitative analysis to estimate the eventual gender gap resulting in each item, which led me to identify an initial sample of 225 items based on the (co)presence of the following criteria:

1. A significant gap in favor of boys in the percentage of correct answers;
2. A significant gap in favor of girls in the percentage of correct answers;
3. An insignificant gender gap in the percentage of correct answers;
4. A significant gender gap in the choice of a specific distractor (for multiple-choice items);
5. An inverted gap between girls and boys among different sub-items of the same item.

I then categorized the selected sample based on: i) item difficulty (measured by the percentage of correct or missing answers, following the INVALSI framework); ii) item typology (e.g. multiple-choice, open-ended or true/false questions); iii) item content according to the National Guidelines for the first cycle (Numbers, Shapes and Figures, Relations and Functions, Data and Previsions.)

Based on a principle of representativeness of the identified categories, I selected a final sample of 21 items: 5 items from grade 2 (the first grade tested in the national assessment) and grade 8 (the final grade of the first school cycle), and 11 items from grade 5 (the transitional grade between primary and secondary school). The "Tennis tournament" item is one of the grade 8 items selected.

New data for the broader study were collected through the voluntary participation of 40 schools across various Italian regions. Since the interest is in students' solution processes, for each item the prompt "Explain how you reasoned to get your answer(s)" was included[1]. Basic instructions for administering the tasks were provided: 1- students' performance would not be assessed; 2- tasks should be completed within a single lesson, with no further constraints; and 3- teachers could clarify item wording if asked. This voluntary participation resulted in the collection – between February and May 2024 – of over 10.000 solution protocols for the 21 selected items.

For data analysis, I adopted the social constructionist paradigm of grounded theory (Charmaz, 2008), an evolution of the original grounded theory method introduced by Glaser and Strauss in the 1960s. This analytical approach explores social reality through an inductively driven systematic praxis,

[1] The INVALSI tests collect just students' answers to the items and not their solution processes.

where theoretical insights emerge from the data rather than being imposed by pre-existing frameworks, acknowledging that researchers actively construct meanings and categories instead of objectively discovering them. Hesse-Biber and Flowers (2019) discuss that social constructionist grounded theory aligns with feminist research principles, which challenge dominant narratives and knowledge structures while emphasizing how socially constructed gendered experiences shape individual perspectives. Grounded theory's iterative process allows for a nuanced exploration of gender as a category of analysis without reinforcing essentialist assumptions. By grounding the analysis in students' explanations, this study avoids a priori assumptions, focusing instead on emerging patterns to guide the interpretation of gendered differences. As the analysis progresses, existing theories in mathematics education will inform the characterization of these strategies. Given the large dataset, the dynamic coding process enables the iterative testing of theoretical hypotheses on unexamined data, refining interpretations until saturation is reached.

The following section presents a case study to illustrate my approach to data analysis and the interpretation and discussion of results.

Case study: the "Tennis tournament" item

The "Tennis tournament" item (Figure 1) was administered in the grade-8 2014 INVALSI test and showed a significant gender gap in favor of boys: 7% in sub-item (a) and 20% in sub-item (b). The INVALSI classification of this item is: *Related area*: Numbers; *Related processes*: solving problems using strategies in different fields; *Keywords*: division, power of a number; *Related goals from National Guidelines*: "recognizes and solves problems in different contexts by evaluating information and their consistency". The discussion of this item is relevant in light of Cooper and Dunne's critique (1999), which highlights the importance of the context to understand the problem-solving processes.

Sixteen players participate in a single-elimination tournament, where each match is one-on-one, and the loser is eliminated.

a. How many games are needed to determine the winner of the tournament?
   A. 8
   B. 15
   C. 16
   D. 32

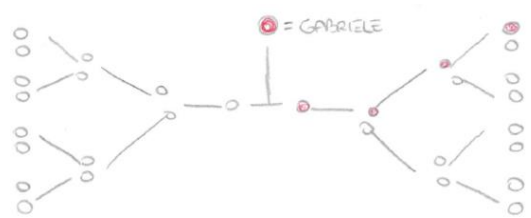
b. Gabriele won the tournament. How many games did he play?

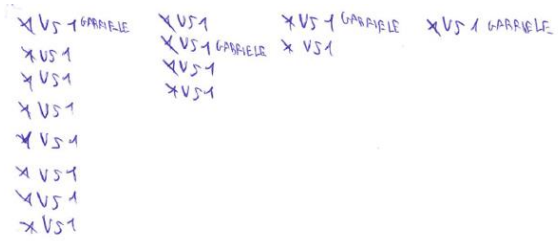
Answer: ……

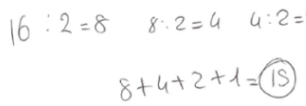
Try to solve this problem, and to explain how you reasoned to give your answers (both a. and b.)

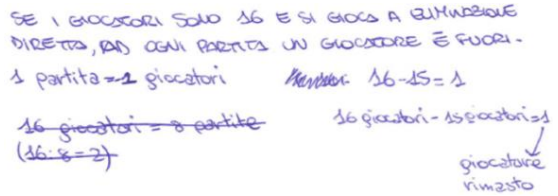
Figure 1: Tennis tournament item

Students' protocols related to this item were collected from 15 schools, located in 10 Italian provinces, and divided into two samples: i) 112 boys and 277 girls attending 8th and 9th grades; ii) 92 boys and 176 girls attending 10th and 12th grades (included in the broader study to examine whether advanced mathematical education impacts solution processes). For the division into boys and girls, I followed the binary categorization adopted by INVALSI (which does not make a clear distinction between sex and gender), even though it does not align with my theoretical view on gender. Specifically, I asked









students to write their names on their solution protocols. Since most Italian names are gendered, and with support from teachers when needed, I was able to code the majority of them as male or female.

Results and discussion

The quantitative data analysis showed that the gender gap was higher than in the INVALSI 2014 results, with gaps in favor of boys of 12% and 16% for sub-item (a) and 28% and 20% for sub-item (b) in grades 8-9 and grades 10-12, respectively. This confirmed the item's suitability for examining "gendered" problem-solving patterns, even after 10 years.

Through the inductive analysis of 657 protocols – with particular reference to the students' descriptions of their reasoning – I identified five main problem-solving strategies. Table 1 describes the identified five categories, providing a paradigmatic example for each category and reporting the frequency of adoption of each strategy in my sample, broken down by gender.

Table 1: Main solution strategies adopted by students, with explicit frequencies

<table>
<tr>
<td>1) The "contextualized diagram" strategy: students use or imagine a precise scheme which clearly refers to the scoreboard of single-elimination sports (mainly soccer) and they count the matches from it. In their explanations they often make explicit references to their sports experiences.</td>
<td>Adopted by:
Grades 8-9
M: 55%
F: 26%
Grades 10-12
M: 63%
F: 28%</td>
<td colspan="2">
</td>
</tr>
<tr>
<td>2) The "non-contextualized diagrams" strategy: students draw the total number of players, usually in two different columns/lines, they make couples, they eliminate one line of players and iterate until they have just 1 player left. Then they count the matches.</td>
<td>Adopted by:
Grades 8-9
M: 13%
F: 22%
Grades 10-12
M: 14%
F: 32%</td>
<td colspan="2"></td>
</tr>
<tr>
<td>3) The "iterative divisions" strategy: students do not use any scheme, but they proceed by dividing by 2 or by making couples and iterate until they arrive to 1.

16 : 2 = 8 8 : 2 = 4 4 : 2 = 2 2 : 2 = 1
8 + 4 + 2 + 1 = 15</td>
<td>Adopted by:
Grades 8-9
M: 18%
F: 17%
Grades 10-12
M: 29%
F: 24%</td>
<td>4) The "non-iterative divisions" strategy: students do not use any scheme, and they just divide the total number of players by 2, i.e. the number of players in a single match.

SE NEL TORNEO SI GIOCA IN COPPIA, SIGNIFICA CHE 8 PERSONE GIOCANO CONTRO 8 PERSONE (16:2)</td>
<td>Adopted by:
Grades 8-9
M: 5%
F: 16%
Grades 10-12
M: 4%
F: 7%</td>
</tr>
<tr>
<td>5) The "N-1" strategy: students do not use any scheme, but they argue, for example, that "If the players are 16 and they play in a single-elimination tournament, at each match one player is eliminated.
$1\ match\ =\ -1\ player$; $16 - 15 = 1$;
$16\ players\ -15\ players\ =\ 1\ winner$"
(translation of the figure on the right).</td>
<td>Adopted by:
Grades 8-9
M: 5%
F: 16%
Grades 10-12
M: 8%
F: 13%</td>
<td colspan="2">
SE I GIOCATORI SONO 16 E SI GIOCA A ELIMINAZIONE DIRETTA, AD OGNI PARTITA UN GIOCATORE È FUORI.
1 partita = 1 giocatori 16 - 15 = 1
16 giocatori = 8 partite (16:8=2)
16 giocatori - 15 giocatori = 1
giocatore rimasto</td>
</tr>
</table>

The mathematical analysis of these categories led me to recognize two opposed categories in terms of their "degree of abstraction". Here, focusing on the 8th and 9th grade samples, I will discuss the most contextualized and the most abstract strategies.

The "contextualized diagram" strategy is the most related to the real context of sports tournaments and the most used by all students. However, a clear "gender gap" emerges: the percentage of boys who drew a diagram resembling sports scoreboards (55%) is more than double the percentage of girls who used this approach (26%). Several students using this strategy recalled their experience with a single-elimination sport to visualize and model the situation proposed, interestingly transferring the context from tennis to other sports (mainly soccer). Once the visualization of the knockout scoreboard was done, students in this category just counted from their scheme of the scoreboard to answer both sub-items. For this strategy, students' contextual knowledge – in this case, their individual familiarity with either watching or playing single-elimination sports – was a determinant factor for the success of their mathematical modeling and, therefore, for their answering. Notably, the "contextualized diagram" strategy was the least fallible, with girls outperforming boys when using it [fallibility rates: 15% and 13% for boys *versus* 8% and 12% for girls for items (a) and (b), respectively].

The "N-1" strategy is the most abstract one, being quite mathematically elegant, and, differently from the "contextualized diagram", not supported by any explicit reference to the real-world experience of sports tournaments. In this case, the percentage of girls using this approach (16%) is more than three times higher than that of boys (5%). The fallibility of this strategy is extremely low for sub-item (a) (~1% for both boys and girls) and extremely high for sub-item (b) (83% for boys and 81% for girls). This was not surprising to me, yet very interesting, because this strategy does not give a clue about how students should count the matches played by the winner and, ultimately, how the tournament works: most of the wrong answers were either "15" or "it's impossible to answer, it depends from the moment in which Gabriele began to play". I coded this latter case as the "King of the Hill" strategy because, in their explanations, students clearly refer to a tournament in which the winning player continues to play until defeat. In this scenario, there is no unique answer to the sub-item (b). As for the "15" answer, they usually combine the argument "I need 15 matches to eliminate 15 players" with "if Gabriele won the tournament, it means that he hasn't been eliminated, so he won all the 15 matches", in a sort of Aristotelian syllogism. In both cases, these wrong answers seem unrelated to a lack of students' mathematical competence or a lack of consistency in their reasoning but rather reflect a different interpretation of the situation. This reveals that the "Tennis tournament" item is based on a clear assumption: everyone knows how a single-elimination tournament works.

Interestingly, similar patterns are observed among 10th and 12th-grade students, indicating that higher mathematical competencies do not reduce the observed gender differences in students' patterns or performance. This suggests that the nature of the item – requiring context-specific knowledge rather than advanced mathematical skills – plays a critical role in shaping outcomes.

In the Italian context, sports - and especially watching sports – are still predominantly male domains. According to the Permanent Sport Observatory (2024), 33% of Italian women report never having practiced sports, compared to 16% of men. In 2022, 63% of men and 44% of women attended at least one live sports event as spectators. Furthermore, 91% of men and 70% of women reported consuming

informational and entertainment content related to the world of sports, ranging from rarely to frequently. The gender gap resulting in the “Tennis tournament” item seems to reflect this contextual bias rather than indicating girls’ difficulty in solving mathematical problems or in “evaluating information and their consistency” (National Guidelines’ goal related to this item).

The core issue lies in the fact that while the “Tennis Tournament” item aims to measure a form of mathematical reasoning, it also mobilizes a significant amount of contextually situated knowledge, which is itself deeply gendered. In this case, the problem’s context privileges students – in Italy, primarily boys – who can draw on their sports-related knowledge and familiarity with tournament structures, mobilizing them as strategies.

Conclusion and further development

The analysis of students’ descriptions of their reasoning and the dynamic coding of their solution patterns revealed the significant role of contextual knowledge, such as familiarity with single-elimination sports, in shaping strategy choice and performance. This grounded interpretation suggests that the gender gap observed in the “Tennis Tournament” item is less a matter of strictly mathematical competence and more about access to this contextual – and gendered – knowledge (if the two can truly be separated). As a result, the “Tennis Tournament” item exemplifies how standardized assessments can unintentionally perpetuate the narrative about inequities by privileging contexts that align more closely with traditionally male experiences.

Although this case study focuses on a specific item where context played a central role in its selection, it emphasizes a broader issue: merely measuring the gender gap through selected answers provides limited insight, while analyzing problem-solving processes and looking for gendered patterns can offer generative insights for the interpretation of underlying factors contributing to these disparities. The broader corpus of items included in my research – representing diverse typologies and contexts – aims to generate more nuanced and comprehensive interpretations of gender differences in mathematics.

Administering items like the "Tennis Tournament" does not disrupt the systemic patterns that reinforce gendered identity and (re)produce disparities. As Varenne (2018) argues, researchers, educators, and policymakers must shift the equity lens away from individuals and categories of people and toward the systems that co-produce differences. This requires committing resources to explore the circumstances and contexts that generate disparities between groups rather than reinforcing narratives of underachievement relative to a normative – and mainly male – standard.

Discourses on mathematics and mathematical ability of support teachers in Italy

Francesco Beccuti[1,2] and Maria Polo[1]

[1]Università di Cagliari, Italy; francesco.beccuti@unica.it

[2]Università di Trieste, Italy

We study essays about mathematics and mathematical ability written by preservice support teachers in Italy, which we analyze discursively in relation to their life experiences and career aims. Overall, while the participants articulate a view of mathematics as a generally worthy, satisfying, and useful form of activity, they nonetheless report a negative personal relationship with it typically after primary school. This is articulated either in connection to a bad experiences with a teacher, as linked to mathematics' challenging growing abstractness, as well as in connection to the participants' own perceived lack of mathematical predisposition or ability. As to the latter, the participants typically depict it as having both an innate and an acquired education-dependent component. After presenting the results of the analysis, we discuss them in view of broader systemic issues connected to the support of the teaching and learning of mathematics in Italy.

Keywords: Special education, Preservice support teachers, Mathematical ability, Discourse analysis.

Introduction

The role that mathematics often has in school and in society as a gatekeeper (Martin et al., 2010) and as a marker of intellectual ability (Nieminen et al., 2024) points to the centrality and problematicity of this subject with respect to phenomena of inclusion and exclusion happening in educational institutions. In particular, discourses surrounding the nature of mathematics and mathematical or general (dis)ability crucially contribute to shape the way in which mathematics is taught and learnt with respect to policies and practices of in(ex)clusion.

As a significant example, the custom of segregating or grouping students according to ability and the connected mathematical pedagogies depend crucially on discourses "about the purposes of education, the potential of students, and the nature of learning" (Boaler, 2020, p. 1). As this example suggests, reaching a full understanding of phenomena involved in inclusive mathematics education involves attending to the related discourses which pervade society and influence the curriculum as well as educational practices. Among these, the discourses articulated by the people involved more directly in the teaching and learning of mathematics appears to be of primary importance. While views on mathematics and mathematical ability have been explored in research with respect to students and teachers of mathematics (cf., e.g., Beccuti et al., 2024; Nieminen et al., 2023; Gildehaus et al., 2024; Kollosche, 2017), it seems that almost no study concentrated specifically on the discourses articulated on these by support teachers. In this paper we thus address the following research question: What discourses do pre-service support teachers articulate around mathematics and mathematical ability in relation to their past life experiences and future career aims?

After addressing this question via a discursive analysis of essays written by support teachers in training in Italy, we reflect on the results in connection to wider systemic issues related to inclusive mathematics education which the analysis will evidence.

Theoretical framework

The philosopher Michel Foucault viewed *discourse* as a primary means through which power and knowledge are woven together, contributing to shape and at the same time being shaped by social structures, cultural norms, and institutions. According to Foucault (1977), discourse is constituted by patterns of knowledge which do not only describe but also systematically construct the shared spaces in which individuals live and thrive as well as concomitantly the characters with which they choose to align their subjectivities to. Understanding discourse is therefore crucial for understanding how knowledge is not only used to describe and represent but also to control, regulate, and administer societal and institutional activities (cf. Kollosche, 2017).

Despite attempts at mitigating the most blatant unjust effects of schooling via the promotion of inclusive policies, schools inherently function directly and indirectly as primary instruments of social gatekeeping through their explicit and implicit role in selection processes justified with the objective of selecting and promoting intelligence, dedication, and merit in view of recruitment in the workforce. Proficiency in mathematics is of foremost importance to these processes, mathematics being a compulsory subject in almost all countries around the world from primary to upper secondary schools. Indeed, the development of mathematical competence or ability is typically predicated to be essential for accessing highly specialized jobs or duties in a society increasingly characterized by technoscientific knowledge. Furthermore, mathematical ability has traditionally been and continues to be narrated to be a proxy for overall intellectual ability and for the capability to solve problems in various non-mathematics related domains (cf. Ernest, 2019). Therefore, discourses on the nature of mathematics and mathematical ability articulated about, around, and in the proximity of those who are predicated as being affected by a disability impairing their school proficiency appear to be paramount for the practices of in(ex)clusion which involve them in schools and elsewhere.

In Foucauldian terms, with respect to phenomena connected to (dis)ability, it is particularly important to attend to how this very same concept and related notions are constructed through discourses (articulated and transmitted explicitly and implicitly inside and outside educational institutions) which impact how different groups of people perceive and address these. Among the affected groups, that of support teacher surely is of primary importance, in this case. It appears thus of foremost relevance to understand and attempt to describe the discourses articulated by support teachers about mathematics and mathematical ability as situated in the cultural and institutional landscape in which their professional activity is incardinated.

The Italian institutional context

Italy represents a particular nationally-situated case where a strong ideological commitment to equity and inclusion appears to pervade the curricular and legislative discursive landscape concerning special education. This commitment started institutionally with the factual abolition of special schools and segregated classes in the 1970s. Nowadays, while few particular instances of special schools still

exist, practically almost all students attend local schools where students are not grouped by ability (D'Alessio, 2010).

In Italy, "normal" secondary teachers are certified as teachers of specific subjects or groups of subjects. While complicated legislative nuances are in place, as a general principle, the completion of a two-year disciplinary-specific master's degree (as opposed to a teaching degree, as in most countries) renders one legally qualified to be a secondary teacher in the corresponding subject(s). In lower secondary schools, the teaching of mathematics is coupled with the teaching of science and typically teachers hold master's degrees in some scientific subject. In upper secondary schools, mathematics is taught alone or coupled with the teaching of physics and typically teachers hold degrees in mathematics, physics, or sometimes in engineering.

Permanent position as support teachers, on the other hand, are accessed after completion of a one-year master's degree. This is an intensive program focusing on special education comprising courses in special psychology, pedagogy, neuropsychiatry, and legislation on special education, as well as laboratories on specific disciplines. While again complex legislative regulations are in place, practically anybody holding a two-year master's degree which is a prerequisite to being a disciplinary teacher (in any subject) can compete for admission to this further one-year master's program. Legally, support teachers are assigned to a class where at least a student with a certified disability is present. Ideally, a support teacher supports the whole class and not specifically the student(s) with disability. Frequently, however, in practice the class proceeds "normally" while the support teacher tutors and interacts primarily or solely with the student(s) with disability (Ianes, 2014).

Experimental context and method

We study 63 pre-service secondary support teachers enrolled in a course within the aforementioned one-year master's program for support teacher qualification in a large research university in the North of Italy. The course is a compulsory laboratory lectured by the first author concentrating on mathematical and logical aspects involved in special education. The participants typically come from a non-scientific course of studies (e.g., literature, history, music, etc.) and their age ranges from about 25 up to 50 years old, with a slight prevalence of female participants. Typically, the participants have had some years of previous experience in school as substitute or non-permanent support teachers.

In the first day of the laboratory the lecturer asked the participants to write an essay entitled "What is to me mathematics" which they wrote individually in the class for about 40 minutes. This group of essays was preliminarily analyzed by means of a thematic analysis inspired by Braun and Clarke (2014) employing the themes developed in the first part of the methodology section of Beccuti and colleagues (2024). These themes are: the challenge of mathematics, the utility of mathematics, the comforting dimension of mathematics, and the relationship to others with respect to mathematics. This preliminary analysis already gave a first picture of how mathematics is viewed by the participants in relation to their of past experiences. However, almost no participant made explicit reference to mathematical ability (possibly in relation to the fact that they never had the occasion to reflect on this issue in their previous educational experiences) and only scattered remark were made concerning their future profession. In view of this, in the second day of the course the lecturer asked the participants to engage in a group discussion concerning mathematics, mathematical ability, and

schooling. Particular topics proposed by the lecturer were if mathematical ability is innate or not and what type of mathematics can and should be taught in relation in particular to disabilities. The participants were encouraged to discuss in groups first and then expose individually their views to the class. Then the lecturer asked the participants to write a follow-up focus essay entitled "What is to me mathematical ability". Again, the participants wrote individually, for about 40 minutes.

Overall, the previously thematically analyzed essays together with the focus essays were further analyzed together by means of a (Foucauldian inspired) discursive analysis, as employed in second part of the methodology of Beccuti et al. (2024). Following these authors, we were not interested in tracing the experience of single individual participants, but in understanding the prevailing *ethos* dominating the chosen group on the selected topics in relation to our research question. In particular, we attended to how the previously selected views of mathematics on utility, challenge, comfort, and relationship to others were articulated with respect to each other and with respect to the participants' articulated notion of mathematical ability. As Walshaw (2016) explained, (Foucauldian-inspired) discourse analyses focus on understanding how the participants' writing reflects their shared understanding of the topics, their positions within the discussion, and the ways their discourse shape their collective knowledge and experience, trying to trace specific *technologies of the self* that the participants express, i.e., ways that articulate and shape how they are perceived by themselves and wish to be perceived by others in the particular and general environments in which they operate. This is in coherence with our theoretical framework, according to which discourse serves as a vehicle for establishing shared norms and truths, determining what can be said and who can speak, what can be seen and what can be done, thus directly influencing how individuals and groups perceive themselves and others with respect to a chosen topic and context (Foucault, 1977). The overall aim of the analysis was to furnish a comprehensive picture of the participants' shared views of mathematics and mathematical ability as stemming from their past and present relationship as well as future association with institutional mathematics in school.

Results

Most of the participants open their initial essays by stating that they deem their past relationship with mathematics as overall not positive or even plain negative. Nevertheless, many participants report a neutral or even good relationship with mathematics in the first part of their schooling experience, often in connection with the positive role of a teacher or in view of its perceived utility in everyday life. Typically, the mathematics of primary or middle school is described as associated with a sense of satisfaction stemming from finding the solution to a problem or from getting some computation right either in the classroom or outside.

> […] I remember that teacher who gave us homework […] [that] I was happy to please.
>
> I could employ it […] for instance at the supermarket where […] I loved to make all ends meet [far quadrare i conti] and have the situation under control

However, the relationship of the participants with mathematics progressively deteriorated, typically from middle or high school. This is explained either with the encounter of a not favored teacher or with the perceived mounting abstractness of the discipline.

> Up until eleven years old, mathematics was a lovely friend, a subject taught by a lovely teacher who could make you passionate; at middle school it became hell, an impossible obstacle […]
>
> […] at high school I lost interest and motivation […] due to a teacher who had little patience.

The participants thus describe a general feeling of discomfort which presents itself each and every time they had to take a mathematical test, often perceived challenge of insurmountable nature almost invariably associated with anxiety and even despair.

> Frustration, inadequacy are just few of the emotions that I associated with this subject […].

Overall, this negative view is justified by many as an general humanistic or artistic disposition which they would possess and to which mathematical achievement seems to be opposed.

> For those who like me have a humanistic disposition [un'indole umanistica], mathematics has always been a too sterile concept without any passion
>
> I feel more affinity with humanistic/artistic subjects where rationality is a bit less important

This is reflected in the view the participants present of mathematical ability, which seemingly some individuals would possess inherently more and others inherently less.

> I always loathed having a more developed logico-mathematical intelligence. I admire who is able in mathematics and I envy them.
>
> Personally, I don't think I have much mathematical ability […]

The participants view mathematical ability as connected to the ease in dealing with numbers and being fast with computations, as well as with to the general ability of solving problems, thinking logically and in general possessing intelligence.

> Mathematical ability represents Intelligence with a capital I […] who possesses mathematical ability is "superior", intelligent, but also mysterious and difficult to accost [inavvicinabile]

As to the problems of the origin and the development of mathematical ability, very few students endorse a completely genetic or "nature" explanation:

> either you have it or you don't
>
> There are people who are more and people who are less apt to do mathematics, so that even reiterate and continuous training could not bring to large improvement, despite the effort and the time employed […]

Noticeably, none of the students however endorse a completely "nurture" explanation of mathematical ability, but more typically state that it is partly innate and partly acquired, without resolving in favor of either option. Overall, the majority of the participants express a positive view of the possibility of nurturing mathematical ability (while overall insisting on the presence of a strong innate component) via proper instruction.

> It is 50 per cent nurtured and 50 per cent innate.
>
> It can be innate but you can also acquire it by experience or in other ways which can be learnt […]

> I think there is […] a completely innate factor [to mathematical ability], but this doesn't mean that it cannot be developed in one's life with exercise.
>
> It is not in my opinion an innate ability but it has to be learnt and exercised for long […] this of course only if cognitive deficit is not present.

Going back to the personal stories of the participants, many affirm that, years after they left compulsory schooling, and especially as a consequence of their recent direct experiences as teachers, they came to terms with their past bad experiences with mathematics. Indeed, eventually they came to appreciate mathematics and its overall utility, to an extent, in everyday life, in modelling scientific phenomena, in computing applications, as well as, more generally, its role in disciplining the mind towards abstraction and exactness (and to its indirect use to access future degrees or professions).

> Afterwards, things changed. I understood the importance of mathematics and of its formulae for describing reality […]

A large majority of the participants reflects on the fact that if they will be called to teach mathematics or to support its teaching, they will in particular attempt to present it in a way that is not too detached from concrete applications as well as

> […] suitable to each student's intellectual and cognitive level.

Indeed, the participants also highlight that care should be used in also conveying overall motivation towards mathematics and stress that teachers should make use of innovative inclusive methodologies (often mentioned in connection to pedagogical theories learnt during their training as support teachers) and methods that may be proper to various levels of intellectual abilities and styles of learning.

> Some pupils can only reach procedural knowledge […] while for others perhaps it is possible to do more by means of innovative methods stressing on everyday practices […]
>
> [the realization that mathematical ability is partly innate] allows me to understand the level to which everyone can reach and that with which I can start with pupils.

Conclusions

As seen, the participants almost unanimously describe mathematics as an important, satisfying, and variously useful form of activity. However, they report either a mostly negative personal experience with mathematics or an initially neutral or positive experience which later deteriorated, typically in connection to a bad experience with a teacher in middle or high school, or else in connection with its growing abstractness. This is articulated as stemming from an overall lack of mathematical ability or an overall non-mathematical disposition of the participants themselves, presented as a general explanation of their failure. Interestingly, the participants see mathematical ability as partly innate and partly acquired, typically favoring a "median" position in the nature-nurture dilemma concerning it. This stance does not appear to derive from previous reflections or dedicated training on the topic, but—we may conjecture—appears to be a discursive point of compromise serving to make sense simultaneously of their overall life story with mathematics, of the progressive commitment to inclusion traditionally ingrained in the working of the Italian system of special education, as well as

of their studies on general pedagogy and cognition. Indeed, this stance on ability may be read as inherently apt to be instrumental to their whole professional endeavor, constituting a particular technology of the self that these participants attempt to enact and which, in a sense, best discursively underlies their specific professional existence as a separated category of teachers.

Generally speaking, the participants appear to subscribe to progressive educational theories of hope (Nieminen et al., 2024), underlying the potential of practices that emphasize diverse mathematical intelligences and contextual learning. This could go in the direction to open up spaces of intellectual and practical challenges to established norms in their future work as support teachers and may help in reframing mathematical ability to include broader or more inclusive definitions of competence and intelligence that challenge the traditional understandings of these notions, as well as, overall, the intrinsically gatekeeping role of mathematical instruction in school and in society. At the same time, nonetheless, the participants' views on mathematics and mathematical ability could fundamentally work in the direction of reproducing systemic disparities, despite the participants' best intentions.

Indeed, the aforementioned partial "innateness argument", coupled with the articulated discursive connection of mathematical ability to general problem solving ability and general intelligence, as well as their overall endorsement of the universal importance of mathematics, could reinforce a view of mathematical ability and mathematical "disposition" as (at least partially) fixed once and for all in an objective sense (both with respect to a universal ideal culture and with respect to an idealized received idea of human cognition). These discursive stances could serve to indirectly reinforce the usual views on the impossibility (or extreme difficulty) of students categorized as disabled to participate in full to school mathematics as well as strengthen the insistence on the connected usual remedial practices focused on a modified, less cognitively challenging, and procedural version of the discipline (cf. Tan et al., 2019).

As said above, the Italian system concerning special education is characterized by a long-established commitment to inclusion which revolves around subject-specialized teachers and generalist support teachers. The system is generally believed to have led to overall improvement impacting positively on the inclusion of special needs students, both in terms of learning and socialization as well as in terms of producing a generally more widespread adoption of diverse and/or innovative teaching methodologies (cf. D'Alessio, 2010). However, as seen, the discourses articulated by support teachers on mathematics and mathematical ability could implicitly foster the institutional concealed reproduction of ableist practices and narratives (somewhat paradoxically conveyed via the words and practices of support teachers themselves). This possibility could evidence a criticality within the Italian system with respect to mathematical instruction, if taken together with the participants' general personal negative disposition towards mathematics and their typical lack of post-secondary education in mathematics. Indeed, as said, for many of the participants the present laboratory is the only post-secondary course specifically devoted to mathematics that they follow before being certified as generalist support teachers. It remains an open question whether perhaps other discursive positionings concerning mathematical (dis)ability might be fostered by alternative and less generalist forms of support teacher training which could be imagined as devoting more time on developing mathematical competences per se as well as reflecting more and more in depth on the nature of mathematics and of mathematical ability.

Mathematical empowerment and participation in inclusive learning settings

Anna-Maria Billigen[1] and Elke Söbbeke[1]

[1]University of Wuppertal, Germany; billigen@uni-wuppertal.de

In inclusive education, all children should work together in their diversity and develop their individual potential. With respect to mathematical difficulties, there are already numerous concepts for inclusive classrooms. In view of the many facets of diversity, however, further concepts and empirical studies are needed, e.g. in the context of mathematical potential or social skills. Social difficulties can overshadow the mathematical potential of children so that they are often unable to show or develop their full individual potential. As part of a larger research project, cooperative learning environments[1] for inclusive teaching have been developed to promote the mathematical potential and social participation of all learners. The article analyzes the extent to which social participation can be developed in a mathematical negotiation process using a case study. On this basis, possibilities of mathematical empowerment in three different domains are discussed.

Keywords: Mathematics education, inclusive education, diversity, empowerment, participation.

Introduction

"*Dustin needs tasks. And I think that's what he's missing in his primary school years and in his biography, that he gets tasks and can show himself*." This quote was made by Dustin's class teacher who was interviewed as a part of this study. The teacher describes Dustin's family background as "difficult". Dustin has a single mother and "difficult circumstances that don't necessarily support him". He was taken in relatively early by his grandparents, where he more or less grew up. In grade 3, custody was withdrawn from the grandparents and transferred back to the mother. This was followed by several changes of residence. During the interview his teacher reflects on what Dustin has already been through and summarizes his situation as follows: "From an early age, Dustin was left to his own devices and had to bite and fight his way through." From the teacher's point of view, this is expressed by the fact that Dustin often attacks other children while playing during breaks, when he doesn't agree with their rules or the way they play. In primary school he was not good at dealing with frustration, for example when losing in competitive games, so that "the whole thing turned into slightly aggressive behavior". Dustin makes threats to classmates and teachers and has to learn to resolve conflicts only verbally and be more considerate to others. In addition to the description of the difficulties in social interaction, the teacher opens up a remarkable perspective in his quote, shown above, to strengthen Dustin: "*Dustin needs tasks* […] *that he can show himself*". From his point of view, such tasks are missing, to help Dustin to show his skills in learning, and in social classroom or school interaction. In this paper the case study 'Dustin' is used to investigate in how far a learner with

[1] In this paper we understand a *learning environment* as a framework for several tasks based on a common mathematical structure (Hirt & Wälti, 2022).

social difficulties can be empowered by a special task design, so that he is not excluded but can participate in joint social and subject-related learning.

Empowerment

The concept of empowerment is characterized by the experience of discrimination and the withholding of participation (Theunissen, 2016). After the concept was introduced into pedagogy, the aim was to empower people through targeted pedagogical efforts so that they gain power and become independent of support. Ernest (2001, p. 123) describes Empowerment as "the gaining of power in particular domains of activity by individuals or groups and the processes of giving power to them, or processes that foster and facilitate their taking of power". Empowerment is aimed, among other things, at a strength that is based on the person and their individual resources, at addressing social disadvantage and discrimination, which should be overcome, and at the professional task of strengthening the vitality of people in a socially marginalized position (Theunissen, 2016, p. 114).

With regard to the empowerment of children in everyday school life, the central question is in what way empowerment can be encouraged and supported by teachers in order to offer help for self-help and at the same time enable the highest possible degree of self-determination (Lindmeier & Meyer, 2020). For this reason, the specific requirements of the learning subject must be taken into account: For the subject of mathematics the achievement of both content-related and process-related mathematical competencies and the understanding of the role of mathematics in everyday life can be understood as contributions to empowerment concerning mathematics. If children and young people are empowered in these, this not only has an impact on their school life, but also on their opportunities to participate in society. Ernest (2001) distinguishes three domains of empowerment concerning mathematics and its uses: (1) The *mathematical empowerment* includes the "Power over the language, symbols, knowledge and skills of mathematics and the ability to confidently apply this in mathematical applications within the context of schooling, and possibly to a lesser extent, outside of this context" (Ernest, 2001, p. 126). (2) When mathematics contributes to participating in a social domain, e.g. work, life and social affairs, it is called *social empowerment*. (3) An *epistemological empowerment* includes the development of personal identity and the growth of confidence in the mathematical and social senses (Ernest, 2001). It becomes clear that these three domains should not be understood separately from each other, but that the aim of mathematics teaching is to empower learners as epistemological agents, by encompassing mathematical, social and epistemological empowerment. For mathematics teaching this means that all children should be empowered to develop their individual mathematical potential using their individual strengths (mathematical empowerment). Therefore, children need needs-based resources in the form of adaptive individual access to the subject of learning combined with challenging mathematical negotiation opportunities. New mathematical knowledge is primarily developed through collaborative, subject-related negotiation processes (Häsel-Weide & Nührenbörger, 2022), so that the ability to learn socially from and with each other always has to be taken into account (social empowerment). The aim should be to offer learners adaptive access to the learning content in a way that they can engage in mathematical activities at their individual level, that challenges them, but does not make them dependent on help. By empowering individual potential, the genuine participation of all children becomes possible and can strengthen confidence in their own subject-specific and social skills (epistemological

empowerment). This orientation corresponds to the idea of inclusion, that aims to recognize and support all learners in their individuality.

Inclusion

In an inclusive education system, all persons should have the chance to develop their individual potential and should be perceived, accepted, and valued in their diversity and individuality. Thus, the goal of inclusive teaching is to support all students in the best possible way (Ainscow et al., 2006). That's why the potential of all students is increasingly focused in academic and educational policy efforts (Dexel et al., 2019). Whereas in Germany, concepts for inclusion, e.g. in dealing with *learning difficulties*, are already established in everyday teaching, many concepts to support *mathematical potential* are designed rather exclusively (e.g. children's university) and offer few possibilities to cooperate, communicate and learn with and from each other (Billigen et al., 2023). Similarly, concepts for dealing with *social difficulties* tend to be exclusive rather than inclusive (e.g. Durlak et al. 2010). However, such exclusive concepts of support do not really correspond to the idea of inclusion. The present study refers to a perspective of inclusion and empowerment as an interplay of joint and individual learning processes. Every learner should develop his or her individual mathematical potential through adaptive mathematical learning opportunities as well as social participation (Krähenmann et al., 2019). In order to promote mathematical potential in inclusive learning settings and at the same time enable the social participation of all children, it is important that learning settings open up an individual access to the subject as well as joint negotiation about mathematical insights. Current studies show that processes of cooperation on a common subject in heterogeneous learning groups are particularly valuable for mathematical learning (Häsel-Weide & Nührenbörger, 2022).

Cooperation and participation

The diversity and heterogeneity of learners can benefit the insights of all so that the joint engagement with a common subject can be fruitful. Therefore, it is necessary that all children *receive the same task*, which is holistic and sufficiently complex, so that it opens up *learning opportunities* for children *on different levels*. By working on a common task, a meaningful discussion about individual strategies and insights can take place. This initiates productive situations of learning with and from each other. In the German didactics of mathematics, the concept of "natural differentiation" is a well-explored concept to reach this (Scherer & Krauthausen, 2010). The children are not restricted by the teacher, but get empowered according to their individual potential concerning mathematics. Thus, this concept offers many advantages for dealing with the diversity of learners. However, looking at inclusive education from a wider perspective that includes particular mathematical difficulties as well as mathematical potential, natural differentiation is not always sufficient to create learning situations for all children. The concept of "parallelization" (Nührenbörger & Pust, 2018) builds on the idea of natural differentiation, but it can offer broader possibilities to realize the demands mentioned above. Due to target-differentiated levels, all learners can be given individual access to the subject of learning. Likewise, this opens up a variety of possibilities for a fruitful communication between the learners. They can contribute their discoveries, which they have obtained at the respective levels, so that social participation is guaranteed for all (Nührenbörger & Pust, 2018).

Methods

The research project aims to promote and empower the individual mathematical potential of all learners even if it is not visible due to social difficulties. To achieve this, parallelized learning environments in combination with natural differentiated tasks have been developed in order to initiate social participation as well as individual learning processes. To answer the research questions, the method *case study* (Lamnek, 2010) is chosen, which allows to identify typical aspects concerning social difficulties, participation and empowerment to reconstruct a holistic picture of the case.

RQ 1: How can the *social participation* in the cooperation between Dustin and Lenny be characterized?

RQ 2: To what extent can initial references to the three *domains of empowerment* be reconstructed?

Before the results are presented, the learning environment and the analysis method is described.

Learning environment "Magic Squares"

The presented learning environment focuses on Magic Squares (MS). MS offer opportunities to discover and explore rich mathematical structures at different levels, which make them suitable for both natural differentiation and parallelization. In a MS the sum of each row, column, and diagonal is equal; it is called the magic number (Figure 1). In MS of odd-order the magic number is related to the odd-order and the mean number (e.g. in a 3x3 MS the magic number is three times the mean number). The current study is an ongoing PhD project, which explores two different parallelized learning environments. In this paper we refer to the learning environment MS, in which so far 31 children (aged 9 to 10 years, grade 4) were videographed working on the different tasks. The researcher also takes the role of the interviewer. The learning environment is divided into three sequences (Figure 2). In the first sequence, children work individually in a naturally differentiating learning environment to become familiar with MS, and to explore first structures. The researcher then forms pairs of students on the basis of the students' outcome from the first sequence. The target-differentiated classification enables adaptive individual promotion and empowerment of the individual potential of all learners. According to the concept of parallelization, some pairs work at level A and other pairs at the more complex level B in Sequence 2. Children working on level A explore relations between mean and magic numbers as well as systematic variations of numbers in 3x3 squares. Children working at level B focus on mathematical structures of different MS of size nxn, so they are challenged to find MS of different sizes (3x3, 4x4, …, nxn) with the magic number 90. Especially the comparison of odd- and even-order squares offers substantial discoveries. In Sequence 3, the students work together in new pairs composed of one learner each from level A and B (Figure 3).

Figure 1: Magic square (3x3)

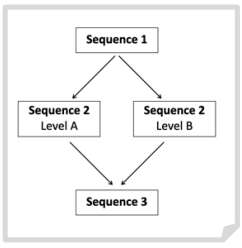

Figure 2: Structure of the learning environment

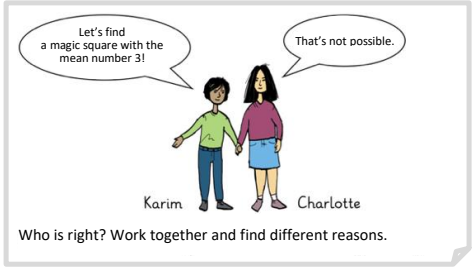

Figure 3: Task in Sequence 3

Both learners can participate in working on this new research task by applying knowledge gained from previous work on level A or B in sequence 2.

Method of analysis

For the research project, the *participation analysis* (Krummheuer, 2015) represents a substantial analytical tool to reconstruct the autonomy of actions of the learners in the interaction with a social perspective on participation. In the concept of participation analysis, four functions of active speakers can be distinguished with regard to whether and to what extent (a) a *new content* is introduced and (b) this content is introduced with *new formulations* (see Table 1): (1) An "author" expresses his *own new idea* of a content in his *own new words*. (2) A "ghostee" introduces his *own new idea* of a content, but adopts the *formulation of a previous utterance*, whereas (3) a "spokesman" *reproduces the content* of a previous statement in his *own new words*. (4) A "relayer" repeats a *previous content* by using the *same formulation*.

Table 1: Participation analysis: Function of active speakers

Function of active speaker	New Content	Own new formulations
Author	+	+
Ghostee	+	-
Spokesman	-	+
Relayer	-	-

The participation analysis can show the responsibility of each learner for the *development* of the *content* and of the joint *social negotiation*. In the following, a short excerpt from the empirical data is presented, and analyzed using the "participation analysis" (Krummheuer, 2015). Building on this, references to the "domains of empowerment" (Ernest, 2001) are elaborated in the discussion.

Results – Case study 'Dustin'

In Sequence 1, Dustin worked on the task individually and with great interest and made some challenging mathematical discoveries. For this reason, he should work on the more complex level B in Sequence 2, together with his classmate Lenny. Before Sequence 2 begins, Dustin's school break is again characterized by social conflicts. Dustin gets into a fight with other children and, therefore, is late for Sequence 2. He enters the room, sits down besides Lenny, but then very quickly begins to immerse himself in the new discovery task: "*Find magic squares with the magic number 90. How do you do it? Give reasons together.*"

After the boys have found a 4x4 MS with Magic Number 90, they try to use the colored impulse card (Figure 4) to explain how it is possible to find such a 4x4 MS. Dustin thinks about what to write down and presumably refers back to the previous procedure by saying "We have" (turn 1). However, he is interrupted by Lenny (turn 2):

1	Dustin:	What should we write? We have#
2	Lenny:	#Wait, look, that is one, two, [*taps on light yellow fields*] one, two [*taps on light blue fields*].
3	Dustin:	Yes, I wanted to say, [*raises the impulse card (Figure 4)*] here. We write, of each color we counted together and looked, that the result was forty-five. And then when we already had three [*taps from top to bottom on*]

Figure 4: Impulse card |

		the first three fields in the left column from their last previous attempt, in which they found a 4x4 MS with Magic Number 90]#
4	Lenny:	#Not forty-five!
5	Dustin:	But it is!
6	Lenny:	The half of the number. Fifty-five ehm forty-five is a half of ninety. And I can already guess that the next one we have to do, if we do a seventy MS next time, I think the#
7	Dustin:	#Thirty-five.
8	Lenny:	We have to calculate thirty-five. I can guess that.
9	Dustin:	That's right, it certainly is.

The participation analysis can now be used to analyze the autonomy of actions and the type of mutual references between the two children on a content-related and social level. For this purpose, the extent to which and by whom a new content is introduced and how this content is continued or rejected is analyzed in each turn:

In turn 2, Lenny is the *author* as he contributes his own idea in his own words. He refers to two fields of the same color (light yellow, light blue) by pointing to them on the impulse card (Figure 4). Dustin responds as well as an *author* by introducing the use of colors to form the sum 45 as a new idea in his own words (turn 3). His wording indicates that he is following the previous intention to write down their done procedure ("We write"). Therefore, he possibly tries to name a strategy of their previous procedure, as he points to three numbers in a column in their found 4x4 MS ("And then when we already had three", turn 3). In general, it would be possible in this way to determine the missing number using the magic number 90. However, Lenny interrupts him again. Lenny then takes on the role of a *ghostee* with linguistic reference to Dustin ("Not forty-five!") by introducing a new content (turn 4). He denies that the sum is 45 and uses Dustin's words for that. At this point a dispute arises (turn 4 & 5) and Lenny seems to have a request for clarification.

The children's statements in the transcript suggest that Lenny and Dustin are arguing on two different levels. Dustin continues to describe the *specific procedure* and states that they first determined the sum of 45 in the two fields of the series (turn 3). Lenny's statements, on the other hand, indicate that he would rather describe a *general structural relationship*: the sum of two fields in a row must always equal half of the magic number (turn 6). As a *spokesman*, Dustin refers to his own statement from turn 3 by reproducing its content in new words. These different levels of argumentation lead to a mathematical controversy between the two boys, which does not cause the breakdown of social cooperation, but leads to a meaningful clarification: In turn 6 Lenny acts as an *author* with reference to the controversy by introducing new content in his own words. To explain his statement, Lenny uses the magic number 70 as another example. Dustin takes up this new idea from Lenny and continues it as an *author* as well by introducing a new content: the sum of the pair of numbers in this case would be "Thirty-five" (turn 7). Dustin is referring directly to Lenny and develops an ambitious new idea further. As a *relayer* in turn 8, Lenny is taking content from his own statement (turn 6) as well as words from Dustin's statement (turn 7). Dustin confirms the joint discovery in turn 9 as a *spokesman* by reflecting the content of turn 6 to 8 in his own words ("That's right, it certainly is"). At this point, it is not yet possible to say whether Dustin has gained any real *structural* insight. However, it becomes clear that the children interact and cooperate with each other honestly on both a mathematical and social level, despite the dispute that arises.

Discussion

The analysis of the case study provides initial indications that both children were given the opportunity to develop mathematical insights through joint negotiation, regardless of social difficulties outside of mathematics lessons. Concerning RQ 1 the numerous roles as "author" can be interpreted as an indication that the boys participate autonomously, because both Lenny and Dustin introduce new content with their own words. This leads to a deep mathematical communication and social participation in which references are made to each other's statements.

Because of the special design of the learning task (individually adaptive access and meaningful cooperative discovery task), both boys worked on a mathematically very demanding task and developed appropriate solution strategies together. The scene presented above indicates initial references to the three domains of empowerment (RQ 2): The boys manage to focus on new mathematical relations in the MS beyond summarizing their approach (*mathematical empowerment;* Ernest, 2001). These new mathematical insights are part of the social discussion. The participation analysis shows that both learners repeatedly make reference to previous statements made by the other, but develop them further in their own words and by introducing new ideas into the discourse. Even when a dispute arises, the discourse does not break off, but leads to new insights. This is remarkable because for Dustin it is often difficult to accept other opinions or rules in social situations (see interview above), which leads to conflicts with his classmates during breaks. The scene presented here provides initial indications that in this mathematical context Dustin is able to withstand both interruptions (turn 2) and counterarguments (turn 4-6) and to use them productively for his own insights (*social empowerment*; Ernest, 2001).

At this moment, further studies with additional case numbers are required to investigate and understand these initial indications in more detail. In addition, the extent to which empowerment on a mathematical and social level can contribute to strengthening children with social difficulties in such a way that the confidence in their own mathematical and social abilities is also strengthened (*epistemological empowerment*; Ernest, 2001) needs to be investigated.

Creating a task to prepare instructors to teach postsecondary mathematics

Sabrina Bobsin Salazar[1], and Eduardo da Silva Schneider[1]

[1]Universidade Federal de Pelotas, Pelotas, Brazil; sabrina.salazar@ufpel.edu.br

We present considerations for the elaboration of a Professional Learning Task (PLT) within the context of preparing mathematics instructors in higher education, focusing on an innovative curriculum that uses technology as a leverage for promoting social justice. We describe the Brazilian context and how instructors are typically trained to teach within this context. Then, we present our study, grounded in the Professional Learning Opportunities for Teachers (PLOT), exploring ideas on how teaching practices can be racialised and/or gendered. We discuss how a PLT must consider elements that integrate mathematical knowledge with its teaching and that aim to challenge mechanisms of oppression affecting traditionally marginalised students in mathematics courses.

Keywords: Teacher preparation, postsecondary mathematics, racialised mechanisms, gendered mechanisms.

Introduction

The aim of this paper is to present considerations for the creation of a Professional Learning Task (PLT) within the context of a professional development of higher education instructors[1] in engineering programs and other science and technology fields (STEM) in an innovative curriculum that uses technology as a lever for promoting social justice in southern Brazil.

This work is set within two main contexts. The first is the need to prepare instructors to teach in higher education, because postsecondary instructors usually learn to teach through the act of teaching itself, without engaging in the thinking, study, reflection, or discussion of the complex task of teaching (Isaia, 2006). The few initiatives that are beginning to be implemented usually focus on higher education pedagogies, disregarding the important connection between the specific area to be taught and its pedagogy, which has been explored in research on Teacher Education since Shulman's seminal studies (1986). Thus, this paper contributes to the discussion of the training of higher education professionals for teaching, within the contemporary precepts of research in Mathematics Education, taking into account the relationship between the content to be taught and its pedagogy.

The second context relates to the social function of public universities in Brazil. We are looking to policies that increased the number of postsecondary institutions, their distribution across the national territory, and the increase in available seats in all public postsecondary institutions. However, this

[1] In Portuguese, the word *professor(a)* is used for *teacher* and *professor* interchangeably. Some of the references that guide our work are in Portuguese and the term is quite ambiguous, it could mean instructor, or professor, or teacher, or any of those in a broader sense. Whenever broader meaning is implied, we will use the term teacher, following the reference. We will use the term *professor* to indicate a tenured track faculty member, and *instructor* to anyone who teaches any postsecondary mathematics course, as it can vary significantly across the world.

expansion has not been accompanied by appropriate actions and policies to support students to complete their undergraduate courses (Paula, 2017). In other words, there has been some democratisation of access to higher education, with traditionally marginalised students beginning to enrol in greater numbers. However, their enrolment has not been supported by measures to ensure they can succeed and graduate. Given the gatekeeping role that mathematics courses play in courses in STEM fields (Bressoud, Mesa & Rasmussen, 2015), these students should not be blocked by these courses. Moreover, beyond merely overcoming these courses as obstacles, it is important that these students can learn and use mathematics as a powerful tool in building a more just society. Therefore, higher education instructors' training must consider how the content to be taught also interacts with dynamics of society, including power systems and social oppression. In particular, in this work, we intend to advance in this area by focusing on racialised and/or gendered mechanisms occurring through postsecondary mathematics teaching practices as described by Leyva et al. (2020).

We planned a professional development session based on the Professional Learning Opportunities for Teachers (PLOT) model, and, in this initial stage, we present our reflections on the question: *what are important considerations with respect to planning a PLT to support higher education instructors to unpack gendered and racialised mechanisms within mathematics instruction?* We first present an overview of the public universities in Brazil and the training of instructors in this context. Then, we briefly describe the curricular proposal within which this training is embedded. At our university, this proposal is in the initial stages of approval and has been deemed viable in a preliminary instance for nine undergraduate engineering programs; thus, preparing instructors is a necessity. We then present the study itself, including the theoretical perspective, methodology, data, and discussion.

Teacher preparation in higher education contexts

Public universities in Brazil have been undergoing changes that alter their social role and raise questions about the practice of teaching in these universities and even in society (Isaia, 2006). We are concerned with the growing admission of traditionally marginalised students into STEM fields, which are predominantly seen as white and male (Leyva et al., 2020). Teaching at universities should support these students to persist in and complete their courses and to take the lead in processes and mechanisms that challenge social oppression. Thus, the training of higher education instructors, with the aim of addressing specific demands related to this university social role, is pivotal.

Training for instructors in higher education seems to occur alongside teaching, throughout their professional careers, and depends on situations and experiences that are not usually shared with others nor are they the result of research that verifies their effectiveness (Isaia, 2006). Additionally, "the idea that those *who know how to do something know how to teach it*"[2] has supported the logic of recruiting teachers (Cunha, 2009, p. 84), contributing to a culture of overvaluing research over teaching within the teaching-research-extension tripod, which is the core foundation of academic activity in universities in Brazil. Such overvaluing of research is reported in various studies and

[2] Translation by the authors from the original in Portuguese: ideia de que *quem sabe fazer sabe ensinar* deu sustentação à lógica do recrutamento dos docentes. (Emphasis in the original.)

evidenced, for example, in many teacher recruitment and career progression systems (Isaia, 2006). As a result, instructor training initiatives are also undervalued, and postsecondary instructors continue to lack specific training for teaching. When such training does exist, it is often the result of individual initiatives rather than public or institutional policies (Cunha, 2009; Sordi, 2019; Isaia, 2006).

In our institution, there are institutionalised instructors training initiatives, although most of these are of a general pedagogical nature. Such initiatives are beginning to emerge in some higher education institutions: Cunha (2009) describes a group of instructors from various fields seeking pedagogical training, which is also generalist in nature. If certainly a step forward in higher education training, since Shulman's (1986) seminal work, we have recognised that pedagogical training cannot only be conceived as separate from content. Therefore, we propose institutionalised training initiatives for instructors, which considers the specific training for teaching mathematics to promote social justice.

The proposed curriculum

The curriculum we are proposing consists of a sequence of mathematics courses that may appear identical to those in a traditional curriculum (differential and integral calculus, numerical calculus, differential equations, and linear algebra), the pedagogical approach and organisation, however, differ drastically. Essentially, there is a pedagogical shift from algebraic manipulation to understanding the mathematical concepts with the development of technological fluency or, even more ambitious, a technology-based and student-centred curriculum focused on conceptual understanding. We propose using technology as a tool to overcome algebra manipulation as a barrier to access deeper conceptual understanding and refocus the calculus program from merely procedural fluency to critical understanding and problem-solving.

We argue that dedicating a large portion of calculus courses to solving intricate or tedious algebraic calculations can have consequences such as reduction in the time available to explore real-world applications, and limited opportunities to interpret the results. The most dangerous implication, however, is the shift in focus on what is relevant in a calculus course. If the algebraic manipulation receives more emphasis than the interpretation of results and the solving of real-world problems, then it is the algebraic manipulation that will prevail as the more important component of the course.

Conceptual framework

This work considers the PLOT model (Ribeiro & Ponte, 2020), represented in Figure 1, as a theoretical framework for designing teacher professional developmental programs, with the goal of providing teachers with professional learning opportunities (PLOT). In this model, such opportunities are provided through the articulation of the Teacher Educator's Role and Actions (TERA), the Discursive Interactions between Participants (DIP), and the Professional Learning Tasks (PLT). In this study, we focus on the design of a PLT, therefore, TERA and DIP are considered as important planning design elements for the PLT. In particular, when necessary, we use the Mathematical Knowledge for Teaching (MKT) model proposed by Ball, Thames, and Phelps (2008) to interpret the connection between the design of a PLT and the other domains of the PLOT model.

However, because the PLOT model does not explicitly address any kind of power dynamics involved in the classroom and we want to foreground our work in the gendered and racialised relations

intertwined in mathematics postsecondary instruction, we are incorporating into this framework elements to bring such issues to light. To do so, we articulate some descriptions of how women and students of colour can be excluded from participation of mathematical practices and discourse from Leyva et al. (2020) with how micro-affirmations, proposed by Cawley and Wilson (2024), can disrupt some patterns in racialised and gendered mechanisms in postsecondary mathematics education. A few pieces within Brazilian context, such as Silva and Powell (2017), suggest that racialized and genderized experiences, even if not manifested in exactly the same way as in Leyva et al. (2020), are equally prevailing and persistent within mathematics instruction. We are grounding our work in Leyva et al. (2020) to use their more detailed descriptions about how such mechanisms occur, and Cawley and Wilson (2024) to glimpse about how to challenge them.

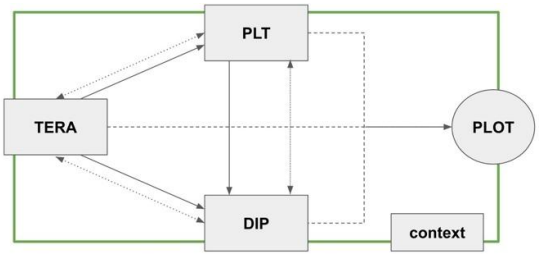

Figure 1: PLOT Model with acronyms translated from Portuguese to English (Ribeiro & Ponte, 2020)

Data collection and analysis

For the mathematical task, we chose the topic of direction fields, as this topic addresses the broader concept of rate of change, which runs throughout the curriculum, from introductory to advanced mathematical courses in engineering programs. We adapted the fall of a body problem, described by the initial value problem $v' = 9.8 - 0.2v$, with $v(t_0) = v_0$, in which the velocity $v = v(t)$ is a function of t, from a traditional differential equations' textbook, raising the level of cognitive demand of the task by shifting the focus of simply solving the equation to connecting different representations related to the concept of rate of change in a differential equation. We incorporated technology accessible to the general population as means to generate one of such representations. Then, we obtained records of practice to include in the PLT by running a workshop to undergraduate students. We journaled our own practice and collected students' solutions of the mathematical task.

In our analysis, we followed a qualitative approach seeking first to capture possible racialised and gendered mechanisms within postsecondary mathematics instruction, that in our case, should be reflected in the PLT. Additionally, how such mechanisms could relate to the PLOT model.

Raising and unpacking potential PLT questions

According to Leyva et al. (2020), Black and Latin* students have fewer opportunities to participate in mathematics classes, instructors often overlook such students in class, not offering support when they need but, specially, not accrediting knowledge whenever they possess it. This kind of practice, fuels and is fuelled by discourses about who knows mathematics. There are not many studies that describe such mechanisms, and even fewer that tries to unveil how to disrupt them. Cawley and Wilson (2024) are one of the few attempts to do so. Drawing from them, showing genuine interest in the students' thought process can be seen as a direct counteraction from what was described by Leyva

et al. (2020). Therefore, it is important to take students thinking into account; in fact, it is particularly important to consider traditionally marginalised students thinking. To achieve such goal, it is, then, necessary to incorporate questions in the PLT that asks instructors, for example, to consider student thinking, to interpret student thinking, to incorporate student thinking in the unfolding of the class.

Using our example, the first question of the mathematical task was filling a table with data from the differential equation $v' = 9.8 - 0.2v$ for some values for v. In a PLT, after initial engagement with the mathematical task itself, instructors can be encouraged to anticipate possible responses from students in a question number (1), creating an opportunity to develop MKT (Ball, Thames, & Phelps, 2008) by connecting the mathematical task to expected student responses. To further this discussion, it is possible, using data collected from the workshop, to incorporate the following question into the PLT: "(2) Considering the following student solutions in Figure 2, how can you interpret them? In other words, do you know how each student filled in their table? What leads you to think that? What questions could you ask to confirm your interpretation?" To create additional opportunities for developing MKT (Ball, Thames, & Phelps, 2008), the following question can be added: "(3) Student C, when asked why they chose these values for the table, answered that they had chosen values close to the target, which in this case meant reaching the ground, with the velocity being zero. Does this answer confirm your assumption? How can this answer modify/refine your assumption? How can this knowledge about the student's thinking inform decisions about teaching this problem/topic?"

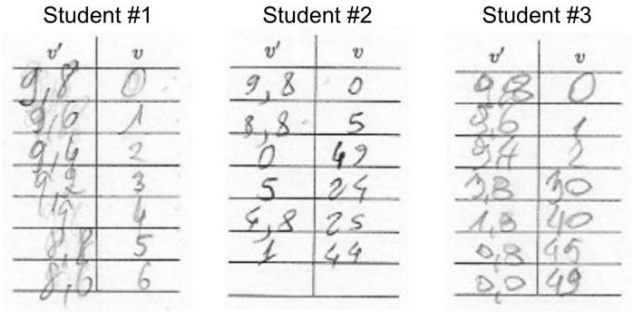

Figure 2: Student's answers.

Moreover, these exact same questions, (1), (2), and (3), when analysed from the perspective of Leyva et al. (2020) and Cawley and Wilson (2024), acquire additional meanings. When directed towards Black and Latin* students, carefully examining the table and listening to the student's reasoning might counteract the action of overlooking their mathematical ability and, consequentially, the distribution of mathematical knowledge altogether. The incorporation of such questions in a PLT needs to be carefully accompanied by TERA to bring such perspectives to light.

Moreover, Leyva et al. (2020) argue that mathematical knowledge is often unequally distributed across race and gender in initial postsecondary mathematics courses. The authors claim that different kinds of instructional events allude exclusionary ideas about who belongs to mathematics and STEM communities. In particular, Cawley and Wilson (2024) assert that leaving part of the work to students with typical assertions found in textbooks ("it is easy to see that", "it is obvious that", or "the proof is left to the reader") can contribute to students feeling a lack of belonging if they cannot see the triviality mentioned by the teacher. Additionally, Leyva et al. (2020) do not detail the event *easy problem*, but

report students who identify differential opportunities for classroom participation and instructor support based on it, which can be associated with student failure to recognise a deemed trivial mathematical fact. To disrupt stereotypical ideas about who can know and do mathematics, Cawley and Wilson (2024) suggest clearly communicating to students they are working in something that is difficult, naming what is difficult about the task and believing students can do and solve the problem.

In our task, we first raised the cognitive demand of the mathematical task, to encourage instructors in to believe students could do it. We did it by shifting the focus of the problem, from solving the differential equation to connecting the different mathematical representations: the algebraic relationship expressed by the equation, the numerical representation given by the table with values of v and v', and the graphical representation given by the slope field. The slope field should be obtained using the *SlopeField* feature of the GeoGebra application. As designed, this task can be carried out on smartphones with internet access. At our university most of the students have access to such phones and some form of internet connection. Additionally, GeoGebra is open, free, and available for the two main smartphone operating systems. Thus, even students from lower-income backgrounds can usually access and complete the task. In the GeoGebra, whenever a slope field graph is generated using only automatic parameters to the *SlopeField* feature, the graph generated may contain an inadequate amount of information and can be displayed in a graphical window that is not very relevant to the problem at hand. Figure 3 shows two slope field graphs for the equation $v' = 9.8 - 0.2v$: one generated using automatic parameters (a), and another with a restricted number of displayed points and a manually adjusted graphical window (b). In this task, technology was used as a tool that enabled the connection of one additional representation (graphic) primarily used to raise the level of cognitive demand of the task. Without the use of the digital resource, the goal of the task could get lost in how to construct such graph (procedurally) rather than reason about it and interpret its meaning.

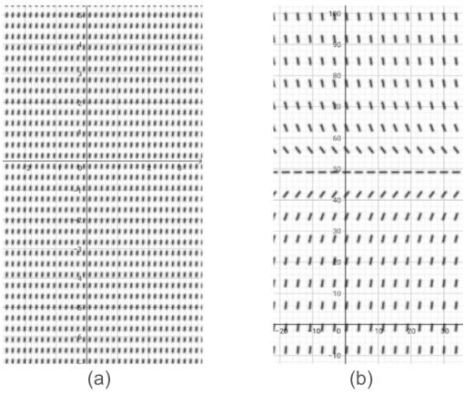

Figure 3: Graphs generated by smartphones using the GeoGebra SlopeField feature.

Then, questions about naming what is difficult might be included in the PLT to afford instructors opportunities to reason about mathematical complexities of the task which will support in naming them to students. In this example, moving from simply solving the equation to connecting the three different representations offer opportunities with respect to: (i) understanding that the table contains values of v and v', but the graph is plotted on a coordinate system with coordinates t and v; also, understanding that v', on the graph, is represented by the slope of each line segment through the

points (t, v); (ii) recognising that points at different values of v, have different slopes, that is, different accelerations v' (in connection with the relationship expressed by the differential equation $v' = 9.8 - 0.2v$ and reflected in the values obtained in the tables); (iii) analogously, understanding that points at the same height on the graph, that is, with the same value of v, have the same slope (same acceleration v'), even if the t values are different. This fact can be interpreted as the temporal evolution of acceleration v' depending solely on the initial velocity v; in other words, two bodies with the same initial velocity, at different times, have the same evolution in acceleration over time; (iv) recognising the limiting velocity or equilibrium solution seen in the asymptote of the graph and, potentially, in the table, when $v' = 0$. In this case, the acceleration is zero, so the velocity remains constant.

While the question "What is difficult about this task? Why?", if added to the PLT, can lead to various interpretations and develop MKT, the teacher educator might plan their TERA to guide the DIP towards the mathematical difficulty of the task with the goal of challenging the neutrality discourse related to the mathematical task that conceals stereotypical views defined by gender and race, and shape mechanisms that create opportunities for unequal participation and support from instructors in the classroom. Therefore, in this problem, it is important for the instructor to recognise the difficulty in obtaining a direction field as a possible qualitative solution to a differential equation. For example, it is challenging to perceive that, based on the representations, whether algebraic, graphical, or numerical, as evidenced in the table, the velocity is not zero as t tends to infinity. It is also difficult to interpret what it means in a direction field for the slopes to be constant for the same v and different t values. And it is particularly important for instructors learning to name what is difficult in the task to name it to students and believe that they students can learn it.

Final thoughts and limitations of this work

A first clear limitation of this work is that the PLT was theoretically analysed, but not empirically tested, therefore, in future work, we plan to carry out workshops with postsecondary mathematics instructors which will give us more data to understand the work of preparing instructors.

One difficulty of this work is the complexities generated by both the level of mathematics explored in the task and the social political dimensions articulated within the context in which it is embedded. To achieve a goal of preparing mathematics instructors with such complex articulation, the collaboration of both authors of this paper was necessary, one with expertise in sociopolitical dimensions of mathematics, but with good transit in postsecondary mathematics, and another with expertise in mathematics, but also with some transit in sociopolitical discussions. Such collaborations are recommended (Bressoud, Mesa & Rasmussen, 2015), but not easily fostered in academic mathematics communities.

Moreover, our analysis shows that the sociopolitical responsibilities are often placed in the hands of instructors, either postsecondary mathematics instructors or teacher educators. At least, it is an essential piece of the PLOT model, because even when designing pedagogical questions to raise racial and gender differentiation in mathematics teaching, much is still left to DIP and how teacher educators are going to moderate them through their own TERA. Such limitation prompted us to include comments on the PLT about possible TERA and intended DIP; however, much is still left to an individual and discretionary space.

Planning for equity: Does Universal Design for Learning hold promise for mixed-ability mathematics classrooms? A scoping review

Aibhín Bray[1], Cian McKenna[1] and Elizabeth Oldham[1]

[1]Trinity College Dublin, the University of Dublin, Ireland; aibhin.bray@tcd.ie

This paper explores the potential of the Universal Design for Learning (UDL) framework to promote equity and inclusion in mathematics classrooms. Disparities in mathematical achievement, often exacerbated by ability grouping, disproportionately affect students from low socio-economic status backgrounds. While mixed-ability classes are recommended to counter this, they present challenges for educators. UDL, with its emphasis on engagement, representation, and action and expression, offers a promising approach to address the diverse needs of students. Through a scoping review of existing literature, this study investigates the evidence supporting UDL's effectiveness in secondary mathematics education. The review reveals limited but promising research, highlighting a need for further studies to explore UDL as a framework for inclusive and equitable mathematics classrooms.

Keywords: Universal Design for Learning (UDL), lower secondary, mixed-ability, disadvantage.

Introduction

It is a well-recognised problem that there are disparities in academic achievement associated with socio-economic status (SES). This is particularly evident in mathematics, with low-SES students in OECD countries "seven times more likely on average than advantaged students to not achieve basic mathematics proficiency" (OECD, 2023, p. 45). However, results from the Programme for International Student Assessment (PISA) consistently show that the strength of the relationship between test scores and socio-economic status (SES) varies markedly between countries (OECD, 2023). This indicates that with an appropriately *equitable* approach – thus, catering suitably for each individual's needs – students can succeed regardless of background (Dietrichson et al., 2017).

While it is important to acknowledge that "gap-gazing" is not always beneficial, particularly through a deficit lens (Gutiérrez, 2008), it is clear from the literature that many factors contribute to discrepancies in achievement. Of particular relevance to this paper is the finding that the achievement gap for students from underrepresented backgrounds tends to widen during the initial years in secondary schooling, a juncture that is understood as being crucial for a student's mathematical journey (McKenna, 2014). This gap is often exacerbated by educational systems that tend to group students by "ability" (or rather, typically, by current achievement level) at this stage, either by school type (e.g., academic or vocational), by syllabus (e.g., "higher" or "lower" level; Advanced Placement), or simply by banding of mathematics classes within a school. Most researchers agree that working-class students are greatly disadvantaged by the incorporation of ability grouping, with students from working-class households disproportionately represented in lower ability groups (Smyth, 2016). Recent research from the OECD (2023) acknowledges that the earlier that students are grouped by ability – contravening *inclusion*, which aims to keep students together irrespective of various characteristics including ability – the stronger the association between SES and performance. An illustration is provided by the situation for Ireland. Irish policies and guidelines maintain a strong focus on inclusion, with policy documents that target both ends of the ability spectrum recommending

the use of mixed-ability classes at lower secondary level, arguing that they are beneficial for all students (Department of Education and Skills, 2020; National Council for Curriculum and Assessment, 2006). Despite this, ability grouping within mathematics, Irish and English is commonplace in Irish schools, with 80% of grade 8 (age ~13-14) mathematics classes grouped by ability, rising to over 90% from grade 9 (OECD, 2013). Aligning with international findings, Ni Shuilleabhain et al. (2021) note that students in Irish schools designated as "disadvantaged" are 40% less likely to study mathematics at higher level than their advantaged peers.

While it must be recognised that upper secondary level offers extra challenges, at lower secondary level there are strong arguments for promoting inclusion through maintaining the open pathways beneficial for less advantaged students by delaying or avoiding grouping. However, if students are not grouped according to (perceived) ability, classrooms will inevitably include a broader range of students, with associated diversity in learning preferences, strengths and barriers. Teaching in such mixed-ability classrooms is not a simple endeavour; Atteberry et al. (2019) note that ability grouping is "often defended based on the contention that detracking and mixed-ability classes are impractical or unworkable" (p. 1). It can be a daunting task for teachers with such mixed-ability classes to create a learning environment that caters to every student in the classroom.

The Universal Design for Learning (UDL) framework, described by Flood and Banks (2021) as "an approach to learning, teaching, and assessment design that is proactive in addressing the varied identities, competencies, learning strengths, and needs of every learner" (p. 2), may have the potential to support teachers and engage students in such mixed-ability contexts. In the present paper, the concept of inclusion connects the ideological notion of equity with the practical considerations of how this might be operationalised in the classroom using the UDL framework (Roos, 2019). The study aims to investigate existing research to identify whether the UDL framework might be an appropriate tool to support secondary mathematics teachers in ensuring equity and inclusion in diverse, mixed-ability classrooms.

Universal Design for Learning (UDL)

Universal Design for Learning (UDL) is a pedagogical framework that was developed by CAST (www.cast.org) in the 1980s. The goal of the approach is to optimise teaching and learning for all students in a way that provides for a diversity of learners, supporting them to develop their own agency. Since the early 2000s, some education systems – for example those in the United States, Australia, South Africa and Ireland – have begun to incorporate UDL as part of their education policy, curriculum development and teacher education (Bray et al., 2024). However, literature to date has focused chiefly on special educational settings and primary or tertiary education, with much less emphasis on secondary mainstream schools (Flood & Banks, 2021).

The UDL framework is divided according to three core principles: *engagement, representation* and *action and expression,* which can be used to guide teachers in the creation of environments that are inclusive of all learners. The *engagement* principle aims to provide students with multiple ways to engage in learning, focusing on the "why" of learning; *representation* supports the provision of choice in how students perceive and make meaning of information – the "what" of learning; and the *action*

and expression principle highlights how to provide students with choice and flexibility in how they demonstrate or share what they have learned – the "how" of learning (udlguidelines.cast.org).

Given the complexity of mixed-ability classrooms in mathematics, and the potential of the UDL framework to support teachers in adopting such practices successfully, this research provides a scoping review of extant literature to address the following research questions: RQ1: What (if any) evidence is there for the use of UDL in secondary mathematics classrooms, in particular, for (RQ1a) mixed-ability mainstream mathematics classrooms and (RQ1b) mathematics classrooms that serve low-SES communities? And RQ2: What lessons can be drawn from the current literature?

Methods

A scoping review is a method used to initially assess the potential scope of research literature on a topic and help determine gaps (Grant & Booth, 2009). It differs from a systematic literature review in its smaller scale and scope. This method has proven to be useful in opening up the field and highlighting that future research in this area is justified, and indeed necessary.

EBSCOhost was used as the primary platform for the scoping review, which was conducted across five relevant databases: Academic Search Complete, British Education Index, APA PsycInfo, APA PsycArticles and ERIC. In order to maintain as much breadth as possible, no time constraint was set on the search, and the search terms were expansive, covering the three main categories of UDL, mathematics, and secondary education. The search was further widened by applying the Equivalent Subject expander, but was limited to Full Texts.

Despite the attempts to maintain breadth, only 16 results were returned. These records were imported into the review management software, Covidence (www.covidence.org) and were subject to a first phase of Title and Abstract screening. Exclusion criteria included a sole focus on primary, tertiary or special education, or on the design of digital tools.

The first two authors reviewed the articles, agreeing on eight articles to be included for full review. At the end of that review, two more articles were excluded, leaving six for data extraction. The data extraction template in Covidence was designed to facilitate easy extraction of key study information (Table 1). The papers were subsequently imported into NVivo for coding and analysis.

Table 1: Study Characteristics

Author	Country	Journal	Title	Study Design	Inclusion focus
Dieker et al. (2022)	USA	Middle School Journal	Seven Equity Ideas for Students with Language-Based Needs in Mathematics	Text and opinion	Language (Multilingual/EAL)
Hunt and Andreasen (2011)	USA	Mathematics Teaching in the Middle School	Making the Most of Universal Design for Learning	Text and opinion	Broad inclusion of all learners

McCracken et al. (2024)	USA	TechTrends	Middle School Students' Conceptualizations and Reasoning about the Fairness of Math Tests.	Phenomenological study	Additional/Special Educational Needs; Multilingual/EAL; Ethnicity; Gender
Moleko and Mosimege (2021)	South Africa	Pythagoras	Flexible Teaching of Mathematics Word Problems through Multiple Means of Representation	Qualitative case study; critical emancipatory research.	Language (Multilingual/EAL)
Staats and Laster (2018)	USA	Education Sciences	Extending Universal Design for Learning through Concurrent Enrollment: Algebra Teachers' Perspectives.	Qualitative research: focus group interviews	Multilingual/EAL; Ethnicity; Socio-economic status
Walker and Hunt (2011)	USA	Mathematics Teaching in the Middle School	Social Skill Development through Math.	Text and opinion	Additional/Special Educational Needs

Results

The first clear result from this review is that there is paltry evidence for the use of UDL in secondary mathematics classrooms. Of the six articles, three involved some level of empirical study, and three were classified as text and opinion. The non-empirical articles were all published in practitioner-focused journals, offering practical suggestions for teachers. The three articles that report empirical results are all qualitative in approach, exploring the benefits of UDL within concurrent enrolment programmes, the teaching of word problems, and assessment. Of the six papers, two have a specific focus on inclusion of learners for whom the language of instruction is not their native tongue (Dieker et al., 2022; Moleko & Mosimege, 2021), one prioritises the social skill development of learners with additional educational needs (Walker & Hunt, 2011), and the remaining three papers have a broad equity agenda (Hunt & Andreasen, 2011; McCracken et al., 2024; Staats & Laster, 2018).

Addressing RQ1, it is clear that, if UDL is to be considered as a framework for equity and inclusion in the mathematics classroom, there is a need for further empirical research to be conducted to evaluate its effectiveness. The three articles that include empirical research do show some promise, with each reporting positive outcomes; they are discussed in turn.

Of particular note in relation to RQ1 (a) and (b) is the research outlined by Staats and Laster (2018). The article provides insight into a large-scale, equity-focused study that successfully incorporates the principles of UDL in mathematics education at upper secondary level with a goal of increasing the participation of students (for instance, of low SES) who are underrepresented in third-level education.

The work of McCracken et al. (2024) highlights an approach to assessment design with its foundations in UDL, arguing that “The Universal Design for Learning (UDL) guidelines can inform

assessment development to promote fairness" (p. 1). "Teaching to the test" is a well-known phenomenon, and the constraints imposed by high-stakes examinations is a commonly cited challenge when attempting to change classroom practice. Creating more inclusive and accessible assessments may be one way to address this. By incorporating elements of UDL into assessment design as well as in teaching and learning, the authors aim to ensure that teaching reflects testing practices.

The third paper that incorporates empirical research is that of Moleko and Mosimege (2021), who consider the challenges for both teachers and learners when it comes to mathematical word problems. The focus of this study is on multiple means of representation, and the authors highlight the ways in which teachers can support their students through the provision of "options for language, mathematical expressions and symbols, as well as options for perception" (p. 8).

While it is important to acknowledge the specific barriers that are addressed in some of the papers, there is also a broader consideration given to ensuring that the material is accessible to all learners, that it is engaging and relevant, and that the students can represent their learning in a manner that suits them. Indeed, with the exception of the work of Moleko and Mosimege (2021), each of the papers addresses all three principles of UDL. In order to address RQ2, therefore, the analysis is organised according to each of these principles.

Recommendations for engagement

Five of the six papers provided recommendations on how to engage students in mathematics, with much of the advice focusing on how to optimize relevance, value, and authenticity. Suggestions include asking students to source examples on social media to illustrate a particular concept (Dieker et al., 2022), and ensuring that the context of a mathematics problem is relevant, or at least believable, for the students (Hunt & Andreasen, 2011; McCracken et al., 2024; Staats & Laster, 2018). Walker and Hunt (2011) and Hunt and Andreasen (2011) highlight the importance of offering choice to students on whether to work alone or in a group.

Finally, Staats and Laster (2018) highlight the suitability of mathematical modelling as a pedagogy that aligns well with UDL, encouraging "multiple ways of engaging mathematical scenarios and expressing solutions" (p. 2). According to the authors, teacher respondents noted a change in their students' attitudes towards mathematics through engaging with the modelling process, stating that "modeling was more enjoyable than the more familiar textbook components of the class" (p. 10).

Recommendations for representation

The six papers all provided some guidance on how to design for multiple means of representation, with the work of Moleko and Mosimege (2021) explicitly focusing on this principle. Within the context of mathematical word problems, the authors suggest that teachers should refrain from a mechanistic approach and should rather highlight "patterns in a given word problem, outlining critical features […], as well as the big ideas regarding the concept that is dealt with" (p. 9). Teachers should also clarify mathematical vocabulary and symbols, syntax and structure, and should support learners in understanding how to "decode" text.

In the work of Staats and Laster (2018) there is a clear correspondence between UDL and the steps of mathematical modelling with which students are supported to engage. The authors highlight that

mathematical modelling, by its nature, supports choice in how to interpret information. Throughout this process, learners develop skills in posing questions, making connections, synthesising information, integrating new information with prior knowledge, and generalising. McCracken et al. (2024) highlight the importance of considering the impact on language and cultural differences when designing fair assessments, as these can "influence students' comprehension of information" (p. 13).

The three "text and opinion" articles offer general guidance on how to add "a range of choice to an already well-designed lesson plan" (Dieker et al., 2022, p. 36). The authors caution practitioners to consider the barriers that their students may face, and to take these into consideration when planning, so that all students will be in a position to make sense of the information with which they are required to engage (Dieker et al., 2022; Hunt & Andreasen, 2011; Walker & Hunt, 2011).

Recommendations for action and expression

Provision of choice is a key feature of UDL, and no more so than when designing for how students interact with and demonstrate their learning. The use of choice boards (Dieker et al., 2022) is one concrete way to achieve this, as is providing students with choice regarding the problem(s) that they want to solve (Walker & Hunt, 2011). Mathematical modelling (Staats & Laster, 2018) requires students to use multiple modalities to express and communicate their learning, including text, equations, graphs, and so forth. In the work of Walker and Hunt (2011) and Hunt and Andreasen (2011), capitalising on peer learning is suggested, with the authors postulating that learners could attempt to summarise the solution strategies of others or students could be required to ask for and offer support from their peers before turning to the teacher.

Many of the suggestions for this principle highlight the importance of strategy development within mathematics, highlighting that there is a need to "focus on the processes and organization of problem solving as well as the conceptual underpinnings of procedures" (Walker & Hunt, 2011, p. 299). In order to develop these skills, it is recognised that there is a need for effective, systematic and timely feedback (McCracken et al., 2024; Walker & Hunt, 2011).

Discussion and conclusion

McCracken et al. (2024) differentiate between *equality*, as characterised by transparency and objectivity, and *equity* as requiring adaptation, diversification, and consideration of the individual. If we wish to have an equitable system, then we cannot expect a "one-size-fits-all" approach to provide it. It is clear from the literature that while *equality* may be maintained within a system that relies on (so-called) ability grouping in mathematics, this approach does not provide *equitable* access to the material. Atteberry et al. (2019) contend that by removing ability grouping in mathematics classes, we open courses "to students who were historically denied access based on lower achievement" (p. 8). In their research, high-achieving students were not negatively impacted by the removal of ability grouping, and the average scores of the lower achievers were the same or higher, despite the larger numbers taking the courses. This offers a strong argument for not rationing access to a high quality, challenging curriculum, but rather striving to ensure that it is accessible to a heterogeneous group of learners with diverse strengths and needs. Staats and Laster (2018) advocate for equitable access to

higher-level mathematics syllabi, noting that "inclusive pedagogy does not make a class less challenging or of lower status" (p. 16).

This scoping review sought to address two research questions. RQ1 sought to identify what (if any) evidence there was for the use of UDL in mathematics classrooms, particularly for low-SES or mixed ability. The easy answer is "very little". Only three empirical studies were identified in the review; each was quite niche in its scope. RQ2 asks what lessons can be learned from the literature. Again, any response to this question must be contextualised within the dearth of available research. It must also be acknowledged that, while the articles reviewed for this study offer some guidance, they do not provide adequate discussion of the pedagogical challenges that can face a teacher when trying to cater for mixed-ability mathematics classes. However, it was possible to extract some general (albeit likely obvious) recommendations in relation to RQ2. If we are to design for equity and inclusion, a first step is to know your learners. It is only once you are aware of students' preferences, and the barriers that they face, that you will be in a position to address them. Secondly, it is important to offer choice, while acknowledging the constraints of the learning goals and intentions. Finally, student-centred pedagogies, such as mathematical modelling, align well with UDL and could offer a "way in" for educators to try out the framework using what may be familiar methods.

The research presented in this article is clearly limited by scale and scope. Only one platform was used in the search, and the full-text requirement may have ruled out articles that could have been accessed indirectly. Despite these limitations, the fact remains that there is very little evidence to date for UDL as an approach to support teachers in creating mathematics classroom that can accommodate diverse learners. While the identified articles offer some insight into the implementation of UDL in mathematics, there is a glaring need for more research in mixed-ability settings at lower secondary level. Given the rising profile of UDL in educational policy, curriculum and teacher education, it is imperative that research into the effectiveness of the approach in increasing inclusion, equity and access is prioritised, in order to avoid *hysteron proteron*, or "putting the cart before the horse".

‘Have-been-doing masculinity’ - emerging gender stereotypes in mathematicians‘ descriptions of their memories of mathematics lessons

Julchen Brieger[1,2], Jule Aufschneider[2] and Marie-Christin Aust[2]

[1]Humboldt University of Berlin, Germany; Julchen.Brieger@zlb.tu-chemnitz.de

[2] University of Technology Chemnitz, Germany

This paper presents the theoretical framework and initial insights from a newly launched research project. The study investigates mathematicians’ recollections of their school experiences, with a particular focus on mathematics lessons and the character traits they identify as instrumental in their development as mathematicians. The data were subsequently analysed with a specific emphasis on the emergence of gender stereotypes. Preliminary findings suggest that male mathematicians tend to attribute their success to innate talent, aligning with traditional notions of natural ability. In contrast, female mathematicians often describe themselves using language typically associated with masculine traits, such as resilience and determination. Additionally, women’s memories of mathematics lessons are frequently framed within contexts of competition and the necessity of possessing a strong will to achieve success.

Keywords: Doing mathematics, STEM careers, STEM education, gender differences.

Introduction

The persistent underrepresentation of women in Science, Technology, Engineering, and Mathematics (STEM) careers is a well-documented phenomenon (World Economic Forum, 2023). In response, contemporary research endeavours to identify the underlying factors contributing to this disparity, particularly those driving women to leave the so-called "leaky pipeline." Rather than framing the inquiry around questions such as "What happened to those girls?" or "Why do women disproportionately opt out of STEM careers?", our approach shifts focus to the narratives of individuals who have successfully established themselves within STEM fields without strengthening the aspect of gender as much. By exploring the common denominators among these successful careers, we aim to adopt a strengths-based perspective, moving away from a deficit-oriented framework that centers on failure and attrition. Our study seeks to understand the formative educational experiences that influenced individuals to "stay in" STEM, with a specific focus on their memories of mathematics lessons during primary school. This emphasis reflects a deliberate departure from the more extensively studied domain of secondary school mathematics and its impact on career trajectories in STEM (e.g., Cerinšek et al., 2013; Nix et al., 2015). The rationale for this focus lies in the potential significance of early mathematical experiences, which may shape children's perceptions of mathematics as a "male-dominated" discipline and establish enduring attitudes towards the subject. Emerging evidence underscores the critical influence of primary school experiences on students' later engagement with mathematics. Marmur and Darragh (2024, p.188), for instance, highlighted the recollections of pre-service teachers regarding their mathematics education, with one student vividly recalling an episode of embarrassment and humiliation in primary school. Similarly,

Sorvo et al. (2017) identified math anxiety as a phenomenon detectable as early as primary school, noting its detrimental effects on students' subsequent mathematical performance. These findings suggest that early educational experiences may play a pivotal role in shaping career choices, particularly with respect to STEM-related pathways. Our ongoing research seeks to investigate the emerging patterns in the memories of individuals who have achieved successful careers in STEM, particularly their recollections of primary school mathematics lessons. This study represents an effort to identify recurring themes and stereotypes within these narratives, which may provide insight into the factors that positively influence persistence in STEM. In this paper, we present preliminary hypotheses derived from the initial findings of a pilot study conducted with mathematicians (representing the "M" in STEM). Although the main data collection phase of the project is still underway, these early results offer valuable perspectives on the role of primary school mathematics education in fostering long-term engagement with STEM disciplines.

Empirical framework: Gender-Gap in STEM-related fields

The persistent gender gap in Science, Technology, Engineering, and Mathematics (STEM) fields remains a pressing issue, with little evidence suggesting significant progress toward equality. Women are significantly underrepresented in STEM careers, comprising nearly half (49.3%) of the workforce in non-STEM occupations but only 29.2% in STEM roles (World Economic Forum, 2023, p. 7). This disparity becomes evident early, as fewer women pursue STEM-related career paths despite increasing educational attainment globally (Delaney & Devereux, 2019). The phenomenon of the "leaky pipeline" further compounds the issue: while women earn 38.5% of STEM degrees, their representation drops to 31.6% in STEM jobs one year after graduation, and only 17.8% and 12.4% in VP and C-suite leadership roles, respectively (World Economic Forum, 2023, pp. 44-45). Critically, such statistics often fail to capture the underlying social dynamics that create and sustain these disparities. Without deeper examination, these numbers risk portraying gender inequality as inevitable or natural, reinforcing perceptions of male dominance in STEM. A more nuanced approach must consider how gender is actively constructed and reproduced within educational and professional contexts. Research highlights secondary school mathematics as a decisive factor influencing STEM career choices (Spreitzer et al., 2024). For example, Nitzan-Tamar and Kohen (2022) argue that the level of mathematics studied and success in science majors like physics and computer science play a crucial role in determining future STEM participation. However, such studies often overlook how educational systems themselves contribute to gendered outcomes. External perceptions of ability, for instance, may be particularly influential for female students, whose choices in STEM can hinge on how their performance is viewed rather than on their actual abilities (Nix et al., 2015). This aligns with findings that women, despite achieving results comparable to men, report significantly lower confidence in their mathematical abilities (Watt et al., 2017). Other studies highlight how classroom dynamics reinforce these patterns. In U.S. secondary schools, for instance, male students completing Algebra II often adjust their self-assessments downward, aligning their confidence with their actual performance, while female students show no comparable shift (Ma & Johnson, 2008). These differences suggest that cultural narratives about gender and mathematics ability continue to influence students' self-perception and subsequent academic choices. By examining these issues through the lens of gender as a social construct, it becomes clear that the underrepresentation of women in STEM

is not merely a product of individual preference or skill. Instead, it reflects systemic biases and institutional practices that perpetuate gendered norms. Addressing these root causes requires moving beyond statistics to understand how gender is enacted and reinforced in educational and professional environments.

Theoretical framework: Gender Stereotypes and 'doing masculinity'

We adopt Greenwald and Banaji's (1995, p. 4) definition of stereotypes as "shared beliefs about traits that are characteristic of members of a social category" and extend this with the insight of Muntoni and Retelsdorf (2020, p. 72), who note that individual traits and characteristics are often overshadowed by those attributed to the broader social category. Viewing gender through the lens of social constructivism ('doing gender'), gender stereotypes can obscure the individual qualities of students in mathematics. In particular, we highlight how the label of being female, or 'femininity,' can overshadow traits such as ambition, rationality, and assertiveness—qualities traditionally viewed as masculine (see table 1). These gender stereotypes can adversely affect young girls' learning of mathematics. For instance, female teachers who harbor insecurities about their own mathematical abilities may unintentionally reinforce internalized gender stereotypes, leading girls to believe that their mathematical skills are inherently inferior due to their gender (Beilock et al., 2010). Additionally, the stereotype of mathematics as a predominantly masculine field (Muntoni & Retelsdorf, 2020, p. 82) can create a self-fulfilling prophecy, where teachers may inadvertently favor boys over girls, offering more encouragement and praise to male students (Becker, 1981; Jungwirth, 2014; Leinhardt et al., 1979). Gender stereotypes continue to hinder women even after school, with job advertisements framed using masculine language—terms like 'competitive' and 'dominant'—resulting in fewer applications from female candidates (Gaucher et al., 2011). Beyond academic success in mathematics, there are various stereotypes associated with gender and masculinity that deserve consideration. For preliminary analysis, we draw on a selected set of deeply ingrained stereotypes. Traditional feminine and masculine traits, as outlined by Murray (2001, p. 248), align with contemporary findings describing women as communal (concern for others, sociability, emotional sensitivity) and men as agentic (assertiveness, independence, instrumental competence) (Hentschel et al., 2019).

Traditional feminine traits		**Traditional masculine traits**	
Gentleness	Sacrifice	Courage	Assertiveness
Modesty	Supportiveness	Strong will	Initiative
Humility	Empathy	Ambition	Rationality
Nurturance	Compassion	Independence	Emotional control
Intuitiveness	Tenderness		
Sensitivity	Unselfishness		

Table 1: Traditional feminine and masculine traits according to Murray (2001, p. 248)

Rather than solely discussing gender stereotypes, some scholars integrate the concept of social processes, using Bakhtin's (1981) distinction between heteroglossia and monoglossia. In monoglossic viewpoints, female traits are inherently linked to the biological sex of women. However, as Francis (2012) argues, heteroglossia is intrinsic to all gender constructions, while monoglossic, binary perspectives tend to "mask and pathologise heteroglossia" (p.1). Disruptions to these binary perspectives, or 'heteroglossic contradictions'—such as girls exhibiting masculine traits—are often subtle, manifesting predominantly at the micro level of individual subjectivity, and are most apparent to those who do not conform to the monoglossic gender order, as is evident within the transgender community (Jaremus, 2020, p. 718). These contradictions are particularly salient in the context of girls and women in mathematics, where "doing mathematics equates to doing masculinity," creating more tension for girls and women who are more invested in their feminine identity than for boys and men (Mendick, 2006, p. 2). Some girls pursuing careers in STEM try to mitigate this perceived 'masculinity' by incorporating traits or interests deemed traditionally feminine (Archer & DeWitt, 2015, cited in Jaremus, 2020, p. 718). Similarly, boys who transgress monoglossic boundaries and are labelled as 'feminine' or as possessing 'female traits' may find themselves excluded from mathematics, as it is often perceived as a masculine domain (Jaremus et al., 2023, pp. 8-9).

Methods, Data collection and limitation of the subjects investigated

For both the pilot study and the main study, we define "having a successful career in STEM" as holding a position in Science, Technology, Engineering, or Mathematics at a level higher than entry-level, with a minimum of five years of professional experience post-graduation. The pilot study focused specifically on the "M" in STEM, restricting the participant pool to individuals in postdoctoral or higher academic roles at German universities. However, this is not the final criterion for a successful career in mathematics, and further data will be collected in the near future. Participants were asked to reflect on their experiences in mathematics lessons during their school years, starting with the earliest memories. Specifically, they were prompted with questions such as, "What comes to mind when you think about your mathematics lessons at school? Please share your experiences." Additionally, they were asked to describe the personality traits they believed had been helpful in learning mathematics, with questions like, "Please describe any attributes or skills that may have been useful in mathematics lessons."

For analysing the pilot study data, we employed a straightforward qualitative content analysis (Mayring, 2014), with a particular focus on emerging gender stereotypes to gain initial insights and structure the interviews. However, the main study, which is planned for the near future, will be analysed using Grounded Theory (Corbin & Strauss, 2015), as it allows for a more inductive approach and provides the flexibility to continuously incorporate and expand upon data collected across various countries, genders, and STEM fields. In this main study, participants will only be asked to provide their school experiences without additional constraints, allowing their responses to emerge more naturally.

First insights

The traits most frequently mentioned by female mathematicians were ambition and assertiveness, which are traditionally categorized as masculine traits according to Murray (2001). This is reflected

in statements such as: *"But I do think it makes a big difference to also learn from others (.) and try to fit in well, and to seek help when it makes sense, right, exactly,"* which demonstrates humility and collaboration but also a strategic approach to learning. Another participant highlighted ambition and competitiveness by recalling a personal anecdote: *"There was another boy who was also very good at math, and we kind of always had a little, well, like a small competition, you know."*

Interestingly, male mathematicians did not attribute any memories or personality traits using descriptions typically associated with femininity. Instead, they tended to emphasize their cognitive abilities and perseverance. For example, one participant stated: *"Uh, I (..) have a very good ability to abstract and can imagine things really well. […] I'm researching how things deform, and for example, I had no problems with things like body constructions or something like that. Because/ well, this object was just there in my head, and I could rotate it however I wanted. I don't think other people have that as much."* This emphasis on spatial visualization skills and abstraction reflects the association of rationality with masculinity. Another participant reinforced this by describing the persistence required for mathematical success: *"Just a little bit, now/ it becomes more apparent at university that you also need to be persistent and have patience."*

Moreover, male mathematicians rarely employed gendered terms when describing their own abilities, instead framing their qualities in terms of capabilities or skills. One participant expressed this by explaining the nature of professional mathematics: *"[…] maybe even starting with the wrong topic, and you just have to stick with it and fight your way through. That's a very important trait; all professional mathematicians I know have phases where they're not sitting in front of a blank page, but in front of pages that end up in the trash because everything they try doesn't work out."* These descriptions underscore the perception of rationality, persistence, and abstraction as essential to success in mathematics—traits that are often aligned with traditional notions of masculinity.

Gender bias in the interpretation of mathematical narratives

Since the use of binary and stereotype-based categorizations in the initial analysis was retrospectively deemed unproductive, a second round of data interpretation was conducted in collaboration with other mathematics education researchers. The primary objective of this re-evaluation was to eliminate potential biases stemming from preconceived notions about gendered traits in mathematical discourse. To achieve this, all data were meticulously cleansed of pronouns and any gender-specific identifiers before the interpretation sessions took place. This ensured that no explicit clues regarding the gender of the narrating participants were available to the researchers during their analysis. By adopting this approach, the study sought to explore whether and how implicit gender associations would still emerge in the interpretative process. Particular attention was given to the pronouns spontaneously used by the mathematics education researchers when referring to the anonymized participants. The results revealed a striking pattern: with only a few exceptions, where researchers explicitly questioned toward the end of a session whether a given speaker might have been a woman, the pronouns *he/him* were consistently used (see Figure 1).

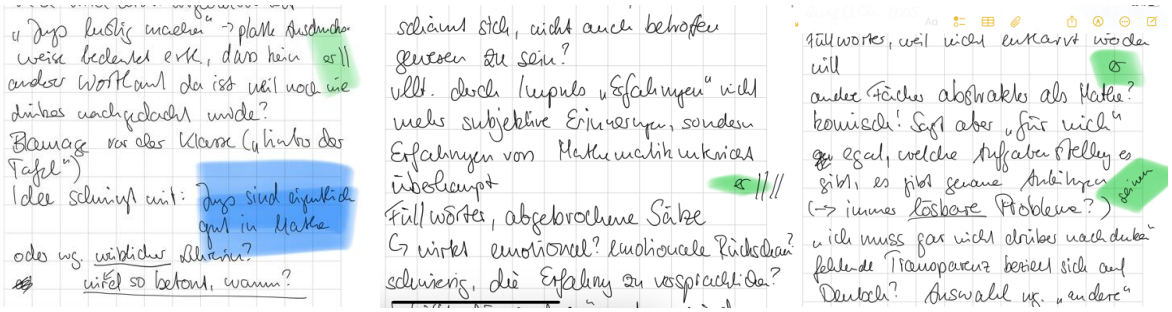

Figure 1: Excerpts from transcripts of the interpretation sessions (in German)

Discussion

Preliminary analysis suggests that both female and male participants framed their school memories and self-descriptions in ways reflecting traditionally masculine traits. This aligns with the concept of *doing mathematics* as *doing masculinity*, where mathematical proficiency is associated with ambition, persistence, and rationality (Mendick, 2006). Male participants tended to present their abilities as inherent skills or talents, avoiding personal or emotional attributions. In contrast, some female participants incorporated elements of compassion or emphasized social learning and collaboration, potentially compensating for the perceived masculinity of their mathematical competence (Archer & DeWitt, 2015). Beyond self-perceptions, interpretative sessions with mathematics education researchers reinforced the implicit association between mathematical expertise and masculinity. Even after gender markers were removed, researchers predominantly used masculine pronouns (*he/him*) when referring to anonymized participants. The occasional questioning of whether a speaker *could* have been female—rather than an even distribution of assumed genders—illustrates the persistence of gendered expectations in academic discourse (Forgasz & Leder, 2017).

These findings align with broader research on gender and competence in STEM fields, which highlights how implicit biases shape perceptions of ability and professional belonging (Carlone & Johnson, 2007; Nosek et al., 2009). The tendency to associate mathematical success with masculinity reinforces systemic barriers for underrepresented groups. While this analysis focuses on gender, it does not yet account for intersecting factors such as race and class. Research on *doing difference* (West & Fenstermaker, 1995) and intersectionality (Yuval-Davis, 2006) suggests these dimensions complicate simplistic gender binaries. Future research will adopt an intersectional approach to explore how multiple identities shape experiences in STEM fields, extending beyond gendered framings.

This paper compares mathematics textbooks from Brazil and Canada to examine how linguistic, cultural, and sociopolitical factors shape educational content and student engagement. Employing a qualitative documentary analysis guided by the Teorema System, the study contrasts Brazil's centralized model via the National Textbook Program (PNLD) with Canada's decentralized approach. The findings reveal that while Brazilian textbooks favor standardization to secure uniform access, this can limit local cultural adaptations; in contrast, Canadian materials integrate diverse cultural and linguistic contexts to resonate with regional realities, albeit with potential disparities in resource allocation. These results underscore textbooks' dual role as pedagogical tools and cultural artifacts and suggest that a hybrid framework combining national consistency with local customization may better promote inclusive and context-sensitive mathematics education.

Keywords: Mathematics textbooks, sociocultural factors, educational policies, comparative analysis.

Initial Considerations

Mathematics textbooks can shape students' learning experiences, presenting knowledge in ways that reflect cultural and political contexts (Fritz et al., 2020). They carry subject-specific language and convey underlying values and priorities (Fan et al., 2013; Gueudet et al., 2021). Planas et al. (2021) describe how textbooks affect second-language learners by linking content with specific forms of language presentation. Gates and Jorgensen (2015) note that textbooks may legitimize societal hierarchies through selective inclusions or omissions.

Research in this area includes studies on how textbooks support modernization ideals in rural settings or frame citizenship and gender (Neto & Valero, 2018; Neto & Pinheiro, 2021; Pacheco & Neto, 2018; Valero et al., 2019). These works show that textbooks can mirror wider social goals beyond disciplinary content (Gueudet & Trouche, 2016; Qi et al., 2025).

This paper examines textbooks from a Brazilian perspective, drawing on a comparison with Canadian materials. The analysis employs the Teorema System (Amaral et al., 2022), comprising (1) contextual mapping, (2) identification of sociocultural and political content, and (3) iterative analysis. This approach addresses textbooks as instruments linked to cultural and ideological dimensions (Fan, 2013). Planas et al. (2021) emphasize that language and culture influence mathematics learning.

Similar findings emerge in comparative studies on how textbooks may integrate or omit cultural content to pursue particular agendas (Cai et al., 2016).

Unveiling the Sociopolitical Dimensions of Mathematics Textbooks

Language and culture are often central in discussions of textbooks, where linguistic differences can help or hinder comprehension (Fritz et al., 2021). Fan et al. (2013) and Gueudet et al. (2021) show that equitable learning depends on recognizing these aspects in teaching materials. Beyond linguistic concerns, textbooks also present perspectives tied to national policies. Jurdak et al. (2018) point out how these materials can endorse certain political or economic viewpoints, illustrated historically by textbooks in China, Saudi Arabia, and other contexts (Kenway & Epstein, 1997).

Some research has noted how materials in rural Brazil may promote specific agendas that guide social and economic development (Neto & Valero, 2018; Pacheco & Neto, 2018). Editors and authors, influenced by governmental frameworks or commercial considerations, also shape textbook design (Gueudet & Trouche, 2016). In settings where centralized systems exist, content choices often follow national standards that aim for uniform coverage (Neto & Pinheiro, 2021). Local adaptation is more frequent in decentralized settings, though variations in funding and oversight can arise (Valero et al., 2019).

Past materials have not always included diverse groups, affecting learners' sense of belonging (Kenway & Epstein, 1997). Some textbooks now feature content on women's contributions or ethnic studies, but digital formats may introduce new differences in access. Considering these factors may inform the design of mathematics textbooks that support a range of student identities.

Methods

This study adopts qualitative documentary analysis based on Bardin (2011) to investigate how Brazilian and Canadian mathematics textbooks address cultural, linguistic, and sociopolitical aspects. The Teorema System (Amaral et al., 2022) guides the process in three phases:

- **Contextual Mapping:** Brazilian textbooks from the National Textbook Program (PNLD) list are extensively used in primary schools. Canadian textbooks employed in the Western and Northern Canadian Protocol (WNCP) illustrate a decentralized environment. The mapping identifies governmental guidelines, cultural settings, and language diversity that shape textbook production.
- **Sociocultural Content Identification**: Informed by Fritz et al. (2020), Planas et al. (2021), and Gates and Jorgensen (2015). Focus on presenting mathematical concepts, cultural representations (e.g., Afro-Brazilian, Indigenous, or multicultural Canadian examples), and language for multilingual contexts.
- **Comparative Analysis**: This approach explores how each system incorporates cultural references, addresses marginalized perspectives, and aligns with policy goals. It draws on

comparative frameworks (Cai et al., 2016; Fan et al., 2013; Qi et al., 2025) to identify similarities and contrasts.

In Brazil, *Matemática: Compreensão e Prática* (Silveira, 2015) and *Projeto Teláris Matemática* (Dante, 2014) were analyzed. *Math Makes Sense* (Pearson Education Canada, 2005–2008) served as the primary reference in Canada. These selections reflect national and provincial curricular frameworks and highlight the differences between standardized and decentralized approaches.

Presentation and Discussion of Data

The findings of the comparative documentary analysis of Brazilian and Canadian mathematics textbooks elucidate the critical cultural, linguistic, and sociopolitical factors that influence mathematical comprehension and engagement. These insights underscore the complex interrelationship between educational content, student experience, and broader societal structures.

Cultural and Linguistic Adaptations

Examining the inclusion of linguistic and cultural dimensions in textbooks clarifies their influence on students' engagement with mathematical content. Fritz et al. (2020) suggest that language in instructional materials shapes students' thought processes and grasp of mathematics. This viewpoint is apparent in the differences between Brazilian and Canadian textbooks. Canadian textbooks integrate cultural scenarios familiar to students, such as hockey or community events, aiming to situate mathematical concepts in relevant settings. *Math Makes Sense*, for instance, provides probability tasks linked to cultural festivals, reflecting Canada's emphasis on multiculturalism and inclusive approaches (Barbeau & Taylor, 2009; Kajander et al., 2018). This practice aligns with Canada's decentralized system, where provinces can adapt resources to local circumstances.

By contrast, Brazilian textbooks (developed under the centralized (PNLD)) tend to feature formal and technical content presentations. Activities typically remain within conventional school contexts, consistent with an emphasis on standardization and nationwide curricular goals (Souza, 2019). While this structure supports uniformity, it may limit the content's cultural adaptability for diverse student backgrounds. Planas et al. (2021) note that bilingual or multilingual environments, such as Canada, benefit from materials designed for varied linguistic needs, whereas Brazil's regional linguistic diversity remains more difficult to address in nationally standardized textbooks.

Sociopolitical Implications

From a sociopolitical viewpoint, textbooks do more than transmit content; they reflect power structures and educational priorities (Jurdak et al., 2018). In Canada, textbooks often emphasize reconciliation with Indigenous communities and multicultural content, aligning with national policies focused on social justice and inclusion (Barbeau & Taylor, 2009). Many activities include data collection linked to daily scenarios, encouraging students to see mathematical ideas within diverse cultural contexts. In Brazil, textbooks have gradually added Afro-Brazilian and Indigenous perspectives, recognizing historical imbalances and advancing cultural representation. Nonetheless, a centralized system constrains local modifications, which may reduce attention to distinct regional

circumstances (Jurdak et al., 2018). These differences show how policy decisions influence textbook design, shaping what is taught and how it resonates with students' cultural backgrounds. In Canada, including Indigenous content is tied to broader reconciliation initiatives, while in Brazil, the national commitment to equity can limit the scope for regional adaptation.

Contributions to Educational Equity: Comparative Study (Brazil vs. Canada)

A comparative analysis of textbooks elucidates distinct pedagogical approaches influenced by cultural contexts and educational policies. Table 1 delineates the key findings, demonstrating how Canadian textbooks emphasize cultural contextualization while Brazilian textbooks adhere to formal standardization.

Table 1: Partial results of the Analysis of Textbooks

Textbook	Example Analyzed	Cultural/Linguistic Aspect	Observation
Math Makes Sense (Canada)	Exercising in sports and hockey	Canadian cultural context: national sports	The exercises incorporate common cultural practices in Canada, such as hockey, providing a closer connection to students' daily lives and facilitating the contextualization of mathematical concepts, as Kajander et.al (2018) discussed.
Mathematics: Ideas and Challenges (Brazil)	Introduction to division	An abstract and formal approach	The presentation of division in Brazilian textbooks follows a technical and formal approach without references to local cultural contexts, reflecting the standardization promoted by the PNLD, as noted by Souza (2019).
Math Makes Sense (Canada)	Probability of cultural festivals	Inclusion of cultural diversity	Cultural festivals are used as the context for probability problems, highlighting the emphasis on multiculturalism and the inclusion of diverse cultural practices, which are in line with Canadian educational policies mentioned by Barbeau and Taylor (2009).
Matemática: Compreensão e Prática (Brazil)	Naming and measuring angles	Use of technical language	The technical language predominates without explicit cultural adaptations, reflecting the centralized curricular uniformity in Brazil, as observed by Gates & Jorgensen (2015).

Textbook	Example Analyzed	Cultural/Linguistic Aspect	Observation
Math Makes Sense (Canada)	Data collection with samples and populations	Application of concepts to Canadian everyday scenarios	The examples of data collection refer to common Canadian everyday scenarios, promoting a practical and meaningful connection to students' realities, as suggested by Kajander et.al (2018) in the educational context of Ontario.
Projeto Teláris Matemática (Brazil)	Ratios and proportions	Traditional Brazilian approach	The presentation of ratios and proportions follows a traditional and abstract line, characteristic of Brazilian textbooks, which priorities strict adherence to national curriculum guidelines, as discussed by Souza (2019).

Brazilian textbooks frequently follow a curriculum-oriented structure, drawing on contexts typical of conventional classrooms. In contrast, Canadian textbooks often integrate diverse everyday scenarios, reflecting the country's ethnic and cultural heterogeneity.

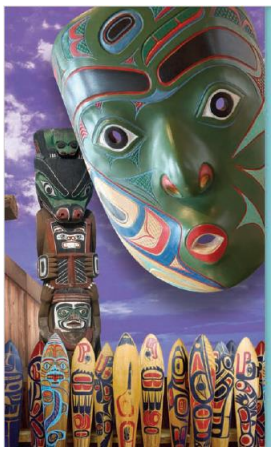

Figure 1: Indigenous Art representations MMS Collection

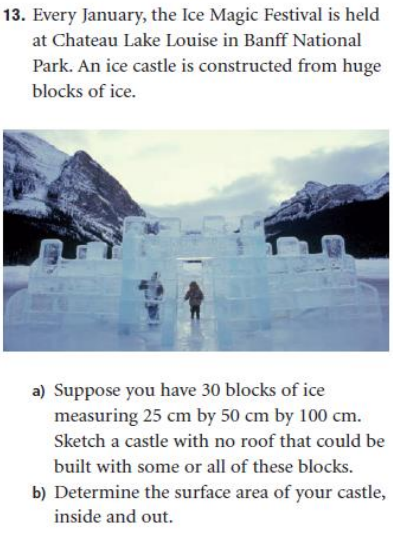

Figure 2: Ice Magic Festival MMS Collection

These materials include illustrations and exercises on contemporary social issues, such as Indigenous reconciliation (Barbeau & Taylor, 2009). For instance, Figure 1 shows how Canadian collections can present geometric transformations directly connected to Indigenous craftsmanship and cultural artifacts, offering students a contextualized perspective on mathematical concepts.

Although Brazil has increased its diversity-related content, many textbooks still adhere to a traditional curriculum. Adapting mathematical tasks for bilingual or multilingual contexts is an important factor. Canadian textbooks often address diverse audiences, including second-language learners, through literal translation and cultural adaptation, making examples more accessible to varied cultural backgrounds. In Brazil, the variety of regional languages, particularly in Indigenous communities, requires specific attention when producing national textbooks.

The federal government's centralized curriculum decisions and distribution policies aim to ensure broad educational access, yet they may limit regional adaptation. By comparison, provincial autonomy in Canada allows educators to tailor resources to local populations, though this process can lead to disparities in funding or materials across different regions (Jurdak et al., 2018). The Figure illustrates how certain Canadian textbooks link local festivals and historical practices to probability, data analysis, or other math topics, indicating the flexibility of decentralized models.

Final Considerations

The findings from this study illustrate how educational policy, cultural representation, and mathematics pedagogy interact in the development and distribution of textbooks. In Brazil, a centralized approach ensures nationwide uniformity, which promotes equity by providing consistent materials to students across different regions. However, this structure may limit the potential for local adaptation and the inclusion of diverse cultural and linguistic contexts.

By contrast, Canada's decentralized model enables provinces to tailor textbooks to their priorities, which can enhance cultural relevance but may produce disparities in content and quality. These contrasting approaches reveal a broader challenge: balancing national standards with local needs. The Brazilian model supports wide access yet may not fully address the country's cultural heterogeneity, whereas Canada's flexible framework could fragment curriculum cohesion. Future research might consider hybrid solutions that combine a core national standard with regional customization, as well as longitudinal studies, to determine how these strategies influence students' mathematical achievement, cultural awareness, and broader educational outcomes. Preliminary evidence indicates that continued examination of how policies shape textbook production and adaptation could shed light on equity in mathematics teaching.

Empowering and disempowering students in a school project on sustainability

Trude Fosse and Kjellrun Hiis Hauge

Western Norway University of Applied Sciences, Norway; trude.fosse@hvl.no

Four fourth-year preservice teachers with a major in mathematics education, were in their practicum in a Norwegian school. They developed an interdisciplinary project related to clothing and sustainable development involving social studies, natural science, and mathematics. The project started with an assignment where the students wrote a reflective text about their clothing habits to make the project relevant for the students. Then they worked in groups on different aspects of the clothing industry and the consumption of clothes. At the end of the three weeks, the students gave an oral presentation, and the projects were graded. We look at how the preservice teachers facilitated student empowerment. While there are examples where the preservice teachers facilitate student empowerment, we conclude that the efforts may also have caused the opposite, disempowerment. We discuss reasons for this and implications for teachers and teacher education.

Keywords: Consumerism, dilemmas, textiles, preservice teachers.

Introduction

This study was conducted with four preservice teachers, Alex, Billie, Charlie, and Drew, and the practicum teacher Jonny during their practicum in 9th grade in a school in the Western part of Norway. The preservice teachers were all master's students in mathematics education. The practicum lasted three weeks, and they were to teach the subjects of mathematics, social science, and natural science. The Norwegian curriculum (Kunnskapsdepartementet, 2019) has *Respect for nature and environmental awareness* as a core value and *sustainable development* as an interdisciplinary topic in school. This includes understanding dilemmas and that "Our lifestyles and resource consumption have local, regional and global consequences" (p. 17). The preservice teachers had no experience conducting interdisciplinary projects but were challenged to do so in their practicum. They developed a three-week project with the intention to make the students aware of the implications of the clothing industry and their own role as consumers while inviting the students to be active in their own learning. We ask: How do the preservice teachers facilitate student empowerment?

Theoretical framework

In this study we have used Ernest's (2002) concepts for empowerment development in mathematics, where fostering self-belief, taking control, and participating in activities are involved. Ernest (2002, p.1) characterizes three domains of empowerment concerning mathematics and its uses: *mathematical empowerment, social empowerment and epistemological empowerment*. He associates mathematical empowerment with traditional mathematics education focussing on having confidence in knowing how and when to use mathematics in school. Social empowerment is more connected to the use of mathematics outside the classroom, to the power of understanding and being able to exercise critical judgments related to mathematics in society, in particular concerning politics, decision-making and uses in the media. Epistemological empowerment depends on mathematical and social empowerment.

It is about confidence in applying mathematics in new situations and a need to be personally engaged "with mathematics so it becomes an integral part of the learner's personal identity" (Ernest, 2002, p.12). Ernest highlights that teachers should encourage all forms of empowerment.

Skovsmose (1992) underscores the importance of mathematics education in fostering informed citizens who can engage with, and transform, society. He introduces the concept of *mathemacy*, which extends beyond basic calculation to include the application of mathematical techniques and reflective thinking. This aligns with Giroux's (1989) view of literacy as a tool for empowerment. Mathematical literacy, therefore, is essential for social and cultural emancipation. As Skovsmose (2004, p. 1) notes, "Mathematics education can mean disempowerment or empowerment." He emphasises that the interpretation of empowerment varies based on the specific context of the learners and that disempowerment can manifest in all types of mathematics education.

Method

The practicum teacher and the authors of this paper gave the preservice teachers the assignment to develop a three-week project on sustainability in three subjects, mathematics, social science, and natural science. We asked them to start by relating sustainability to the students' own lives. The preservice teachers chose textiles and the clothing industry as the sustainability topic and prepared the project. It started with an assignment where the students wrote a reflective text about their clothing habits to make the project relevant for the students. Then they worked in groups on different aspects of the clothing industry and the consumption of clothes. At the end of the three weeks, the students gave an oral presentation. The student projects were graded by the preservice teachers.

Data material consists of video recordings, audio recordings, and student assignments; all recordings are transcribed and anonymised. We went through the transcribed data and marked situations where the preservice teachers facilitate student participation, where they connect the topic to the students' lives and the preservice teachers reflect on their own teaching related to participation. In the analysis, we use Ernest's (2002) criteria for empowerment to show how the preservice teachers facilitated student empowerment. We do not have data to conclude on whether the students were empowered or disempowered.

Analysis

Now follow some analysed examples of how the preservice teachers facilitated empowerment.

The reflection notes

The first task given to the students is to write a reflection note on their own clothing habits. Mathematics is not applied in this initial part of the project, but we include it because it sets the stage for the three-week project. Some of the students write relatively long texts about how they are conscious about shopping quality clothes and only what they need. They seem to be concerned about sustainable development and act thereafter. Although the task was closely connected to the students' own lives, some expressed that they did not know what to write, and it seems that these students copied each other.

Toward the end of the day, the practicum teacher, Jonny, and the preservice teachers, Alex, Billie, Charlie, and Drew, reflect on the first lesson. Alex brings up problematic aspects of the task which may explain why some students hesitated when working on the task.

Alex:	I felt many reflected well on their own habits, and so on, but then I kind of "what is OK to ask?" […] If someone can't afford the clothes they want, it can be hurtful for some.
Drew:	That should be paid attention to.
Alex:	[…] It can't be like, " Yes, very good, you donate to the Salvation Army”". We're not judging people.

Alex suggests that the task can have two negative effects. The first is that it can be hurtful to reflect on clothes for those who feel they cannot afford to buy what they want, a worry that is relevant given that clothes represent status and that students at this particular school come from both wealthy homes and less privileged homes. The other effect Alex suggests is that the task is articulated in a way that some may feel judged because they are not conscious of how their habits impact the environment. Thus, because the task may cause students to feel inferior, the task may disempower some students.

From the preservice teachers' plans, we see that they intended to return to the students' habits related to clothing, asking whether the students think differently about their own habits after having learned more. We don't know whether the preservice teachers actually did this. In any case, this suggests that the preservice teachers expected that after having learnt about how various fabrics pollute the environment, having learnt about working conditions in clothing factories that produce cheap clothes for people in the global north, and having learnt about harmful effects of clothes consumerism, the students would have other thoughts about their own habits and role. The preservice teachers may have had a plan to empower the students to understand the consequences of their own habits, in line with social empowerment, where mathematics played a role in this understanding. They may even have planned to facilitate students' epistemological empowerment as the project, including the mathematical content, could lead to a change in habits and identity as a consequence of students being personally engaged with the project. On the other hand, the preservice teachers may have chosen not to return to this reflexive question because of reasons Alex mentions in the above excerpt. Maybe they were afraid of disempowering students due to causing envy, guilt, shame, or indifference to being part of consumerism.

The group task

After the initial task, the students were divided into groups to work on group projects. The preservice teachers let the students choose a topic related to the textile industry, and their choices spanned from fast fashion to emissions from the transport of textiles. While the preservice teachers gave some short lectures related to sustainability and textiles, the students were also supposed to find information on the Internet. The students were thereby given freedom, trust, and responsibility. Through letting the students take ownership of what information was relevant for their group project, the preservice teachers facilitated all forms of empowerment: mathematical empowerment, as students may feel in control of the mathematical content; social empowerment, as students can become more confident about how mathematics is used outside the classroom; and epistemological empowerment, as the

students may feel empowered to take into account mathematical information, how mathematics is being used in other contexts as well and how mathematics can influence the students' identity.

Developing a checklist

The preservice teachers soon discovered that the students retrieved numbers and statistics uncritically from the Internet, so they arranged two mathematics lessons on being aware of questionable aspects of statistics. After discussing a graph from the media in detail, Charlie led an activity where the students were asked to contribute to making a list of what they should be aware of when evaluating and including statistics in their projects.

Charlie: I thought that we, together, now, could actually make a checklist with what is important to consider when you're reading statistics, like this one. Would anyone like to share with us? What is important to look for when you read diagrams and statistics? We have talked a lot about this now. Will it be easier to contribute when you've discussed it a little in the groups? Then I think we'll do this now, OK? Take some time and talk in the groups, come up with some points which can be useful when reading statistics.

It seems that Charlie intends to let the students take ownership in making the checklist. He asks for suggestions, then repeats his question, probably to clarify in case someone missed what he asked for. When nobody answers, he hints that the students can draw from the discussion they just had. He then changes strategy and makes the students come up with suggestions in their groups first. Charlie thus makes an effort to empower the students to develop the checklist.

A little while later, Charlie continues in plenary.

Charlie: OK? Now I've been around a bit on different groups. There are many who have come up with sensible things. If we're going to make a little list of points that might be good to have when you read diagrams, what points do we want to include on it? Yes?

Student 1: Be critical.

Charlie: Be critical, yes. We can include that. [keyboard crunching] Yes?

Student 2: Check where the information comes from.

Charlie: "Check where the information comes from." Yes? Other things? Yes?

Student 3: Properly understand the numbers.

Charlie: Properly understand the numbers, yes. [keyboard crunching] Do we have more stuff? Yes?

Student 4: To read the headline.

Charlie: Read the headline, yes. Important to see. [crunching] Do we have more stuff? You girls had many points.

Student 5: See what the x-axis and y-axis are saying.

Charlie: Read what the different axes are saying, yes. [crunching] Can we include one more point? There's one more thing I'd like us to include, at least. Yes?

Student 6: It's a bit like what has already been said, but look at how the diagram is made.

Charlie: Absolutely. It's super important, right? Because it says something about the whole impression we get from the chart and the numbers, right? […] you can look at your graph and consider these points we now have made. […] because we require that you use statistics in your project.

This time, Charlie receives suggestions from the students, and all suggestions are typed into a file he makes available for all to use in their projects. He facilitates student empowerment by inviting the students to contribute to the checklist, types their suggestions almost word by word, and connects their suggestions, i.e. the checklist, to their assignment. By applying the students' input, Charlie facilitates the students' gaining of power of what is important to consider when they continue their group work. Six students contributed, but because the students worked on the list in groups, the students who contributed can be seen as representatives of their groups, so even more students have contributed.

Charlie facilitates mathematical empowerment, as the activity is situated in the classroom, connected to the students' projects, and is related to the ability to read mathematical texts and make sense of them. However, we consider it more relevant to connect the activity to social empowerment as the intention of the checklist is for the students to be critical of what the diagrams they find contain, how they are used in the text, and whether they are relevant for their projects. It can be argued that Charlie facilitates students' epistemological empowerment as well because the checklist is intended to be relevant in general, which implies students' future experiences with graphs in the media. While many students might have been empowered by this activity, some might have felt disempowered, for example, if they didn't understand this or the previous task or didn't come up with suggestions in their group.

Evaluation of the group task

When almost three weeks have passed, the groups present their projects, and the preservice teachers grade the projects and the efforts of each student and give feedback to each group and each student. We here present selected feedback to two groups, both of which have chosen fast fashion. Charlie gives feedback to one of the students in the first group:

> Charlie: You show that you are reflective in the presentation. You manage to show that you see connections. And why "fast fashion" exists. You draw in several sides of the issue. What we noticed a bit is that you could use the sources a little more actively, and when you brought this up with the working conditions at the factory, you could have elaborated on this a bit more. We think. But during the process of this work, you show that you take responsibility in the group. You cooperate and help the others quite well. So, we've rated you overall, a 5+.

Charlie is providing positive feedback as he states that the student is reflective, includes several perspectives, and contributes positively to the group, while Charlie also has suggestions for improvement. He facilitates both mathematical and social empowerment implicitly as mathematics has been part of the group project. Because Charlie comments on several reflective and critical aspects of the presentation, it could be argued that he facilitates epistemic empowerment as well. The student received a good grade, 5+ (English B+), which may facilitate empowerment since it can contribute to strengthening the student's confidence. However, good grades may not be empowering in cases when students do not feel they earned the grades, which then would have the opposite effect. As Ernest (2002) emphasises, it is more important that the students feel personally engaged with mathematics, so they have a sense of "self-image as successful in mathematics" (p.12). He also

accentuates that students who have been mathematically empowered often receive personal encouragement from the teacher and have a good relationship with the teacher (p.12).

The following excerpts are from feedback given to another group who also had worked with fast fashion. They opposed to fast fashion and highlighted problematic aspects related to sustainable development.

> Drew: Yes. What we have written about the group together is that you have worked well and efficiently throughout the whole process. You cooperated well and made a very nice presentation. […] You appear unbound by scripts, and we can hear and see that you have worked well together and are collaborating. Your academic content is sound, and you are very familiar with the content, are reflective, and have included criteria from all the school subjects. In a good way. We sense that you have been very united and agreed on what to do in class and at the presentation. And cooperate well.

Billie then gives feedback to each of the students in the group. In the middle of her feedback, she adds:

> Billie: […] And I think it was very nice that you talked about problems with fast fashion […]

The students in this particular group got very good grades. As indicated in these excerpts, they receive positive feedback from the preservice teachers which facilitates certain areas of empowerment, but perhaps not others. The excerpts suggest that attention is given to school-centred values, skills, and knowledge, such as cooperation, answering given questions, presentation skills, argumentation, and reflectivity. What is not emphasized is the understanding of the problems and what to do with them. The only feedback explicitly related to sustainability aspects is the statement Billie showed above. The preservice teachers may thereby have facilitated mathematical and social empowerment as the feedback on academic content could be related to mathematics and how it was applied. However, little emphasis was put on critical aspects of the students' group project, which may have been part of their identity as concerned consumers. The preservice teachers may thus have failed to facilitate epistemological empowerment. The good grades and the positive feedback might therefore have supported mathematical and social empowerment while disempowering the students concerning epistemic empowerment.

Discussion and conclusion

We conclude that the preservice teachers intended to empower the students through the three-week project, but their efforts may also have caused the opposite. The initial task on reflecting on the students' own habits may have empowered the students who were concerned about clothing consumerism, but may have disempowered the students who struggled with what they were to write about, perhaps feeling inadequate about this moral task. Furthermore, the students played a key role in developing the checklist, where Charlie, one of the preservice teachers, often wrote down the input from the students' word by word, showing that Charlie valued the input, which facilitated student empowerment in all Ernest's (2002) domains of empowerment. Yet, this might also have caused disempowerment if there were students who felt they were unable to contribute.

We consider the fact that the student groups could choose topics and find sources of information themselves as a significant example of how the preservice teachers facilitated student empowerment.

The students were given trust and responsibility through the freedom to choose, which is a way to facilitate empowerment, which may have affected in particular those who were concerned about environmental issues. Some of the topics chosen by the students were less consumer and individual focused, such as emissions from transport, and may have been satisfactory for the students who perhaps were less concerned about sustainable development. This may have empowered some students. Furthermore, giving feedback and grades can also be a way to empower students, where, e.g., good grades could inspire the students to continue to critically explore mathematics-based information in the media, while not so good grades could disempower students. The preservice teachers' project plan indicated that they wanted to empower the students to act sustainable. This could be the case for some students who already felt they had a sustainable lifestyle or for those who were inspired to change their habits. However, the three-week project could well be disempowering for those who felt guilt or did not wish to change to a sustainable lifestyle.

We would like to emphasize two important points. One is that even students who received good grades might have been disempowered because what engaged them – moral aspects of consumerism – seemed to be less valued in the preservice teachers' feedback. This is a dilemma of teaching in general. In the real world, the problems of consumerism, working conditions and unfair distribution of goods are far more important than, for example, balancing emphasis on school subjects in argumentation. The preservice teachers seemed to aim for transformative learning, empowering the students, but were trapped in a system where certain aspects of learning are to be valued, and where normative and political viewpoints are not essentially valued when deciding grades. This aligns with Zipin's (2009) exploration of boundaries between lifeworlds and schools, where good pedagogical intentions can sometimes come into conflict with institutional norms and expectations. We expect this is a common paradox regarding normative projects on sustainable development.

Our second point is that empowering students to think and act differently concerning sustainable development is particularly challenging. Sustainability crises can be overwhelming and make students disillusioned and disempowered. Moreover, the crises demand a change in lifestyles, which may be perceived as unpleasant, painful or not justified by many. However, we believe that these are not arguments for avoiding such issues. Rather, these aspects need to be explicitly taken into account. We, the researchers and the practicum teacher, did not prepare the preservice teachers for disempowering aspects of sustainability projects, but now we have learnt that these are essential to include in our teaching and supervision.

In summary, this study delves into the intricate dynamics of fostering student empowerment within the realm of mathematics and sustainable development education. Our findings reveal a nuanced interplay between efforts to empower students and unintentional instances of disempowerment.

Looking ahead, it is imperative for teachers, preservice teachers, and teacher educators to critically reflect on their approaches to projects on sustainability to ensure that empowerment is authentically fostered among students and that attention is paid to handling or avoiding disempowerment concerning those who disagree with normative implications of living sustainable lives. This necessitates a holistic approach that not only encourages autonomy and responsibility but also cultivates critical thinking, empathy, democratic virtues, and active citizenship in addressing complex

societal issues. Sustainable development is a crucial topic in society and therefore relevant for teaching and learning. Teacher training programs therefore need to raise preservice teachers' awareness of dilemmas and paradoxes they will experience in school. From this study, we have become aware of the significance of being explicit about interdisciplinary contexts on sustainability in our plans for teacher training in our mathematics courses. Perhaps we need a new category of empowerment which is related to the context of the applied mathematics in order to emphasise these aspects.

Further research is needed where insights from other academic disciplines are incorporated, such as sustainability education research, transformative education research and feedback in classrooms.

What does it take to make a change? Pre-service teachers' positionality when working with mathematics inspired by Critical Mathematics Education

Trine Foyn[1], Suela Kacerja[1], Lisa Steffensen[2]

[2]Western Norway University of Applied Sciences. Department of Language, Literature, Mathematics and Interpreting. Bergen, Norway.

In this paper we explore why our surprise by pre-service teachers' lack of cracking out of their traditional ways of working with mathematics was rather foolish. Norwegian and South African researchers cooperated in developing a full-day session for pre-service teachers in Norway, inspired by Critical Mathematics Education, hoping to challenge the students' traditional ways of working with mathematics. The topic was "Clean water", and the teaching included an open approach to mathematics through this topic, also connecting personal stories from South Africa and issues of global fairness. We hoped to give the students new ways of approaching and working with mathematics that day, but we felt that we could have done better. Analysing video data from one episode through the theoretical lens of Holland et al. (1998) makes us argue that we were rather naive to expect students to rapidly position differently as mathematics learners.

Keywords: Critical mathematics education, pre-service teachers, figured worlds, positionality.

Introduction

"It seems like they just pushed the pause bottom!", one of the researchers exclaimed when examining video data from a teaching session where a group of Norwegian pre-service teachers (PTs) worked with an open mathematics task inspired by critical mathematics education (CME). The PTs had just joined a conversation with a researcher from South Africa, exploring the big difference in access to clean water in the two countries, including political perspectives connected to this. Interestingly, when the conversation ended, the PTs did not seem to connect the emerging issues in the conversation to the mathematics task they were given, even though 'Clean Water' was the topic of the day. Instead, they went back to where they had stopped before the conversation with the South African researcher. We were first surprised by this; it was like this conversation was an isolated happening not connected to the way the students negotiated their approach to work with mathematics. What we saw as a golden opportunity to engage with mathematics differently, was lost. This episode has made us reflect on perspectives connected to the challenge of changing an existing approach to work with mathematics.

Designing and trying out teaching materials that promote new ways of engaging with mathematics teaching and learning is a central aim of the research project 'Mathematical toolkit design North-South' (Kacerja et al., forthcoming). In this project, researchers from Norway and South Africa cooperate in designing research-based toolkits inspired by CME and focusing on teaching mathematics for topics such as sustainable development. We chose to use 'Clean Water', because access to safe water is crucial for human life and is one of the 17 sustainability goals (UN, 2024).

Also, while Norway is at the lowest end of the water risk scale, South Africa is at the highest. We were partly inspired by Skovsmose's (2023) classroom example, *Use of Water*. These research activities align with the new mathematics curriculum in Norway (Ministry of Education and Research, 2019) and the need for South African students to cope with mathematics as a gatekeeper for completing schooling (Julie et al., 2019). The hope is that the toolkits we design and try out with PTs at the University will promote new ways to experience mathematics, and hopefully inspire the PTs to implement such activities in mathematics for school students.

In this paper, we explore why our surprise by the PTs' resistance to accept, what we saw as an invitation to work differently with mathematics, was kind of naïve. We discuss some crucial challenges connected to changing PTs' ways of engaging with mathematics in light of critical mathematics teaching. Our research question is: *How can we understand students' ways of engaging with mathematics in a teaching session inspired by Critical Mathematics Education?*

CME and students' opportunities to participate

Our research project is embedded in a critical mathematics education perspective (Skovsmose, 2023). It is concerned with addressing critical societal issues as part of mathematics while at the same time addressing mathematics critically in all its forms and opening up new possibilities for PTs to explore such focus in engaging with mathematics. A toolkit is a collection of materials we use for teaching a given socio-critical topic in mathematics teacher education, such as literature, different prompts, discussion tasks, etc. (Kacerja et al., 2024). In line with Skovsmose's (2023) presentation of what CME is, we are concerned about the activities that the students will work on, the nature of the problems that are addressed, and how the PTs are invited to interact. In landscapes of investigation (Penteado & Skovsmose, 2022), teachers support students' investigative work by inviting them to wonder about mathematical, sometimes taken from real life. It is up to the students to accept the teacher's invitation and engage with the mathematics, with questions like "what if", and explore the situation at hand from different perspectives.

In previous research, Kacerja et al. (2017) and Kacerja et al. (2021) used the Body Mass Index (BMI) as a context for PTs of mathematics from Norway and South Africa to explore ideas of mathematics in society and point their attention towards being critical of the uses of mathematics. It was found that the PTs accepted the invitation, engaged with the mathematics of the BMI, criticised its uses in several critical contexts, and questioned the people using the BMI and their reasons for doing so. The PTs also discussed if it would be appropriate for them to use such an index to discuss in their mathematics classes. Similarly, Register et al. (2022) found that although PTs could select relevant CME topics, they need more experience with mathematisation, dealing with controversial or challenging discussions, and developing potential students' actions. Several research studies involve sustainability issues. For instance, Helliwell and Ng (2022) discuss how teacher education can support PTs in engaging in climate change issues by developing their practices and offering tasks that align with sustainable futures. Examples of their practices included the PTs watching short videos, engaging in face-to-face discussions, investigating chosen web resources, and designing lessons involving sustainability they would like to implement in future practices. Similarly, Steffensen and

Kasari (2023) described a Norwegian teacher educator inviting her PTs to examine and reflect on important societal issues, such as the Gulf of Mexico oil spills in 2010 and littering in a hiking trail near the students' home. The aim was to bring awareness of the role of mathematics in these issues and to call for action.

Steflitsch (2024) highlighted that students can engage in CME tasks by discussing the mathematics involved, the societal topic, or social aspects in classrooms. As mathematics teachers, it may be considered safer to stick to "the mathematics". However, various examples exist where mathematics teachers engage in the societal issue. For instance, Steffensen (2023) described how PTs expressed they wanted their students to learn mathematics while raising awareness about environmental sustainability. During the practicum, they engaged their 5th-grade students in picking litter, measuring, estimating, and discussing consequences in a modelling activity. Similarly, Steffensen and Kacerja (2021) found that lower secondary school students also accepted the invitation and engaged in critical discussions about climate change. The students found themselves an online carbon footprint calculator, which they started to explore from different sides by making changes in the values of the different variables of the calculator while also reasoning about the effects of those changes in one's life and its significance and feasibility. These examples are inspired by a CME perspective to change the traditional ways of students doing mathematics and engage them with the critical nature of the uses of mathematics in society. In all the examples, PTs and students accepted the invitation to go beyond the traditional mathematics tasks and work with mathematics from a critical perspective, even discussing mathematics' effects on the groups of people it addresses.

Theory – positionality within a figured world

To understand PTs' way of engaging with mathematics in new ways, we will draw on Holland et al.'s (1998) theoretical framework and, in particular, their concept of positionality. Using this framework means that we also need to include the concept of figured worlds. This means that when we try to understand the nature of PTs' positionality as mathematics learners, we need to see the class of PTs in mathematics as a figured world. As Holland et al. (1998) state, a figured world is a "socially and culturally constructed realm of interpretation in which particular characters and actors are recognised, significance is assigned to certain acts, and particular outcomes are valued over others" (p. 52). Moreover, as Holland et al. describe, it is important to underline that the class of PTs in mathematics is a local world with its own valued qualities, and it will be the frame for understanding all the happenings and actions within it. Even though figured worlds are local worlds, they are also fluid worlds, which are influenced by surrounding worlds and its values (Holland et al., 1998). That means the students' previous experiences as mathematics learners will also influence the PT class. Importantly, figured worlds carry a common shared narrative, a storyline, or a standard plot. The standard plot of a figured world works as an unwritten guideline for how to act; like a backdrop for interpretations of the acts that take place within the figured world.

When examining PT's positionality, Holland et al. (1998) emphasise that this is seen in two ways: in relation to the other actors within the figured world and the figured world itself with its standard plot. Moreover, positionality is connected to how the actors see themselves regarding access to power,

privilege, and entitlement, which affect the possible ways of acting or their social position in the figured world. This is not static, the development of social position or disposition relates to voice oneself, to enter spaces, to refrain or to self-censor from activities that happen over the long term and during social interaction. The actors of a figured world will position themselves through indicators of claims that will give access to what to say and which spaces to enter. This means that the way PTs enagage with mathematics in a session needs to be seen in light of what they see as possible acts and how they see themselves entitled to act in a particular way. Actors in a figured world get to know 'their' position as they participate in its everyday practices, which might be out of awareness, more like just mundane happenings (Holland et al., 1998). Understanding the PTs' positionality and their access to change their ways of working with mathematics means we have to pay close attention to what seems to be the standard plot of the class. Importantly for us, using this theoretical lens, is how we can understand individual change or how change can come about. Sometimes, actors might experience happenings that make them conscious of the position they have developed, which has been unmarked so far. They may notice how some of the usual acts or more dramatic activities may affect their entitlement in accordance with their social position. New ways of seeing their social position, or the space they can enter, may lead to reconsidering which acts are possible. This can lead to the possibility of affecting their own behaviour. "Ruptures of the taken-for-granted can remove these aspects of positional identities from automatic performance and recognition to commentary and re-cognition" (p. 140). Thus, positional identity can become "more or less conscious, more or less habitual, moving sometimes out of awareness, (...), and at other times toward consciousness and susceptibility to manipulation" (p. 237). Indeed, this theoretical lens emphasises that by drawing on the different resources at hand, individual's ability to improvise within the frame of the figured world and 'guide their next acts' is a source of redirection through 'serious play' (p. 272).

Methodology

The data for this study was collected as part of a full day of teaching in a mathematics education course for two classes of 4th-year PTs, where we tried out a toolkit about water consumption. Mathematics education researchers from two different Norwegian universities and one university in South Africa collaborated in planning this full-day session. The toolkit included a video as a kick-off activity on water consumption, tasks involving water consumption, literature about risk, sustainability and uncertainty related to CME, ethical issues and teacher perspectives in teaching controversial issues that the PTs were given beforehand. The video was followed by a presentation by one of the South African researchers talking about access to clean water from his context, contrasting the situation in Norway. After some plenary comments, the students were given a worksheet and were divided into groups of 4-5 to discuss various questions on a work-sheet as; how much water is needed to (Task 1) wash your hands, (Task 2) shower, (Task 3) brush teeth, (Task 4) wash clothes.

We collected video and audio recordings of the plenary discussions and nine groups in line with data collection and ethical considerations required by the Norwegian Centre for Research Data (SIKT), and data is anonymised. For this paper, we focus on one group of PTs whose way of engaging with the task was interesting to us. Thus, the example we present here is one episode that unfolded in the class without pretending or aiming to be representative or generalisable.

We looked at the data in teams of three researchers, and the videos were watched individually and in groups. This made us notice and discuss interesting episodes in light of the research project's aim. Also, data were transcribed, and our analysis became an iterative process by going back and forth between video data, transcripts, individual perspectives and perspectives the group discussed. The chosen episode shows a sequence with three PTs, which we saw as a golden opportunity for changing existing approaches to working with mathematics. We closely examined the transcripts and video data to get insight into the PTs' positioning as they work with mathematics. Our focus was on elements such as: The use of language to enter spaces or not; the opportunities the student used or not; the nature of the conversations by focusing on flow, content, contradictions, and easygoingness; the style of their talk; expressions that signalled surprises, strong emotions etc.

Analysis

We are zooming in on a situation with Simon, Adrian, and Thomas, just after the two plenary situations in the beginning of the lesson. The PTs were invited to choose either one of the given tasks or a topic they considered to be appealing and connected to the topic "Clean water".

The young men explained to one of the researchers that they were interested in how much water was wasted in the bathroom. The researcher acknowledges this approach, and the young men proceed to discuss how to estimate how much water is used, starting with hand-wash. This was one of the suggested task on the work-sheet, actually task 1. The young men start a conversation, interacting smoothly, discussing how they can estimate how much water will be used when washing their hands.

Simon:	I can go to the bathroom and take the time.
Adrian:	Now I'm looking for FHI's hand-washing tutorial.
Simon:	Is it ok if we wash our hands for about 30 seconds?
Adrian:	It says to wash the water with soap, and water will take 40-60 seconds.
Thomas:	But the difference between what you should do and what you do…
Adrian:	I don't wash my hands for 1 min
Simon:	No, me neither. No, but according to this one here - you should do it... we can say that maybe you are in contact with water for 20 seconds

They consider information from webpages about how much time they will use and reflect on their experiences. The conversation moves in a nice flow, with no conflicts; they are initiating questions, responding fast, and suggesting various things, but at the same time, they quickly agree, like they are on a well-known path for how to collaborate. Importantly, these three young men have been working together on several occasions over their first years as teacher students, and it seems like there is a pattern among them that Adrian and Simon are positioning themselves by taking up active roles, asking questions, suggesting alternatives and actively accepting a suggestion, with Adrian as the moving force. Thomas is taking up a more passive positioning by being more silent and refraining from the activities Adrian and Simon seem to take up naturally. With the words of Holland et al. (1998), it appears like these three young men are entering spaces based on habitual acts developed over time. They choose the first task suggested on the worksheet, and it seems they are acting along the script of the way of how to work together as students in mathematics, or in line with the standard plot.

Suddenly, Vincent, the researcher from South Africa who presented the perspective of access to clean water in the plenary talk, approaches the boys. He says, "How are you doing?" The young men answer politely, and Vincent starts talking about the South African situation.

Vincent:	The most important for me is the poor [...] When there is no water, they have to buy water to drink. So where do they get the money to buy water? Can you see it?
Adrian:	Yeah, I can see that. How is the situation in South Africa with jobs and such?
Vincent:	Unemployment is close to 48%. That's pretty high. Especially among the youth? So, if you have a high utilisation rate with these problems, it's chaotic.
Adrian:	But what is the biggest jobs in South Africa?
Vincent:	Construction, mining, ... farming. ... They got a lot of money to do it. It disappeared. It's getting better. It was quite low [Vincent explains about corruption and goes into a dialogue with Adrian about hijacking and criminality. Adrian then adds:]
Adrian:	There are two different worlds here in Norway and in South Africa.

These young men seem to be entering this conversation in a habitual way, welcoming Vincent's initiative to discuss with them. As in the first sequence, Adrian takes up an active positioning by joining the conversation with his previous experience. They connect to the conversation by asking questions on what seems perfect in timing and drawing on his experiences about South Africa, which are linked to several topics. Again, we notice the nice flow in the conversation; it is a smooth-running way of moving between the actors in the conversation. It is worth noticing that the conversation seems to influence Adrian; he comments on the large contrast between Norway and South Africa. It is as if he re-reflects about the Norwegian situation in light of this conversation with Vincent.

The conversation between Vincent and the PTs ends here. Vincent leaves, and the young men are looking at each other. After about 2 seconds, Adrian again takes the word.

Adrian:	Number one, then. Shall we think about it? Because it said, you should use 40 to 60 seconds. But large parts had to be scrubbed. You just have to rinse and scrub, then rinse again […] It's maybe 20 seconds out of the 40 seconds you're underwater.
Simon:	But how many seconds does it say you have to ...
Adrian:	40 to 60. But that was the whole process. Yes. 40 to 60.

The young men moved quickly and directly back to their conversation before Vincent appeared, and they didn't comment on the discussion with Vincent in sense. There are no expressions of any feelings or reflections about it. It is as the conversation vanished when Vincent left, and the students had just pushed the pause button for the first conversation among the three of them, which was connected to the given task, during the second conversation involving political issues connected to clean water. This surprised us; it was the topic of the day! When Vincent left, it was like they pushed play to continue. Moreover, in our analysis, we did not see any signs from the young men's talk that they saw the dialogue with Vincent as an opportunity to change either their approach to working with the task or the content of the task. It was just like they stayed on the same path as before, even though it was said that they could freely choose how to work on this topic. Moreover, our analysis made us not see any signs that the PTs seem to be aware of being entitled to or having the power to change directions in their work. We noticed that it was like they went back automatically to what they had started. What we researchers saw as an opportunity to rupture their normal way of working with mathematics through their conversation with Vincent did not affect their way of seeing their entitlement. It did not create a moment of rupture with their typical

approach to mathematics or the standard plot of being a PT in mathematics. Instead, it seemed to be more of a sidestep. They did not improvise or entered the space differently. The conversation with Vincent appeared more like a mundane activity, being polite but unconnected to mathematics. Our analysis made us notice that they kept relating to their traditional positioning as PTs in mathematics through this sequence.

Discussion

In this section, we will revisit the research question: How can we understand students' ways of engaging with mathematics in a teaching session inspired by Critical Mathematics Education? Our analysis has made us notice that the PT's ways of engaging with the mathematics in the sequence explored seem to not carry any sign of change to their traditional way of engaging with mathematics. The PTs seemed to act along a standard plot of how to work with mathematics, without connecting the real-life experiences the conversation with Vincent presents, to the mathematics they chose to focus on and engage with. Drawing on Holland et al.'s (1998) framework, it seems like the conversation with Vincent were not a dramatic enough incident to make any rupture to their habitual ways of working with mathematics, and the PTs seem not to see their social position differently through the sequence; our analysis didn't help us to see any signs indicating that the PT entered the space, their ways of engaging with mathematics, differently. It rather seemed like they automatically stayed on a habitual way of engaging with mathematics, starting with task 1, and continuing on that task even though being involved in a conversation included political issues connected to the topic of the day. This has made us reflect on if the PTs see themselves as entitled to change their already chosen approach to their work. We don't have an answer for that in this paper, but investigating our data from the full-day session may bring us closer in the future.

Even though the literature (Kacerja et al., 2017; Kacerja et al., 2021) points out how PTs and students engaging with CME accepted the invitation to go beyond the traditional mathematics tasks and work with mathematics from a critical perspective, our analysis has made us aware that it sometimes seems to be challenges connected to this. Our analysis makes us aware that it sometimes takes more than what we as teachers think it takes to make PTs go beyond their traditional ways of working with mathematics. Instead of blaming the PTs for not engaging differently than what seems to be their traditional ways of engaging with mathematics, the lens of figured worlds makes us aware that we need to see the happenings in the classroom in light of the broader discourses of education. Figured worlds are fluids worlds, hence we need to include the bigger dynamics of mathematics education, such as what it means to do and learn mathematics, both in the past and the present. Importantly, this makes us as researchers aware of that it takes more to create change, we need to see what we are doing in our classrooms in light of the bigger dynamics of mathematics teaching and learning.

We have learned from the literature (Register et al., 2022) that PTs sometimes need more experience with mathematics dealing with controversial issues to develop actions. To see PTs change in their ways of engaging with mathematics over time are in line with Holland et al. (1998) theories of change. They emphasize that sometimes there might be dramatic incidents that create change, and other times there will be more slow-moving forces that develop change. For the sequence explored in this paper, we will not argue that our aim of promoting students' new ways of engaging with mathematics failed

or that the PTs did not engage in a fruitful way with mathematics. As Holland et al. (1998) emphasise, sometimes we need to see incidents as seeds of change, or as the first steps towards change.

Bridging the political and the historical in mathematics education: a dialogue with in-service teachers

David Guillemette

Université du Québec à Montréal, Département de mathématiques, Montréal, Canada;
guillemette.david@uqam.ca

In this contribution, I describe a participatory research implemented with four in-service secondary school mathematics teachers in Montreal, Canada, about mathematics cultural and historical dimension. Through the reading of culturally and historically diversified texts, the participants have reflected how mathematics is and has been shaped by the economic, social and symbolic structures within which it is practiced and developed. Anchored in a dialogical approached for the data analyses, the objective was to describe teachers' and researchers' interactions and reflections. Three main thematic emerged from our analyses: Otherness, Hospitality and Reflexivity, from which I developed a reflection on the teachers' practices in relation to social and political issues in/of mathematics education.

Keywords: Social and political dimension of mathematics education, history of mathematics, ethics, dialogism, teachers' practices.

Exploring cultural and historical dimension of mathematics

There is a close relationship between the history of mathematics and mathematics education that has repeatedly been developed and implemented. Especially within research in mathematics education, this relationship has been explored very early, particularly by the International Study Group on the Relations between the History and Pedagogy of Mathematics (HPM Study Group). Affiliated with the International Commission on Mathematical Instruction (ICMI), the HPM Study Group aims to investigate different conceptions and views of mathematics. Its members study different eras, mathematicians, regional and national mathematical schools, mathematical textbooks, and many other topics from the history of mathematics. They seek to connect the history of mathematics as a discipline, its roles in education, and the roles that it continues to have in developing mathematical instruction and the curricula around the globe (see International Mathematical Union, 2021).

In the HPM literature, it is now quite well established that, when learners engage with the cultural or historical mathematical artefacts, especially in the context of the exploration of primary sources, it may provide a sense of "unfamiliarity". These special experiences put the learners on foreign ground, this phenomenon is often referred to as *dépaysement* [disorientation] (Barbin, 1997; Pengelley, 2011). Several studies have shown that the educationally rewarding aspects of such *dépaysement* are that students become more inclined to keep an open mind in relation to mathematics and mathematical concepts (Furinghetti et al., 2006; Guillemette, 2017), and that it may lead to "meta-level" learning (Kjeldsen & Blomhøj, 2012). In this paper, I will explore and question this phenomenon, emphasizing on its social and political aspect.

Toward the social and political dimension of mathematics

In literature, one can find different positions about the idea that the exploration of cultural and historical dimension of mathematics can lead to social and political reflections. It was, for instance, one of the main points of D'Ambrosio's ethnomathematics research program, for whom mathematics has always been shaped by the economic, social and symbolic structures within which it was practiced and developed. He suggests that the original source of abstraction (mathematical and otherwise) is to be found in the material production of life and cultural ways to engage with others. It is within the economic, social and symbolic structures of the society that the needs to be satisfied in educational terms are defined, as well as "ways" of satisfying these needs. These "ways" are in fact "ways of doing things": they appear as "knowledge". This is where the ethnomathematics perspective find, within the social and the historical, its fundamental ontological and epistemological basis. Let's remember that ethnomathematics is a "research program about the history and philosophy of mathematics" (D'Ambrosio, 2006, p. 17).

More recently, researchers focusing on equity and power relations in mathematics education have also been interested in the history of mathematics. They see the encounter with mathematics as something shaped and produced by wider cultural and societal contexts that is inherently social and political and grounded in the history of mathematics and mathematics education. In this sense, the exploration of the history of mathematics could be an occasion to get an awareness of the contexts in which mathematics and mathematics education are embedded in ways that reproduce, challenge or disrupt power relations. For instance, Rochelle Gutiérrez stated that "the importance of the history of mathematics is not just to show that certain racial or cultural groups contributed to the knowledge we have today but to also highlight the ways in which settler colonialism or White supremacy are linked to scientific projects" (2017, p. 16). She emphasizes on the need to acknowledge the settler colonialism and ask whose history and whose language is part of mathematics.

More globally, taking a historical and cultural perspective on mathematics, could foster a repositioning of mathematics education as a social and political project. The political, here, of course, has to be understood as governmentality; that is to say the forces that can determine the behavior or the conduct of the others. Governmentality can find its space of action, of course, in a society, but also in a classroom, in a family or in oneself. The question is to understand better how this link can appear in the context of mathematics education and in what sense. For this contribution, in search bridging the political and the historical in mathematics education, I will take a close but different path of ethnomathematics and equity perspective, the paths of ethics.

Ethics and the experience of otherness

My own research (Guillemette, 2017) on preservice teachers engaging with historical texts has pointed out two interrelated elements: the experience of otherness as well as empathy. The phenomenological description that I provided of the *dépaysement* (see above) of the future teachers show that they make serious efforts to understand different mathematical cultures through history, especially when engaging in the reading of historical texts and exploring historical artefacts. Their difficulties to understand past mathematicians' culture and way of doing mathematics often led to frustration and students can answer *violently*.

As the French phenomenologist Emmanuel Levinas (1971/2010) put it, violence is the thematization of the Other, a reification of the Other, a way to make the Other a Mine. This is where the concepts of otherness and empathy join. With Levinas, empathy can be understood as an effort to establish a nonviolent relation with the Other. Within the experience of otherness, empathy is this modality of being that tends to keep the Other's subjectivity free and alive, to keep it mysterious and indefinite.

Yet, when engaging in the reading of historical texts, we observe that the subjectivity of the mathematicians from the past is arduously preserved by the preservice teachers. They hardly maintain an empathic relation. In the suffering of the *dépaysement*, the answer is often violent, as the author of the historical texts are hardly considered in their own terms, in their mathematical and sociohistorical context. This said, this experience of *dépaysement* is important, because, within these difficulties, I have shown that the students perceived their future pupils as also being confronted with mathematical texts to be interpreted. Aware of the possibility of engaging in violent way, the students can feel *responsability* concerning the mathematical activity which will take place in their classrooms: that of welcoming their learners and their reasoning in a nonviolent way. That is why I suggest that the readings of culturally and historically distant texts in mathematics, through the *dépaysement* that it generates, support the development of empathy toward the classroom and an openness to marginality and diversity in the mathematics classroom, that is to say, in Levinassian terms, a nonviolent mathematical education.

Furthermore, I developed subsequently an ethical perspective on the exploration of cultural and historical dimension of mathematics in the context of teachers' education (Guillemette & Radford, 2022). Based on Mikhaïl Bakhtin (1895-1975) and Emmanuel Levinas (1906-1995) philosophy of otherness, this perspective tries to foster dialogical educational readings of historical texts that questions the self in its theoretical assumptions and offers vicarious aspects around the ways of *being* in mathematics and ways of *doing* mathematics. The encounter with the past is thought as an engagement with a foreign culture where the students reacted to it in terms of an agentic culturally and historically situated positioning in which their subjectivity shows itself polyphonically in the reception of the text and its unavoidable estrangement. Referring to Bakhtin, this dialogical, engaging, polyphonic reaction is called *answerability*. Within this perspective, have been stressed some elements necessary for the preservice teachers to enter into a dialogue with mathematics from another culture, such as the responsive/engaging relations regarding the mathematicians and the setting of a 'dialogical window' in the experience of otherness. An experience of otherness indispensable, I believe, for the reinterpretation and development of the meaning and orientation of mathematics education itself, for teachers' and students' understandings of diversity, for openness to pedagogies recognizing students' and teachers' diverse experiences, needs and perspectives and for inclusive mathematics education.

Toward a dialogue with in-service teachers

In this quest for bridging social and political issues in mathematics education with cultural and historical dimension of mathematics, and having in mind this ethical perspective introduced above, I decided to focus on in-service teachers. The choice of this population was motivated by the fact that cultural, historical, social and political issues are now strongly emphasized in teacher education

programs. In the province of Quebec (Canada), the new *Référentiel de compétences professionnelles: profession enseignante* (Professional Skills Framework for Teaching), in reference to a new cross-disciplinary skills set, explicitly states that teachers must act as ethical professionals with respect to diversity (Gouvernement du Québec, 2020). It is specified that "… on the part of teachers, acting ethically also implies adhering to a certain number of dispositions (attitudes or values) that influence how they carry out their duties" (my translation, *id*., p. 81). It is mentioned that "socioeconomic inequalities challenge schools and teachers in their ability to promote equity and inclusive education by using the levers of intervention available to them in a social justice perspective" (p. 17). These expectations weigh heavily on the shoulders of mathematics teachers.

Furthermore, despite effervescence in the research community and the publication of numerous large-scale studies (see Rubel, 2018), empirical research on the topic remains scarce in the French-speaking world and among in-service teachers (Guillemette & Nicol, 2016). Teachers were identified as being interested in both political and historical issues but reported being poorly trained and lacking in pedagogical resources that could be mobilized in the classroom, citing lack of time and the difficulty of following the curriculum when considering these issues (*ibid*.).

This is why I formulated these research objectives: 1) document the epistemological and pedagogical reflections of in-service secondary school teachers engaging with culturally and historically distant artefacts, 2) describe how pedagogical tools are developed for their classroom through jointly produced activities, and 3) describe their experienced and apprehended constraints and problems. For this contribution, I will focus here particularly on the first objective.

A participatory research

These objectives call for implementing a qualitative study anchored in a comprehensive paradigm. Moreover, these objectives address both the production of research knowledge and the professional development of practicing secondary school teachers in a unified manner. This prompted me to adopt a participatory approach. Four secondary school mathematics teachers were recruited (they had taken part in a professional workshop on reading historical texts led by us two years earlier). Participants were mid-career teachers (10–25 years of experience; two women, two men). A meeting was held to set goals and working arrangements. Three other meetings (150 minutes) took place in the next month. We discussed "historical situations" in order to explore together possibilities for classroom implementation and potential challenges. These "historical situations" (Mesopotamian numeral system, Ptolemy's trigonometry, al-Khwarizmi (4^{th} model for solving 2^{nd} degree equation), Cavalieri (volume of the ball), Arbalestrille (Jacob's staff)) consisted of short excerpts of historical texts derived from HPM literature. There were no historical or pedagogical explanation or assumption but only brief introductions by me. The excerpts were essentially a basis for explorations and discussions, a catalyst to create dialogue. Videotapes of the collaborative meetings, transcription of the audio, and a research diary constituted the data.

A dialogical approach

Aware that diversity and difference may occur in relation to who is doing the research and is being researched, posing methodological and ethical issues, I try to constitute a particular methodological positioning: a dialogical approach (Abtahi & Barwell, 2019; Guillemette, 2017, 2021).

This approach is based on the concept of dialogism developed by Bakhtin. It emphasizes that discourses are inevitably embedded in a dialogue. I'm referring here to dialogue both at the level of language and at the level of ideas and ways of being. For Bakhtin (1981), when we speak, we invest ourselves subjectively: no word can be uttered without an evaluative accent, without an attitude or mode of being regarding what we speak (agreement, sympathy, objection, and so on). The same is true of listeners and their reply. According to Bakhtin, this embodied dialogue constitutes the very fabric of the horizon of meaning of human beings. The "Other" provides, in this context, an additional and external perspective (called exotopic) necessary for the conceptualization of the self as a cohesive and meaningful whole (and vice versa). This dialogical interaction is crucial in the human intersubjective experience and in the formation of a properly ethical consciousness. In this perspective, we account for the multiplicity of the reflections of the participating teachers and researchers in their dialogical interaction.

The conducted dialogical analysis assumed that all discourses, including inner one, are dialogically structured and presupposes an addressee. The main question was therefore to know "from where" the different points of view arose. Specifically, each utterance was considered a "proposition," the next one a "reaction," and the next one a "reaction to a reaction" or "a conclusion". Each utterance was then described, not only in its "literal meaning," but from a "dialogical meaning," i.e., how it appeared in the chain of utterances. Concretely, a spreadsheet editor was used to work on every utterance of significative excerpts of the transcriptions of the video recordings. For each of the utterance was indicated: (1) its "literal meaning," the description of which was guided by a thematic rubric (pedagogical reflection, orientation of co-production, or constraint) and a mode of activity (goal, action, or operation), and (2) was indicated its "dialogical meaning," described from its situation (proposal, reaction, conclusion) and its evaluative orientation (agreement, sympathy, objection).

To gather and make sense of the analysis results overall, a "dialogical narrative" (Guillemette, 2017, 2021) was produced. These short texts will make it possible to present and contrast the participants' (including researchers') various postures, while preserving and promoting their dialogical character.

Some emergent thematic

At this moment, I'm still working on the dialogical narratives. This said, from the first part of analysis and the ongoing elaboration of the dialogical narratives, few interesting ideas and reflections appear.

The first thematic is *Otherness*. By pointing out to the links between past and present modes of doing and being in mathematics, history is perceived as an invitation to consider, in our context, teaching and learning mathematics in accordance with the way in which teachers and students engage in classroom activity. In other words, history reveals the actuality of mathematics education. An invitation to attend to the sensuous manners in which, today, teachers and students bring mathematical ideas to the fore and produce mathematical meanings, sensuous manners which could include

perceptual activity, gestures, kinesthetic actions, language, and the use of artifacts, symbols, graphs or diagrams for instance, all kinds of manners that could be discussed, problematized or reinvented.

It was particularly the case when discussing Ptolemy's trigonometry. In the Almagest (Book 1, Chapters 9 to 11) Ptolemy describes his construction of a table of chords, used as a geometric tool to build is astronomical model. He explains the mathematical construction of his table, quite equivalent to the sine function for angle measurement values α from 0 to 180 degrees (see figure 1).

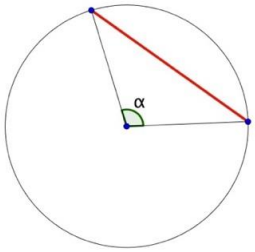

Figure 1: The length of a chord associated with different arcs

Ptolemy trigonometry is understood and practiced in slightly different manners from what we can usually encounter in schools. First, the idea is not to reason on triangles, but on the length of chords associated with given arcs in a circle. In fact, the word "sine" comes from the Latin word "sinus" that means a cavity, a hollow or more broadly a gap or an opening[1]. In a way, the idea of Ptolemy is not to explore mathematically the triangle (or to solve right triangle), but to establish the length of different chords in the unit circle. We reveal here partially lost or occulted senses of mathematics concepts and notions, grounded more concretely in the experience of life and culture, maybe in a more sensuous and direct mode of being in mathematics.

In this experience of otherness in mathematics, when the history enters the game, for the teachers, there was a kind of awareness of the productive aspect of the mathematical activity, including the activity of the classroom. That is to say a kind of a sense of awareness of how mathematics affects us and how we affect mathematics, a productive dialectic between mathematics and the contextualize event of teaching and learning mathematics. Again, here, a sense of responsibility and insight of the sensuous manners in which, today, teachers and students produce mathematical meanings.

A second emerging thematic is *hospitality*. To be a meaningful mediator, cultural and historical elements of mathematics need to appear as something problematic, it must become an enquiry. Such a task, of course, is extremely difficult. With in-service teachers, we can only vaguely perceive its contours. Concretely for the participants, when referring to these elements in the classroom, the gaze turns more unto the teacher, as he becomes a kind of storyteller, this brings special responsibility, different from the usual position of the mathematics teachers. A special attitude toward novelty and that need to be enacted, communicated and shared, novelty of ways of being and doing. New manners that are not the same of that is usually awaited.

[1] Showing an important further cultural circulation, the words *sinus* come from the translation of *jaïb*, which is the Arabic word for cavity or hollow. The word *jaïb* is related phonetically to *jiva*, which is the word for chord in Sanskrit.

The third thematic is more explicitly grounded in the social and the political, the thematic of *reflexivity*. Through our explorations, considering that most of the texts that we read were, in a sense, pedagogical one. Participants were asking: Why mathematics education? Where I want to go with my students? Through these fundamental questions, there was a kind of reconsideration of school mathematical activity. In this perspective, two interrelated ideas emerged. First, the fact that denying learners the opportunity to engage in authentic activity (i.e., posing their own problems, making conjectures, making mistakes, being creatively frustrated, etc.), it is to deny them, in a way mathematics itself, as mathematics, within this cultural and historical perspective appears as something profoundly human, grounded in cultural, scientifical and esthetical context and endeavor. Secondly, mathematics education appears to be linked with social demands that can be critically assessed as mathematics education too has a history and that mathematics education in embedded in it cultural, social and political context. It is interesting to see how the historical, the epistemological, the social and the political intertwine in this precise context.

More generally, my own impression is that there is something there maybe to think about otherness, its valorisation and its defense in a way. Because this experience seems to open the possibility to develop a kind of flexibility for teachers especially. There is an educational reward in terms of social and political awareness for the teachers in the fact of "living a distance". An experience that can help to figure out the mediation of mathematics by the surrounding culture, to perceive learning mathematics as learning a certain manner to be-with-others. A difficulty here is to learn to give ourselves to the otherness of the Other, which is, in a way, the only way to understand ourselves. I would say with Hanna Arendt (1958), to get ready for *action*, that is to say to belong to the world through speaking and acting which take place in the public sphere, which is the very possibility to initiate something new, the possibility to have a beginning. This creation of the new is for Arendt what she calls the miracle of freedom.

Conclusions

In this contribution, I describe some emerging results from a participatory research with in-service teachers on cultural and historical dimension of mathematics. Within an ethical perspective, I brought reflections on the teachers' practices in relation to social and political issues in/of mathematics education. Through these explorations, I discussed diversity and difference in a broad sense and refer to various ways of doing mathematics within the realms of the cultural, the social and the political. I can conclude that the experience of otherness was particularly significant here. These ethical implications should be addressed, explored and developed as it seems to be an interesting way to bridge social and political to cultural and historical issues in mathematics education. Otherwise, on a more research-based perspective, I hope, within this project, having addressed elements of social, cultural or political aspects of mathematics education as well as methodological and epistemological perspectives that could organize such research.

Curriculum: A restricted or restricting Resource?

Katharina Jablonka-Cohen[1] and Reza S. P. Nazir[1]

[1]Freie Universität Berlin, Faculty of Education and Psychology, Germany; k.jablonka@fu-berlin.de

This paper aims at making the discretionary spaces that mathematics curriculum documents communicate to teachers visible by a method of analysis based on Basil Bernstein's notion of framing. The analysis presented is part of an international comparative project. The outcomes show differences in the framing and varying degrees of discretionary spaces granted to teachers for making decisions on how to teach mathematics to their students. Additionally, the outcomes point to the often subtle communication of discretionary spaces including contradictory messages that are conveyed by the issuing school authorities.

Keywords: Mathematics curriculum research, comparative education, turkey, germany.

Introduction

> Competencies of students are at the center of pedagogical processes, meaning the use of capabilities, knowledge and skill for solving problems. This means, that the paths to the achievement of these goals are undetermined. It is the teacher's fundamental responsibility to choose these paths. (Standing Conference of the Ministers of Education [KMK], 2023, p. 5)

Educational policies in Germany emphasize teachers' control over how to teach and aim to reflect this idea in curriculum documents. Hence, large discretionary spaces can be assumed that are necessarily filled out when recontextualizing the curriculum in the classroom. This paper aims to make these discretionary spaces in curriculum documents visible and hence, the mechanisms of control between teacher and the issuing authorities of the curriculum document. However, what this means for the practice of teaching has yet to be explored. This paper is part of a larger study[1] that seeks to explore how variations in realization of curriculum objectives that are shared across educational systems are brought about and how they are executed by schools and teachers. In the comparison, mathematics features as the exemplary school subject, which underwent an international harmonization in light of comparative achievement studies of its curriculum objectives.

By using the notion of *framing* from the complex theorizing apparatus of Basil Bernstein as a methodological tool, two official mathematics curricula are analysed and then compared. The two documents stem from Germany and Turkey, where educational policies and consequently curriculum documents differ significantly from each other. The comparison of these contrasting cases is used to establish a refined understanding of the scope of discretionary spaces in mathematics teaching.

Mathematics Curriculum in Germany and Turkey

We compare the Berlin Mathematics Curriculum [BMC] (Senate Department for Education, Youth and Family, 2023) and the Turkish Mathematics Curriculum [TMC] (Turkish National Ministry of Education [MEB], 2018), as the surrounding project has chosen these two educational systems due

[1] Deutsche Forschungsgemeinschaft (DFG) - Project number 446370134

to their dissimilarities, including e.g. the differences descending from the Turkish centralized approach and the German federal approach to education. The BMC as well as all other Curricula of the federal states of Germany are based on national standards for education (*Bildungsstandards*), which are substantially influenced by the NCTM (KMK, 2004). In the federal state of Berlin, the BMC is legally defined as the basis for school education and published with the status of an administrative regulation by the Senate Department responsible for Education of the state of Berlin (2024, §10 Abs. 1 & §11, Schulgesetz Berlin). The TMC was written and published under coordination of the Turkish Ministry of Education (MEB, 2017). It is influenced by the international OECD framework following the PISA tests and has been revised several times since the AKP-administration came into office in 2002 (Ozturk-Akar, 2022). According to a directive of the MEB from 2019 (MEB, 2019) the TMC serves as the basis for educational activities in school.[2]

Thus, both documents are considered as the basis for mathematics education in their respective context. Despite these contexts differing profoundly from each other, the curricula can be considered similar in terms of their function and objectives, allowing a comparison.

Theoretical Framework

Framing in its original theoretical framework looks at the mechanisms of control in a pedagogic relationship between a transmitter and an acquirer. The educational sociologist Basil Bernstein was able to connect macro and micro level of educational practices by making these mechanisms visible in pedagogic relationships. The framework can only be briefly presented, considering Bernstein's complex underlying understanding of power relations and mechanisms of control in a society.

Power relates to the creation, legitimization, and reproduction of boundaries between categories in pedagogic practice and therefore creates a certain order of things. Control refers to how these power relations are governed in a pedagogic relationship (Bernstein, 2000, pp. 7–12). Control is made visible by the elements of *framing*, consisting of two types of discourses. The instructional discourse [ID] refers to *selection, sequence, pacing,* and *criteria* of a specialized discourse, such as mathematics teaching. The domineering *regulative discourse* [RD] refers to the social relations embedding the ID (Bernstein, 2000, p. 13). The analysis of these five elements can make discretionary spaces visible by assigning Framing values ('weak' or 'strong') to them. While a weak *framing* allows for more discretionary space for interpretation or deviation for the acquirer, a strong *framing* limits this space and leaves the transmitter in more control.[3]

Framing has been used to analyse data from educational settings with different aims (e.g. Al-Ramahi & Davies, 2002; Boelt et al., 2020; Hoadley, 2006; Straehler-Pohl, 2012). Here data usually constitutes of classroom observation and interviews. In this article, the analysed data consists only of written documents. Therefore, it is important to note that the pedagogic relationship is not limited to an educational context but can be found in any field where knowledge is transmitted and acquired

2 The research has been conducted before 1st of September 2024 before the new Turkish Curriculum was put into practice.

3 It is emphasized that the acquirer can only seemingly be in Control, as the acquirer can only be granted Control by the transmitter according to Bernstein (2000).

(Bernstein, 2000). The framework established here understands the official curriculum document that is written by actors on the macro-level of the educational system, disconnected in time and space from educational practices, as the transmitter and the teacher as the acquirer. The document communicates to teachers what legitimate enactment looks like, leaving discretionary spaces to fill.

In this study, the relation between education authorities issuing the curriculum and teachers is considered, as in the studies by Mutemba (2012) and Ferreira & Morais (2010). The idea of a document exercising control, or, *interacting* with its reader disconnected in space and time is found in Wolff (2022), who states that official documents allow their reader to draw conclusions about activities, intentions, and considerations of their authors and publishing entities. Hence, official documents such as mathematics curricula are understood as actively interacting with those who read them, allowing to draw conclusions about control exercised from transmitter to acquirer. Wolff (2022) further argues for the maxim of "order all points" (p. 512) that is based on the idea of the artificial character of a document, revealing its content explicitly and implicitly to its readers. It aims to consider all aspects of the document as possibly meaningful. This approach is adopted in the present study to amplify the possible scope of analysis, as compared to Mutemba (2012) and Ferreira and Morais (2010), who consider only explicit statements on *How* to teach.

Studies that operationalized the concept of *framing* classify the elements of *framing* by assigning values on a scale of 'weak' or 'strong' (Ferreira & Morais, 2010). In our study the international comparison allows us to develop a relative comprehension of 'weak' and 'strong', as the surrounding project understands the comparative approach inter alia as a method to further develop theoretical concepts by involving unfamiliar or unexpected observations (Broadfoot, 1999). Comparing the elements of *framing* on the system level in Turkey and Germany therefore makes it possible to identify and highlight discretionary spaces that otherwise may remain unseen.

Methods

Before analysis both Curriculum documents were translated by the authors, who are German and Turkish native speakers, to ensure a maximum of conservation of meaning and allowing to pivot to the original language when analysing. Layout and structure were equally conserved as close to the originals as possible. The translated samples were chosen according to the surrounding project, which focuses on mathematics of the 4^{th} and 8^{th} grade. Therefore, all continuous text of the mathematics curriculum and any text or tables concerned with the 4^{th} and 8^{th} grade were translated.

For analysis, Wolff's (2022) principle of *order all points* was defined as the consideration of implicit or explicit *Statements* when looking at layout and content. Aspects of order, arrangement and word count are subsumed as layout, semantic meanings are subsumed as content.

For the analysis of content, five elements of *framing* were defined to create a shared understanding:

- *Criteria*: How a teacher or their teaching can be evaluated. It includes any statement about objectives for teachers and their lessons.
- *Selection*: Statements about what mathematics teaching entails and what a teacher does.
- *Sequence*: What comes first, what comes second, etc., when teaching.
- *Pacing*: How much time single elements of teaching are given.

- *Regulative Discourse*: Not primarily concerned with what mathematics teaching looks like, but with social relations and the creation of hierarchies between author and reader.

Statements for the five elements were identified and analysed in each document, allowing a first assessment of the *framing* of each element. While some statements allowed an isolated analysis, many had to be assessed in the broader context of the document and meanings in the original language had to be discussed. The results were compared in a subsequent step and finally discretionary spaces were evaluated according to the findings. Due to the limited format, only a few exemplary findings are presented and cited here.

Findings

The *criteria* in both documents show significant differences. The BMC formulates mathematics teachers' objectives that have a long-lasting influence on pupils but remain underspecified, such as the embedding of mathematics in the pupils' lives (BMC, p. 5), while the TMC describes these objectives more thoroughly, also formulating them for all actors in educational practices. The criteria mentioned allow conclusions on when to evaluate the teaching as well as what points to consider. According to the TMC all actors in education aim to achieve e.g. the following objective:

> Ensuring that students completing primary education, according to their level of development and individuality, become individuals with moral integrity and self-awareness, self-confidence, and self-discipline, possessing basic verbal, numerical, and scientific reasoning skills as well as social skills and aesthetic sensitivity necessary for daily life and effectively using them to become individuals oriented towards a healthy life. (TMC, p. 4)

Despite not only addressing the pupils' mathematical outcomes, the criteria formulated in this statement are directed towards mathematics teachers. Details about when and what to evaluate are becoming clearer when compared to a similar statement of the BMC:

> In mathematics lessons in elementary school, pupils acquire the basic competencies of general mathematics education. This lays the foundations for further learning in secondary education and for a lifelong, successful engagement with demands that involve mathematics. (BMC, p. 5)

Considering the word count, positioning and phrasing used, the BMC shows a much weaker *framing* than the TMC. At the same time, the TMC communicates these objectives as not only the mathematics teachers' responsibility, leaving space for interpretation.

The *selection* is mainly concerned with teaching and assessment to reach pupil outcomes. The TMC elaborates its learning objectives in continuous texts for each grade and provides explanations that accompany each learning objective, which are identified by a code that include the subject (e.g. M for Mathematics) and numbers that identify the grade, learning area, sub-learning area and number of the objective. The document also provides points to consider when implementing the curriculum and elaborates further points and assessment practices in bullet points. All mentioned aspects are provided in detail, often directed towards a teaching entity, as shown in the following example of a learning objective that contains directives providing a limit of teaching and specified activities/tasks:

> M.4.1.6.4. Compares at most three fractions with equal denominators.

a) Models such as length, area, number line are used during comparison activities.

b) Big/small symbols are used when making comparisons. (TMC, p. 47)

The BMC also explicates its learning outcomes in continuous text and tables, however, using far less words and using a more passive language when addressing a teaching entity. Learning objectives are formulated as so-called *learning outcomes* focused on pupils, statements on *how* to teach are rare. Additionally, learning objectives are phrased in a way that allow more content to be included as shown in the following example:

> Arranging fractional numbers on the number line
>
> Comparing and ordering common fractions by direct comparison, finding the common denominator and on the number line (BMC, p. 40)

Despite covering the same topic of arranging fractional numbers, the TMC provides more detailed directives to the teacher, while the BMC only communicates what the pupils should be able to do, at most *suggesting* activities and setting no limits. Overall, the *framing* of the Selection of the TMC is very strong. The *framing* of the Selection of the BMC is weak, except for statements on individualization and pupil orientation as in this example:

> Lessons must enable an individual learning development, which is supported by guidance tools for learning such as learning journals, competency grids or self-assessments (BMC, p. 37)

Here, the BMC provides a similarly strong *framing* to the TMC, as these statements include more details on how to teach and are emphasized by constant mentions, which appears to be in contrast to other aspects of the BMC.

The *sequence* and *pacing* of the TMC appear in a very strong *framing*, as both aspects are communicated in the form of tables and accompanied by explications. In these tables a sequence for the teaching of learning objectives is given, as well as a time distribution in hours and percentages (TMC p. 21). There is no Sequence or Pacing given for other aspects of teaching, such as evaluation practices. The BMC provides a very weak *framing* of both elements, as there is no allocation of time or Sequence to any of the teaching practices. The only Sequence given is concerning pupil outcomes and this Sequence is communicated to the teacher as to be individualized for pupils.

The regulative discourse in both documents often accompanies statements of the elements of the ID, e.g. when referring to pupils' general dispositions to be acquired in the lessons (c.f. criteria above). But it can also be analysed when looking at statements that are exclusively concerned with social relations and hierarchies between transmitter and acquirer. While both documents tend to communicate implicitly what a legitimate teaching practice looks like, the TMC includes statements, where a 'we' is addressed. The 'we' allows the document to formulate the importance of what it says on behalf of the reader, who is not only addressed but seemingly an active part and has responsibility for a collective. Additionally, a few statements in the TMC communicate discretionary spaces directly to the teacher and limit them right after, e.g. when the TMC expects evaluation practices to be the task of teachers and not of the document (TMC, p. 7), followed by a list of seven guiding principles starting with a maximum alignment with "all components of the teaching program" (p. 7). The

Regulative Discourse in both documents can be understood mainly as a mean of legitimization of the documents' messages to the reader. The frequency of these legitimizations led to a 4-way distinction that allows a more structured approach. The four categories are shown in Table 1.

Table 1: Regulative Discourse between school authority and teacher

	unwarranted	warranted
Directive	Very strong Framing	Strong Framing
Suggestion	Very weak Framing	Weak Framing

The categorization of statements is dependent on phrasing (directive or suggestive) and legitimization (warranted or unwarranted). Suggestions leave more decisive space for the reader than Directives. Unwarranted Suggestions are understood as the weakest form of control, while Warranted Suggestions will give a reasoning or legitimacy to follow the Suggestion. An unwarranted Directive can be seen as the highest form of control, and therefore a very strong *framing*, as a warranted Directive leaves the reader in more control by participating in the knowledge behind it. Both documents include few unwarranted suggestions, while unwarranted directives were more prevalent in the TMC. Warranted directives were most common in the TMC, as the document puts emphasis on legitimizing its content through legal and seemingly factual statements, e.g.:

> The learning objectives and explanations in both groups are perfect, up-to-date, valid, and capable of establishing relationships with daily life in the educational process. (TMC, p. 4)

While the BMC contains more warranted suggestions than the TMC, warranted directives can also be found, especially when it comes to pupil orientation and individualization, e.g.:

> Depending on the degree of learning impairment, pupils do not reach the set standards in its entirety or at the specified point in time. This is taken into consideration by individualizing the lessons offered. (BMC, p. 14)

The RD regarding the relation between author and reader as conveyed through the layout differs strongly. While the BMC includes shorter and fewer statements, that are usually presented within a continuous text, the TMC presents a clear structure that makes the information more accessible. Considering all previously mentioned points, the *framing* of the Regulative Discourse of the TMC is considered very strong and the BMC is generally weak but strong when it comes to pupil orientation.

Discussion

The introductory quote to this article from the German Standing Conference of the Ministries of Education speaks of underdetermined paths and the teachers' responsibility to choose these paths. Using the elements of *framing* as means to identify discretionary spaces, this statement is only valid to a limited extent for the Berlin Mathematics Curriculum. While many elements of teaching leave large discretionary spaces for the mathematics teacher, the embedding Regulative Discourse restricts these spaces by focusing on pupil orientation and individualization. To put it into the words of the KMK, some of the possible paths to be chosen when teaching are essentially hidden, while others are promoted. The Turkish Mathematics Curriculum on the other hand, promotes and sometimes even allows only one path and therefore limits the discretionary spaces. This is especially evident when

discretionary spaces are encouraged but at the same time limited, leaving the document in Control over these spaces. The findings hint towards the distribution of power between the issuing authorities and teachers. The effects of this power relation could be meaningful when analysing classroom practice, as the discretionary spaces granted to teachers and schools by curricula constitute possible restrictions that affect the teachers' autonomy for making decisions. For example, the identified limits set for the teaching of the topic of fractions in the TMC, that are not present in the BMC, may grant teachers in Berlin more space to adjust the mathematical content to the students' perceived abilities.

Even when interaction is limited to a document and its reader, Bernstein's (2000) theory of *framing* can be essential regarding a dominant RD. The method of considering the maxim of *order all points* (Wolff, 2022) allowed for the consideration and comparison of elements previously not considered, e.g. the way of structuring the curricula. The established 4-way distinction certainly ignores other possibilities that are neither suggestions nor directives. As this distinction resulted from comparing the two documents and finding differing ways of legitimizations, it should be further refined in future projects. Despite profound differences the comparison of two Mathematics Curricula from different national contexts revealed further findings relevant for future research, such as the addressing of a collective in the TMC, the conspicuous statements regarding individualization in the BMC or the tasks or materials to be used when teaching certain mathematical topics formulated by the issuing authorities. The method is limited when it comes to the interpretation of meaning which is dependent on the researchers' knowledge on the subject, the educational system and language. Additionally, it became clear that learning objectives or outcomes are communicated for pupils and rarely address teachers directly. Considering these challenges, the focus on mathematics has proven to be useful for the comparison, as the documents showed similarities regarding objectives and outcomes and details such as materials, while having highly different approaches vis-à-vis methods and communication. Further research is needed to confirm the validity of the presented method, and the outcomes will need to be confirmed and differentiated in following research for this project.

Cultivating teacher leaders in hierarchical schools and school systems

Richard Kitchen[1], Lorenzo Gonzales[2], Monica Martinez-Archuleta[2] and Ali Bicer[3]
[1]School of Teacher Education, University of Wyoming, Laramie, WY, USA; rkitchen@uwyo.edu
[2]Los Alamos National Laboratory Math and Science Academy, Los Alamos, NM, USA
[3]College of Education & Human Development, Texas A&M University, College Station, TX, USA

"The Lab" offers professional development in mathematics referred to as the "Institute" for pre-tertiary teachers who work in northern New Mexico. The primary goal of the Institute is to support their learning of specialized mathematical knowledge. A socio-political theoretical perspective is used to explore the opportunities that three minoritized teachers had to engage as teacher leaders in mathematics in their schools and school system after participating in the Institute over many years. Though the teachers characterized themselves as teacher leaders in mathematics, it will be shown that a ceiling existed for them that limited their growth as leaders. This ceiling resulted from the fact that the teachers worked in a hierarchical school system in which they experienced a lack of administrative support. We argue that to cultivate teacher leaders in mathematics, PD facilitators should consider the political context of school districts in which their participants work.

Keywords: Mathematics professional development, politics of education, teacher leaders in mathematics.

Hierarchical school systems are a historical legacy of European colonialism (Williams, 2019). A defining characteristic of hierarchical school systems is the centralization of authority and decision-making in the administrative structure of a school system, which often limits leadership opportunities for teachers (Bimber, 1993). In the U.S. context, hierarchical school systems are a common feature of schools situated in economically underserved areas of the country that largely serve minoritized students (Newmann et al. 1997). Teachers who work in hierarchical and bureaucratic U.S. school systems found in economically underserved communities tend to be isolated from other teachers and administrators, inhibiting the development of teacher leaders in mathematics (Kitchen, 2003). This is problematic because teacher leaders in mathematics are needed to improve the teaching and learning of mathematics in schools situated in economically underserved communities (Kitchen, 2020; Kitchen et al., 2021).

In this paper, a sociopolitical theoretical perspective is used to explore opportunities that three veteran, minoritized[1] teachers had to develop and engage as teacher leaders in mathematics. The three teachers worked in a hierarchical school district that served an economically underserved community in the United States. The three teachers highlighted in this study were unique because of their long-term engagement in professional development (PD) offered through the "Lab." Every academic year since 2009, the Lab has offered PD trainings in mathematics, referred to collectively as the "Institute." Institute participants are elementary- and secondary-level teachers of mathematics, almost all of whom teach in highly diverse, economically underserved communities located in northern New

[1] In the U.S. context, other terms that are commonly used and are essentially synonymous with "minorized" are "culturally and linguistically diverse" (CLD) and "people of color" (See Kitchen et al., 2021).

Mexico, USA. Six full-day trainings during the academic year and a week of full-day summer sessions are offered annually through the Institute. The main goal of the Institute has been to cultivate teachers' mathematical content and pedagogical knowledge—teachers' "specialized mathematical knowledge" (Hill et al., 2005). Throughout, teachers solve problems collaboratively in the Institute and learn about the value of working together, rather than in competition.

In this study, we address the following two research questions:

1. How did teachers who work in a rural, U.S. context characterize themselves as school leaders in mathematics?
2. What opportunities do teachers in a rural, U.S. context, have to engage in mathematics leadership in their schools and district?

We argue that "PD facilitators" who want to cultivate teacher leaders in mathematics should consider the political contexts of the school districts in which their PD participants work. PD facilitators are Mathematics Teacher Educators (MTEs) who lead PD for practicing teachers of mathematics (Karsenty et al., 2023). Facilitators "manage the PD activities, set norms for interactions, support teachers' exchange of experiences and insights, monitor the discussion, and work with teachers toward the goals set for the PD" (p. 28). Before we address our research questions, the research literature on teacher leadership and our theoretical perspective are provided.

Teacher Leadership

Teacher leaders are defined as a teacher or group of teachers who influence colleagues and school leaders to improve learning and achievement (York-Barr & Duke, 2004). Teacher leaders also support their colleagues to improve conditions at their schools and seek to develop a democratic and collaborative school culture (Muijs & Harris, 2006). Teachers become leaders in mathematics as their confidence increases in their specialized mathematical knowledge and instructional abilities (Chval et al., 2010). Teachers build a sense of empowerment as leaders as they develop instructional strategies that lead to increased learning for their students (Godoy-Penteado & Skovsmose, 2009). Teacher leadership includes both formal and informal leadership roles (Liu, 2021). Informal teacher leadership roles can include introducing new teaching techniques to colleagues or mentoring a novice teacher. More formal teacher leadership roles could include taking on the head of a department (Liu, 2021). Among the characteristics of teacher leaders is that they value collegial professional relationships, are student-centric, and are continually engaged in professional development (Hunzicker, 2017). The social, political, and structural contexts of schooling such as how much teacher expertise is valued are among the conditions that support or inhibit the development of teacher leaders (Danielson, 2006). In addition, teacher leadership is influenced by the degree to which school leaders foster teachers taking up leadership (York-Barr & Duke, 2004).

Transforming schools situated in post-colonial countries through teacher leaders

A legacy of colonialism is the historical inequalities found in schools in post-colonial countries (Nyamnjoh, 2012). An outcome is the marginalization of minoritized students who attend schools located in poor communities in the United States, resulting in these students having inequitable access to a challenging education in mathematics (Leonard & Martin, 2013). These schools often lack

resources such as instructional materials, have high teacher turnover rates, and offer second-rate instructional programs (Ingersoll & May, 2012). Educational disparities found in U.S. schools that largely serve diverse, economically underserved communities can also be found in post-colonial countries. As just one example, disparities found in South African schools that serve Blacks are comparable to inequities found in U.S. schools that serve poor, minoritized students (Chirinda et al., 2022). Decentralizing hierarchical school systems can improve access to educational opportunities for students when school leaders distribute leadership opportunities to teacher leaders (Spillane et al., 2003). Distributed leadership models demonstrate the crucial role that teacher leaders can play to positively transform a school's culture (Meyer & Slater-Brown, 2022).

Socio-political theoretical perspective

A socio-political theoretical perspective involves examining educational policies and practices from the viewpoint that differential access to educational opportunities is grounded in differences based on racialized and classed experiences (Battey, 2015). A sociopolitical theoretical perspective places issues of power center stage such as the economic, social, cultural, and political contexts of learning (Tabron et al., 2021). According to Foucault (1977), power and knowledge are in a dialectical relationship that operate to further produce one another. For example, school administrators leverage their knowledge about leadership, teachers, students, and community as a means to help develop a school's learning environment. The administrator's ability to influence the school setting demonstrates the power embodied by the administrator. After initially examining whether teachers identified as leaders in mathematics based on their experiences as participants in the Institute, we use a socio-political lens to study how power, as embodied in hierarchical school systems, limits the development of teacher leaders.

Methods and data sources

We use research strategies used in phenomenology to examine how three minoritized teachers understand, interpret, and qualify their lived experiences (Creswell & Poth, 2018) regarding opportunities provided to them to develop as leaders in mathematics. In-depth interviews were the primary data source for this study. By listening to the teachers, a description of the essence of the research participants' experiences related to leadership was created (Creswell & Poth, 2018). Teachers' narratives were examined through a socio-political lens to interrogate opportunities and barriers that participants had in their schools and district to grow as teacher leaders in mathematics.

Participants

In this study, we employed purposeful sampling. The three participants were unique because they had been part of the Institute for at least four years (few had done this). All three participants worked in the same school district (District M), but not the same school. All three are Hispanic[2] women. One of the participants taught at the middle school level (grades 6-8 in the United States) and the other two taught at the elementary school level. All were veteran teachers who had taught for 15 years or more.

[2] Hispanic is a commonly used term in New Mexico denoting someone of Spanish ancestry.

Data collection

Semi-structured interviews were carried out via Zoom with the three research participants in December 2021. Each interview was carried out by a different author. Each interview was recorded and lasted between 30 and 45 minutes. Eight interview questions were asked, one with a pre-determined probe question. The goal of the interviews was to engage the research participants in a conversation through the use of open-ended questions (Riessman, 1993). At times, an interviewer asked a probe question to help clarify a participant's response and promote conversation, both characteristics of phenomenological studies (Creswell & Poth, 2018).

Data analysis

We used a thematic analysis approach in which the initial goal is to collect the description of experiences and then to inductively group similar experiences (Creswell & Poth, 2018). To address interrater reliability, the four authors conducted a thematic analysis independently, identifying themes found across the interviews. We met once via Zoom and engaged in an iterative process of discussing the themes that emerged across the interviews, reflecting upon, and then clarifying participants' views (Creswell & Poth, 2018). Through this iterative process, we achieved substantial agreement about the themes that emerged from the data. We also analyzed these themes through a sociopolitical lens to consider the themes regarding the political contexts that the participants shared about their work.

Results

The following two themes were identified in response to the first research question: Leadership and teaching confidence and teachers' views of themselves as leaders. The following three themes were identified in response to the second research question: Taking on leadership roles, administrators' reactions to teachers' participation in the Institute, and school leadership and the status quo.

Leadership and teaching confidence

In their narratives, the research participants related growth in their leadership skills with their nascent confidence to teach mathematics for conceptual understanding. For instance, Ava said, "Participating in the Institute has been supportive in terms of me becoming a teacher leader because it helps me to have more confidence in my own mathematical abilities and to explain things to others." This was a common view shared by all the research participants.

Teachers' view of themselves as leaders

Ava described how her colleagues viewed her as a leader simply because she had been a teacher for many years. She explained why she was the only teacher leader in mathematics at her school:

> I don't know of any other teacher leaders presently that are in the school that I'm at other than myself… I have mentored pre-service teachers and first-year teachers, so that is something that I have done. I have partnered with other teachers to give professional development, and plan those activities…

Victoria also saw herself as a teacher leader. She said, "I'm on the team that's working for the after-school math program to put that together for students, that same team is working on the school math intervention plan." She also characterized her role as a teacher leader in mathematics as follows:

> I also feel when my grade level team has questions whether it's about the math standards, the pacing guide, just different aspects when it comes to math, they feel comfortable coming to me, and I can give them suggestions, ideas. I can say, you know, 'I've tried this in the classroom. This is what I found has worked for me.' Or tell them 'you might want to try this if they're struggling…'

In summary, similar to Chval et al. (2010), the participants attributed their emergence as teacher leaders to their increased confidence in their mathematical knowledge and development as teachers of mathematics to their sustained involvement in the Institute. Similar to Hunzicker (2017), the participants' increased confidence led to the development of their identities as leaders. They also saw themselves as teacher leaders because they had mentored teachers and had led PD for their colleagues. The research participants' responses regarding the second research question follow now.

Taking on leadership roles in the Institute and their schools

Ava believed that teachers who had participated in the Institute for many years should have opportunities to assist and mentor other teachers during the Institute: "Several of us who have done this for so long could be put into other roles where we might be able to assist those people in the activities or assist them in some way, other than just being a participant." She believed that PD facilitators such as MSA should work intentionally with school/district leadership so that school/district leaders can continue the work initiated by MSA.

How administrators responded to teachers' participation in the Institute

Ava told us that while "administrators are supportive and see the importance of [the Institute]… they kind of just leave it up to us to attend and implement." She believed that school administrators did not follow up with teachers after they attended the Institute. Analogously, Sofia said: "I just sometimes feel like we learned something and then it's not supported enough to allow the teachers to do what they need to do to branch out to their colleagues in a positive and supportive way." A recurring argument made by Sofia was that teacher leaders were not provided administrative support to develop their colleagues' pedagogical skills. From Sofia's perspective, rather than supporting them to work to improve their colleagues' instruction, administrators exerted their power:

> They are embedding themselves into the Institute as a participant, rather than a support. So, it's almost as if they are learning everything for themselves, all over again, rather than looking at their role as a support system. And that's definitely been a hinder. It's like they're looking at us more as a threat, I guess, that we would know more about different math strategies than they would.

School leadership and the status quo

Sofia talked on several occasions about how her school district administrators were primarily interested in preserving the status quo power structure:

> You know there's a power broker mentality [in the district that was a carry-over from the previous administration]… I think it's getting better, but it does still leave that bad taste in your mouth when you do have certain situations that still keep popping up and it's hard for teachers that, you know, want to gain traction.

Sofia continued by describing how some teachers "have either taken on really strong leadership roles that kind of suppressed the others and so that again stops collaborative work." She explained: "It's one person being overpowering, and it's her way or the highway. This person has the admin's back [because they're 'buddies']. Then it becomes the one-man show."

Ava shared that school administrators placed more attention on getting lesson plans from teachers than on student learning. Ava doubted that her school district's administration was committed to cultivating a culture of learning in the district:

> Their [administrators'] focus is in a different place… When we have our meetings, it's only focused on getting those lesson plans done, which to me is not where the focus should be. It should be on, you know, how are the students thinking, how are they learning, or what are they doing in the classroom… And what are the outcomes of the strategies that we're using?

Analogously, Sofia did not believe that district administrators were committed to building a learning culture:

> But the culture of learning needs to be built and I think admin has to be the backbone of that and allow teachers to either be teacher leaders and not micromanage that and allow it to happen organically. Hopefully, teachers build that relationship of being able to talk about math all day long because that's happening now.

In summary, we explored the distributed opportunities the teachers had to be leaders in mathematics. Similar to Chval et al.'s (2010) study, we found out about the challenges that the research participants dealt with to become teacher leaders such as a lack of administrative support. Ava and Sofia described that their administrators did not support them to improve their colleagues' mathematics instruction. Sofia noted that there was historic precedence in District M concerning the administration brandishing power and perpetuating its power. Moreover, school principals and district administrators rarely afforded teachers leadership opportunities.

Discussion

The three research participants gained confidence in their mathematical knowledge and in their abilities to teach mathematics through their involvement in the Institute (Kitchen et al., 2021). They viewed themselves as teacher leaders in mathematics. Similarly, their colleagues regarded them as teacher leaders in mathematics. However, according to Ava and Sofia, their work as school leaders was not particularly respected or valued by school leaders, resulting in the participants being granted few leadership roles (Liu, 2021). Similar to Newmann et al. (1997), we found that distributed leadership was not a priority in a hierarchical, U.S. school district populated by diverse, economically underserved students. Teacher development as leaders was restricted in District M. From a sociopolitical perspective, the District M administration used its power to prevent teachers from engaging in shared decision-making associated with mathematics programming in the school district. A unique contribution of this study is that it shows how a ceiling may exist on teacher leaders in mathematics who lack distributed leadership opportunities, particularly for teachers who work in hierarchical school systems in which maintenance of the status quo is a priority.

PD facilitators in mathematics need to consider the political context of schooling (Danielson, 2006) if one of their goals is to cultivate teacher leaders among their PD participants. Given the educational inequalities in countries that experienced colonization in particular (Nyamnjoh, 2012), PD facilitators in post-colonial countries need to take into account the political context of schooling as a means to explicitly develop the skills their PD participants need to become teacher leaders in mathematics. Considering South Africa as just one example, PD facilitators should prioritize cultivating teacher leaders who have the skills needed to positively transform mathematics education for Black students. Moreover, as immigration from the Global South to the Global North is fueling growing interest in the Global North in diversity, much can be learned from research conducted in ethnically and racially diverse contexts in which power has operated to exclude diverse perspectives (Pineda & Mishra, 2023). To take on leadership roles in hierarchical school systems, teachers need explicit support from PD facilitators to learn strategies that they can apply to challenge a status quo that limits their opportunities to cultivate their leadership skills.

Contribution to sustainability competences through mathematics education

Paula López-Serentill[1], Marta Gual[1], Nataly Pincheira[1] and Angel Alsina[1]

[1]Universitat de Girona, Faculty of Education, Girona, Spain; paula.lopez@udg.edu

To effectively contribute to a more inclusive and sustainable future through mathematics education, it is essential for mathematics curricula to incorporate sustainability competences. We have analysed the presence in the curriculum of keywords that are related to terms involving the GreenComp sustainability competences, organized into four areas: 1) embodying sustainability values, 2) embracing complexity in sustainability, 3) envisioning sustainable futures and 4) acting for sustainability. The results show that the area most present in the subject of Mathematics is embracing complexity in sustainability, while the least present is embodying sustainability values. We conclude that it is necessary to increase the presence of sustainability competences in the mathematics curriculum and the teacher training programmes.

Keywords: Sustainability, education for sustainable development, sustainability competences, mathematics education, primary education.

Introduction

Since the first international calls on sustainability to address social, environmental and economic crises began to emerge several decades ago (e.g., Orr, 2013;Tilbury, 2011; UNESCO, 2015), Education for Sustainable Development (ESD) has been gradually incorporated into all educational stages, from early childhood education to higher education, to promote the development of sustainability skills (e.g., Bianchi et al., 2022; de Haan, 2010; Rieckmann, 2012; UNESCO, 2017; Wiek et al., 2011). To enhance teacher professional development in sustainability competences, the curriculum must integrate ESD in a cross-cutting manner. Therefore, at present, it does not seem to make much sense to train teachers to teach mathematics if this has no impact on the great challenges and changes of our times. Mathematics teachers should be provided with the necessary knowledge and tools to play an effective role as agents of social change. Preliminary studies have investigated the integration of ESD into the curriculum in general. Guardeño and Monsalve (2024) describe how ESD has evolved in the Spanish educational system through laws from 1985, noting that the latter proposes various updates and brings ESD to light for the first time in the school curriculum, thus responding to the problems facing society involving the Sustainable Development Goals. At the same time, these authors also analyse the curriculum of Ireland, noting the longer history of ESD policies and underscoring the addition of specific subjects, in addition to promoting a cross-cutting approach, as is the case in Spain. More specifically, Tesfamicael and Enge (2024) analysed the presence of sustainability in the Norwegian mathematics curriculum, noting that although the mathematics curriculum does not explicitly incorporate terms such as “sustainability” or “sustainable development”, which could imply that mathematics and sustainability are not connected, its six basic elements

- exploration and problem solving, modelling and applications, reasoning and argumentation, representation and communication, abstraction and generalization, and mathematical fields of knowledge - offer opportunities to integrate sustainability learning. Vásquez et al. (2022) analyse the primary education curricula of four Latin American countries, Colombia, Costa Rica, Chile and Mexico, showing that, in general terms, the teaching-learning process of mathematics is poorly aligned with ESD, with a low presence of key competences for sustainability. Based on these data, the authors conclude that these findings represent a roadmap, both for teacher training institutions and to provide a new educational approach that, through mathematics education, can be used to promote student understanding of the different problems (social, economic and environmental), as well as the measures that must be taken to transform and work for a more sustainable world.

Taking as a starting point these studies, the purpose of this paper is to determine how sustainability competences have been integrated into the current primary education curriculum in Spain (MEFP, 2022), in particular in the section of this document regarding the mathematics knowledge area. To this end, the GreenComp European sustainability competence framework (Bianchi et al., 2022) has been taken as a reference, as it is one of the pillars on which the MEFP itself is based to promote a certain competency model in keeping with the leading supranational recommendations (Saiz, 2022).

GreenComp: a framework for analysing sustainability competences

As stated, this paper relies on the Greencomp report (Bianchi et al., 2022), regarded as one of the foundations of sustainability (Saiz, 2022), as a framework for analysing sustainability competences in the Spanish primary education curriculum. The report GreenComp (Bianchi et al., 2022) is from Science for Policy series of the Joint Research Centre (JRC), the European Commission's science and knowledge service, which aims to provide factual scientific support to the Union's policy-making process. Table 1 shows the two main elements of the framework (areas and competences) and provides a description of each competence.

Table 1: Adaptation of the European GreenComp framework of sustainability competences

Area	Competence	Description
Embodying sustainability values	Valuing sustainability	Reflecting on personal values and their cultural variability. The goal is to raise awareness of the diversity of values and their relevance in ethical and sustainable decision-making.
	Supporting fairness	Supporting equity and justice for current and future generations, learning from past experiences to promote sustainability.
	Promoting nature	Recognizing the interdependence between humans and nature, promoting respect and empathy towards other species.
Embracing comp	Systems thinking	Understanding of the interaction between elements within and between systems, in different scales and subject areas.

	Critical thinking	It involves critically evaluating information and arguments, identifying assumptions, and questioning the status quo.
	Problem framing	Formulating challenges as sustainability issues, considering their difficulty, people, time and place.
Envisioning sustainable futures	Futures literacy	Planning for sustainable futures, developing alternative scenarios and identifying actions to achieve them.
	Adaptability	Promoting the ability to manage transitions and challenges in complex sustainability situations, making decisions in the face of uncertainty and ambiguity, while considering risk.
	Exploratory thinking	Adopting relational thinking by linking various disciplines, using creativity and experimentation with innovative methods
Acting for sustainability	Political agency	Navigating the political system, identifying responsibility and accountability for unsustainable behavior, and demanding effective policies for sustainability.
	Collective action	Promoting the ability to act collaboratively with other agents to promote change.
	Individual initiative	Identifying one's potential for sustainability, recognizing what actions can be taken.

Methods

In keeping with the goal of our study, which, as indicated, consists of determining how sustainability skills have been integrated into the current primary school mathematics curriculum in Spain, we adopted a descriptive qualitative approach (Cohen et al., 2017), relying on the content analysis method using syntactic units as a research technique (Krippendorff, 2013). The Spanish curriculum law includes the principles of basic education (from 6 to 12 years old) and lays out the organization and minimum teaching content of primary education in Spain. In this document, for each area of knowledge of primary education (Understanding Nature, Society and Culture; Art Education; Physical Education; Education on Civic and Ethical Values; Spanish Language and Literature; Foreign Language; Mathematics and Religion), specific competences and basic knowledge are defined.

The keywords were stablished using a set of exclusion keywords related to the four GreenComp competence areas described in Table 1. To do so, the following were considered: a) propose an initial list of keywords generated from the description given in the GreenComp document for each of the 12 competences; b) review of the keywords by three European experts in the field of ESD; c) analyse the curriculum to ensure consistency between it and the keywords; and d) incorporate some keywords that were omitted in the first list and involve the topic in question. The final keywords used in the coding process for each area where:

- Embodying sustainability values: Values (personal, sustainability); empathy / empathize; equity / inequity; justice; nature; ecosystem(s).
- Embracing complexity in sustainability: Systems thinking / systematic perspective / systematic relationships / systematic vision; Critical thinking / critical spirit / critical analysis / critical reflection; Interaction; connection(s); interdisciplinary / interdisciplinarity; complexity; global problems.
- Envisioning sustainable futures: future; plan / planning; scenario; uncertainty; risk(s); adaptability / adaptation; change(s); imagining / imagination; creativity.
- Acting for sustainability: Social justice; collective action; collaboration / collaborate; community; responsibility / responsibly; initiative.

Results

In keeping with the goal of our study, we first analysed the presence of sustainability competences in the curriculum to obtain an initial overview of their presence in the different areas. We then focused our analysis on the area of Mathematics.

We have identified the presence of the terms related to the sustainability competences defined in GreenComp (Figure 1) in all the Spanish primary education curriculum including all the knowledge areas, and we have also identified which of these terms are located specifically in the area of Mathematics (Table 4).

Table 2: Distribution of terms related to sustainability competences

GreenComp areas	Keyword	All the curriculum *f*	Mathematics area *f*
1. Embodying sustainability values	Values (personal, sustainability)	54	1
	Empathy / Empathize	29	1
	Equity / inequity	6	0
	Justice	9	0
	Nature	19	0
	Ecosystem(s)	7	0
	TOTAL	**124**	**2**
2. Embracing complexity in sustainability	Systems thinking / systematic perspective / systematic relationships / systematic vision	7	0
	Critical thinking / critical spirit / critical analysis / critical reflection	38	8
	Interaction	49	1
	Connection(s)	22	15
	Interdisciplinary / Interdisciplinarity	13	2
	Complexity	0	0
	Global problems	1	0
	TOTAL	**130**	**26**
3. Envisioning sustainable futures	Future	10	5
	Plan / planning	0	0
	Scenario	1	1
	Uncertainty	18	7
	Risk(s)	18	1
	Adaptability / adaptation	6	1
	Change(s)	20	1
	Imagining / Imagination	2	0

	Creativity	23	1
	TOTAL	**98**	**17**
4. Acting for sustainability	Social justice	2	0
	Collective action	0	0
	Collaboration / collaborate	18	1
	Community	29	0
	Responsibility / responsibly	36	6
	Initiative	9	3
	TOTAL	**94**	**10**

The data in Table 2 show that the competences in the area "Acting for sustainability" are the least present in the Spanish primary education curriculum. In the Mathematics section, the scarce (or almost zero) presence of terms related to the area "Embodying sustainability values" is striking, while the area with the greatest presence in both the entire Spanish primary education curriculum and in the mathematics section is related to the area "Embracing complexity in sustainability".

Below is an example of an extract from the mathematics section of the curriculum that showcases one of the keywords that have been related to each of the GreenComp areas.

Table 3: Examples of fragments of the primary education Spanish curriculum related to GreenComp areas in the section of mathematics

GreenComp scopes	Term	Fragments
1. Embodying sustainability values	Values (personal, sustainability)	"The goal of this specific competence is for students to work on the values of respect, equality and peaceful conflict resolution, while solving the mathematical challenges proposed, developing skills of effective communication, planning, inquiry, motivation and trust, in order to create healthy relationships and work environments, for example, through participation in diverse teams with assigned roles. This allows building healthy, supportive and committed relationships, strengthening self-confidence and normalizing situations of coexistence in equality" (p. 105)
2. Embracing complexity in sustainability	Connection	"Knowing a variety of strategies makes it possible to confidently deal with challenges and it facilitates engagement. Recognizing the connection between mathematics and other areas, with real life or with one's own experience, increases the mathematical toolkit of students. It is important that students have the opportunity to experience mathematics in different contexts (personal, school, social, scientific, humanistic and environmental) to become accustomed to identifying mathematical aspects in multiple situations". (p. 104)
3. Envisioning sustainable futures	Uncertainty	"Probability as a subjective measure of uncertainty. Recognition of uncertainty in everyday situations and by conducting experiments." (p. 112)
4. Acting for sustainability	Responsibility / responsibly	"Collaborate in the distribution of tasks, assuming and respecting the individual responsibilities assigned and using simple teamwork strategies aimed at achieving shared goals." (p. 113)

Related to the area "Embodying sustainability values", the keywords "values" and "empathy", which are only found once each in the mathematics section of the curriculum, are related to the competence of supporting fairness. The values promoted are respect,

equality and peaceful conflict resolution, which contribute to the support of equity and justice for current and future generations. There are no terms related to the other competences in this field.

Related to the area "Embracing complexity in sustainability", the keywords "interaction", "connections" and "interdisciplinarity" in the mathematics section of the curriculum relate to the competence of systems thinking. The curriculum acknowledges that connections between different mathematical ideas, as well as identifying the mathematics involved in other areas of everyday life, contributes to interpreting diverse situations and contexts, providing a global and interrelated view of the world. Such a vision helps us understand that mathematical ideas are not isolated elements, but are rather related with one another, giving rise to a whole. The keyword "critical thinking" on the one hand, it encourages observation and reflection in the understanding of random phenomena in everyday situations; on the other, it promotes analysis and adaptation of solutions to the proposed context and the implications they would have from various points of view.

Related to the area "Envisioning sustainable futures", the keywords "uncertainty", "risk", "adaptation" and "change" have been identified within the mathematics section of the curriculum. All of them contribute to the development of personal skills that help adapt to new situations, take risks and accept error or changes as part of the learning process, and adapt to situations of uncertainty in everyday situations.

Related to the area "Acting for sustainability", the keywords that are found in the mathematics section of the curriculum are related to the competences of collective action and individual initiative, but none in relation to the political agency competence. On the one hand, the keywords "collaborate", "responsibility" and "responsibly" contribute to collective action by fostering coordination, collaboration and cooperation among peers to solve problems more effectively. On the other, whenever the keyword "initiative" is found in the mathematics curriculum, it is in relation to individual initiative, sensing one's own potential and showing initiative to seek solutions or strategies to the problems posed.

Discussion and conclusions

This paper has analysed how the Spanish primary mathematics curriculum is integrating sustainability competences, since the curriculum is (or should be) a frame of reference that guides the teaching activity of teachers. To carry out the analysis, we used the GreenComp report (Bianchi et al., 2022) as a reference.

From this analytical perspective, we have identified "Embracing complexity in sustainability" as the most present area of the sustainability competences, with the most recurrent terms being associated with "critical thinking" and "connections". This result is not surprising, since, on the one hand, the Spanish curriculum has a specific mathematical competence on "solving problem situations", which seeks to, among other purposes, promote "critical reflection on the adequacy of the solutions to the proposed context and the implications they would have from various points of view (responsible consumption, health, environment, etc.)" (MEFP, 2022, p. 103). On the other hand, there is another specific competence on "recognizing and using connections between different

mathematical ideas, as well as identifying the mathematics involved in other areas or in everyday life" (p. 104). By contrast, the least present area is "Embodying sustainability values", which is surprising, especially if we take into account that in the new mathematics curriculum, specific competences of a socio-affective nature have been added, which describe the skills to be achieved personally, emotionally, and socially.

In light of these findings, on the one hand, we conclude that the area of Mathematics knowledge can contribute to the development of some sustainability skills, due to the very nature of mathematical skills, in line with the data from Tesfamicael and Enge (2024). Thus, there is a practically natural relationship between learning mathematics and sustainability skills related to critical thinking, systems thinking and the ability to establish connections, both between knowledge in the area of mathematics, but also in relation to other areas of knowledge.

The study also exhibits certain deficiencies in the mathematics section of the curriculum, specifically regarding the GreenComp areas "Embodying sustainability values" and "Acting for sustainability". Although we identified the presence of keywords fromboth areas), these are scarce or appear with meanings different from those attributed from the ESD framework. Thus, sustainability appears as a pretext to solve certain mathematical questions. It is presented as context, a backdrop against which to solve a challenge, but the values themselves are not discussed in depth, nor is the students' ability to propose or carry out actions that contribute to the development of sustainability reinforced. It is in this sense that it is necessary to lay out guidelines that allow the establishment of an Agency for Action, whose goal is to promote a greater presence of these sustainability competences in the mathematics curriculum of all educational stages, and teacher training programmes since the decisions of the present will determine the future.

Mathematics Education and the arenas of new conflicts over inequality – a theoretical framework for research?

Andrea Neuenfeldt[1] and Timo Dexel[1]

[1]University of Münster, Faculty of Education, Münster, Germany;

andrea.neuenfeldt@uni-muenster.de

Research on inequality in mathematics education has gained both quality and quantity in the last decades. Since then, new social conflicts and debates have risen. In this paper we therefore present a framework for analysing inequalities and related attitudes developed by the sociologists Steffen Mau and colleagues. We argue that the theoretical assumptions build a useful framework for conceptualising and understanding mathematics educational research on social, political and cultural aspects. To do so we will explain the idea of arenas of new conflicts over inequality. We will then use the theoretical framework to categorise previous mathematics educational research by way of example and re-read it against the background of these new conflicts. Finally, we will analyse data from an own empirical study on practices in early mathematics education to show its heuristic potential.

Keywords: Inequality, research framework, practices in mathematics education.

Introduction

One of the most renowned approaches to conceptualising equity in mathematics education research is known to be Rochelle Gutiérrez's dimensioning of access, achievement, identity, and power (Gutiérrez, 2012). Numerous studies work with this scheme and generate highly relevant findings in the context of diversity and social and political challenges of mathematics education (e.g. McGraw et al., 2023; Mintos et al., 2019). Research also shows that prospective teachers are quite capable of noticing and recognising diversity – but have difficulties when they need to transfer this topic to the teaching and learning of mathematics (Hummel & Bohlmann, 2022). In addition, social conflicts have intensified over the last 15 years and new ones have emerged. The question arises as to whether these conflicts can be identified in the practice of mathematics teaching and in the mathematics educational research. In addition to Gutiérrez's approach, we want to ask how *inequality* can be conceptualised. We propose an approach by the German sociologists Steffen Mau and colleagues (2023), who describe four arenas of new conflicts over inequality, as a heuristic scheme to understand inequality in both mathematics educational practice and research.

The four arenas of new conflicts over inequality

Mau and colleagues (2023) offer a multidimensional approach of conflicts over inequality that enables a profound analysis of the conflict space. They counter the assumption of a two-camp polarisation in German society with a more differentiated picture of four dimensions of inequality conflicts. According to the authors, the core of inequality conflicts are discourses in the context of socially anchored forms of marginalisation and disadvantage on the one hand and preferential treatment on the other. In a society, there are always several conflicts over inequality that occur in parallel and are in some respects interlinked, which is why Mau and colleagues use the term ‘arena’.

Inequality arenas are then rather independent fields of discourse that make it possible to organise the pluralised structure of political disputes and to grasp and analyse dynamics more precisely. According to the authors, the typology of the four arenas is not a new theory of inequality, but a heuristic for structuring the conflict space. It incorporates the work of various sociologists, e.g. Bourdieu's capital theory and the associated symbolic battles for recognition.

The four arenas that Mau et al. (2023) distinguish are labelled *up-down*, *us-them, in-out,* and *today-tomorrow*. Up-down inequalities refer to social status groups and economic redistribution. These are vertical inequalities in terms of material resources, income, and wealth. People have varying degrees of economic capital and the market value of professional qualifications differs, which creates a socio-economic divide within a society. Us-them inequalities relate to societal recognition of diversity, e.g. gender, sexual identity, race, and so on. The focus is on identity policy issues relating to diversity, experiences of discrimination or marginalisation, and recognition of social groups within a society. It is about the prestige of individuals and groups as well as access to resources and positions in the sense of social inequality due to attributed membership of a particular group. As people differentiate between their own group and 'others' by drawing boundaries, the question of what is considered 'normal' and worth recognising is also negotiated here. In-out inequalities refer to the dualism of closure and access, especially with regard to openness towards immigrants. Relevant issues can be categorised according to whether they relate to the territorial border (e.g. controlling immigration) or whether they concern the membership border (e.g. migrants' access to public services). The arena of today-tomorrow inequalities deals with conflicts over ecology and climate protection or change. These are urgent questions of our time that require action today, the results of which will only become visible in the future. Issues such as lifestyle, preservation of property or the fair distribution of burdens arising from climate policy measures are becoming increasingly relevant and are giving rise to dynamic debates.

In their study Mau and colleagues analysed the attitudes of German citizens to issues that can be assigned to the four arenas of conflict (e.g. the immigration of workers from non-EU countries). They summarise that a division in German society cannot be identified, although there are major differences between the arenas. The arena of in-out inequalities is the most polarised; differences in terms of class and education have a particular impact. Our aim is now not do deliver specific information about beliefs on these conflicts, but to use them as a heuristic to understand inequalities in mathematics education.

Social, political and cultural aspects in mathematics education

In order to use the conceptualisation with existing research, we will reanalyse selected studies in the context of social, political and cultural aspects in mathematics education against the background of the four arenas. The first arena to emerge is the 'classic' *up-down* conflicts associated with social stratification. A study conducted by Daniela Steflitsch (2023) is interesting for this context. Steflitsch carried out elements of critical mathematical education in a socially rather homogeneous, privileged classroom. The students discussed the issues raised about the distribution of wealth in a more meritocratic way, rather than focusing on equity, indeed some emphasised the need to make unemployed people more accountable. Using the scheme presented, these attitudes can be interpreted

as an *up-down* conflict in which the privileges of one group in particular are defended. However, it is interesting to note that an *us-them* logic also shines through in the study:

> They distinguished themselves from the 'poor' and the 'rich'. Depending on the focus of argumentation, this meant that they either felt they belonged to the privileged group since they were better off than the lower or bottom percent or that they were in the group of less wealthy and, therefore less privileged people, as they are far apart from the upper or top percent. (Steflitsch, 2023, p. 1848)

Mau et al. (2023) describe this arena as one in which battles for recognition are fought out. While the up-down arena is determined by property and markets, and the in-out arena by birth, the unequal recognition of social groups is also a question of positioning. Only through a certain social position is it possible for students to freely assign themselves to a group and, depending on the argument, not to be considered rich and privileged – although they certainly are in an objective comparison with people affected by poverty. We will take another example to use the *us-them* arena as a heuristic. Hunter and Hunter (2024) conduct a study where they challenge what they call the *story of achievement gap*. In this story aspects of certain groups of students including for example ethnicity are related to who can learn mathematics successfully. "A common response by policy makers and educators alike has been to fix the storied problem of those deemed unable to learn mathematics by putting in place a range of interventions." (Hunter & Hunter, 2024, p. 501-502). However, by taking collectivist approaches to mathematics learning instead of a rather competitive individualistic approach "Pacific understandings of reality, values, and knowledge generation are positioned as the basis of a research paradigm" (Hunter & Hunter, 2024, p. 505). Looking at this approach through the lens of an *us-them* arena shows an interesting shift in discourse. Whereas the story of the achievement gap is clearly suitable to create an 'us' in western society and Indigenous groups are stated as 'them', Hunter and Hunter manage to turn it around and create a new 'us'. How is this possible? Once again, processes of positioning happen, but in this specific case the authors fabricate recognition for a marginalised group. In this context, the third arena of inequality – *in-out* inequalities – deserve special attention. They result from the differences between members and non-members of nation-state societies and the power to define who is a member lies primarily with those who are already there. Interestingly, this is not the case with indigenous peoples. Exclusion was caused by force, which is now tried to be reversed to some extent through empowerment. With the heuristics mentioned, these processes can be understood as renegotiations about who actually belongs to a certain (mathematical) practice and who does not. Mathematics educational research that can be described by the fourth arena of inequality *(today-tomorrow)* has gained much more importance in the last few years. As an example, we highlight the work of Armando Solares-Rojas and colleagues (2022). They provide a methodological design for a didactic intervention with teachers from a school located in a community facing socio-ecological issues caused by massive environmental pollution. In a socio-critical perspective of mathematical modelling they enable "understanding mathematics as a tool that allows modelling phenomena, specifically social-ecological phenomena in a school's communities, to study and analyse them, within the school setting." (Solares-Rojas et al., 2022, p. 207). Solares-Rojas et al. (2022) point out, that the children participating in the project have never known something different then environmental pollution in their community. The modelling skills required today are useful for

the imagination of ‘tomorrow’ and are updated with regard to reflections that are highly relevant for future generations. These examples show, that the arenas can be used to re-interpret mathematics educational research and to broaden the understanding of it. Could it be a tool for analysing data as well?

Empirical validation – three case studies

In this chapter we discuss the heuristic model of the four arenas with empirical data. We try to show the usefulness of it by three different case studies: A classroom discussion in one smaller group, a teacher presentation, and a modelling task. The first two cases are drawn from an ethnographic study conducted in the very first weeks of different primary schools (Dexel et al., 2024).

Case 1 – Why is calculating important?

The following scene has taken place in the first lesson in a Montessori-School in an upper-class neighbourhood.

Mrs R.:	What do you need to write a letter to a friend?
Jakob:	A pen and a sheet of paper.
Mateo:	...and a stamp!
Mrs R.:	Yes, that’s right, but what do you need to be able to write this letter?
Mila:	Maybe we should know the letters?
Mrs R.:	Exactly. First you learn the letters. So it’s important to learn to read and write in order to be able to write a letter. Why is calculating just as important as reading and writing?
Jan:	So that you can recognise the numbers on the houses.
Mrs R.:	Well, what exactly do you mean by numbers?
Jan:	Well, there’s always a number on every house
Mrs R.:	That’s right. These numbers are called house numbers. Which house number is on your house? My house has the number 8.
Mila:	Mine has 11 on it.
Jakob:	Mhh. 27 on my house.
	[…]
Marie:	My parents taught me that. When you see two and four, you don’t need to run any more. So I can remember the number.
Mrs R.:	Oh, so you live in the 24th, but why do you have to learn calculating?
Jan:	Well, so that you know that three plus three equals six.
Mrs R.:	Ok, and what do I need to be able to work that out for?
Frida:	So that you know how much you have to pay.
Marie:	I always get 50 cent pocket money every Monday.
Mrs R.:	What do you do with your pocket money?
Marie:	Well, I go to the shop and see what I want and then I collect the money until I can get it.
Mrs R.:	Yes, what do you do with the money so that you know how much you have? Do you weigh it or what do you do with it?
Marie:	[laughs] No, I count it.

The scene shows a classroom discussion between the teacher, Mrs R., and the smaller group of first-year-learners, in which six children take part. Although the teacher sticks to a teaching by asking, the conversation initially appears cognitively activating. The children are interested, participate actively, and contribute their ideas and experiences about writing letters, house numbers, and the relevance of calculating. Based on the heuristics of the four arenas of new conflicts over inequality, the following can be stated at the same time:

Writing letters is a cultural practice whose importance has diminished nowadays and which has been replaced by digital alternatives (e.g., Email or messaging services). Nevertheless, the children who take part in the discussion are familiar with it and know what is needed to write a letter – in terms of the materials required (sheet of paper, pen, stamp), but also in terms of the relevant knowledge (e.g., letters and house numbers). According to Bourdieu (1979/1987), this knowledge is incorporated, i.e., internalised cultural capital, which is mainly acquired in the family upbringing. The children can now utilise this capital in the classroom, where it allows them to follow and actively participate in the classroom discussion. At the end of the scene, the conversation turns to the topic of pocket money. Marie reports that she is saving her pocket money until she can buy things that she would like to have. This focus on long-term personal goals expresses a sense of distinction and thus a pattern of behaviour that is typical of children from privileged backgrounds. In contrast, children from socially disadvantaged backgrounds often exhibit a short-term habitus. Actions are reviewed in terms of their immediate benefit in order to be able to fulfil needs quickly and with limited resources (Bourdieu, 1979/1987; El-Mafaalani, 2015). Overall, a middle-class orientation can be recognised in this scene. There is talk of letters, house numbers, and pocket money. It is also taken for granted and presented as a matter of course that one should learn to do maths. This reveals a potential conflict in the arena of *up-down* inequalities. Class affiliation, mediated by habitus forms and the extent of cultural capital, significantly determines how successfully children can take part in classroom discussions.

The interaction between the teacher and Marie at the end of the scene is also interesting. Although it is Marie's first ever lesson, she immediately recognises that the teacher is aiming her questions at the practice of counting. She also understands the funny way in which the teacher is framing the conversation and is able to react appropriately. In this interaction, the two create a form of 'us' that probably functions perfectly due to similar habitus and thus creates recognition. At the same time, however, this excludes children who cannot deduce from the interaction that this first lesson is supposed to be about maths. A potential conflict over inequality could arise here. In the scene described, however, such a conflict does not emerge openly, which may be related to the upper-class neighbourhood in which the school is located. Nevertheless, as conflicts in the up-down arena are discussed less frequently by the middle class and also from a greater social distance (Mau et al., 2023) – partly because the members are not affected by poverty and low status – children from socially disadvantaged backgrounds can 'fall by the wayside' as teachers lose sight of the fact that the reality of their lives is different.

Case 2 – Jòzefina, you will try!

The next scene is from a multilingual classroom in a big city in western Germany. The topic of the current series of lessons is arithmetic triangles. The pupils have already worked on one arithmetic triangle together with the teacher on the blackboard and have started on a second one. We could observe that the teacher, Miss M., sometimes switches between German and English in order to address a girl. Most of the following dialogue was held in German. In the transcript we underlined the initially English phrases.

> *Jòzefina (recently immigrated to Germany) seems absent and looks dreamily around the classroom. The teacher discusses an arithmetic triangle on the blackboard with the pupils in plenary.*

Miss M.: Now we have all the inside numbers. Now we can do the maths as normal. Who will do the maths and write the number here on the board. Jòzefina, you will try. Do you want to try to calculate. Four plus five (short break) or five plus four (taps on the five and the four). Five plus four or four plus five (taps on the four and the five again) how much is that?

In this short episode, we see that the teacher addresses Jòzefina, who recently immigrated to Germany, as she looks around the classroom, lost in thought and – at least it can be assumed – finding it difficult to follow the classroom discussion due to the language barrier. Miss M. now actively integrates Jòzefina and switches languages quite naturally during the conversation so that Jòzefina is put in a position to solve the maths problem. This reveals a topic of *in-out* inequalities, namely access and openness towards immigrants. The way Miss M. deals with Jòzefina concerns the question of the membership border and (in this example) migrants' access to education. However, the teacher's actions do not create a conflict in the in-out arena. Rather, she ensures that Jòzefina can actively participate in the lesson and is thus recognised and valued as a member of the class. Therefore, the recognition of diversity, which is a central point of inequality in the *us-them* arena, can also be observed here. An 'us' is created, into which Jòzefina is integrated by her teacher. In comparison to the first scene, a positive resolution of a conflict over inequality is visible here. Although an 'us' is created in both scenes, it is potentially exclusive in the first scene, as it arises from the similar habitus of the teacher and the socially privileged children. This could exclude children from lower status groups, whose realities of life are not taken into account and are not recognised. In contrast, inclusion is created in the second scene when Jòzefina is included in the plenary session by the teacher and diversity is recognised. In this case, a practice of teaching that is aware of inequalities becomes visible (see Hummel & Bohlmann, 2022). While the teacher's practice of teaching illustrates a positive, inclusive resolution of the conflict in the *in-out* arena, it is also possible to ask critical questions at a meso or macro level – for example about access to bilingual classes or schools.

Case 3 – Mathematical modelling with the 'refuelling-problem'

We would now like to turn to a classic modelling task and examine it against the background of the fourth arena, *today-tomorrow* inequalities. The modelling task we want to put up for discussion is an optimisation task that involves finding the best petrol station in border areas with different fuel prices (Blum & Leiss, 2005). It can be found in current task books for mathematics teachers, e.g. in Greefrath (2018). The question is whether a trip to a nearby foreign country for refuelling is financially worthwhile. This depends on many factors, including fuel prices locally and abroad, the distance to petrol stations, fuel consumption, and so on. Although this task offers potential for modelling real-life issues taking into account various factors and promoting process-related skills (e.g. reasoning) as well as content-related skills, it can be described as controversial from the point of view of today-tomorrow inequalities. Considerations on the ecological consequences of such 'petrol tourism' should be included in the deliberations. In this way, the task can be viewed in a larger social context that goes beyond the cost savings for individual people. Furthermore, the task can also be interpreted in a historical context: While the environmental catastrophe was already visible in 2005, such content was still being published completely uncritically as best-practice examples in magazines for teachers. The interpretation as a generational conflict enables a reflective classification of mathematical tasks against the background of social changes. To specify these changes, we can

draw on work by Weiss and Kaenders (2023) who critically reflect on another modelling task that individualises the global social problem of the climate crisis as a problem of one's own diet. Interestingly, both tasks are published in the same teacher magazine. Whereas 2005 the crisis was neglected, tasks are now driven by a zeitgeist that learn students "to cope with social problems by reflecting and changing one's own consumer behaviour." (Weiss & Kaenders, 2023, p. 1865). This is a rich discussion for mathematics lessons in school that is more likely to come up when looking at modelling tasks as symbols of inequality-conflicts.

Discussion

Mau et al. (2023) describe different dimensions of new inequality conflicts, rather than a clear distinction. However, this vagueness also enables a reflexive analysis. Various conflicts over inequality overlap in the aforementioned studies and interactions, and negotiations of difference thus become clear. Through the arenas, an analytical separation of what is at stake here and what is being negotiated can be determined more precisely. It is interesting to note that in our material the conflicts are resolved in one direction, we were unable to recognise any factual conflict (at least not in one and the same scene). In case 1, for example, children from lower status groups are potentially excluded from participating in the classroom discussion (up-down inequality), but an open conflict (e.g. between the teacher and a pupil) is not evident in this scene. It might be worthwhile to take a closer look at open discussions among students in the classroom. All in all, we consider the heuristic of arenas to be a helpful additional instrument to become aware of certain aspects of both mathematics educational research and practice. We do specifically not see it as a replacement for Gutiérrez's (2012) scheme. A future task would be comparing the two approaches to check if there are different outcomes. Two more limitations must be mentioned: If only looked through the lens of arenas, only these conflicts are seen and others are lost from view. The case studies were carried out in German schools, analysed from German researchers and the framework was created in German/western society. It would be interesting to analyse international data in an international research group. Further research and discussions are needed.

It is a challenge for second language learners to solve mathematical word problems in a language they still are learning. Language, as well as norms and contexts cause trouble. In this study three-year study, eighteen middle grade pupils, in 4th - 6th grade, have been intra-acting with materialities, such as strategies to solve mathematical word problems. Elaborating on how relational practices and boundaries within word problems and pupils might be created, attention is given to pupils' and word problems' intra-actions. We draw on Barads relational onto-epistemology and uncover how material entanglements play out around mathematical word problems when pupils talk about them. Strategies like "guess and try", can function as a way to multilingual pupils' agency solving word problems, but "naked" number tasks do not.

Setting the scene

To ensure sustainability regarding pupils, the society and the world, multilingual pupils must feel and experience that they are included, also in mathematics classrooms. This study is part of a three-year project in a multilingual mathematics classroom in a suburban area in Sweden. In the multilingual classroom, second language learners often must learn mathematics in a language they still are learning. It's then challenging to solve mathematical word problems (here Swedish), because language, norms and contexts cause trouble (Barwell, 2003; Caligari et al., 2021; Norén & Caligari, 2020). Word problems regularly produce difficulties for all pupils (Verschaffel et al., 2000), but pupils learning in a second language often struggle more than first language speakers (Moschkovich, 2002).

This study draws on ethnographic methodology (Hammersley & Atkinson, 2019 and Barad's agential realism (2007), which theorizes the entanglement of matter and meaning. Participant observations within a material discursive practice created the data with pupils, teachers, researcher and non-human materialities such as world problems, textbooks, mathematical strategies and experiences. Also, interviews with pupils and informal chats with teachers and pupils become part of the material discursive practice, considering the different aspects of materiality, practices, spaces, bodies and objects.

All pupils engaged within this study are second language learners and speak other mother tongues than Swedish. Some are born in Sweden, and others are more newly arrived. Eighteen middle grade pupils, in their 4th - 6th school year (10-13 years), have been intra-acting (Barad, 2007) with the materialities, such as strategies to solve mathematical word problems. The teaching was organized to grow second language learning pupils' knowledge in solving word problems. The pupils often worked in pairs when solving the problems.

Content and language learning teaching (Swain, 2001) were integrated and developed in the mathematics classroom; thus, mathematical concepts were made accessible. The aim was

furthermore that pupils' skills in the Swedish mathematical academic language would be developed at the same time as strategies to solve mathematical word problems were learned. Strategies taught were for example "guess and try", "draw a picture" and "make a table". When the project was coming to an end, in 6th grade, the pupils were interviewed in pairs, at a time the pupils had completed the National Test in Mathematics (NP) for their age group.

Talking about materialities, school mathematics textbooks that teachers rely on, contain many word problems that cause various problems for pupils s. Swedish pupils used to solve these written mathematical tasks 59% of the lessons and above half of the time they do it individually (Bergqvist et al., 2010. Solving mathematical word problems is a social practice (Barwell, 2018; Caligari et al., 2021) and teachers deal with social contexts when teaching (Chapman, 2006). Barwell (2003) has also shown that middle school multilingual pupils in UK used their narrative experiences to make sense when solving and creating their own word problems.

We elaborate on how relational practices and boundaries within word problems and pupils might be created. We give attention to materiality and account pupils' and word problems' intra-actions, embracing Barads (2007) relational onto-epistemology and ask:

- How do material entanglements play out around mathematical word problems when pupils talk about them and practically try to solve them?

Theoretical framing – creating a way forward

For three years, one researcher spent at least one mathematics lesson per every third week in the classroom with the pupils and one of the teachers, sometime both teachers. Being there, engaging with pupils and the material-discursive practice created experiences to the researcher. The experiences were produced in fieldnotes, photos and videos. Pupils' produced materials and teachers plannings were also collected. Thus, a lot of data was construed. All data generated are not used in this paper, but an ethnographic understanding lies like a grid in the background. The data production was "read together", meaning that all data and experiences are in continuous conversation and relation with each other (Murris & Bozalek, 2019). The interviews draw on produced data in the way that one researcher's and the pupils' materialized experiences can refer back to three years of mathematics classroom work. The 18 interviewees had participated in the activities in this multilingual mathematics classroom for middle school, that means, from 9/10 – 12/13 years of age, in 4th, 5th and 6th grade. All parents were given information about the study and gave written consent for their child to participate. The pupils had given their consent to intra-act with us, and their names are fictive.

The interviews were transcribed and analysed using a Baradian theoretical perspective, meaning that that the data became produced in process and is read together in entanglement, and lens by lens, we were zoomed in and out within materials and productions. In Baradian words, the methodology is diffractive. The reading was made in and out, back and forth, so all the data became entangled with our experiences and the material-discursive practise. We identified agential cuts (think of a cake with mixed ingredients and you cut a very thin piece of the cake). We posed questions concerning for example what pupils gave expressions of

remembering what kind of strategies that became created within productions and experiences. The production of reading the material in entanglement included how to report the analytical process. Thus, we have undertaken a systematically, extensive reading and re-reading of the transcripts, made summaries, and finally we narrated the intertwining intra-actions with the pupils and the word problems. We considered material entanglements by using Baradian (2007) ways of formulating 'material relations' intra-acting with pupils and word problems.

Rather than resembling the position of pupils and mathematical word problem as separate individuations, the Baradian methodology let us view the pupils and the word problems as entangled in intra-actions. This is in contrast to sociocultural perspectives, that since at least 20 years back, have been widespread withing the body of research in multilingual mathematics classrooms (Barwell, 2005; Caligari et al., 2021; Moschkovich, 2002; Norén & Caligari, 2020). Learners are then viewed as participants in social practices as a way of socializing into the mathematics classroom community as well as the language practices in that classroom. Drawing on Barad's onto-epistemological theory emphasizing embodiment and de Freitas and Sinclair's (2013) "relational ontology" (p. 457) the materialities are bound together in processes of becoming.

When interviewing the pupils, the word problems were intertwined within bodily minds and matters, power and experiences in ways we hadn't thought of. These aspects became agentic within intra-action in the material-discursive practise. The sociopolitical perspective being created within the material-discursive practise, engaging in solving mathematical word problems were not just about socialization or mathematics classroom practices, the power also became agentic. As an example, pupils expressed strong feelings about word problems and about the process of solving them. It seemed like the word problems "did" something with the pupils, the word problems became agentic intra-acting with the pupils. Barad (2003, 2007) notes that ongoing relationships and a mutual transformation process grow within the material and the human regardless of human intervention. With the words of Pickering (1995), material agency means that material objects "do things in the world" (p.9). To Barad (2007) all matter – non-human and human – are entangled (intertwined) in mutual material-discursive interconnections. It means that we can't unconnect matter and people. If we do, we lose sight of their reciprocal composition. Engagement and creations within non-human and human materiality reconfigures potentials and patterns of mathematics classroom practices, such as solving word problems. In this paper, the word problems are material objects, and we turn to Barad's (2003, 2007) theoretical toolbox in which "matter and meaning are entangled and interdependent in intra-activities" (Norén, 2018, p. 152). Reading the data production a relation to mathematical power becomes created. This means that the power of mathematics, who's mathematical voice becoming agentic, were produced as a result.

Word problems do things

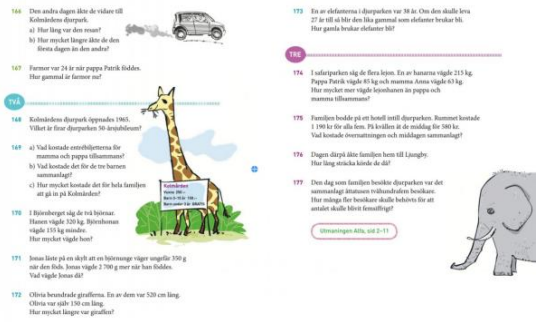
Reading the materials with a Baradian perspective made us intra-act with the material-discursive practice. Also, in this study the results are being presented entangled with discussion and materials. We start the result-discussion by intra-acting with a word problem and illustrations taken from the textbook Alfa for schoolyear 4:

Figure 1: Illustration by Johan Unenge in the textbook Alfa (2014), printed with permission

This is the Svensson family from Ljungby in Småland. This summer, they went to Kolmården's zoo.
The ages of the family members are written in the figure.

How much older is
a) daddy than mammy?
b) Jonas than Miranda?
Look at the map. The journey started in Ljungby. The first day they went to Jönköping and then to Mjölby. How long was the distance?

This specific illustrated word problem's (Norén & Caligari, 2020) intra-action, with pupils in 4th grade, emerged when the pupils in reaction to the introduction of the task, in the middle of the autumn semester, completely "derailed". There was no indication of any student trying to solve the mathematical word problems. The pupils protested orally, in uproar, shouting to their teachers and fellow classmates. Bodies became agentic intra-acting with the material of word problems. Hands were waving, pupils/bodies were running back and forth in the classroom and jumping up and down intra-acting with chairs. Chairs became slamming and desks were shaking. The room became loudly and unsecure.



The amount of text was immense (see fig 2) and generated resistance within the pupils towards the word problems. When word problem solving strategies were taught and the strategies intra-acted with the pupils and the word problems, the power of dealing with the word problems became agentic. Engaging within texts and illustrations, the pupils later in the autumn semester solved the word problems (Norén & Caligari, 2020).

When remembering the occasion in an interview, one student said:

> Men till och med i femman så hade jag fortfarande, när jag såg textuppgifter, jag var bara jag orkar inte med det här, jag ska gå ut. Fast till slut så läser jag, jag var bara, det var enkelt, jag gör det nästa gång igen.
>
> *But even in fifth grade I still had, when I saw word problems, I was just – I can't take this, I'm going out. But in the end, I read, I was just, it was easy, I'll do it again next time.*

Still, in 5th grade word problems caused trouble for the pupils. Besides teaching about strategies teachers used second language learning methods, like choosing challenging tasks, scaffolding language and enhancing dialogue (Gibbons, 1998).

Figure 2: page 44 and 45 in the Alfa textbook, illustrations by Unenge (2014), printed with permission

We're not translating the word problems. We show them to illustrate the pupils' and the word problems' intra-actions. The derailment was a consequence of the immense amount of text.

In the interviews, one student referred to strategies that were taught during 5th grade, the focus was on ‘guess and try’, ‘draw a picture’ and ‘draw a table’ (from fieldnotes). Relating to a huge number of written tasks in general, a student, in 6th grade, said[1]:

> För nu har vi typ så här tränat in det och så där, för om vi jämför som i fyran, vi förstod ingenting. Det var jättemycket text och sådant där, och nu är det som, ja, en textuppgift, då tänker jag bara gissa och pröva, jag kan bara använda gissa och pröva eller rita en bild. Förut visste jag inte ens vad jag skulle göra, jag läste texten och räckte upp handen.
>
> *Because now we’ve sort of trained on it and so on, because if we compare like in the fourth grade, we didn't understand anything. There was a lot of text and stuff like that, and now it’s like, well, a text assignment, then I’m just going to guess and try, I can just use guess and try or draw a picture. Before I didn't even know what to do, I read the text and raised my hand.*

This excerpt follows the former one, referring to the teaching in fifth grade, though it here becomes a bit clearer that experiences, ”we´ve sort of trained” and the strategy, ”guess and try” become agentic. When the statements are read together with the illustrations and the task, a discursive practice is created where anxiety, difficulty and powerlessness arise. When strategies such as “guess and try” and “draw a picture” are added to the practice, matter become as trustworthy as language. Thus, agency, power, engagement and confidence in one's own ability to tackle the word problem is instead created.

Other pupils related to the NP, specifically relating to the use of the strategy ‘guess and try’:

> I actually did it on a national exam assignment. It was like this algebra, it was like this x times two equals five something, I don't know what it was, then I guessed and tried first six, seven, then it worked.

Again, in the excerpt above, a pupil intra-acts with the strategy “guess and try” entangled with the word problem. The strategy ‘does something’ to the student. In intra-action the strategy becomes agentic. In the intra-action with the materialities word problems, strategy and experiences of use of the strategy, mathematical engagement become created. The experience of the strategy enables the student to become agentive and to become mathematical within the intra-action. The discourse in which the word problem is produced, and has been produced in, become agentic to. The discourse and the entangled experiences, enables mathematical intra-actions to be created and to become agentic. The strategy “guess and try” when training before NP become agentic and valued, enabling the student to intra-act and to get engaged within the material-discursive practice. The agential cut becomes created within security and confidence in one's own skills and experiences. When one researcher engaged within the discursive-practice and with the pupils talking about it in interviews, the pupils were discussing that the strategies, taught in grade five, could be used when solving word problems in the (NP) for 6th grade.

> Pupil 1: Yes, I remember for sure although I was guessing …
> Interviewer: Guess and…?

[1] We give the original transcript in Swedish just once, because it takes to much space. We have translated the quotes from Swedish to English.

Pupil 1:	Try. I still do, and I passed NP because of that.
Interviewer:	Did you?
Pupil1:	I feel like I passed NP because of that.
Interviewer:	Yes [turning to the second student]. Did you also use 'guess and try' then?
Pupil 2:	No, my brain doesn't work during NP, unfortunately

In reading the interview with the two pupils, mathematical engagement was created for one pupil in intra-action with the strategy "guess and try", while the other pupil expresses "my brain doesn't work". In this dialogue it's noticeable how the NP, and the experiences of it, intra-acts with both pupils. This is read as not just an intra-action with two materialities, the pupil and the word problem, but also within the materialized context, with experiences and imaginations intra-acting with NP. The pupil who could not use the strategy, where the "brain doesn't work", in that intra-action, the mathematical engagement does not become agentic. Instead, it is the negative experiences and imaginations that "kicked in" and become agentic. These experiences are not anchored in beliefs in one's own capacity, power or mathematical independence and engagement. Thus, the strategy "guess and try" does not become agentic in intra-action with the word problem as other experiences "kick in" and become agentic. These experiences are associated with mathematical uncertainty, anxiety and a non-engagement.

In another excerpt, we can again read a pupil's' experiences becoming agentic:

> Thus, I can count in Somali. I also use Swedish too, for example I might have a candy bag, it costs 19, I might have 38, I'm going to buy something for mom, yeast for example. Then I calculate how much I need like this, so yes.

The pupil expresses that s/he can count in Somali and Swedish. When a student's counting in several languages is valued in the classroom, being multilingual becomes an asset. In intra-actions, experiences of tasks, languages and mathematical contexts can become agentic in intra-action with, for example, a word problem. The experience enables mathematical engagement to become agentic. With this way of reading human and non-human materialities, it becomes significant for what is valued in mathematics classrooms. Valuing all resources in teaching, discussing mathematics in everyday life and creating contexts where mathematics can be used and become significant, 'does' something with the pupil's experiences and belief in their own knowing and mathematical engagement.

> When you solve word problems, then you must make long answers like this after and show how you thought about the answer, because if it's a long question, you must have a long answer. So, for example an algorithm, if you're going to solve it, then you just must give the answer, you understand?

The above excerpt shows how intra-action with word problems can evolve when strategies on how to tackle a word problem are lacking. The pupil doesn't express any strategy in the intra-action with the word problem. It is his/her experiences of how word problems "usually" are required to be solved that becomes agentic. The mathematical task becomes the material that has and produces the power, and that determines what mathematical engagement is "requiring". Confidence in one's own knowing and power over the mathematical engagement is not given space in intra-action with the word problem above. In intra-action with tasks

without words, with set-up or algorithms, mathematics becomes mechanical. The task takes on a life of its own and power over what is done. Tasks that include numbers and arithmetic must only be "solved" and given an "answer". The student says this type of tasks as simpler "just to give an answer". The word problem becomes the one having the power. The intra-action with the pupil, the experiences and the word problem, and no intra-action with strategies, disengage the student in the discursive practice.

At the end of every interview, the pupils were asked what they think about working with word problems. Most of the pupils answer that they don't like it, and one of them says:

> Det är det värsta. Jag önskar att alla uppgifter med text kunde tas bort i matematikböckerna och de skulle bara innehålla siffror och tal, det är lättare då.
>
> *I think it's the worst. I wish you could remove all the text from the math book and just have the numbers, it's easier then.*

In the excerpt, numbers and words in the textbook become agentic. The texts become agentic in a negative way and the numbers in a positive way. If the words were removed from the textbook, "everything would be easier". The numbers make the mathematics easier. Mathematics may not become part of the student's every day or future life, or a way to take on challenges and to solve problems that arise. Thus, when the mathematics and the textbook have the power and make decisions, pupils just solve tasks, in the easiest way possible. Materialities are agentic participants in the mathematics classroom.

Conclusion

Reading the data embracing the theory of Barad (2003, 2007), and in contrast to using sociocultural theories, made us intra-act with the productions and the material-discursive practice. Experiences, mathematical engagement, non engagements, language, power, materialities, and discourses became entwined within intra-actions, becoming agentic and made creations. The creations produced the result of the study. Strategies, for example "guess and try", can function as a way for a mathematical engagement to become agentic in intra-action with word problems. Tasks with numbers and arithmetic create mathematical engagement, but not power. The power stays with the task itself and the pupil only must "do" and "answer". Consequently, mathematics teachers can secure future multilingual students' mathematical power in classroom work with word problem solving, by engaging material strategies in their teaching. To end this paper, we assure that material entanglements play out around mathematical word problems when multilingual pupils experience and talk about them. Talking with Barad (2003) all matters matter.

Patterns of mathematics capital among Swedish higher education mathematics students

Lisa Österling[1], Nhu Truong[1], Paola Valero[1], Anna Danielsson[1], Maria Berge[2] and Bruna Nunes[1]

[1]Stockholm University, Department of Teaching and Learning, Stockholm, Sweden;
lisa.osterling@su.se

[2] Umeå University, Sweden

This paper presents a survey study of the mathematics capital of first-semester mathematics students in Swedish universities. A cluster analysis shows how mathematics capital is distributed among three clusters of students, distinguished mainly by parents' or significant others' relation to STEM. In one of the clusters, students had much family support, and talked about mathematics outside school. In the middle cluster, students had acquaintances in STEM but to a less extent engaged in mathematics outside schools. In the third cluster, students liked mathematics but had little mathematics capital. Demographics were similar between the clusters, except for students' age, and parents' level of education. We conclude that for Swedish students with little mathematics capital, the trajectory into higher education mathematics can be longer, but it is a possible trajectory.

Keywords: Mathematics capital, socio-political studies, higher education mathematics, inequalities in education, survey methods, cluster analysis.

Introduction

It is a well-known "fact" in mathematics education research that socio-economic conditions shape students' opportunities to engage in mathematics (e.g., Valero & Meaney, 2014). While this has been well researched in school education, it has been less investigated both for the transition into higher education and in higher education itself. Aspects of knowledge, attitudes (e.g., Biza et al., 2016) and, more recently, identity (e.g., Lahdenperä & Nieminen, 2020) have been highlighted as important for starting and staying in higher education mathematics. Recent socio-political studies of higher university mathematics (e.g., Arideja & Andrews-Larsson, 2017) invite us to explore in which ways enrolling in a mathematics programme is supported by the mathematics specific configurations of material-economic, cultural, and social resources available to students.

Understanding differences in the availability of resources for students' engagement with mathematics is important for research concerned with equitable access to and success in university mathematics. For more than a decade now, researchers in the U.K. have taken a Bourdieusian approach to study the significance of subject-related capital on students' aspirations and engagement in science, technology, engineering and mathematics (STEM) from school to higher education (e.g., Godec et al., 2024). The concepts of science capital (Archer et al., 2015) and mathematics capital (Williams & Choudry, 2016) have been proposed and utilised to identify and explain subject-specific aspects of the social reproduction of inequality with and through education, particularly in societies where STEM skills and knowledge are seen as values connected to power. Thinking further with these scholars, *mathematics capital* can be conceptualised as the interconnected series of "skills and

resources that individuals acquire […] that can generate forms of social advantage in [mathematics] educational settings" (Hernandez-Martinez, 2020, p. 51-52). Mathematics capital is mobilized through the activities and relationships available for individuals belonging to different groups of people in society. As Archer and Mendick argue (2024), making visible how differentially acquired mathematics capital supports and reinforces the development of identities casts light into the connection between social reproduction and aspirations and choices leading to the study of mathematics in higher education.

Although enlightening, studies of mathematics and science capital have so far mostly been produced in the U.K., a society with strong social stratification. Thus, the question of how generative these studies can be in other societies is open. In the Nordic countries, research has shown that despite policies of educational equality and democratisation, education is still an important reproductive force of social differentiation and inequality (Osman et al., 2021), particularly when it comes to participation in higher education. To reduce financial obstacles, Swedish higher education is free of charge and students have access to additional government financial support. Despite these efforts, students from academic family backgrounds dominate the more prestigious university programmes in Sweden (Börjesson & Broady, 2016), whereas students from less educated families more often attend minor, local university colleges (Carlhed, 2016). Also, mathematics and physics are programmes with a documented highly uneven recruitment in terms of gender and social class (Börjesson et al., 2016). It is reasonable to hypothesise that skills and resources connected to mathematics that are available to different types of students may help cast light on such lingering disparities. Thus, the purpose of this study is to understand the distribution of mathematics capital of students who enrol in higher education mathematics in Sweden. We ask: What characterises the mathematics capital of Swedish first year higher education mathematics students?

Methods

This paper presents results from a survey study conducted among first-semester students in higher education mathematics in Sweden. The survey was designed to assess the different dimensions of mathematics capital that students perceive to have accumulated throughout their upbringing and prior educational experiences. The survey drew on the validated instruments in the ASPIRES project (e.g., DeWitt et al. 2016), and connected recontextualisations to Denmark in the SCOPE project (e.g., Pedersen & Nielsen, 2024) and to Finland in the Finsci project (Kaakinen et al., 2023). We selected, translated, and adapted those instruments to suit the Swedish context and the intended target group of mathematics students. We assumed that the categories of science capital outlined by De Witt et al. (2016) would also serve for mathematics capital, and therefore we structured the questions around: who one knows in mathematics/STEM, what support one gets for choosing to study mathematics, what activities and resources related to mathematics were available during one's upbringing, and what significant other's thoughts are about me and mathematics. Additionally, the survey included demographic questions about gender, age, place of origin, area of upbringing, and parents'/guardians' level of education. Selected survey items analysed in this study will be presented in the results section.

The survey was disseminated via e-mail to the entire cohort of approximately 500 students enrolled in either a Bachelor of Mathematics or a Bachelor of Engineering Mathematics programme, offered

at 12 universities in Sweden. The survey was administered at the beginning of their studies, and before their first examinations. We received 150 responses. To assess potential sampling biases, we cross-checked the survey data against Swedish registry data. We found a slight overrepresentation of female students and a marginally lower proportion of older students in our sample compared to the overall population. Given the specific and narrow scope of our study, generalisations are to be made with caution beyond the targeted programmes.

Data analysis

We started with a cluster analysis of responses to the mathematics capital questions to group respondents based on their configurations of mathematics capital. Based on these clusters, we first described the mathematics capital in detail, and thereafter discussed how demographics such as age, gender, or parents' educational background relate to the identified clusters.

A hierarchical cluster analysis was performed, using Ward's method (Jaeger & Banks, 2023) to determine the optimal number of clusters, followed by a *k*-means clustering to assign respondents to clusters. This resulted in three mathematics capital clusters, named McA, McB, and McC. An ANOVA test was run to verify which questions significantly differ between the three clusters. To interpret what characterises each cluster, the positive answers to each mathematics capital question were summarised within each cluster. Finally, cross-tabulations and chi-square tests were used to examine significant differences in demographic variables across the clusters.

Results

The cluster analysis grouped respondents in three clusters, based on the patterns of their responses to questions related to mathematics capital. Among the 150 mathematics students, 39 were assigned to cluster McA, 67 to McB, and 47 to McC, and a visualisation of the patterns is given in Figure 1.

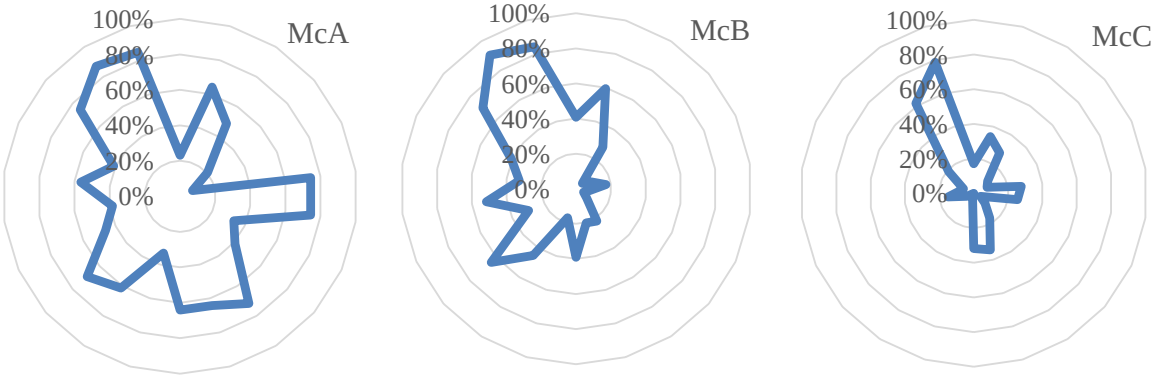

Figure 1: Each graph represents one cluster, and one node in the spider-web graphs represent the proportion of positive responses to a question related to mathematics capital. (More detail below)

Comparing the diagrams in Figure 1 gives that both the size and the patterns differs between clusters. The diagram för McA covers the largest area, showing that many resources related to mathematics capital were available for students in this group. In McB, the size and the pattern is different, with low proportions to the right side of the diagram. The diagram for McC covers the smallest area, and

few resources related to mathematics capital were available to the group of students in this cluster. From this overview, we now explore the characteristics of mathematics capital within each cluster.

Who do you know in STEM?

Figure 2 presents the responses to the question "Who do you know that works in science, technology, medicine or mathematics?", distributed on the three clusters.

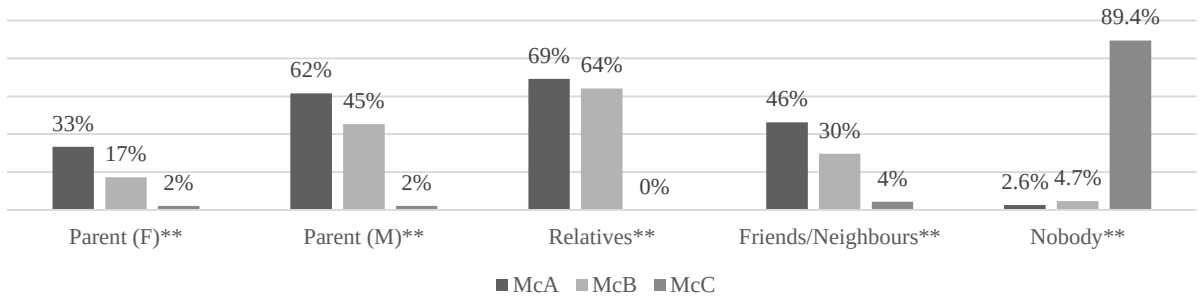

Figure 2: Who you know in STEM?[1]

This question distinguishes cluster McC from McA and McB. The diagrams show that in McC, most students have no acquaintances in STEM; while many in the cluster McA report having parents/guardians, particularly male (Parent (M)), in STEM, and many students in both McA and McB report having relatives or friends in STEM.

Support for choosing mathematics

The question "How important, or not, do you think the following were in supporting your pathways into choosing the programme?" addresses the importance students attribute to support from persons or social contexts, as of the alternatives in Figure 3.

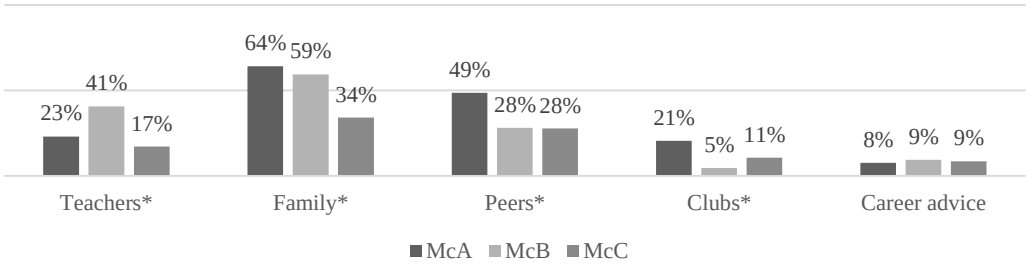

Figure 3: Important support for choosing mathematics

In general, the findings indicate that the importance of support received from teachers, family, peers, clubs differ significantly between clusters, where McA report they received the most support. One

[1] STEM – Science, Technology, Engineering and Mathematics. In all figures, significant differences between clusters according to the ANOVA are indicated by ** for a 99,9% level and * for a 95% level for each item.

exception is career advice, which is attributed little importance for all clusters. The other exception is teachers' support, which is important for 41% in McB, compared to 19% in McA and 17% in McC.

Activities and resources related to mathematics

The mathematics-related activities and resources students had access to outside formal education are part of their mathematics capital. The question asked was "What are the media or social contexts where you took part of mathematics, outside formal education, during your upbringing?"

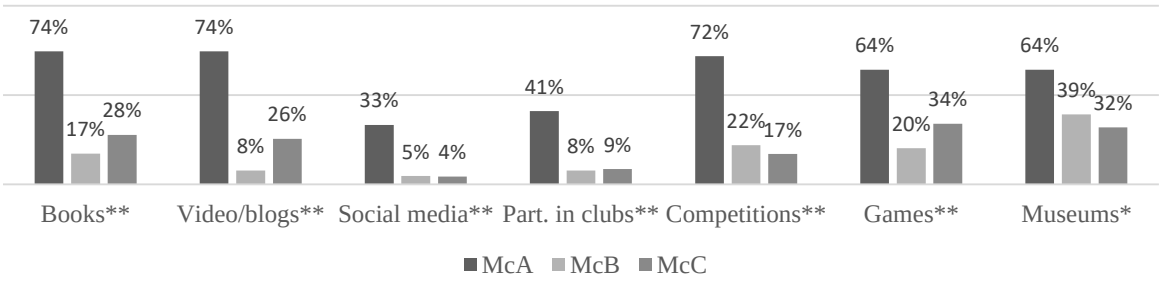

Figure 4: The mathematics related media or resources

We found a significant difference between McA and the other clusters concerning their reported access to and use of media with mathematical contents. In Figure 1, this is what shows at the right side of the diagram, where McB and McC had very low rates. Students in McA report they have engaged with mathematics-related books, YouTube videos or blogs, social media, games, clubs, and competitions. Significant differences between McA and the other clusters were also found concerning who had access to museums or science centres.

Significant others' thoughts about me and mathematics

We also asked about what significant others think about mathematics: "During my upbringing, a significant other thought that…". The following alternatives were provided: "…explained to me that mathematics is useful for my future", "…specifically encouraged me to continue with mathematics after high school", "…thought it was important for me to learn mathematics when I was in school", "…thought mathematics is interesting" and "…thought I was good at mathematics".

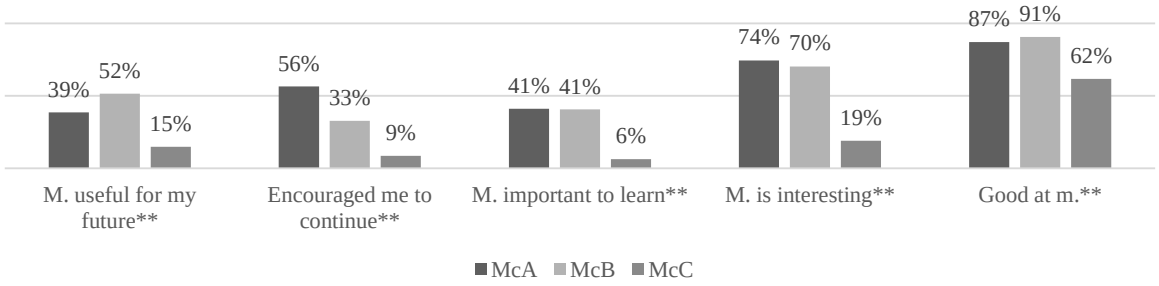

Figure 5: Significant others' thoughts about me and mathematics (M. is used for mathematics)

The majority of students reported they had been told they were good at mathematics by significant others. Nevertheless, this was notably less common in McC. Students in McA or McB were more

likely to have received encouragement to continue to study mathematics after upper secondary school, and to have significant others who think that mathematics is important to learn, who have explained how mathematics is useful for the future, and who think mathematics is interesting. In contrast, students in McC rarely report such strong encouragement related to mathematics.

One question assessed students' own thoughts about mathematics: "It is important to have a basic understanding of mathematics even for people who don't work in mathematics or science", which students in all three groups agree is important. This question, together with the question about being good at mathematics, are the only questions to which a majority of students in McC agree.

Demographic differences between mathematics capital clusters

The demographic variables we included generally show no significant differences between clusters, including gender, area of upbringing (rural or urban), or students' or parents' country of birth. Hence, these variables do not contribute to how mathematics capital clusters were formed. Also, no significant differences between clusters were found in the school achievement, where in all three clusters the majority reported to have good grades in mathematics, and the majority (119 out of 150 students) attended a mathematics-intensive upper secondary programme.

Differences between clusters were found in the educational level of parents. It is lower in McC, where 50% has at least one parent with a university education, compared to 85% in the other two clusters. In addition, there was a significant difference in the age distribution between clusters. Among the 13 students older than 25 years of age, nine were in McC, and four were above 30 years of age when enrolling mathematics higher education studies. As a contrast, in McA, two students were under 18 years old, and hence have had an accelerated educational path.

Discussion

Our analysis allowed to identify three distinct patterns of responses to the five studied dimensions of mathematics capital. All students have acquired sufficient skills in mathematics, evidenced by the fact that they report having good grades in upper secondary mathematics, and have qualified to enrol a mathematics programme at university. Also, the majority of students had been told they were good at mathematics, and they think a basic understanding of mathematics is important for people outside science and mathematics. These findings resonate with earlier research (e.g., Biza et al., 2016; Lahdenperä & Nieminen, 2020) showing the importance of mathematics knowledge/skills, attitudes and identity for entering and staying in higher education mathematics. However, our analysis makes visible the differences between students in relation to other material-economic, cultural, and social resources available for students. We interpret such differences in terms of the availability of resources related to mathematics capital in each cluster. Students in McA have an extensive range of resources contributing to building their mathematics capital, such as parents/guardians —mainly male— with an education in STEM, people around them talking positively about the importance of mathematics, and participation in mathematics-related activities during their upbringing. Students in McA to a high extent engage in extracurricular activities or media related to mathematics, as different from students in McB and McC. Students in McB, the largest cluster, have had access to some resources, but the pattern show how for them, teachers rather than family are an important resource. In contrast, the

students in McC do not report access to many resources, except having been told they are good at mathematics. Against the odds, this group has found a way to enter higher education mathematics.

Earlier research has shown how social factors affect participation in higher education in general (e.g., Osman, et al., 2021). It has also been shown how science capital captures dimensions of significance for participation in STEM-disciplines in particular (Godec et al., 2024). The concept of mathematics capital has a similar relevance for participation in mathematics education (Williams & Choundry, 2016). Mathematics capital grasps the configuration of social, material and cultural resources that differs among social groups and that also have a significance for entering higher education mathematics. In this study, clusters did not show to be significantly different concerning gender and place of origin. Yet, a demographic variable that was significantly different between clusters was parents' educational level, a well-known factor associated to successful participation in education (e.g., Börjerson & Brody, 2016). Also, students' age differed between clusters, where older students were more commonly part of the cluster with less resources related to mathematics capital. Hence, it could be hypothesised that the presence of mathematics capital makes the trajectory for deciding to enter the study of mathematics at university smoother and faster; or, in other terms, that the lack of mathematical capital require for these Swedish students a longer trajectory to make the decision to enrol in mathematics programmes. The results show that students with little mathematics capital manage to enter higher education mathematics in the Swedish system. This does not mean that the support offered to them is sufficient. We see that mathematics capital is unevenly distributed, and we find it particularly concerning that support from teachers is reported to have little importance for students in McC, who might need it the most.

We hope that our results raise awareness about the difference in mathematics capital students bring to higher education. We call for qualitative research to follow up these results to better understand the identified differences in patterns and what it entails to enter higher education mathematics for students with little mathematics capital; what are the obstacles, the expectations for the future, and what makes the students feel they belong (or not) in higher education mathematics.

Gender differences in optimistic, realistic, and pessimistic mathematical self-concepts among first-year STEM students

Pia Tscholl[1]

[1]University of Innsbruck, Department of Subject-Specific Education, Innsbruck, Austria;
pia.tscholl@uibk.ac.at

This contribution examines (1) whether a gender gap in mathematical self-concept can be found among first-year STEM students at the University of Innsbruck and (2) if the accuracy of mathematical self-perception relative to performance differs by gender. The study analyses samples of 302 and 260 participants using linear mixed-effects models and chi-squared tests. The results show that female STEM freshmen have a higher mathematical self-concept than their male counterparts. Further, women show a larger proportion of optimistic self-concepts – i.e. higher self-concepts than expected based on their mathematical performance – compared to men. Based on theoretical considerations, it is assumed that this is the result of social and criterial comparisons. Overall, gender-specific filter mechanisms appear to persist when entering STEM degree programs, which different stakeholders should consider in the future.

Keywords: Women, self-concept, mathematics, STEM, higher education.

Relevance

As one of the 17 UN Sustainable Development Goals, goal 5 calls for gender equality and the empowerment of all women and girls. This includes ensuring equal opportunities across social, economic, and political domains and ending discrimination against women. Increasing female representation in STEM (Science, Technology, Engineering, and Mathematics) fields is vital to these efforts, as women remain underrepresented (Binder et al., 2021; Goldman & Penner, 2016; Sax et al., 2015). Moreover, with many countries facing a shortage of skilled STEM workers, encouraging women to enter these fields is increasingly important (Bünning et al., 2020).

To determine the causes of female underrepresentation in STEM fields, Kanny et al. (2014) conducted a meta-narrative systematic review of 324 academic publications from the 1970s to the early 2000s. The psychological factor of *self-confidence* emerged as the most commonly cited reason for women not pursuing STEM studies. More precisely, choosing a STEM major is frequently associated with having a strong mathematical self-concept (Goldman & Penner, 2016; Musu-Gillette et al., 2015; Sax et al., 2015).

Austria presents an intriguing case for examining the complex relationship between gender, mathematical self-concept, and STEM enrolment, as this paper will demonstrate. Furthermore, this study introduces a novel perspective by assessing the accuracy of mathematical self-perception relative to actual performance by gender. This approach yields new insights into marginalisation processes at the intersection of mathematics, higher education, and gender.

Theoretical background

Self-concept

Most of the early research on this phenomenon focused on the broad idea of self-concept and frequently lacked a sound theoretical framework. Consequently, Shavelson et al. (1976) developed a well-defined self-concept model that is organised, multifaceted, hierarchical (see Figure 1), stable, developmental, evaluative, and differentiable. They describe self-concept as "a person's perception of himself" (Shavelson et al., 1976, p. 411), shaped by environmental and social influences.

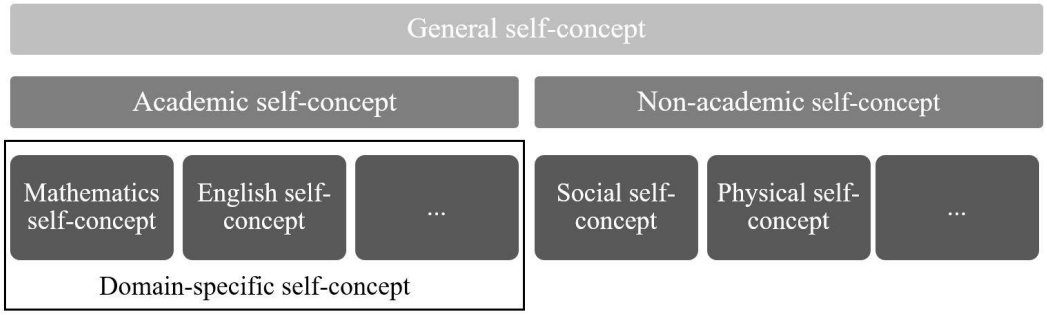

Figure 1: Hierarchical structure of the *self-concept* model according to Shavelson et al. (1976), figure based on Filiz et al. (2020, p. 2)

As Figure 1 shows, the *general self-concept* is divided into an *academic* and *non-academic self-concept*. The academic self-concept is

> generally defined as one's perceived competence in a specific domain (often an academic subject) in a normative way (in comparison to peers or the average person) that includes both cognitive and affective evaluations of the self. (Sax et al., 2015, p. 815)

The perception of one's cognitive and affective competencies in a *specific* academic area, i.e. English, is known as the domain-specific self-concept (Filiz et al., 2020; Sax et al., 2015). The domain-specific self-concept in mathematics is known as the *mathematics* or *mathematical self-concept*.

Mathematical self-concept development

Marsh's (1986) *internal/external frame of reference model* (I/E model) posits that the domain-specific self-concept is shaped by *internal* and *external* comparisons. Internal (*dimensional*) comparisons contrast one's mathematical abilities with those in other domains, often verbal skills, while external (*social*) comparisons involve measuring against peers (Dickhäuser et al., 2005; Marsh, 1986). Recent research expands the model by adding *temporal* and *criterial* dimensions (Dickhäuser et al., 2005; Geisler et al., 2023). The temporal dimension reflects comparisons between past and current performance (Wolff et al., 2019), while criterial comparisons involve self-selected or externally set benchmarks (Geisler et al., 2023). So:

- The better my skills in another domain, the worse I will rate my math skills and vice versa (*dimensional*, formerly *internal*).
- The worse the math skills of my peers, the better I will rate my math skills and vice versa (*social*, formerly *external*).

- The better my past performance in math, the more cautious I will be in assessing my current performance and vice versa (*temporal*).
- The better my performance is assessed by external criteria such as school grades, the better I will assess my performance and vice versa (*criterial*).

Empirical findings on mathematical self-concept and gender

The positive relationship between mathematical self-concept and performance has been repeatedly highlighted by extensive research (Heyder et al., 2019). Further, Goldman and Penner (2016) discovered that STEM career aspirations are more strongly correlated with one's mathematical self-concept than with academic success. Other researchers, such as Musu-Gillette et al. (2015) and Sax et al. (2015), concur with this conclusion.

Unfortunately, there is evidence that girls – even at the same performance level – exhibit a lower mathematical self-concept than boys since elementary school (Fiedler, 2024; Heyder et al., 2019; OECD, 2015). This trend extends into the tertiary education sector: it is typical for female STEM students to have a lower academic self-concept than their male peers (Fiedler, 2024). This applies to both STEM and non-STEM fields, where women exhibit a lower mathematical self-concept according to data from about 1.5 million first-year students from American baccalaureate-granting institutions between 1971 and 2011 (Sax et al., 2015).

Paasch and colleagues' (2017) study provides an Austrian example of such gender differences at secondary school level: The analysis of roughly 76,000 fourth-graders reveals that among students with similar mathematical proficiency, 7% of boys and 13% of girls had a pessimistic mathematics self-concept – a lower self-concept than expected based on performance outcomes (Paasch et al., 2017). Data from 83,000 Austrian eighth-graders show that 16% of the girls but 9% of the boys hold a pessimistic mathematical self-concept, while 21% of the girls but 27% of the boys exhibit an optimistic mathematical self-concept – one that exceeds performance-based expectations (Paasch et al., 2017).

Data and methods

Research questions and hypotheses

While numerous international studies have explored the relationship between gender, mathematical self-concept, and its influence on performance and career aspirations, research on this topic within the Austrian tertiary education sector remains scarce. Austria is intriguing in this context, as it exhibits significant gender disparities in mathematics education. According to the 2022 PISA study, which focused on mathematics, Austria – alongside Italy – recorded the largest performance gap between boys and girls. Moreover, girls in Austria receive on average 46 minutes less mathematics instruction per week than their male peers (Toferer et al., 2023). These distinctive circumstances underscore the need for a focused, country-specific examination of mathematical self-concept and STEM career aspirations as a function of gender in Austria. Additionally, it is still unclear whether the gender-specific patterns of *optimistic* and *pessimistic* mathematics self-concepts can be found in the tertiary education sector. Thus, the research questions are: (1) Is there a gender gap in mathematical self-concept among first-year STEM students at an Austrian university? (2) Is the mathematical self-

concept of STEM freshmen realistic, optimistic, or pessimistic, and are there gender differences in this regard?

Given the research findings of the previous section, it is hypothesised that (1) women exhibit a lower mathematics self-concept and (2) women own a pessimistic mathematics self-concept more often and an optimistic self-concept less often compared to men.

Sample and statistical methods

Given the limited availability of local data in Austria on the relationship between gender, mathematical self-concept, and STEM studies, a quantitative study serves as a valuable first approach to identifying trends in this area. In a subsequent phase, qualitative research methods will be essential to gain deeper insights.

A sample of 100 **s**cience- ($n_f = 39$; $n_m = 61$), 102 **t**echnology- ($n_f = 26$; $n_m = 76$), and 100 **m**athematics-freshmen[1] ($n_f = 65$; $n_m = 35$) at the University of Innsbruck is used to answer the research questions. The sampled first-year STEM students completed an extensive mathematical performance test with about 130 closed-end exercises from the areas of *numbers and functions*, *equations and inequalities*, *vectors and coordinate systems*, *geometry and trigonometry*, *integral and differential calculus*, *stochastics*, and general *mathematical thinking*, an assessment of mathematical self-concept created and validated by the Austrian Federal Ministry of Education[2], and a demographic questionnaire to obtain the necessary data. Mathematical performance data and self-concept scores were further categorised as *high* and *low* based on median splitting. According to Paasch and colleagues (2017), people with an *optimistic* mathematics self-concept fall into the low-performance group but are in the *high* self-concept category. Conversely, a *pessimistic* self-concept applies vice versa. People who fall into the *high* or *low* group for both maths performance and self-concept have a *realistically high* or *realistically low* self-concept respectively.

To answer the first research question, a linear mixed-effects regression model was fitted with *gender*[3] as the main independent input variable. The *standardised self-concept score* is used as the dependent output variable, while the obtained maths performance score (0-100), the last school grade in mathematics (1 – very good – to 4 – sufficient), age categories (15 - <20, 20 - <25, 25 - <30, or >= 30), the degree program (S, T, M), and the nationality (Austria, Germany, Italy, other) serve as control variables.

To address the second research question, nearest-neighbour matching was employed to pair the 130 women from the original sample with the available men, ensuring (mathematical performance) comparability. A chi-squared test was applied to determine whether the proportions of optimistic, pessimistic, and realistic mathematics self-concepts differ significantly between males and females.

---

[1] These students voluntarily participated in a mathematics bridging course at the named university. The ***e****ngineering* branch was excluded due to the small sample size. Nevertheless, the term *STEM* is still used throughout the manuscript.

[2] Excerpts of the questionnaire used can be accessed in German at https://p-gw.github.io/oegp-2018/.

[3] The available options for gender identification were *female*, *male*, and *non-binary*. However, the *non-binary* group was excluded from the analysis due to insufficient sample size for a meaningful quantitative study.

Results

Findings for the first research question

The fitted linear mixed-effects model yields an R-squared value of 0.56 for the fixed input variables. The fixed factors that were statistically significant in at least one category are reported alongside their β-coefficients, standard errors, and p-values in Table 1.

Table 1: β-coefficients, standard errors, and p-values of the fixed factors of the fitted linear mixed-effects model

Variable	Estimated β-coefficient	Standard error	p-value
Intercept	-0.976	0.253	< 0.001
Gender = Female	0.196	0.09	0.03
Math. performance test score	0.017	0.004	< 0.001
Last school grade = 2	-0.391	0.102	< 0.001
Last school grade = 3	-1.045	0.131	< 0.001
Last school grade = 4	-1.665	0.193	< 0.001
STEM = M	0.549	0.11	< 0.001
STEM = S	0.375	0.107	< 0.001
Age = 20 - <25	0.189	0.09	0.037
Age = 25 - <30	0.409	0.273	0.136
Age >= 30	-0.028	0.286	0.921

As Table 1 shows, the primary input variable *gender* is significant ($p = 0.03$): Ceteris paribus, the standardised self-concept score increases by roughly one-fifth of a standard deviation ($\beta = 0.196$) when *gender* is changed to female. Furthermore, the self-concept score is significantly influenced by age category, STEM degree program, last school grade in mathematics, and performance on the mathematical assessment. In contrast, nationality does not have a significant effect on mathematical self-concept and is therefore omitted from Table 1.

Findings for the second research question

Despite an equivalent mathematical performance, the proportion of optimistic, realistic, and pessimistic mathematical self-concepts (see Table 2) differs substantially by gender according to a chi-squared test ($p = 0.021$). Subsequent chi-squared tests for each category reveal a significantly (p

= 0.014) higher proportion of females who own an optimistic mathematical self-concept. The odds of having an optimistic mathematical self-concept are 2.292 (95% confidence interval: 1.121 – 4.864) times higher for women than for men.

Table 2: Number of participants by gender (male, female) and degree program who fall within the categories of optimistic, realistically high, realistically low, and pessimistic mathematical self-concept.

	Science		**Technology**		**Mathematics**		**Total**	
	Female	Male	Female	Male	Female	Male	∑ Female	∑ Male
Optimistic	7	4	3	4	20	7	30	15
Realistically high	18	19	2	6	25	14	45	39
Realistically low	8	14	19	31	15	7	42	52
Pessimistic	6	13	2	4	5	7	13	24
∑	39	50	26	45	65	35	130	130

Discussion and outlook

The outcomes of the first and second research questions contradict the stated hypotheses: Women exhibit a higher mathematical self-concept when entering a STEM degree program at the University of Innsbruck, but they overestimate their mathematical abilities more often. This leads to a higher proportion of optimistic self-concepts among females.

Theoretical explanations for these unexpected results are rooted in the *social* and *criterial* comparative frameworks. First, the *social* comparison was found to be highly relevant, especially for females in Austria (OECD, 2013). Second, the *criterial* comparison emerged as the most important frame of reference according to Geisler et al. (2023). Based on these two reference dimensions, it is reasonable to assume that women who choose a STEM degree program come from secondary school classes with a low mathematical performance level. As a result, they had the opportunity to develop a strong mathematical self-concept in *social* comparison, despite their relatively moderate mathematical abilities – also called the *big-fish-little-pond effect* (Geisler et al., 2023). Due to their relative superiority compared to the rest of the class, they probably achieved good grades, which in turn enables a good mathematical self-concept based on the *criterial* dimension. This explanation, which accounts for the results of both the first and second research questions, is underpinned by the results of PISA 2022 (Toferer et al., 2023): Girls in Austria systematically receive less mathematics instruction than boys because they are more likely to attend schools that are less mathematics-intensive and, consequently, classes with a relatively lower level of mathematics performance.

This suggests, however, that women from mathematically strong secondary school classes may be less likely to pursue STEM careers, despite having adequate mathematical ability. This argument

aligns with the research findings of Goldman and Penner (2016), which show that self-concept has a bigger influence on career decisions than performance.

In addition to these psychological explanations, constructs from sociology or social psychology, such as power relations or *brilliance beliefs*, play a significant role when analysing these results. Due to page limitations, these are omitted in this contribution but should be considered in broader discussions.

Apart from the explanation, the key finding of this research is that men and women in Austria still undergo different comparison and filtering mechanisms when it comes to STEM career aspirations. Particularly, women need to have a higher-than-average self-concept in mathematics to choose a STEM degree program. This results in several suggestions for (1) scholars, (2) policymakers, and (3) universities:

(1) It needs to be investigated whether these results can be replicated at other universities and, if so, to identify the filtering mechanisms causing them. Furthermore, research that not only focuses on gaps but also highlights potential is necessary.
(2) The discovered inequities must be taken seriously by policymakers: Laws and other initiatives should address gender inequality and increase societal awareness. To address the lack of STEM workers in Austria, it is crucial to guarantee equitable access to these fields.
(3) Universities need to account for the found gender gaps while recruiting new students and providing remedial instruction for STEM degree programs. Furthermore, it is crucial to support and enhance the accurate self-perceptions of men and women in mathematics.

Active listening for storylines experienced by Indigenous and newly migrated mathematics students

David Wagner[1], Sacha Dewolfe[2], Julianne Gerbrandt[1] and Zyrene Estallo[1]

[1]University of New Brunswick, Canada; dwagner@unb.ca

[2]Mount Allison University, Canada

From our interactions with Indigenous and newly migrated mathematics students, we describe our team's efforts to surface the students' experiences and conceptualisations of those experiences. Our shifting approaches inform theorisation of positioning, especially in relation to the key concept of storylines in that theory. In particular, we identify challenges in surfacing student experiences, and in naming their conceptualisation of those experiences as storylines.

Keywords: Indigenous knowledge, immigrants, student diversity, culturally relevant education

Storylines and experience

We share here our efforts to find generative ways to interact with Indigenous and newly migrated mathematics students in order to listen to their accounts of their experiences and how they conceptualise those experiences. We have been theorising our work around positioning (e.g., Herbel-Eisenmann et al., 2015) because we are interested in the opportunities for mathematics students who identify with groups who are often marginalised by colonial ideologies of what mathematics should include and value—thus our interest in Indigenous students and students from families who have recently arrived in migration.

People position each other. For example, a teacher may have certain expectations of an Indigenous student that they do not have for other students. These expectations are informed by many things, including previous interactions with Indigenous students, dramatizations of interactions between teachers and Indigenous students in popular culture, or stories that others have shared about their own experiences. People also enact positions. This means that a newly migrated student, for example, could interact/act in a way that aligns with the expectations their teachers have for them. Or they could resist the way their teacher positions them and instead interact/act in a different way. Whether the people involved are aware or not, there are power relations at work in such positioning.

According to theorisations of positioning, in any interaction people position each other within known storylines (Davies & Harré, 1990). In this way, storylines are at once social structures and structures of power that enable people in interaction to make sense of the interaction. Storylines present ideas about which actions are available and which ones are unavailable to the people involved, while positioning is the allocation of power within a structure. Research that focuses on storylines (e.g., our research), addresses the fundamental structures underneath interactions.

We are interested in those structures in mathematics classrooms because they describe what mathematics is for students in those classrooms. Further, we have an interest in all students having access to the powerful social/citizen tools associated with mathematics, and this interest motivates us to promote practices that would support students who have traditionally had less access to these tools.

While most research using theories of positioning focuses on the positioning (e.g., Sengupta-Irving, 2021), the theorisation typically sees a triad at work, including the three elements of (1) positioning, (2) storyline, and (3) speech/communication act (e.g., Harré, 2012). The people involved in an interaction are associated with positions in a story, which guides their choices about how to interact. Storylines are under-researched, both in mathematics education and in other disciplines. There has been some work on storylines in our field—for example, Andersson et al. (2022) and Rodney et al. (2016) have explored storylines related to learning mathematics that appear in news media, while Gerbrandt and Føyn (2023) described the difficulties of recognizing storylines as they emerge during a mathematics education conference. And there is research in our field bearing similarity to storylines using other conceptual tools to address structures of interaction and power in mathematics education.

Our research context

For this reflection on how to listen to student experiences and conceptualisation of those experiences, we draw on our current research project that seeks to document the storylines that underpin interactions involving Indigenous and newly migrated mathematics students in Wabanaki territories. The region commonly referred to as New Brunswick, Canada, was never ceded or surrendered by the Wabanaki peoples who have lived with the land for millennia. The project aims to work with participant students' mathematics teachers to co-develop teaching approaches that would build on strengths identified in the storyline work.

Two major social movements in Canada are relevant. Following the Truth and Reconciliation Commission hearings and published calls for action (e.g., TRC, 2015), there has been new interest and accountability amongst mathematics teachers to develop proactive and responsive pedagogies for Indigenous and settler students. Meanwhile, human migration has been increasing and politicised; mathematics teachers have been looking for guidance in how to teach new immigrants appropriately.

We have interviewed Grade 7 and 8 students to identify storylines. Here we describe our shifting ways of engaging with the students and reflect on the success of these approaches in terms of surfacing storylines that might be useful in the development of strengths-based approaches to teaching mathematics. Our reflection raises questions about how to make a welcoming space for students to share their experiences, and how to connect this to storylines.

What is a storyline?

Storylines provide communication/action repertoires for people in an interaction. People decide what known storyline they associate with the interaction and then use that storyline to position others in the interaction, to choose their own words and actions, and to interpret the words and actions of others. Herbel-Eisenmann et al. (2015) have drawn attention to a limitation of researchers naming storylines, given that researchers rarely participate in the analysed interactions. In our current and previous research projects we have had to decide how to identify storylines and how to describe (or name) them. For example, one of us was a contributor to the work of Andersson et al. (2022) that identified storylines in Norwegian newspapers and other public media regarding mathematics education and either Indigenous or newly migrated students. In that work there was considerable dialogue about

how to name storylines, subsequently leading to the organisation of a PME working group focused on the twin challenge of identifying and naming storylines (Simensen et al., 2022).

In our current project, we continually revisit and reflect upon our reasonings for identifying storylines. We have come to recognise that we are more interested in our research participants' experiences than in finding the best words to name the storylines they fall within. The name of the storyline is not the storyline. Rather, the name indexes a known story (or set of stories). Thus, we have come to see value in the name being brief and evocative: it should connect people to experiences and conceptualisations that they perceive to be common. In order to focus on stories, we have chosen storyline names that include a subject and action—this is a grammatical criterion that distinguishes identifying storylines from identifying themes. Finally, because we are interested in the positioning, we want the name of a storyline to indicate some kind of explanation for the behaviours and actions in the stories associated with the storyline. In brief, the criteria we developed for naming storylines are:

- brevity
- including subject and action (grammatically)
- including an explanation of behaviour

For example, the storyline "Teachers respond to students differently based on the students' reputations" is relatively brief. The subject is *teachers* and the action is *response*, so there is action with clarity about agency. The explanation for action refers to a teacher *judging* students on the basis of their reputations.

At a recent conference presentation, someone asked us how to correctly name a storyline. Our answer was/is that we are not aware of a standardised way to do this. From conversations with Bronwyn Davies, whose collaboration with Rom Harré introduced the concept of story line to positioning theory, we know that she sees the *line* in *storyline* much like she writes about lines of flight in her current work on new materialism (e.g., Davies, 2021): as a point of departure, open to possibility (like a tangent line, shooting off from a circle, in our mathematically-informed conceptualisations). And we know that she sees Harré's conception of the *line* in *storyline* as more rigid, like a boundary, as he has focused on rights and responsibilities in his development of positioning theory (Davies, 2022). We are more inclined to see theory as continually in process, contested (e.g., Bjerre, 2021) and in conversation with applications of the theory in different contexts.

We want our choices about storylines to open possibilities for a productive transformation of mathematics learnings spaces, and we imagine these spaces as welcoming to the particular strengths exercised by Indigenous and newly migrated students. It would be frivolous to try to kill a storyline because storylines are pervasive. For us, the ultimate goal of storyline work is to redeem pathology-based storylines and thus provide bases for alternative ways to deem/identify the people at play in them. We suggest this can be achieved by identifying opportunities to pivot within a given storyline (Gerbrandt and Wagner, 2022). For example, it would be hard to convince people to stop saying that mathematics is full of mystery (because so many mathematically inclined people like to see mathematics this way), but it could be possible for us to work with people to play with the idea of mystery in mathematics, identify anchor points that are important to them, and pivot the story to light new visions for the possibilities for action (e.g., Andersson & Wagner, 2018).

Such pivot work will be important in our collaboration with teachers in the next phase of this research project. But first we need to surface the storylines, name them, and connect them to accounts of experience. We now turn to that process.

Listening through conversation

In the first context of our research project, Dave (the first author) connected with a teacher who, for more than a decade, has worked as a support teacher for the Indigenous students from a local Wabanaki community. Given the history of terrible experiences at the hands of settlers and colonising institutions, it takes time and care to develop relationships of trust with Indigenous students. This teacher's endorsement and collaboration accelerated the students' willingness to speak openly about their experiences (i.e., to trust). In other words, trust can be shared, to some extent, from an already trusted person. Drawing on the teacher's knowledge of the students, we connected with a group of eight students in a series of six biweekly one-hour meetings.

During these meetings, Dave asked questions about what was *happening* in their math classes—sometimes asking students to describe something interesting, or recent, or frustrating. After a student identified something that happened, Dave probed with questions about what is *really happening* when things like that happen, and questions like "Why would [the person] do that?" Those conversations would compare the math-related experiences with other interactions—sports, friendships, etc. The teacher once told Dave that the students looked forward to these discussions and referred to them as "Dave coming to ask us hard questions."

Using the triad of positioning theorisation, the *happening* is a communication act or a series of communication acts, and the description of what is *really happening* is the storyline. After this series of group conversations, we synthesised the stories and dialogue to bring them back to the students. From discussion amongst ourselves about the deep knowledge emerging from the recorded interactions, we synthesised the foci with the following storylines, formulated around the elements in the principles for naming storylines discussed above—brevity, action, explanation:

1. We have to try hard to learn math.
2. Teachers respond to students differently based on the students' reputations.
3. Math is important.
4. The math we do in school is not interesting.
5. We are more worried about failure than attracted by success in math.
6. How I feel about my math performance depends on my expectations for myself.
7. Math teachers don't understand native people [i.e., Indigenous people].
8. Math should be done in silence.
9. Something about parents… <not sure what>

In interviews with the individual students Dave read the storylines one at a time and asked for example stories that illustrate those storylines. For #9 he said that there was a lot of talk about parents but he could not identify a storyline succinctly, and he asked each student if they could say what the storyline might be. One of the students provided a storyline: "Parents expect you to do well." After this, Dave replaced #9 with the student-provided storyline. It became clear that #5 and #6 were not like the

others: the students said they were not sure about them. Emerging from those conversations, Dave learned that it was helpful to ask students if they thought the statement is true, and to ask if they thought the statement is something people say or think. For #5 and #6 almost all the students said the statements were true (indeed, these emerged from their earlier interactions) but that they were not statements that people think or say. This dialogue underscored two things for us. #5 and #6 are not storylines: they are not known stories. And the students' analysis reminds us that storylines do not have to be true to be well known: a storyline's power is independent of its truth.

Following the principle of OCAP (ownership, control, access, possession), "First Nations have control over data collection processes, (…) they own and control how this information can be used" (https://fnigc.ca/ocap-training/). Thus, for the learning from our interaction with the Wabanaki students, they themselves and their community are the most important people to report to. Sacha (second author) identified an elder from the students' community as a person to report to first, and the teacher endorsed this choice. After Dave spent several hours with the elder to report on what happened thus far in the research conversations, the elder joined the next gathering of the student research group. The elder told the students of their own experiences as a student and as an adult dealing with Indigenous and settler peers and with "authorities". The students asked questions and told the elder about some of their experiences in and related to school.

Listening through prompting with identified storylines

The conversations with Wabanaki students informed our approach to newly migrated students. Again, the first challenge with addressing these students was garnering their interest and trust, but we did not have the benefit of a teacher ally with longstanding relationships. We also know that many newcomers are cautious about what they say about their experiences of migration because many of them are in the process of qualifying for residency status. And many of them come from political contexts that prompt them to be extremely cautious of their information getting into the wrong hands.

Dave and Zyrene (Author #4) met with some classes to tell them about the research and invite participation in interviews. In the first session, we used the approach as with the Indigenous students—asking for examples of things that happen in math class and following up with questions about what is really happening—but the students seemed bewildered by this activity. The dynamics of being in a larger group of people and experiencing linguistic barriers probably impacted their ability to answer questions that are unlike the questions they are accustomed to in school or their other cultural contexts. So we switched to an approach informed by the interviews with the individual Indigenous students, in which Dave would read a storyline, ask if it is true, and then ask if they think others believe it to be true. Dave and Zyrene used storylines from the Indigenous students and from the research contexts in a sister project in Norway (Andersson, et al., 2022). For example, Dave would say, "When I do math, I need to use my first language" (Andersson, et al. 2022) and ask students to put up their hands if they thought it was true (fewer than half of the students said it was true). He then asked students to put up their hands if they thought some people *think* it is true (almost all the students thought that some people think it is true). The students were laser focused on these questions, locking eyes with Dave in a way he has not experienced in a classroom before, which indicated to us the students' serious engagement with the questions. The struggle to decide whether to put their hands

up or not was evident on students' faces (even students who had been in Canada less than a month). The students were invested in these storylines, to recognise the importance of these storylines.

Following Zyrene's suggestion that an infographic might help engage students during small group interviews, we designed the image shown in Figure 1. We prompted students to talk about their experiences by pointing to the relevant parts of the infographic, focusing on the storylines and the accounts of "something that happens." Each interview began with example storylines, like we had done in the large group, asking if the students thought the storyline is true. In the intimacy of a small group of students (2–4), we could follow up with more detail, asking who thought it was true, and then asking for examples of things that they have experienced in school. Students talked about their experiences in Canada, sometimes comparing them to experiences in school in other countries.

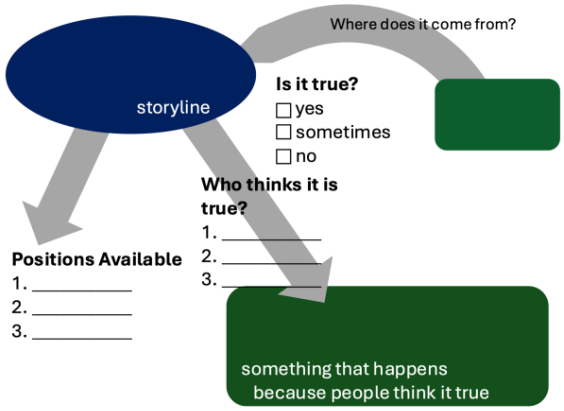

Figure 2: Infographic illustrating the relationships among experiences, storylines and positioning

Then we asked students for examples of interesting or frustrating things that happened in their mathematics learning. From those experiences we pointed to the storyline image and asked what someone must believe to be true for them to behave in the way they did in the interaction. We found that students were readily able to describe experiences and to reflect on reasons and beliefs that underlie the interactions in those experiences—i.e. the storylines. We found, however, that the students did not look at the infographic much. Sometimes we invited students to write on the infographic to fill in some of the details, but none of them engaged in that offer to any significant extent. The graphic organiser might have paradoxically functioned as a barrier, where the bright colours and sharp lines might be associated with professional documents rather than as tools to support idea generation. It might be that students wanted to tell us (humans in interaction with them) their stories, but they were not interested in putting those stories into an abstracted structure.

Discussion

Developing method: In conversations with colleagues about this project, it seems that both the naming of storylines and the methods for surfacing storylines are of particular interest. We suspect that this interest owes in part to the sometimes illusive and intangible nature of storylines. While we might agree that there is a storyline informing our interactions in a given situation, say, between a teacher and a student (e.g., students listen to their teachers), we are also aware that each storyline is rooted within a cultural context. In our interviews with Indigenous and newly migrated students, language,

culture, and identity influenced data collection in visible and invisible ways. For instance, among newly migrated students who were in the early stages of English language learning, there were visible challenges with ensuring they understood the researcher's questions. Though students used digital tools to support multilingual comprehension, the translation apps required loading time and slowed down comprehension. More research is needed to explore the ways that storylines are surfaced across linguistic and cultural divides. We do not know how our attempts to support cross-linguistic communication interacted with students' assessments of the storylines we described.

Surfacing storylines: We sometimes hear educators say "representation matters". Some storylines are visible, recounted in popular culture, such that a majority population could easily recognise themselves holding one of the available positions in the interaction. Saying "representation matters" seems to be a call for available positions in mainstream storylines to start including unexpected or underrepresented voices. This move leaves the dominant stories dominant. So we are motivated to identify different storylines (less recognisable in mainstream/majority/popular culture) from experiences of marginalised populations, which can include positions that are not as universally familiar. Our efforts to surface such stories (described above) is a challenge because those stories are not as familiar to us as mainstream stories. These storylines exist (our findings have surfaced several of them), but they are not as visible and tangible because they come from marginalised groups, thus they are especially important to identify. Indeed, this challenge helped us recognise the distinction between inviting new people into dominant stories and hearing the stories of marginalised people.

We also reflect on the very real positioning that occurs during the research process. What storylines are available to guide the interaction between student participant and adult researcher? How does this positioning influence the resultant data, in turn informing the researcher's understanding of the participant's experiences? We ask ourselves these questions and sit with the unknowing. Even as we sit with the collection of student experiences voiced through stories, we are informed and constrained by the storylines at our fingertips. Assigning a name to a surfaced storyline reflects the preconceptions we carry throughout the process. And the confirmation or refutation of these newly pronounced storylines is again achieved as we participate within the boundary of a storyline.

Pivot points and next steps with teachers: As noted above, we promote the surfacing of storylines not known in mainstream culture. It will be helpful for mathematics teachers to know these, to better understand the experiences of their students. We also have to contend with the mainstream stories, which cannot be killed (because they are in the mainstream), but may, perhaps, be pivoted. This is our next challenge—how to do this in a productive/effective way. We think that the experiences described by marginalised students in relation to those storylines can help us identify what aspects of those stories may be worth keeping and thus be maintained as pivot points to redeem those stories.

Acknowledgment

Categorising subjective relevance of mathematics education

Chiara Nadine Wang[1] and David Kollosche[1]

[1]University of Klagenfurt, Austria; chiara.wang@aau.at

The importance of learning mathematics is rarely doubted. Nevertheless, among students, there is often a lack of concrete ideas about why mathematics education may be relevant to them. These ideas depend on many determinants such as age, culture, social environment, socio-economic variables, interest, self-image, and teaching and teachers. Therefore, they are very individual. Without claiming to be exhaustive, the aim of this paper is to derive dimensions of relevance from theory and, where possible, supplement them with examples from empirical research.

Keywords: Subjective relevance of mathematics education, relevance dimensions of mathematics education.

Introduction

Why is it relevant for me to learn mathematics? What are the benefits of mathematics education for later life? These questions are often posed by students in the mathematics classroom. We propose that these questions are not only an expression of dissatisfaction but also a plea for meaning. Previous research has shown that, when asked for what relevance they see in mathematics education, secondary school students usually merely name the learning of contents for elementary applications, which does not provide relevance to much of what is covered in secondary mathematics education and limits the possible relevance to learning (Kollosche, 2017b; Sachdeva & Eggen, 2023). We assume that such a limited discourse provides hardly any opportunities to experience mathematics as something personally meaningful. Our overall research project is concerned with the questions of how far other discourses about the personal relevance of mathematics education can be identified and how such discourses can be developed among students.

We understand "subjective relevance of mathematics education" as the relevance that students attribute to their engagement in institutionalised mathematics education. We use the phrase "engagement" instead of "learning" because we do not want to narrow the focus down to learning. Instead, students can find mathematics education relevant for different reasons, including the logical nature of mathematics, its gatekeeper function to well-paid jobs, or the self-discipline that mathematics requires. We call such reasons "dimensions" of subjective relevance.

We address the further conceptualisation of subjective relevance of mathematics education elsewhere (Kollosche & Wang, 2024). There, we argue that subjective relevance of mathematics education is important to study for at least three reasons: first, to better understand and improve the performance and motivation of students in the mathematics classroom; second, to better understand and improve the offers of the mathematics classroom in the light of what students find to be subjectively relevant; and third, to better understand mathematics education as a social institution which forms mathematical subjectivities and requires a legitimisation of its existence. To avoid any confusion, we want to stress that it is not our goal to find ways of manipulating students so that they come to believe in the relevance of mathematics education. Here, we want to highlight more specific aspects that are

especially relevant for a critical perspective on the socio-politics of mathematics education: Even if we accepted mathematics education in its current forms, it could be argued that a better knowledge of possible dimensions of subjective relevance would emancipate students, for example, through enabling them to reach better decisions where to invest effort and where not to, or to make demands from other students, teachers, and schools as to what should be offered in the mathematics classroom. Knowledge of the different dimensions in which students come to find mathematics education relevant for them could allow to better create an educational environment which answers to the needs of students. Eventually, discrepancies between what students find to be relevant and what classrooms offer could help to better understand the socio-political nature of the mathematics classroom, for example, concerning the mathematical subjectivities whose development it facilitates or obstructs (e.g., Kollosche, 2018), or concerning the question which social groups are constructed as mathematically able (e.g., Stinson, 2013).

How to study relevance dimensions

The importance of mathematics is demonstrated not only by its global role as a core and compulsory subject (Heymann, 2003), but also by a general consensus among students that it is important to learn mathematics (Kislenko et al., 2007). However, when asked why students think mathematics education is important, they often offer one-dimensional, fragile, and thus easily collapsing ideas about the relevance of mathematics education (Kollosche, 2017b; Sachdeva & Eggen, 2023), such as the idea that you need mathematics in your daily life. As in many other areas, the conviction that mathematics or mathematics education is relevant often reproduces discussions in society without questioning (Ernest, 2004) and is significantly influenced by these discussions. However, based on this basic attitude, questions automatically arise about why mathematics education is important and for what purpose. We assume that the ideas of why mathematics education is personally relevant for someone can vary and that there will be no normative, complete list of relevance dimensions.

In this paper, we want to provide an overview of as many dimensions of the subjective relevance of mathematics education as possible. To achieve this, dimensions of subjective relevance derived from theory and empirical studies are presented. Regarding the theoretical backgrounds of the dimensions we will discuss, we have decided to limit ourselves to selected publications on the educational theory and the sociology of mathematics education instead of conducting a systematic literature review. These two orientations allow us to include both normative and descriptive perspectives on the relevance of mathematics education.

We acknowledge that this choice of literature is very limited and only a first step. With this paper, we do not want to conduct a systematic literature survey, nor do we claim to present an exhaustive categorisation of subjective relevance of mathematics education. Instead, we want to start a discussion about subjective relevance, its importance, its conceptualisation, and its study. Our categorisation can be understood as a first attempt of theory building in that matter. Including more publications might allow us to identify further dimensions later. We also draw insights from empirical studies which have gathered data on why students find mathematics education to be relevant. Interestingly, such findings can challenge the education theory and sociology of mathematics education. An example of this would be the idea that somebody assumes mathematics education to

be personally relevant to be able to help other people, such as helping their own children with their homework (Sachdeva & Eggen, 2023).

As a way of presentation, we present phrases that can follow the beginning of the sentence "Mathematics education is relevant for me because...". The dimensions that we present in this way are no quotes from literature or student data. They rather constitute ideal types of these dimensions in the sense of Weber (1949), that is, "logical constructs" whose "function is the comparison with empirical reality in order to establish its divergences or similarities, to describe them with the most unambiguously intelligible concepts, and to understand and explain them causally" in order to aid sociological analysis (pp. 42–43). However, we will elaborate on how these dimensions are addressed in literature or by students.

Findings

The following paragraphs show our findings. They each start with our formulation of the dimension in question, followed by accounts of where these dimensions have been addressed in literature or by students. In some cases, we also elaborate further on the dimensions, for example, concerning their distinction from other dimensions.

Mathematics education is relevant for me because I need mathematics in daily life. This is a very general statement that is stated very often. From an education theory perspective in the sense of the concept of general education, on which there exist extensive discussions, especially in German-speaking countries, one aim of school, and thus also of mathematics education, is to prepare students for life, as a result of which what they have learnt should be personally applicable and useful in practice (Heymann, 2003; Winter, 1995). However, the prevailing idealistic view of qualifications that should be applicable and usable in everyday private and professional life (Heymann, 2003) reflects the subjective relevance of mathematics education only to a limited extent, as mathematics is more than just an aid in everyday life. Some scholars question the use value of mathematics education altogether (Pais, 2013). When examining empirical studies on this dimension, it becomes obvious that students often mention situations related to shopping, for example, as the following excerpt from an interview study conducted by Kollosche in Germany in 2016 shows: "You need mathematics to avoid being cheated, for example, at the cash desk" (Kollosche, 2019, p. 55, our translation).

Mathematics education is relevant for me because mastering elementary mathematical calculation techniques is fundamental. This statement reflects the importance of elementary mathematical calculation techniques. Furthermore, it emphasises the fact that in terms of content, most of what is to be learnt in mathematics education, especially in German-speaking countries, appears to be of little use to the broad masses, i.e., to those for whom mathematics is no longer an essential part of their lives after completing their education. Following the assumption of Heymann (2003), all the content necessary for daily life has been taught until the 7th school year and, as studies show, everything beyond this is often forgotten anyway (e.g., Department for Business, Innovation and Skills, 2012). Performing elementary mathematical calculation techniques or calculating percentages are, for example, dominant examples of subjective relevance at the content level among students, as the following excerpt from an interview study conducted by Sachdeva and Eggen (2023) in Norway confirms: "especially just plus and minus and division and … multiplication … these are things I find

very useful …" (p. 12). Content that is addressed at higher school levels is rarely described as relevant. Reasons for this could be that the students do not yet know what they can use the content for and that mastery of the content is not necessary in everyday life. In addition, there are a number of technological aids available, particularly in the field of operations, which means that even fewer mathematical skills and knowledge are required of the majority of people (Borovik, 2016). Conversely, these technological aids, especially their (further) development, require more mathematical knowledge from mathematical experts. This leads directly to the relevance of mathematics education in connection with the profession, which is also frequently mentioned by students in several studies (e.g., Dobie, 2019; Sachdeva & Eggen, 2023) and discussed next.

Mathematics education is relevant for me because you need mathematics in almost every job. The perceived relevance of mathematics education in connection with future jobs certainly depends strongly on the students' level of development and how much they have already been involved with different jobs. The proportion of mathematical skills and knowledge, as well as the content required, varies from profession to profession, and therefore, the relevance attributions also differ. From the perspective of education theory, Heymann (2003) argued that the different mathematical requirements of different jobs imply that these mathematical requirements cannot be a part of general education but have to be covered in vocational education. Empirical studies show that in particular children with specific job expectations see the relevance of mathematics education for their future job, as the following quote shows: "I want to be a farmer like my parents and that requires a lot of mathematics, for example, statistics" (Kollosche, 2019, p. 56, our translation).

Mathematics education is relevant for me because mathematical skills are crucial for your opportunities in the labour market. Mathematics is repeatedly ascribed the function of gatekeeper to economic access, full citizenship, and higher education (Stinson, 2004). This effect appears to be strong in countries such as the US, where mathematics is not compulsory throughout the school career but can be dropped at some point. The deselection of advanced mathematics courses by students is usually accompanied by reduced opportunities in the labour market, which means that the gatekeeper function of mathematics often correlates with exclusion, and the subjective relevance of mathematics education takes on a completely different meaning. From a sociological perspective, in addition to qualification, selection and allocation are central functions of school (Kollosche, 2018). Grades as a means of selection usually have a major influence on students' educational paths and, subsequently, on their career paths. In mathematics education, selection often plays a special role in the sense that the mathematics grade in the private sector, for example, has a stronger weighting than other grades. This may be related to the fact that mathematics education is said to demand many qualities that go beyond the content area (e.g., meta-competences or character traits, see below) (ibid.). The usefulness of mathematics education in connection with getting a job is also repeatedly mentioned by students in empirical studies. For example, one student in the study conducted by Dobie (2019) mentioned: "I think it is the most useful because you are more likely to get a job if you are good at math" (Dobie, 2019, p. 40).

Mathematics education is relevant for me because I need mathematics education to pass the tests and to graduate. To a certain extent, this statement is related to the previously discussed dimension of subjective relevance. For many career paths it is a requirement to be graduated or at least to finish the

compulsory school with positive grades. Examinations of all kinds play a particularly central role in this context. This can ultimately lead to students seeing the relevance of mathematics education in passing exams to advance to the next school level, to be able to start an apprenticeship, to obtain a degree, and to gain the right to study or to avoid being assigned to a certain social position. The following quote from an interview study by Sachdeva and Eggen (2023) proves that this relevance attribution exists among students: "I do not know how useful it will be in the future ... I have not experienced a situation where I would need it except for the tests ... so ..." (p. 12).

Mathematics education is relevant for me because I can work completely within mathematics without any reference to another discipline. On the one hand, Winter (1995) demanded that mathematics education has to be application-oriented and has to address real-life problems. On the other hand, reducing mathematics education solely to applications is not representative for the extensive significance of mathematics, which is also considered a particular intellectual experience due to its internal logical order. In this sense, Winter (1995) demands that mathematics education should allow students "to get to know and understand mathematical objects and facts, represented in language, symbols, pictures and formulae, as intellectual creations, as a deductively ordered world of its own kind" (p. 37, our translation). Searching in empirical studies for statements which are linked to this dimension leads, for example, to the following statement of a student from the interview study conducted by Kollosche in Germany in 2016: "I think it's crazy, somehow positively crazy, that you can think up such abstract things in mathematics and then think about them for so long." (Kollosche, 2019, p. 56, our translation). This statement not only expresses the positive experience when doing mathematics, but it can also be something in which a student sees the relevance for themself.

Apart from the predominantly content-related, application-related and career-relevant subjective relevance dimensions discussed previously, the following mathematical meta-competences, by which we mean competences that are independent of the mathematical content, are also particularly important in mathematics education. In fact, these competences are all aspects of mathematical literacy and are often also referred to as key qualifications. However, they still play a subordinate role in education due to the frequent dominance of calculation tasks that often require nothing more than applying a learnt schema, which is also reflected by the students' responses in several interview studies concerning the relevance of mathematics education (e.g., Sachdeva & Eggen, 2023). Nevertheless, precisely these competences make responsible citizens and cannot be outsourced to technology.

Mathematics education is relevant because it helps me in solving problems. The ability to solve problems and, thus, the use of heuristic strategies, illustrate a central competence, which was also formulated by Winter (1995) as one of the three basic experiences that mathematics education should allow. The subjective relevance in this context lies in applying these problem-solving skills to problems encountered outside the mathematics classroom. However, at this point, it is important to mention that there is no evidence that the heuristic strategies taught in mathematics education can be applied outside of mathematics education (Kollosche, 2018).

Mathematics education is relevant because it helps you to learn to think logically and argue coherently. These competences play a central role in mathematics education due to the deductive

structure of mathematics and represent further dimensions of subjective relevance as mathematical meta-skills, which are also important beyond mathematics education, for example, when writing an essay. In addition, mathematics education can contribute to adopting a critical attitude towards reports and statistics circulating in the public domain. This was described by Heymann (2003) as "development of critical thinking" as one of the tasks of general education. On this relevance dimension, there also exist students' thoughts: One student in the interview study conducted by Kollosche (2019), for example, mentions: "I find mathematics totally logical. You don't have to look everything up or just know it, you can work it out for yourself" (p. 56, our translation).

Mathematics education is relevant for me because it helps me to concentrate and work in a disciplined way. In addition to concentration, solving mathematical problems often requires students to be able to stay disciplined. This is also a finding from empirical studies. According to these, students state that mathematics education requires concentration and self-discipline (e.g., Kollosche, 2017a). Therefore, it can be assumed that mathematics education can also train and promote concentration, which can be considered relevant.

However, it is questionable whether mathematics education is partly responsible for promoting character traits (e.g., perseverance, frustration tolerance, ability to concentrate, accuracy) or whether mathematics education rather tests them. At least, there is no evidence that mathematics education actually has an influence on character traits (Kollosche, 2018).

Mathematics education is relevant for me because it allows me to help other people if they have difficulties in mathematics. Although this statement cannot be categorized appropriately in terms of education theory or mathematics education sociology, empirical studies show that mathematics education can also be relevant for someone for this reason. One student, for example, answered the question whether mathematics education will be important for himself/herself later in life in the interview study by Sachdeva and Eggen (2023) in Norway like this: "Yeah … I maybe think that too … like if you will have children then you can help them with their work." (p. 15). This is a dimension that, like many others, is certainly not relevant for everyone, but at least for a few and is probably also strongly dependent on character.

Conclusion

Looking at the subjective relevance dimensions we mentioned in this paper, it is clearly recognisable that relevance attributions, even if mathematics is closely linked to society and its needs, are something personal and, therefore, individual. Thus, there exist neither right nor wrong ideas of relevance. We acknowledged earlier that the above list is certainly incomplete. We are engaged in an empirical study in which we will collect further data about students' subjective relevance and will report on that on a later occasion. This might be the first study where students are directly asked in how far and why mathematics education is relevant for them, while the above-mentioned studies used different questions, for example, on the general importance of mathematics education and the consequences of their answers for the relevance they see in it can only be assumed.

However, our research interest is not only empirical in nature. We also look forward to a further theoretical conceptualisation of subjective relevance, which could begin with a theory-based

organisation of the dimensions we discussed. Candidates for such background theories include Bourdieu's adaption of the Marxist concept of use and exchange value (Williams, 2012), expectation-by-value theory (Eccles et al., 1983), self-determination theory (Ryan & Deci, 1984), and the theory of basic desires (Reiss, 2016).

The most important thing is to offer students dimensions in which mathematics education can be experienced as personally relevant. In this context, it is problematic that the image of mathematics is usually blurred and reduced, not only among students but also in society as a whole. Therefore, it is unsurprising that subjective relevance dimensions which go beyond everyday practical benefits such as shopping are rarely recognised by students. In order to offer students the opportunity to experience other dimensions of relevance, it is necessary to address them in the classroom actively. The subjective relevance dimensions discussed in this paper could provide a basis for this. Findings on the possible further development of ideas of subjective relevance in mathematics education with students are an urgent research desideratum, which we will address in a project in the coming years.

Socially just relationships between mathematics teachers and learners

Pete Wright

University of Dundee, Dundee, United Kingdom; pwright002@dundee.ac.uk

This paper discusses the importance of relationships between teachers and learners of mathematics when considering socially just approaches to mathematics. The need to focus on relationships is justified with reference to mathematics teaching in primary and secondary school contexts. Findings from three research projects facilitated by the author are revisited through a new lens informed by relevant research literature. Three fields of educational research that relate to socially just relationships are explored: relational pedagogy, relational authority and relational agency. Insight generated through this review is used to identify implications for future research and practice.

Keywords: Social justice, relationships, teachers and learners, mathematics.

Introduction

In this paper I discuss the importance of focusing on relationships between teachers and learners when considering socially just approaches to teaching mathematics. I revisit the findings from three research projects I have facilitated, all of which involved working collaboratively with teachers in conducting participatory action research. These include the Teaching Maths for social Justice (TMSJ) project (Wright, 2017), the Visible Maths Pedagogy (VMP) project (Wright, Fejzo, & Carvalho, 2022) and the Primary Maths and Social Justice (PMSJ) project (Wright, Kelly, & Hilton, 2024). I review relevant findings from each project through a new lens, based on relationships between teachers and learners, informed by relevant theories that are presented in the paper.

The common methodological approach involved recognising the complementary expertise of the academic/teacher researchers and reflecting critically on existing practice. Teacher researchers played a key role in the research design, for example by leading the planning and evaluation of research lessons and collecting data from students (through interviews/surveys) to evaluate the impact of their actions. Data were collected from the teacher researchers through recording reflective discussions during research team meetings and interviews. Thematic analyses were carried out on the transcripts.

The three projects referred to above draw on a conceptualisation of socially just mathematics teaching that includes four essential elements:

- Employ collaborative, discursive, problem-solving, and problem-posing pedagogies which promote mathematical sense-making and the engagement of all learners with mathematics.
- Promote mathematical inquiries that resonate with learners' real-life experiences and that help them develop greater understanding of their social, cultural, political, and economic situations.
- Facilitate mathematical investigations that develop learners' individual and collective agency, enabling them to take part in future social action for the public good.
- Challenge common myths surrounding school mathematics, expose processes that lead to the marginalisation of some learners, and open up to scrutiny what it means to be successful. (Wright, 2024, p. 26)

The importance of socially just relationships

The persistent associations between students' socioeconomic status and their mathematical achievement and participation have been well documented (Boaler, Altendorf, & Kent, 2011). School mathematics continues to serve as gatekeeper qualification determining students' future access to higher paid employment and higher status further education courses. School mathematics makes a significant contribution towards what Bourdieu argues is the primary function of the school, that is to reproduce the dominance of the privileged groups within society from one generation to the next (Bourdieu, 1998). Teachers of mathematics play a key role here as, in the students' eyes, they represent the authority of the school. Bourdieu poses the following paradox for any teacher wishing to convince their students of their desire to disrupt this cycle of reproduction within their classroom:

> Either you believe I'm not lying when I tell you education is violence and my teaching is legitimate, so you can't believe me; or you believe I'm lying and my teaching is legitimate, so you still can't believe what I say when I tell you it is violence. (Bourdieu & Passeron, 1990, p. 12)

If teachers are to play a role in challenging inequity within mathematics education, then they need to question their own behaviour and actions within the classroom, and how they are perceived by students, which necessitates fundamentally reappraising the basis of their relationships with learners. They need to become more aware of the discourses they are subject to, many of which are generated by myths associated with mathematics learning, and which strongly influence their practice in the classroom. Bourdieu would argue that, since teachers of mathematics have experienced being relatively successful learners themselves, they are more inclined to accept conventional approaches to teaching mathematics as legitimate and adopt them in their own practice.

One example of a discourse that permeates the teaching profession (and society more generally) is a belief that mathematics is neutral and value free, a claim that has been discredited by critical mathematics educators (Skovsmose, 2021). A tendency to ignore the value-laden nature of mathematics means that teachers (and managers, researchers and policy makers for that matter) are more likely to neglect the importance of relationships in teaching mathematics. This has varying implications for different phases of education.

In the primary phase, at least in the context of Scotland and England with which I am familiar, one teacher normally takes responsibility for the pastoral care and wellbeing of all students in their class (who they teach for most subjects). Primary teachers therefore tend to appreciate the importance for general learning of developing supportive relationships with students based on mutual trust and respect. However, there is often a lack of appreciation of how the principles on which these relationships are built can be applied when teaching mathematics. Alienation and anxiety that many young children experience in learning mathematics can be an important factor in students becoming disengaged from the subject, particularly those from marginalised groups who tend to have less-positive dispositions towards learning. Aldridge and Gifford (2018) attribute such alienation amongst students in primary schools in England to discourses of accountability with students often being tested and assigned levels by teachers on a weekly basis. A resulting tendency to focus on closing the gap in mathematics attainment generates deficit views of learners resulting in damaging strategies such as separating low attaining children from their peers in mathematics lessons (not normally the case

in other subjects), thus denying them access to the full curriculum. Aldridge and Gifford also highlight the increasing prevalence of teaching approaches in mathematics that emphasise answer-getting, rather than sense making. Hence, cultivating positive relationships in the mathematics classroom is key for primary teachers who wish to address social justice and inequity.

In the secondary phase, those mathematics teachers who fail to recognise the value-laden nature of the subject tend to see relationships as unimportant in the mathematics classroom and are often guilty of leaving responsibility for the emotional wellbeing of students to others. In this way, negative attitudes towards the subject are reinforced and manifest themselves through disengagement and negative behaviour, resulting in sanctions that continue the downward spiral. There are other myths surrounding mathematics that damage students' learning. These include the unjustified value that is often attributed to working alone in silence, completing as many questions as possible in the shortest possible time, and avoiding errors at all costs. Whilst these are seen as desirable behaviours by many, they do not reflect what real mathematicians do or effective approaches for enabling students to develop powerful mathematical knowledge and the socio-mathematical agency they need to apply this knowledge collectively to solve real life problems (Wright, Kelly, & Hilton, 2024). Cultivating socially just relationships between mathematics teachers and learners, based on trust and empathy, is necessary if students are to engage in discussion and debate around the nature of mathematics and the best way to achieve success. This reflects the fourth essential element of socially just mathematics teaching highlighted in the Introduction.

Focusing on relationships between teachers and learners of mathematics offers a 'way in' for teachers who may be less willing to make wholesale changes to their teaching repertoire. Since changes identified through raising awareness of relationships can be enacted immediately, it is a potentially powerful strategy for extending the group of teachers who are committed to addressing issues of social justice in their practice.

Much has been written about relationships between teachers and learners in general education, although there is limited literature that relates this to socially just mathematics teaching. In the next sections, I will begin to address this by looking at three fields of educational research that relate to socially just relationships between teachers and learners of mathematics: relational pedagogy, relational authority and relational agency. For each of the three fields, I draw connections to the findings from one of the research projects by viewing the findings through a new lens focusing on relationships between teachers and learners (which was not a primary focus for any of the projects).

Relational pedagogy

Relational pedagogy involves prioritising relationships between teachers and learners over other aspects of education (Aspelin, 2014; Felten & Lambert, 2020). It is often characterised by the desire to establish a cooperative classroom ethos and democratic classroom practices, in which learners take responsibility for their own learning, and which provide opportunities for the growth of mutual trust and understanding between teachers and learners. Noddings (2013) advocates for an ethics of care within education that encourages teachers to consider the need to establish positive and compassionate relationships with students as the basis for pedagogical decisions they take. Watson (2021) expands on what this might look like in the mathematics classroom, suggesting that care in

mathematics education should involve the teacher prioritising listening to (rather than talking to) students, drawing on students' interests, experiences and ideas in developing mathematical meaning, and working alongside students on mathematical tasks.

English et al. (2023, p. 6) articulate five different types of "pedagogical listening" that teachers might engage in during students' productive struggle on open-ended tasks. These strategies, which aim to respect the contributions of learners (as human beings) rather than merely evaluating correctness, are described below. "Empathetic listening" involves the teacher suspending their own judgement of a student's response and focusing instead on what the response says about the student's feelings and how they are making sense of their own world. "Supportive listening" involves encouraging students to listen to each other's mathematical ideas and hence cultivate an inclusive classroom community. "Educative listening" involves teachers posing questions that help students to reflect on what they are struggling with so that they may better understand the nature of the problem. "Self-reflective listening" involves teachers listening carefully for unexpected responses from students that might help them better understand students' learning processes. "Generative listening" involves teachers looking for opportunities to generate new directions in a discussion that will enable better understanding to emerge.

The TMSJ research project, which I conducted with a group of five secondary mathematics teacher researchers from 2013 to 2014, focused on exploring strategies for translating theories relating to social justice into classroom practice (Wright, 2017). The following extract from Brian's (one of the teacher researchers) reflections at the end of the study demonstrates the impact of focusing on social justice in the mathematics classroom on the developing relationships between teachers and learners.

> Through this project … I have come to see the privileged role that mathematics plays in the way individuals are judged and categorized. Due to the project, I ended up discussing these features with students. We also discussed and evaluated the emotional baggage they brought with them to their mathematics lessons. This was particularly constructive with a low achieving (penultimate) set of girls who had already experienced 3 years of secondary school mathematics. Their emotions were overwhelmingly negative: anger, frustration, despair and general unhappiness. By working through these explicitly, and highlighting the pre-eminence of mathematics in society, we were able to find much common ground and thus change the atmosphere in the class. It moved from a teacher attempting to get students to do what they want (e.g, staying on track with the scheme of work), to a teacher helping students to both beat the present (education) system and to be able to engage confidently with a world where much is predicated by mathematics (tax, high paying jobs, shares, etc). A key component of my approach was also to listen a lot (to all sorts of things within and outside the maths curriculum!) and speak encouragements frequently (vital where one of the key barriers was a lack of confidence). (Brian, reflective report)

What comes across clearly is Brian's growing appreciation of the need to listen to students and engage in discussions with them about their feelings towards mathematics and the role it plays in society. This resonates with relational pedagogy's focus on prioritising relationships between teachers and learners and facilitating the development of mutual trust within the classroom.

Relational authority

The relational pedagogy outlined above resonates with Freire's (1972) dialogic approach in which the teacher (or educator) poses questions that engage learners in dialogue that helps them articulate their own perspectives, engage with developing ideas and hence develop a greater appreciation of their own real-life situations. This requires a fundamental shift in the relationship between teachers and learners that challenges conventional assumptions such as the teacher being the sole provider of knowledge. Bernstein (2000, p. 46) argues that a socially just pedagogy involves the cultivation of "personal" authority, in which teachers negotiate classroom rules with students, rather than exerting "positional" authority by resorting to their position of power as a teacher to impose rules.

Bernstein (2000, p. 26) argues that children from more privileged backgrounds are better able to interpret the rules of the game that govern success in the mathematics classroom, including how to "recognise" the mathematics within a task and how to "realise" an appropriate response. Since these rules tend to be less visible when adopting the inquiry-based pedagogies called for as part of the conceptualisation of socially just mathematics teaching highlighted earlier, some researchers have argued that they risk further disadvantaging students from marginalised groups (Lubienski, 2004; Morgan, Hordern, & Hoadley, 2019). However, rather than using this as a justification for adopting more teacher-centred pedagogies (in which the rules for achieving success are more visible), I argue that socially just mathematics teaching should involve teachers discussing and sharing their pedagogic rationale with students so that all learners, including those from marginalised groups, are better prepared to achieve success whilst engaging with inquiry-based or progressive approaches.

The VMP research project, which I conducted with two secondary teacher researchers, Tiago and Alba, from 2017 to 2019, aimed to develop strategies for helping all students to recognise the teacher's intentions when adopting progressive approaches to teaching mathematics (Wright, Fejzo, & Carvalho, 2022). The findings demonstrated how, through holding open and transparent discussions with students about their reasons for adopting particular teaching approaches, teachers can help learners to develop a greater appreciation of their pedagogic rationale and how to respond appropriately to achieve success. The following extracts from interviews with two students, Keira and Neal (both identified as belonging to relatively low socio-economic groups), show how such discussions can lead to an increased understanding of the rationale for agreeing a model solution to a problem (Keira) and for sharing solutions with other students (Neal):

> I learnt, like, more understanding of why we do, like, why we write down stuff in our book. And, like, if you do working out, and we discuss it, then we write it down. I understand why we do that more. (Keira, Interview 1)

> Like, some people could have different, like, reasons why … because, like, not everyone thinks the same. So, like, you could have your own reason, whereas someone else could have their own reason for their own solution. (Neal, Interview 1)

One of the teacher researchers, Alba, reports how students developed a greater appreciation of the strategy she adopted for identifying important information in a question, after she discussed the reasons for doing so with the whole class:

> So, I thought it was a really productive chat/conversation with the class. Like [Student B], for example, he's an EAL [speaker of English as an additional language] student, and for him to be able to say … "pick out relevant information" … one of the reasons he struggles in tests is he doesn't understand what the question's asking him, even though his maths is actually very, very good. So, for him to realise that importance is quite encouraging, to know that, OK, this could be useful to him. (Alba, Research Group Meeting 13)

Through making their pedagogy more visible to learners, the teacher researchers developed greater levels of relational authority and facilitated a more dialogic approach towards learning.

Relational agency

Student agency is often neglected in mathematics classrooms with a tendency to assume that learning mathematical procedures in an abstract way, completely disconnected from real-world problems, is sufficient to provide students with the powerful knowledge they need to become active members of society. However, Manyukhina and Wyse (2019) emphasise that powerful knowledge depends on the agency of the knower. Whilst Bernstein (2000) argues that abstract and specialised knowledge is powerful in that it enables learners to extend their horizons, Muller and Young (2019) contend that powerful knowledge also requires learners to understand 'disciplinary meaning', i.e. how new knowledge is generated within a discipline. This can only be achieved by providing mathematics learners with opportunities to consider new lines of inquiry, make conjectures, pose questions, listen to other people's ideas, consider different solutions, justify and explain their ideas (Mason, Burton, & Stacey, 1985). Such opportunities depend on teachers cultivating relationships in which learners have greater levels of agency over the direction their learning takes. Biesta (2022) warns that, in promoting learner-centred approaches, care must be taken not to lose sight of the purpose of education. He argues that the teacher's role should be to direct students' attention towards the world they live in, enabling them to develop as subjects who can understand and act upon their world.

The PMSJ research project, which I conducted with two co-researchers and six primary teacher researchers from 2021 to 2022, explored how teachers can pursue their interest in social justice through the teaching of mathematics (Wright, Kelly, & Hilton, 2024). One aspect we were particularly interested in was the development of 'socio-mathematical agency', i.e. students' ability to use mathematics effectively in arguing collectively for social change. The following extracts demonstrate how teacher researchers provided greater opportunities for students to use mathematics to explore issues of interest to them and to incorporate mathematical ideas into their arguments for change. This had a significant impact on the teachers' own views of mathematics, particularly their thinking about relationships with learners, as well as enhancing students' socio-mathematical agency.

> And I think, once you start to see the children actually grapple with these issues, and form quite well-articulated opinions … it's really important that we give them a chance to start to understand the problems, and give them a voice to say what they think. (Rose, Year 5 teacher, Interview 2)

> The activities that we did came out of things that the children were interested in at the time … and I think that particularly supports our lower attainers. And they felt like they had a bit of a choice in what we were doing. (Kate, Year 1 teacher, Interview 2)

> So, we, kind of, saw that, when they went off doing their independent task … the children had a better overview at the end and were able to feedback during the plenary, and actually give answers that had reasoning behind them, rather than just: "This is the answer and that's it." … the children have more to say about social justice, or fairness, equality, doing the maths, where it made an impact on their own lives. (Emma, Year 1 teacher, meeting 5)

The findings suggest teachers were successful in cultivating relationships with students that contributed towards generating higher levels of learner agency within the mathematics classroom.

Implications for research and practice

I have highlighted in this paper the need for a greater focus on relationships between teachers and learners of mathematics. Whilst research projects that involve addressing issues of social justice in the mathematics classroom will inevitably consider such relationships, insight generated in this area is often implicit within the findings rather than explicit. I argue therefore that participatory research into mathematics and social justice is needed that foregrounds relationships between teachers and **l**earners. Teachers should be encouraged to critically reflect on existing relationships, and their characteristics, by considering how (and the extent to which) they:

- enhance the contribution that mathematics plays to reproducing inequity
- produce or exacerbate mathematical anxiety and alienation
- promote discourses that misrepresent mathematics as individualistic and value-free
- present mathematics as primarily about answer-getting rather than sense-making

Teachers should be encouraged to identify characteristics of existing relationships that might be considered socially just, by considering how (and the extent to which) they:

- promote a cooperative classroom ethos and democratic practices
- embrace pedagogic listening and enhance dialogic teaching
- make the teacher's pedagogic rationale more visible to learners
- cultivate students' socio-mathematical agency

Through a genuine collaboration with teacher researchers, academic researchers can help identify and articulate what socially just relationships between teachers and learners of mathematics might look like in the classroom and explore strategies that might be employed for their cultivation.

Gender differences in mathematics education in prison context

Giulia De Rocco[1], Chiara Giberti[2] and Agnese Ilaria Telloni[3]

[1]Alma Mater Studiorum – University of Bologna, giulia.derocco@unibo.it

[2]University of Bergamo, Italy; [3]University of Macerata, Italy

Keywords: Gender differences, Prison context, Adult education, Inclusion.

Introduction

In recent years several studies have focused on gender differences in mathematics (Leder & Forgasz, 2008) and international standardized assessments continue to confirm that male students overperform female students in most countries (e.g. OECD, 2023). This gap is closely linked to social and cultural factors, as well as stereotypes influencing metacognitive aspects of mathematics (Leder & Forgasz, 2008), and this has a strong impact also on career choices of females. This study explores gender differences in the teaching and learning of mathematics within the prison context, a setting rarely addressed in educational research and even more in mathematics education. The prison is considered a "total institution" (Goffman, 1961), which disciplines and reshapes bodies and personalities through mechanisms of control (Foucault, 1975), significantly impacting teaching processes. The promotion of cultural and professional growth during detention is a key element in fostering social inclusion.

This work is part of the Italian national project Learning Mathematics in Prison (LeMP) which investigates the conditions and challenges of teaching mathematics within a prison setting, focusing on the insights of the teachers involved. In this preliminary study focused on gender, we will consider data coming from national reports and teachers' perspective to understand which are the peculiarities of teaching mathematics to male and female students in the prison context in Italy. Thus, our research questions are: How do mathematics teachers perceive gender difference within the school prison context? How do they perceive this difference in relation to mathematics learning?

Methods

In the first year of LeMP project four teachers from the three prisons in Italy were involved in semi-structured interviews aimed at exploring their motivations and perceived roles. Interviews were conducted in one-hour online meetings by researchers; in this poster, we focus on the part of the interview aimed at discussing observed differences among students, with a focus on gender. All interviews were audio-recorded and transcribed. The researchers carried out a thematic analysis (Braun, Clarke, 2021) of the collected data, identifying recurring patterns in the teachers' perceptions of gender biases. Excerpts concerning these differences classified and collectively discussed. The analysis was supported by ethnographic tools (Geertz, 1973), such as fieldnotes, which provided contextual depth and enriched the interpretation of findings within the complex dynamics of the prison environment.

Discussion of preliminary results and further steps

In Italy, women represent only 4.3% of the prison population, a stable percentage that renders them a marginal group often overlooked in terms of educational resources and programs. Previous

schooling, future expectations, and gender stereotypes deeply shape their learning paths. Moreover, there is lack, or near absence, of data and studies addressing gender dynamics in this specific context. In the interviews teachers report significant differences in the experience of detention between women and men.

Discussing more specifically issues related to their learning experiences, teachers observed that female students often struggle with focus, influenced by emotional labor, guilt, and family responsibilities. Female students often face psychological and emotional challenges, including depression and guilt related to family responsibilities, which can disrupt attendance and engagement (a teacher said:*"They had an intermittent frequency, because sometimes they were really depressed, so they took therapy.")*.Gender biases among teachers also emerge, as they tend to view female students as more vulnerable, underestimating their abilities (a teacher noted: "*In female sections, women are often mothers, and they suffer due to guilt about being away from their children, which makes them more vulnerable")*. Teachers noted stereotypes about women's mathematical abilities and education, often framing it as preparation for traditionally female-dominated jobs (beautician, seamstress, waitress), and in which mathematics competences are not considered as fundamental. Regarding previous education, the interviews do not provide clear data, reflecting the lack of detailed information in ministerial reports on women and education in prison. Data from interviews with other teachers will be collected next year and, to go further, and get a direct perspective on learning mathematics in prison, in order to include them in designing new educational tools.

TWG 11: Teaching and Learning of Discrete and Computational Mathematics

Thematic Working Group 11
Teaching and learning of discrete and computational mathematics

Simon Modeste[1], Sylvia van Borkulo[2], Ulrich Kortenkamp[3], Janka Medová[4], and David Zenkl[5]

This TWG was newly created for CERME 14, emerging from the encounter of the interests of a previously existing group entitled *Algorithms* (Weber et al., 2022) and a prospective group project on discrete mathematics, based on common observations on recent trends in mathematics linked with computer science.

Indeed, the development of computer science in the last decades has generated changes in the content and practices in mathematics. In particular, it has contributed to the recent emphasis and success of discrete mathematics, a classical topic in mathematics. Also, the development of computer science has led to the growth of computational approaches in mathematics, fostering applications and new ways of thinking and doing mathematics. These evolutions in mathematics, and the related needs for future generations, require and produce new content in school that our TWG intends to address. The topics covered by the TWG are taking a growing place in many current curricula around the world, and have entered into the common core of mathematics as described by international organizations like OECD. For this reason, research developments, and insights are expected by teachers, teacher educators, and policymakers.

To address these challenges at CERME 14, the TWG invited research papers that discuss empirical, theoretical, methodological, or philosophical issues pertaining to the teaching and learning of discrete and computational mathematics, including the following themes: all aspects of discrete mathematics, i.e., both classical subjects, and subjects invoking new needs for computer science like combinatorics, graph theory, discrete geometry, automata, game theory, cryptography, etc.; manipulation and representation of mathematical objects and data in computer science, simulations and discrete modelling, new computational views on classical mathematical objects, computational approaches in mathematics; links between mathematics and computer science, their foundations, concepts, ideas, and methods; algorithms in mathematics, the study and analysis of algorithms; computational thinking, and programming in mathematics; proof, proving, and problem solving in discrete and computational mathematics. Given the current curricular issues, our TWG has interest in these topics in pre-school, primary, and secondary levels, as well as studies at university level, and the implications for teacher education.

We were pleased that the 25 accepted papers and posters presented at CERME 14 covered a wide diversity of the targeted topics. We organized them following four themes.

The first theme was "Implementing Computational Thinking in mathematics", a topic gaining prominence in educational curricula across various countries (Ye et al., 2023). However, participants noted that CT is still a somewhat ambiguous concept, with overlapping definitions and differing interpretations across mathematics and computer science. While CT is often associated with computer science, its core elements, such as algorithmic thinking, problem decomposition, and debugging, have deep roots in mathematical practice. This blurring of disciplinary boundaries sparked ongoing debate throughout the conference, particularly regarding the extent to which CT should be integrated into mathematics education and how it should be differentiated from both mathematical and computer science content.

A key focus of the sessions was on practical implementations of CT in mathematics classrooms. Several presentations illustrated how CT is introduced at different educational levels using both unplugged (offline, physical) and plugged (digital, screen-based) approaches. Throughout the discussions, the interplay between CT and traditional mathematical concepts was a recurring theme. Presenters and participants explored how CT practices, such as writing and testing algorithms, using simulations, or modelling real-world problems, could deepen students' understanding of core mathematical ideas like functions, variables, and spatial reasoning.

Despite the enthusiasm for CT's potential, the conference also highlighted several challenges. A major concern was the risk of conceptual confusion, especially when overlapping terms like "variable" or "algorithm" have different meanings in mathematics and computer science contexts. Educators must also grapple with questions about sequencing: should students first engage with problem solving and then implement solutions in code, or vice versa? How to integrate CT meaningfully into existing curricula without overwhelming teachers or diluting mathematical content? There was general consensus that CT should be seen not merely as a content area but as a way of thinking and working that can enrich mathematics education when used thoughtfully and deliberately.

Finally, the conference encouraged a broader philosophical reflection on the role of CT in education, and on its conceptual consistency. There was agreement that CT offers opportunities for students to engage in hypothesis testing, error analysis, and iterative refinement, practices that align closely with mathematical reasoning. However, participants also acknowledged the need for clearer identification of the concept, curricular scaffolding, and teacher support to realize these possibilities fully.

The second theme was the "Links between mathematics and informatics". In this theme, theoretical and experimental research contributed to discussing the relation between the two disciplines. This included reflections on the place and role of algorithmic thinking or computational thinking in mathematical topics like problem solving in arithmetic, or in combinatorics (e.g. Josefus problem), or in creating algebraic expressions. The extension of problem solving models from mathematics to computer sciences was also discussed. Some papers discussed the relation between programming and mathematics, questioning in particular the way programming is integrated in mathematics textbooks, or the development of abstraction skills in programming tasks (using augmented reality). Another promising topic discussed was the potential of interactive theorem provers in mathematics education, and the design principles for

related learning environments. More generally, a paper questioned how the conceptual knowledge from computer science can enlighten some questions in mathematics education. The diversity of the contributions permitted rich discussions, both on practical and theoretical aspects regarding interrelations between computer science, programming, and mathematics.

The third and fourth themes were connected to discrete mathematics (Sandefur et al., 2022). The third theme explored the "nature and diversity of discrete mathematics", questioning specific topics like graph theory, or tiling problems, but also the way discrete mathematics can connect or is connected with other mathematical topics. The covered topics of the individual contributions were completely different.

The first topic was devoted to an analysis of the surface-level isomorphism strategy that helped students to solve the Catalan number task efficiently. Presentation of a three-step deterministic model allowing identifying proving processes and objectifying students' activity in problem solving was the second topic. The third topic covered experiences with the discovery learning method of graph theory, showing that students remember mistakes they made while proving. The last topic was devoted to the analysis of Hungarian curriculum, which has a long tradition of weaving discrete mathematics topics through the whole curriculum.

Through the general discussions, there were many questions and answers about what discrete mathematics is. When talking about the characteristics of discrete mathematics, participants mentioned the accessibility to students, the development of problem-solving skills, and its connection to computer science. This led to discussions about the reasons and interests for teaching discrete mathematics, e.g., development of the skill to organize things, needs for computer science education, development of many problem-solving skills...

The fourth theme was covered by a group of communications specifically dedicated to "combinatorics", which seems to be the most developed part of discrete mathematics in curricula in many countries. Combinatorics, very common in curricula, has been much investigated in the past, and contributions covered various questions in this area, such as students' recurrent difficulties and errors, specific strategies and approaches in combinatorics, and teaching and learning issues, including the use of programming/algorithmic skills in combinatorics.

A key tension identified throughout the sessions was between teaching efficient combinatorial formulas and fostering deeper structural understanding. Instruction that explicitly highlighted combinatorial structures greatly enhanced students' ability to transfer knowledge. Successful strategies included systematic listings, identifying bijections, and student-generated problems. We had some discussions about the term "isomorphism" in combinatorics, which presupposes the preservation of some organizational principle, rather than just a cardinal equality, but which needs to be clarified.

Research underscored differences in how students generalized numerical patterns — some naturally extended counting processes, while others depended exclusively on numeric or algebraic patterns, potentially leading to superficial generalizations. Effective strategies recommended were partial enumeration, checking smaller cases, parity verification, and algorithm-based enumerations.

The final discussion connected the two main topics in the TWG. There was a shared vision that solving a combinatorial problem is equivalent to understanding an algorithm that would enumerate

its solutions—bridging proof, pattern, and program. Enumeration problems provide a natural playground for CT practices, mainly algorithmisation and abstraction. Conversely, CT tools give combinatorics an experimental dimension; when closed formulas are unknown or unwieldy, an executable algorithm is the solution. Participants called for curricular materials that intertwine these perspectives from an early age.

Only one theme was under-represented in the TWG: the teacher education issues. In the call for papers, we explicitly asked for contributions related to teacher education, as it is essential for any innovation in curricula. For many countries, discrete and computational mathematics is an exotic subject, for others it belongs to the standard curriculum for historic reasons or traditions. In our view, it is necessary to bring these different perspectives together. However, substantial contributions that belong *both* to the area of teacher education *and* our subject matter focus area are rare. While the subject matter is being addressed in some countries, due to its novelty, these programs may not be ready for research yet. Also, if there is research related to teacher education in this area, it can easily be reported in one of the TWGs that are specific to research in teachers' professional development that have a longer tradition than our TWG, which met first at CERME 14. Nevertheless, all participants in the group agreed on the fact that there is a need for good educational programs that help teachers to exploit the full potential of this non-standard topic in mathematics teaching. So, for the upcoming CERME conferences, we will continue to offer room to discuss teachers' professional development and curricular issues, and specifically encourage this kind of contribution. It might also be worthwhile to consider a joint session with TWG18, TWG27, or TWG15 in particular. Our analysis of the contributions to CERME 14 has shown that there were contributions to these groups that could have been included in TWG11 as well.

Apart from that, we were very happy to see that in the discussion, participants, whatever their principal interest, were equally involved in our two main topics, computational mathematics and discrete mathematics. The collective discussions and work showed rich connections between discrete and computational mathematics, and confirmed that it is interesting to join and make them interact. Many perspectives are opened, and we hope that the TWG will be able to develop long-term collaborations on these "hot topics" for mathematics education.

Shut-the-Box: Fostering computational thinking through the mathematical modelling of games

Lukas Bayer[1] and Martin Bracke[1]

[1]University of Koblenz, Mathematical Institute, Koblenz, Germany; bayer@uni-koblenz

This study investigates the presence of computational thinking (CT) aspects in a mathematical modelling project with secondary school students, focusing on the game Shut-The-Box. Participant observations were conducted and relevant scenes were coded for various CT aspects. The findings reveal that multiple CT aspects emerge during the modelling process, particularly in relation to the need for simulation when addressing the game's stochastic nature. As simulations require precise formulations of problems and solutions, and Shut-The-Box facilitates easy unplugged simulation and data generation via playing the game, we suggest that such games may serve as suitable contexts for fostering CT through mathematical modelling.

Keywords: Computational thinking, mathematical modelling, simulation, mathematics education.

Introduction

The relationship between mathematics and computational thinking (CT) has been an active area of research for several years now. While the research has mostly focused on the areas of algebra and geometry, research on integrating CT into the mathematics curriculum in the area of probability and statistics is lacking (Ye et al., 2023). Seeing as most CT frameworks consider using or creating simulations in one way or the other as part of CT (Shute et al., 2017; Weintrop et al., 2016), using stochastic experiments and simulations seems to be a fitting vehicle to enrich mathematics education with computational thinking.

As CT is seen as a problem-solving process (Wing, 2010) and with the presence of modelling in existing CT frameworks (Kallia et al., 2021; Shute et al., 2017; Weintrop et al., 2016), the relationship of CT and mathematical modelling is an interesting, yet mostly unexplored area of research. Ang (2021) explored this relationship from a theoretical point of view by highlighting different mathematical modelling problems and approaches and how different aspects of CT can be found within the modelling process. Ang (2021) argues that the different aspects like abstraction or pattern recognition would normally be seen as mathematical problem solving and concluded that the use of computational tools is what differentiates CT from mathematical problem solving.

Regarding existing empiric research, Villa-Ochoa et al. (2022) observed future teachers in a bachelor's degree program during the development of mathematical modelling projects to identify aspects of CT during the process. Kar Teck et al. (2023) on the other hand investigated the development of CT through a mathematical modelling task in seven school students by combining a rating of the students CT ability on a scale from 0 to 2 with data from interviews and tests deployed before and after the modelling task.

To add to the empirical body of literature regarding CT and mathematical modelling, we investigated the aspects of CT in a mathematical modelling project with secondary school students with three different problems (Bayer et al., 2024). To highlight the connection between CT and the area of

probability, we focus solely on the group that worked on optimal strategies for the game Shut-The-Box in this paper.

Theoretical Background

The concept of computational thinking (CT) and what it encompasses is heavily discussed in the literature. An often cited definition describes CT as "the thought processes involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent" (Cuny et al., 2010, as cited in Wing, 2010, p. 1).

To further identify these cognitive processes and aspects that are connected to or needed for CT, multiple frameworks have been proposed to identify the aspects underlying CT (e.g., Weintrop et al., 2016). Following a review of such frameworks, Shute et al. (2017) developed a framework focused on the foundational understanding of CT in K-12 subjects. The framework consists of six facets of CT, namely *decomposition, algorithms, debugging, iteration* and *generalisation*. The facet of abstraction is further subdivided into the categories *data collection and analysis*, *pattern recognition* and *modelling*, while the facet of algorithms has the subcategories *algorithm design*, *parallelism*, *efficiency* and *automation*.

As CT is often seen as a skillset that is transferable to other disciplines (Shute et al., 2017), there have also been efforts to connect CT to mathematical thinking (MT) and integrate CT into mathematics education. Kallia et al. (2021) considered both CT and MT as problem-solving processes as *contextualisation activities*, that is, the connection of real-world contexts to mathematical and computational concepts. They identified four distinct cognitive activities in this process: (1) translating from a context into a model, (2) working within the model, (3) translating the result from the model back into the context and (4) verifying that the solution solves the problem. This is depicted in Figure 1.

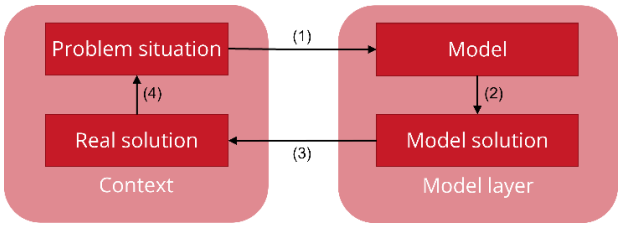

Figure 1: Contextualisation activities with the model layer being of either mathematical or computational nature. Adapted from Kallia et al. (2021).

Kallia et al. (2021) considered the integration of CT in mathematics education by viewing it as using mathematics as a context for CT. The combination of the two processes resulted in the process modell, that is depicted in Figure 2. While the model in Figure 1 for MT as a contextualisation activity is similar to different mathematical modelling cycles (e.g., Blum & Leiß, 2007), the model in Figure 2 is structurally similar to the mathematical modelling cycle under the influence of digital tools with added computer model proposed by Greefrath (2011).

Following a literature-informed Delphi study, Kallia et al. (2021) furthermore identified multiple aspects of CT present in mathematics courses, namely *data analysis*, *data representation*, *abstraction*,

decomposition, *algorithmic thinking*, *pattern recognition*, *automation*, *modelling*, *generalisation* and *evaluation*. Those aspects mostly coincide with the facets identified by Shute et al. (2017).

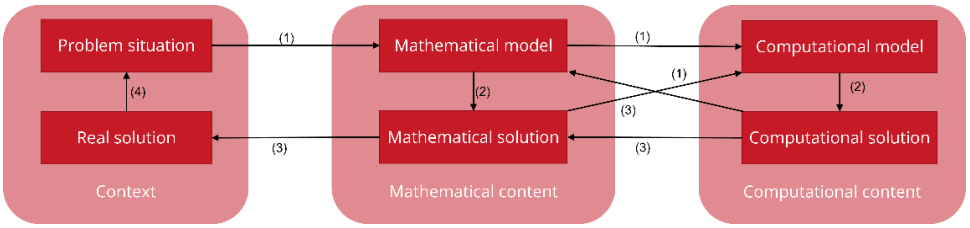

Figure 2: CT in the context of mathematical thinking. Adapted from Kallia et al. (2021).

Methods

Since mathematical modelling and CT both describe problem solving processes and, regarding the cycles of Greefrath (2011) and Kallia et al. (2021), follow similar steps, we looked at common aspects of CT during mathematical modelling activities of secondary school students in a larger study reported in Bayer et al. (2024). For this paper we want to take a closer look at one of the modelling projects – Shut-The-Box – and the possible implications of the stochastic nature of the game for the interplay of CT and mathematical modelling. The research question for this paper is therefore given as: *What aspects of CT are present in the mathematical modelling of the game Shut-The-Box with secondary school students and how do those relate to the stochastic nature of the game?*

As outlined in Bayer et al. (2024), we observed mathematical modelling activities during a modelling project with fourteen students from grade 9 to 11 at a secondary school in Germany, which was part of a project week at the school. The modelling project was offered by a teacher supported by two researchers and a trainee teacher as supervisors. The groups worked for four days on their respective projects and presented the results on the fifth day during a school festival.

The observed group consisted of four male students, with one from grade 11, one from grade 10 and two from grade 9. Their modelling problem was to find an optimal strategy to play the boardgame Shut-The-Box. In the version the students investigated, there are ten tiles numbered from 1 to 10. The player rolls two six-sided dice and adds the numbers together. The player then flips any number of the remaining tiles (a combination of tiles or a single one), whose sum matches that of the dice. The game ends, when no tiles can be flipped to match the rolled sum. For multiple players different evaluation schemes can be applied to determine the winner, for example, adding the remaining tiles as penalty points and trying to score as low as possible or playing as many rounds as possible.

The modelling activity of the group was observed by one of the researchers and relevant scenes were summarized descriptively into an observation protocol. The protocol was than analysed using a deductive qualitative content analysis approach based on Mayring (2014) and coded by three researchers for emerging or underlying CT aspects.

The codes were based on the aspects and cognitive activities given by Kallia et al. (2021): *data analysis*, *data representation*, *abstraction*, *decomposition*, *algorithmic thinking*, *pattern recognition*, *automation*, *modelling*, *generalisation*, and *evaluation*. Following a first scan through the material of all three groups of the modelling project, the codes *debugging* and *data collection* were added, which

are also present in the facets of Shute et al. (2017). As Kallia et al. (2021) didn't define their aspects, the codes are mostly based on the understanding of Shute et al. (2017) of those aspects with two exceptions: *modelling* and *generalisation*. As the activity itself was a modelling activity, the aspect of modelling was heavily discussed between the researchers as this aspect seemed to be present in most of the scenes due to modelling being a complex process itself. Thus, we applied a similar constraint as Villa-Ochoa et al. (2022) and modelling refers only to the formulation of a (mathematical or computational) model, such as a simulation, in our coding scheme.

Shute et al. (2017) understand generalisation as the ability to transfer CT skills to other domains. For this research however, we understand generalisation as a way of generalising from special cases to the general problem and generalising solutions to be transferable to other problems and contexts.

We also looked for occurrences of the main idea of CT as given by Cuny et al. (2010, as cited in Wing, 2010), that is, scenes, where the formulation of a problem or solution with an external agent in mind could be observed and coded them respectively.

Results

The group began by playing the game to explore the context and came up with a draft for four initial strategies, that they considered to be advantageous. Each of the four students adopted one of them to play against each other. If a student can't follow his rule, even if there would be a legal move left, he loses. The strategies of the students were the following:

1. Student A can only flip combinations of tiles, for example, if an 8 is rolled, only 3 and 5 or 1,3,4 can be flipped, but not 8 itself.
2. Student B can only flip a single tile, that is, the tile with the sum as number.
3. Student C tries to keep the lowest tiles (1,2,3) as long as possible.
4. Student D alternates between using combinations of tiles and flipping over a single tile

Over the course of ten games, they noted for each strategy how many rounds they could play and then played another ten games to note the sum of remaining tiles for each strategy, revealing that they had not chosen an evaluation scheme for multiple players yet. According to this data, student B could play the most rounds on average, while student D had the lowest mean sum of remaining tiles. They chose the strategy of the latter as their candidate for an optimal strategy and played a single round with that strategy against the teacher. They lost that round and deemed the strategy to be not optimal. The teacher reminded them that a single game might not be good evidence to discard their strategy.

While the formulation of the strategies can be seen as formulations of *algorithms*, the students also *collected data* on the strategies by playing multiple rounds and then *analysed the data* for picking a favourable strategy. They *evaluated* the chosen strategy in the real context against an opponent with an unknown strategy, albeit that they used only one game to declare that their strategy is not optimal. This could also hint to a missing understanding of the underlying randomness of testing a strategy.

A fifth strategy was then developed by the students around the "usefulness" of each tile. It couldn't be observed if this strategy was already based on the calculations of probabilities or a result of the experience of playing the game. In any case, CT is present here in the form of *pattern recognition* as

they either analysed the structure of the probability distribution to identify less used tiles in combinations or recognized the "flexibility" of some numbers during play. This fifth strategy revolves around trying to flip the tiles 10, 9 and 8 as soon as possible and keeping the tiles 2,3,4,5 as long as possible resulting in a weighting for possible combinations.

While evaluating this strategy against the trainee teacher, the student playing the game was told by a second student which tiles to flip after each dice roll based on the strategy. This can be seen as a form of CT in terms of the definition by Cuny et al. (2010, as cited in Wing, 2010) with the playing student as the *external agent*, who is guided by the second student step-by-step through the strategy.

After input from the trainee teacher, the group started working on a tree diagram to analyse the optimal choice for each role. Their goal was to play as long as possible, that is, taking as many turns as possible and they approached the problem in the fashion of a greedy algorithm. The first dice roll was used to calculate the probability of losing with the next roll, for example, rolling a 3 first, flipping the tiles 1 and 2 and then rolling a 2 would result in a loss. The combination of tiles with the least probability to lose with the next roll was considered optimal and can be seen in Table 1.

Table 1: Optimal choices for the first round in Shut-The-Box

Dice Roll	2	3	4	5	6	7	8	9	10	11	12
Optimal Choice	2	3	4	5	6	7	8	9	10	1+10	5+7

They continued this scheme for the second round and calculated the loss probabilities for each combination of possible optimal choices in the first round and dice rolls in the second, which resulted in the strategy described in the matrix in Figure 3. The first number in the row lists the dice roll in the first round followed by the optimal choices of tiles to flip sorted by possible rolls in the first round. For example, rolling a 2 in the first round and rolling a 12 in the second round would result in flipping the tiles 9 and 3 as an optimal choice.

The students and the trainee teacher discussed if it would be plausible to calculate the third round, but after a short consideration, they decided that after the first two turns they would recede to one of the heuristic strategies identified earlier, namely the strategy of preferably flipping the less used tiles while holding on to the important tiles, that is, those used in more combinations.

Possible strategies for evaluation were discussed by the students with one of the researchers, who suggested to use a random number generator (RNG) to model the random opponent's behaviour. The trainee teacher wrote down all possible tile combinations for all possible dice rolls for the students. The students then simulated a random opponent by using a RNG via smartphone and this list of possible combinations to determine a random flip of tiles. They played 100 games against this simulated random opponent and won 80 games with their strategy.

The process of developing their final strategy addresses many different CT aspects. The most prominent one being *decomposition*, as the students develop their strategy by first looking at only the first round of the game. Ignoring non-optimal combinations for later rounds can be seen as a form of

abstraction, as this reduces the complexity of the calculations by ignoring certain paths in the probability tree. Finally, they *evaluated* the optimality of their strategy against a random opponent. The random opponent was defined by a RNG and list of possible combinations for each turn and can be viewed as an unplugged computational *model* as the behaviour of the random opponent was precisely defined, which would make later automation possible.

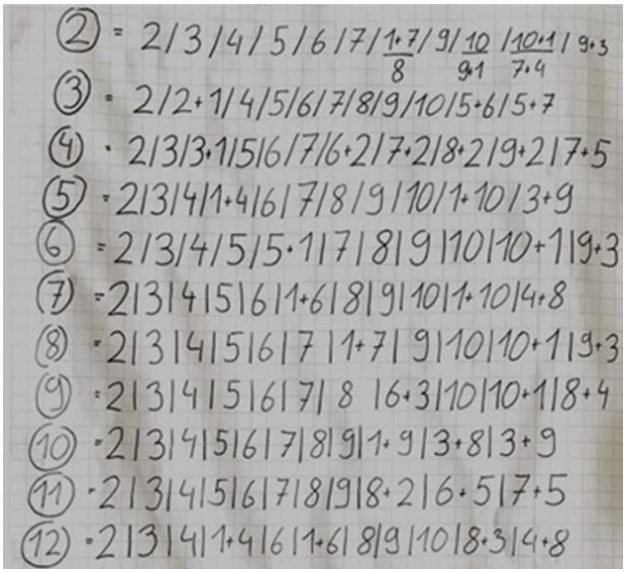

Figure 3: Optimal choices for the second round of Shut-The-Box.

Discussion and Conclusions

Regarding the presence of CT aspects when modelling the game Shut-The-Box, the results show that the CT aspects *data collection, data analysis, pattern recognition, abstraction, decomposition, algorithms* and *evaluation* were present in the modelling project. CT in the sense of Cuny et al. (2010, as cited in Wing, 2010) was also identified when designing a random opponent or evaluating the fifth strategy.

Comparing this to the considerations of Ang (2021), the game requires to work "from processes to model". Problems requiring this approach are described by multiple processes or in the sense of Shut-The-Box by game rules. Ang (2021) suggests, that constructing a simulation can help solving such problems as they allow for an exploration of the context to get a better understanding of the problem. Simulations can also help to discover patterns as a basis for possible solutions and allows to evaluate solutions by simulating the problem multiple times and applying the law of large numbers to get approximate probabilities.

Although the students didn't construct a simulation of the game (for example by implementing it as a program), them playing the game allowed for the same exploration phase to get a better understanding of the problem and collecting data to discover patterns. They also played multiple times to evaluate solutions in the sense of approximating win rates. This becomes especially evident when they evaluated their final strategy by simulating a random opponent and playing the game a hundred times. We argue that this practice of experimentation is a preliminary step towards Monte-

Carlo simulations and thus simulating the game itself. As mentioned, the group still used simulation to model a random opponent by using a random number generator and a list of feasible plays each turn, although this was partly suggested by one of the researchers. In essence, their approach as well as the observed CT aspects overlap with Ang's considerations for a "from processes to model" approach. While Ang (2021) sees the main difference between mathematical problem solving and CT in the usage of digital tools, we present an opposing view. We argue that the essence of CT is the definition given by Cuny et al. (2010, as cited in Wing, 2010) and that digital tools merely allow for an external agent that doesn't interpret the "input" using context knowledge. In contrast to the research of Villa-Ochoa et al. (2022), this project was not conducted with a focus on the application of digital tools. Besides the usage of calculators for the probabilities and a random number generator for the evaluation of the strategy, the group worked completely unplugged while still showing signs of CT in the sense of Cuny et al. (2010, as cited in Wing, 2010). This indicates that games like Shut-The-Box, or more generally problems that lend themselves to a "from processes to model" approach (Ang, 2021), are applicable contexts to address CT in mathematical modelling projects.

Besides the connection of the evaluation strategy of the group and Monte-Carlo-Simulations, , the possibility (and potential need) for collecting and analysing data and constructing a simulation in a stochastic context like Shut-The-Box presents a chance to foster CT in the area of probability and for CT to support students in dealing with similar problems. The usage of simulations encompasses the essence of CT in such problems, as it is necessary to formulate the problem itself but also the solution for evaluation in a way that it can be systematically carried out multiple types. The students lacked a clear, "implementation-ready" definition of their heuristic strategy for turns three and forward, but their experimentation practices and the definition of the random opponent can be seen as preliminary steps towards simulations of the game.

Games like Shut-The-Box allow for a low thresh-hold experience without need for digital tools as experimenting and collecting data is done by playing the game itself and formulating strategies for the players. The stochastic nature of the game carries a need for data collection and analysis to recognise patterns for finding strategies or to evaluate strategies. To apply the law of large numbers for evaluation of strategies, those strategies have to be formulated in such a way that players can precisely execute them over and over again. Therefore, such games also offer a high ceiling by providing motivation for simulating and automating the game and the solution.

We aimed to provide further empirical insight on the relationship between mathematical modelling and CT with a focus on stochastic contexts. The results of this paper however are limited to the observations of a single modelling project. Further research should identify how mathematical modelling can be used to foster CT and how a focus on CT might influence the modelling process. Furthermore, future research should also focus on the simulations of stochastic problems in the classroom as a vehicle for CT in mathematics education.

Arrow cards as representation when programming educational robots – Algorithmitizing as an interplay between encoding and decoding

Carina Büscher[1]

[1]University of Cologne, Germany; carina.buescher@uni-koeln.de

Programming educational robots in primary school is one way to promote computational thinking (CT) from an early age. One of the central CT activities is algorithmitizing, i.e., creating a step-by-step sequence of elementary instructions to solve a problem, in this case to navigate the robot. This paper presents the results of a design research study investigating how arrow cards, as a representation of the elementary instructions, can support algorithmitizing in the context of educational robots. The empirical results indicate that when using arrow cards, algorithmitizing consists of an interplay of encoding and decoding elementary instructions. The change of presentation to the arrow cards can, on the one hand, demand more precision but, on the other hand, also pose challenges. Implications for teaching practice are discussed, and an outlook on ongoing follow-up studies is provided.

Keywords: Educational robots, computational thinking, programming, primary school, design research.

Introduction

Computational thinking (CT) is "the thought processes involved in formulating a problem and expressing its solution(s) in such a way that a computer – human or machine – can effectively carry out" (Wing, 2017, p. 8). Wing (2017) states that CT is an essential skill in the 21st century, on par with reading, writing, and arithmetic. Hence, CT is increasingly considered as an important learning content in school that should be learned as early as possible, including in maths lessons (Wang et al., 2022).

One way to foster CT in primary schools is through programming educational robots. The term CT originally goes back to Papert (1980), who first used the term CT in the context of programming educational robots. He developed the programming language LOGO in order to enhance mathematical learning, enabling learners to explore abstract mathematical concepts through programming. Recent approaches adapt Papert's ideas by programming educational robots for navigating paths to be followed, which requires algorithmitizing the intended motion sequences (del Olmo-Muñoz et al., 2024; Seckel et al., 2023).

In a design research project, a teaching-learning arrangement was developed in which the process of algorithmitizing was to be supported by planning the path with arrow cards (Figure 1). The arrow cards symbolize the possible buttons of the used robot, in particular forward and backward movements of 15 cm, as well as left and right turns of 90°. Arranging the sequence of elementary instructions with the arrow cards can be seen as a representation of the algorithm. This article is dedicated to understanding how the algorithmitizing processes – initiated by using this representation – proceed and the implications for instructional support.

Theoretical background

Algorithmitizing as one CT-activity

Computational thinking generally describes a way of thinking that allows a problem to be described in a way that a computer could solve it (Wing, 2017). Various conceptualizations exist regarding the components of CT (Selby & Woollard, 2013). This paper distinguishes between the following CT activities and differentiates them more precisely in the context of programming plane figures:

- "Reusing and Modifying: Reuse and modify existing code as needed
- Decomposing: Decompose a problem into subproblems
- Testing and evaluating: Testing and targeted adaptation
- Algorithmitizing: Plan a step-by-step approach
- Abstracting: See general properties in special cases
- Generalizing: Inferring a common aspect from different special cases" (Büscher, 2025, p. 368)

This paper focuses on the CT-activity of algorithmitizing. In the context of educational robots, this means creating a sequence of elementary instructions for navigation along a specified path.

Potentials of educational robots in mathematics education

Some studies deal with the question of how the use of educational robots can promote computational teaching. Seckel et al. (2023) conducted a systematic literature review of 25 articles to provide didactic orientations for integrating CT into mathematics lessons using educational robots (such as the Blue-Bot). Among other orientations, they recommend that tasks involving educational robots should establish clear connections to the mathematical content and to be adaptive to the learners' needs. This raises the need for further research on possible pathways and obstacles of learners' ways of algorithmitizing, enabling teachers to effectively respond to the learners. Hong (2023) also conducts a literature review to investigate the overall effect of educational robots on learners' computational thinking. In the study, Hong (2023) analysed 27 experimental and quasi-experimental research papers from the last decade. One result is that educational robots have a significant positive effect on learners' computational thinking development, with the most significant effect at the early childhood level. This speaks in favour of using educational robots as early as possible.

Other studies delve deeper into how the use of educational robots can affect the teaching and learning of mathematics. Francis et al. (2022) found in an intervention study that learners' spatial reasoning improved after participating in a robotics-based intervention. Forsström & Kaufmann (2018, p. 18) show in their literature review that "including programming in mathematics education could improve student motivation to learn mathematics and improve student performance in mathematics". Del Olmo-Muñoz et al. (2024) conducted a mixed-methods study to investigate metacognitive control in learners' problem-solving processes when programming educational robots. Learners were asked to navigate to one of two targets, with the closer target being more difficult to reach because more turns were required. The results of the qualitative sub-study with 82 learners show that younger learners do not base their decisions on the difficulty of the task. In particular, limitations in the learners' ability to express themselves could be observed here. In the subsequent quantitative sub-study, 117 learners

worked with a floor-robot simulator. Their results show the learners' need for metacognitive ability when choosing which path an educational robot should take.

The conditions under which educational robots effectively yield beneficial outcomes remain an open question. Among other things, the development of suitable teaching-learning arrangements as well as more precise empirical insights are needed into how exactly the use of educational robots can promote computational thinking among learners. This article is therefore concerned with a qualitative investigation of initiated computational thinking at the micro level and investigates the following research question: How can a teaching-learning arrangement support learners' activities of algorithmitizing and what are possible learning pathways and obstacles for learners?

Method

The results presented here come from a larger design research project. The aim of the project is (1) to develop a teaching-learning arrangement to promote computational thinking and spatial reasoning using educational robots and (2) to identify typical learning pathways and hurdles as well as conditions for success of the design principles used. Therefore, the project uses a design research approach with a focus on learning processes (Prediger et al, 2015). This article focuses on the applied design principle "using arrow cards to represent the algorithm" and analyses the initiated learning processes with regard to learners' algorithmitizing.

So far, 12 learners (grade 1 and 2) have taken part in design experiments in teams of two. Each team participated in two sessions with a duration of 45 minutes each. No learning robots were previously introduced in the classroom. But some participating learners had previously attended a workshop. The design experiments took place during school. They were videotaped and fully transcribed. The qualitative data analysis was carried out in an approach based on grounded theory (Glaser & Strauss, 2017) to identify ways how learners use the representation when algorithmitizing.

Design

One aim of the teaching-learning arrangement was to promote algorithmitizing in the context of educational robots. Specifically, the learners' task was to create a sequence of elementary instructions to make the robot move along a given path. The robot could be programmed by the learners by subsequently pressing the buttons for moving or turning. The whole sequence of moving and turning could then be executed by pressing the start button. This can be challenging to the learners, because there is a risk of steps being forgotten. It is also more difficult to modify the algorithm if an error occurs because the algorithm is not recorded anywhere. Therefore, one design principle on which the conception of the teaching-learning arrangement was based is "using arrow cards to represent the algorithm" to support algorithmitizing. The idea behind this design principle was to fix the sequence of elementary instructions and thus make them accessible for later modification. It was also intended to reduce the complexity of the programming process, as the planning of the path was decoupled from the implementation on the robot.

One task in the teaching-learning arrangement was to move the robot along the specified path to the target field (Figure 1). The labelling of the fields with A-E (rows) and 1-5 (columns) was only added for this article in order to be able to describe the children's gestures in a comprehensible way. During

the survey, the fields were not labelled for the children. In accordance with the design principle described above, the first step was to lay out the sequence of movements using the arrow cards (Figure 1). Only in the second step were they to transfer the planned route to the robot. If an error occurs somewhere and the robot leaves the path during execution, the learners were encouraged to find the error location and modify the algorithm laid out with arrow cards. This is repeated until the learners arrive at a correct algorithm and the robot moves as desired after execution.

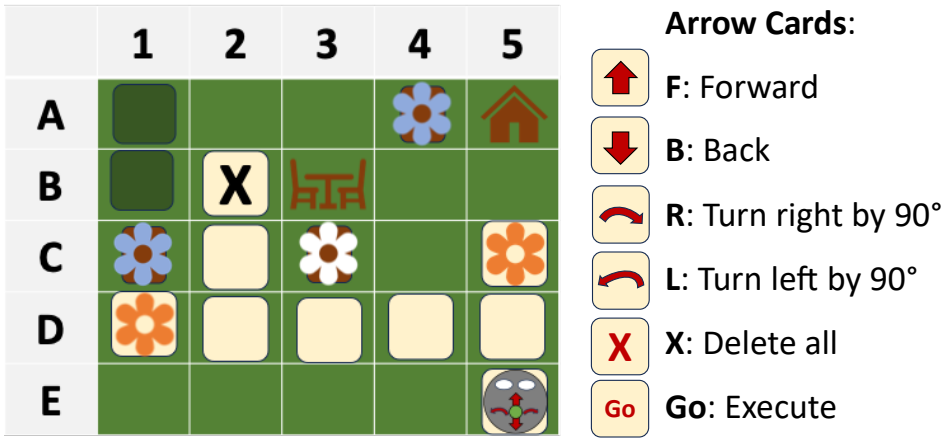

Figure 1: Reconstruction of the map with robot and path (left) and cards (right)

Empirical insights: interplay of encoding and decoding arrow cards

The empirical analysis revealed two main ways how learners used the representation of arrow cards for the algorithm: *encoding* and *decoding*. While *encoding*, the learners lay out a sequence of arrow cards in order to represent a possible programmed pathway. Errors can occur here, and the encoded pathway does not always match the intended pathway. While *decoding*, learners translate a pathway encoded through arrow cards into a movement sequence of the robot. The learners' processes of algorithmitizing consisted of frequent changes between these two ways of using representations.

In this paper, the exemplary case of Elena and Malte is presented to illustrate the possible complexity of an algorithmitizing process when the arrow cards are used as a further representation. Elena had no previous experience with educational robots. Malte had attended a workshop in a different context. The transcripts are a literal translation from German ('#' indicates an interruption).

201 Elena: Forward once. [points to D5]
202 Malte: [picks up F-card]
203 Teacher: Exactly, # lay the cards over there, where Elena is sitting. [M. lays card]
204 Elena: # Left. [takes L-card; lays it left to the F-card] then left. [points to D4] then forward [points to D3]

Encoded pathway: L, F

In Turn 201, Elena suggests „forward once" and points to the field D5. She uses it to describe the route to be taken and points to the target position of the planned movement. Malte then picks up a F-card (Turn 202) and places it in front of Elena on the teacher's instructions (Turn 203). Elena says "left" and takes an L-card. She places it to the left of the F-card, presumably because that is the

direction in which the robot should move from her perspective. Up to this point, *encoding* has been the main feature, as they describe the route to be taken and try to express this through the cards.

205 Malte: And then again [picks up a F-card and wants to lay it right to the other cards].
206 Elena: No, here. # [points to the left side of the cards laid]
207 Malte: # Then it's here and then it turns like this. [imitates the robot's movements on the garden mat with hands; one field forward, then turn 90 degrees to the left] [Elena switches the order of the cards laid]
208 Elena: Wait, delete first. [picks up Delete-card and lays it at the beginning]
209 Teacher: [smirks]
210 Malte: And then it goes forward like this [moves the robot one field forward]
Encoded pathway: X, F, L, F

Here you can first see the disagreement as to where the next forward card should be placed. Malte is in favor of placing the card on the right (Turn 205), Elena on the left (Turn 206). This shows an obstacle when *encoding*, because the learners disagree on whether the cards should be placed from right to left or left to right. Malte then describes the path laid out so far, clearly indicating the robot's position and its subsequent movements according to the cards. He therefore *decodes* the cards that have been laid so far. He does this partly verbally and partly through gestures by simulating the movement on the mat with his hand (Turn 207). Elena then swaps the two cards into the correct order. Malte then places another F-card and manually moves the BlueBot one field forward accordingly (Turn 210). Both the *decoding* of the path taken so far and the subsequent *encoding* of the next step are therefore supported by gestures for visualization or by manual movement of the robot. In order to focus more on spatial reasoning, the teacher asks them to avoid moving the robot manually (Turn 211).

211 Teacher: Try doing this without moving it. [Puts robot back to the beginning.]
212 Malte: [acknowledges].
213 Elena: So, [points to the fields D5, D4, D3 and remains at D3] Then we need forward once again.
214 Malte: [picks up a F-card]
215 Elena: So, so, so, so [brushes her finger across fields E5, D5, D4, D3, D2]; Yes, this forward. [adds F-card from Malte] . [points to C2] Then [3 sec] right, I think. No, left.
Encoded pathway: X, F, L, F, F

Elena taps on the fields D5, D4, D3 one after the other, presumably mentally retracing the path she has already taken with the cards. This would be a new *decoding* of the cards laid so far. However, she then seems to interpret the L-card as a movement to the left, which reveals a possible misconception during decoding. Upon reaching D3, she realizes that another forward movement is needed (Turn 213). Malte picks up a F-card (Turn 214), but says nothing. However, the card still indicates *encoding* for the next step. Elena runs her finger along the path again, field by field, and comments on each step, saying “so” (Turn 215), until she reaches D2. She seems to see this as confirmation that another forward movement is necessary, as she takes Malte's F-card, and adds it to the sequence (Turn 215). Again, this illustrates the connection between *decoding* the previous planned path and then *encoding* the next step. However, the misconception that the L-card is also associated with a movement from D5 to D4 seems to persist. She then taps on C2, which in her opinion is probably the next field to be reached, and initially says: “then right”, but also indicates

uncertainty with “I think”. And then corrects to “no, left”, but does not explain this further (Turn 215). This shows difficulties when *encoding*.

Malte then uses gestures again to *decode* the cards laid so far and to visualize the associated movements:

216 Malte: Like this, [imitates forward movement of robot over garden mat with hand] then he turns like this [turns hand 90° on the spot] and then once forward [points to D4] then again [points to D3] then he has to go forward again. [takes a new F-card and wants to place it] #
217 Elena: # [holds hand over D2] it is like this, isn’t it. No, right [rejects F- card from Malte, reaches for a R-card and puts it on] It goes like this.
218 Malte: [puts F-card back]
219 Teacher: Wait, Malte, you have to talk to each other. Look, Malte just wanted to put another forward. You didn't want that, Elena?
220 Elena: [makes forward movement with hand over path on the map and lands on the left red flower] He then walks over the flowers like this.
221 Teacher: He then walks over the flowers?
222 Elena: Yes.
223 Malte: No. #
224 Elena: # It stands like this [points to D2 and makes a turning movement to the right] # then it turns around and then it can go forward [lands with hand on target field]

Encoded pathway: X, F, L, F, F, R

Malte (correctly) assumes that the robot is still on D3 according to the cards laid so far (Turn 216). Here, he decodes the path laid so far by describing the movements verbally on the one hand and visualizing them with gestures on the other (Turn 216). Based on this, he realizes that the robot then has to “go forward again” and picks up a F-card (Turn 216). Elena is of the opinion that the robot is already on D2 based on the cards played so far (Turns 217, 220, 224). Thus, they disagree on *decoding* the path laid so far. In Elena's case, this could possibly be due to the misconception that the L-card already includes a forward movement. The different *decoding* then leads to them having different suggestions when *encoding* the next step. In this interplay of *decoding* and *encoding*, both use gestures to visualize the intended movements.

225 Malte: # So, when he moves forward like this [makes a movement with his hand over the garden mat from E5 to D5] then he turns around like this [shows 90 degrees turn to the left on D5] then once forwards [shows forward movement on D4] and then again [shows forward movement on D3].
226 Elena: This is that. [points to two laid F-cards] And then remains [hand on D2; puts away R-card]
227 Teacher: Does it then stand, does it stand after the, after the second forward here? [points to D2] or here? [points to D3]
228 Elena: There [points to D3] then forward [points to the F-card] and then this one [points to D2 and then points to R-card in her hand]
229 Teacher: So three times forward? [Malte adds F-card]
230 Elena: Yes. [places R-card at the end]
(As the process continues, they also add two missing F-cards and Go-card at the end)

Encoded pathway: X, F, L, F, F, F, R, F, F, Go

Here Elena seems to find Malte's visualization convincing, she corrects her assessment and is now also of the opinion that another F-card is necessary. However, it remains unclear whether she was

only persuaded by the situation or whether the cause was really clarified (that a turn movement is not also a forward movement). At least this has not yet been explicitly clarified.

Discussion and Conclusion

Educational robots can be an effective tool for fostering computational thinking at an early stage in primary school (Hong, 2023; Papert, 1980). Such programming activities can also improve students' mathematical performance (Forsström & Kaufmann, 2018). However, more detailed insights are needed into how computational thinking can be effectively supported and how learning processes actually take place in the context of educational robots.

A larger design research project is therefore investigating, among other things, which design principles can be used to develop a teaching-learning arrangement that specifically promotes computational thinking, and how the learning processes initiated in this way proceed. The aim is to further develop the teaching-learning arrangement for classroom practice and to gain deeper insights into typical learning processes and obstacles.

This article focused on the design principle of 'using arrow cards to represent the algorithm' to promote algorithmitizing in the context of educational robots and examined the learning processes initiated. In this context, algorithmitizing primarily refers to creating a step-by-step sequence of elementary instructions to navigate the robot along a given path.

The empirical results show that learners do not simply plan the route once in advance, then encode it with arrow cards, and finally transfer it to the educational robot. Instead, there appears to be a complex interplay between *encoding* the next planned step or steps and then *decoding* the previously planned path to reorient themselves spatially before (re-)encoding the subsequent steps. Overall, arrow cards, as a representation of the algorithm, seem to support the algorithmitizing process to a certain extent because the algorithm can be visualised with it.

However, it has also been shown that difficulties in correctly interpreting elementary instructions can arise during both encoding and decoding. One possible misunderstanding seems to be that an L-card also means a further step forward. In the future, it will be worthwhile to conduct a more detailed inventory so that teachers can be made aware of the difficulties that may arise. Other learners also showed a similar interplay between coding and decoding, along with the associated potentials and difficulties. This should be investigated in more detail in follow-up studies.

Studies already point to the potential of using educational robots to support mathematical learning (Francis et al., 2022). Although this was not the focus of this paper, there is still some potential for using arrow cards as a presentation to evoke spatial orientation. The processes of encoding and decoding seem to require spatial orientation, which can, in turn, present certain challenges. The empirical examples shown here illustrate that learners use many gestures, which seems to support both encoding and decoding. This could point to the embodied nature of mathematics learning (Núñez et al., 1999), which could provide a useful perspective for understanding learning processes with educational robots. The possibilities and limitations of using educational robots should also be examined more closely in this regard in the future.

Algorithmic thinking in problem solving between Mathematics and Computer Science: a case study in modular arithmetic

Marta Crippa[1], Laura Branchetti[1], Violetta Lonati[1] and Luca Lamanna[1]

[1]University of Milan (Statale), Italy; marta.crippa2@studenti.unimi.it

Using modular arithmetic as a case study, this research aims to explore, with an interdisciplinary view between Mathematics and Informatics, the ways in which students use algorithms, strategies and heuristics in problem solving activities. In particular, an analytical tool has been developed to analyse the different approaches used by students when confronted with a task at the boundary between Mathematics and Informatics. Our work has provided insights on how such a tool allows a possible characterisation of different problem solving approaches, which may be more oriented towards Mathematics or closer to Informatics, and could be a useful tool in the analysis of tasks to be proposed to students, in order to highlight the characteristics considered useful for the development of algorithmic thinking.

Keywords: Algorithmic thinking, interdisciplinarity, modular arithmetic.

Introduction

When considering Mathematics and Informatics (or Computer Science), we are dealing with two disciplines whose development followed different historical paths. On one hand, Mathematics developed over the past centuries, building upon practical needs before aiming at providing a generalisation of such issues. On the other hand, Informatics is a relatively young discipline that has become more and more relevant in nowadays life. Both disciplines, however, in their history, generated a debate about their philosophical and epistemological framing, giving rise to different points of view (Tall, 2002; Eden, 2007). Looking at the two disciplines' forms of thought we observe how literature of research provides different characterizations of the so called 'mathematical thinking' - MT - (e.g., Schoenfeld, 1992) and 'computational thinking' - CT - (e.g., Wing, 2006) as typical forms of thinking of each one of the disciplines but, in both cases, without reaching an unambiguous and agreed definition. However, nowadays, the two expressions are recognized by the scientific community together with their relevance in education (OECD, 2023). For what concerns the specific case of computational thinking, in spite of this international and widely shared recognition as a key form of thought, there still is an ongoing debate on how to teach it in school: on the one hand, computer scientists seek Informatics as a discipline that should have an autonomous role within school curriculum (e.g., Caspersen et al., 2019). On the other hand, scholars with different backgrounds (e.g., Li et al., 2020), consider that computational thinking should be included within the broader set of STEM disciplines already provided for in school curricula (e.g., Mathematics) spreading it with an interdisciplinary approach. In this frame, literature shows how the two forms of thinking are not disjoint, with different contributions studying the interrelations between Mathematics and Informatics (Kallia et al., 2021) and, more in depth, between mathematical thinking and computational thinking highlighting how, for instance, the activity of resolution of problems represents a common ground between the two disciplines (Kallia et al., 2021).

With a specific focus on the latter, in this paper we would like to reflect on the concepts of algorithm (Korfhage, 2003), strategy and heuristic (Schoenfeld, 1985) and explore the ways in which they are involved in problem solving activities that straddle the boundary between Mathematics and Informatics. These concepts intersect the boundary between the two disciplines and are intrinsically linked to a form of thinking, so-called algorithmic thinking - AT - in the sense proposed by Futschek (2006) - which in turn straddles the concept of mathematical thinking and computational thinking, being part of both (Stephens, 2018). Due to the links that these topics have with the two disciplines, we propose to adopt an interdisciplinary perspective between Mathematics and Informatics, i.e., we want to adopt an approach that enhances the viewpoints of the two disciplines and, at the same time, compares them, highlighting their points of contact and, possibly, those of divergence. In this sense, in order to frame our work and valorise the elements typical of each discipline and those common to both, we refer to the concepts of boundary objects, boundary crossings (Akkerman & Bakker, 2011) and the family resemblance approach (Erduran & Dagher, 2014), which combine the need to highlight disciplinary identities with the need to cross the boundaries between them (Satanassi et al., 2023). In particular, in this paper we will take an interdisciplinary look at the process of problem solving in the case of a course in modular arithmetic, with the aim of investigating the ways in which students use algorithms, strategies and heuristics, and observing whether and how different uses may refer to approaches that are specific to Mathematics or to Informatics. The chosen topic lends itself to an interdisciplinary approach and, in particular, by delving into its applications with students, it is possible to work on problem-situations on the border between two different disciplines therefore stimulating students to design, apply and describe different solving procedures.

Theoretical framework

To frame our work, we took inspiration from the model for mathematical problem solving proposed by Schoenfeld (1985) who, underlining the intrinsic complexity of the process of resolution of a problem, characterised the elements occurring in the process such as the concept of strategy and heuristic. The solver, taking into account his or her resources, must choose a strategy that will enable him or her to produce a solution, making appropriate use of heuristics, i.e., rules of thumb, to better understand and solve the problem. Therefore, according to the author, the problem solving process directly involves the solver and is influenced by several factors: the resources available to the solver (i.e., the tools available to him/her in terms of knowledge, procedures and skills), the solver's control (i.e., the way in which he/she uses his/her knowledge, applies heuristics and makes operational decisions) and the solver's beliefs system. As far as the Informatics context is concerned, the problem solving activity of the computer scientist is also based on the concepts of, for example, strategies and heuristics, but it concerns the resolution of problems of a computational type (Papadimitriou, 1993), i.e., characterised by a specific functional connotation: a computational problem is given by a set of instances I associated with a question Q about them, and solving it means finding an automatic method, called an algorithm, that allows the question to be answered correctly for all instances of the problem. With reference to the definition proposed by Korfhage (2003), an algorithm in Informatics is defined as a method for solving a problem, and its implementation in a language understandable by a computational agent leads to the creation of a programme. The definition of an algorithm determines a finite sequence of steps for any input and must produce the answer for the input (or a

declaration of the impossibility to get an answer for that input). This definition, technical and proper to Informatics, has a different meaning from that used in the mathematical context, where it has historically been reduced to a synonym for "procedure" (Fant, 1993). Similarly, in Informatics, the concepts of strategy and heuristic are used not only in the description of the activity of the problem solver, but also to refer to the methods used by algorithms to find a solution to a problem, that is, to find the answer to any instance of the problem.

We can now summarise the research question as it follows: taking an interdisciplinary view across Mathematics and Informatics, which are the heuristics, algorithms and strategies that a group of secondary school students develop in a problem-solving activity?

Methodology

To tackle our research question, we conducted a case study involving a group of Italian secondary school students attending an extra-curricular project on modular arithmetic. In particular, the group consisted of 26 students of the first year of upper secondary school (grade 9, 14-15 years old) attending a scientific specialty with particular attention to the teaching of mathematics (i.e., "Mathematical Lyceum" - a national experimental project in some Italian upper secondary school). The group of students belonged to a class that did not include Informatics as a curricular topic but, instead, in the context of the Mathematical Lyceum, had additional hours in mathematics compared with other school specialties. In some of such additional hours the students took part in a course on modular arithmetic designed by us and aimed at introducing students to the fundamental concepts of modular arithmetic and exploring its applications leading students to work in a context (that of discrete mathematics) which intersects Mathematics and Informatics. The activities designed for the course were all workshop-based and involved the use of artefacts – in the sense intended according to the theory of instrumental genesis (Rabardel, 2003), in which an artefact is linked to the patterns of use that users assign to it rather than an instrument on itself. Moreover, the activities aimed at getting students to work on a series of tasks through the following structure: working in random groups and through the use of artefacts, the students were requested to solve some tasks dealing with modular arithmetic and whose solutions were later shared and commented in a collective discussion led by the teacher and in which they were requested to formalise, justify and, possibly, generalise the solving procedures they had developed. After the completion of some of the activities the students were proposed a series of tasks to be completed autonomously at home as homework and discussed and revised collectively at school at the beginning of the next session of the course. The research presented in this paper will focus on one of the tasks proposed across the whole course, in particular one of the tasks that was proposed during one of the group activities proposed in class – here in an English translation.

> **Task**: You want to compare the residue class modulo 6 of a string of length $136=17\cdot 8$ and a string of length $10=5\cdot 2$, but among the strings you have available, there is no string length 136. Given the lengths of the strings you have available, is it still possible to perform the comparison? If so, what do you observe? To answer the question, you can help yourself with the hexagon and the strings you have available.

The students were given a regular hexagon with pegs at the corners, numbered from 0 to 5, and strings to be tied to the pegs, whose lengths were an integer multiple of the side of the hexagon. Using the polygon, the pupils were able to find the corresponding modulo 6 rest class for each of the lengths of strings available to them by rolling the strings around the given hexagon. However, the use of artefacts is not strictly necessary to solve the task: the student can apply the algorithm for calculating the residue class modulo m to the numbers 136 and 10 to find the residue classes of the two numbers and, by comparing them, finding that they are equal. We chose to focus this paper on this task because it provides students with the opportunity to approach it from different perspectives that are, for example, the execution of known procedures to perform operations or developing approaches exploiting the artefacts that students were given for the activity. Students' answers were collected in written form. Once the protocols were collected, we proceeded with a qualitative content analysis with inductive category formation (Schreier, 2012). We analysed the protocols generating a list of codes that was updated as all the solutions were analysed – rapidly converging toward a saturation – and grouping them in more general categories. In particular, for what concerns the study presented in this paper, we chose to focus qualitatively on the labels and the categories that resulted from this inductive process rather than on the quantitative analysis of the indicators, to detect either the use of existing or the creation of new algorithms, to analyse the development of heuristics and solving strategies, and to explore the expressions used by students to present algorithms and strategies.

Results

The labels that emerged from the data analysis process are grouped into three categories that, in our view, represent the possible dimensions in which students move when solving a problem (see Table 1). In particular, we distinguished: i) the design dimension (P), which gathers all the labels highlighting the aspects related to the development of a method for solving a problem; ii) the application dimension (A), which gathers all the labels useful for highlighting the aspects related to the practical execution of a procedure; and iii) the description dimension (D), which gathers all the codes related to the choices made by the students in terms of the structure and form of the answer given and the language used to describe and justify the choices made.

Table 1: codes and dimensions emerged from protocols' analysis

P-dimension	A-dimension	D-dimension
P1: artefact P2: use P3: combination P4: distinction P5: knowledge P6: generalisation	A1: example A2: instance A3: passage	D1: natural D2: symbolic D3: programming D4: structure D5: interpreter D6: command D7: action D8: reasoning

In this first part of the section, we propose a brief description of the categories and codes that emerged from our analysis, together with a brief description of the approach they describe. With regard to the P dimension, the following codes were identified: P1 – Artefact: identifies a student's development of an argument based on the use of an artefact. P2 - Use: students refer to an already known algorithm, using it exactly as it was proposed, without combining it with other algorithms they know. We also use this label when students mention a simple learned algorithm, treating it almost as a property or definition now acquired. P3 - Combination: the learner, proposing a new procedure, combines some already known algorithms. We also use this label when the combination designed by the student, although not explained in the answer, emerges from the steps taken and when the student combines simple learned algorithms, treating them almost as properties or definitions now acquired. P4 - Distinction: the students recognise that it is necessary to distinguish special cases for which the procedure they have designed behaves differently from the general one. P5 - Knowledge: this code identifies the situations in which the students' reasoning shows that they reflect critically on the situation they are dealing with and rely on their knowledge to decide what is the best way to solve the problem. P6 - Generalisation: the student's reasoning generalises the task proposed by considering the specific case suggested by the question as an application of a more general procedure.

For dimension A the following codes were identified: A1 - Example: students exemplify their strategy, i.e., they apply the whole strategy to a concrete example. A2 - Instance: students apply the strategy they have worked out to the problem situation of the question. A3 - Passage: students exemplify a single step of the solving strategy, i.e. they use a concrete example to explain a single step of their strategy.

For dimension D, the following codes were identified: D1 - Natural: pupils use natural language, i.e. colloquial language. D2 - Symbolic: students use the typical elements of mathematical formalism, such as the congruence symbol modulo m, the residual class symbol modulo m, etc. We also use this label when students reduce the whole solving strategy to a formula. D3 - Programming: students use elements characteristic of the formal language of programming, such as "if...then". We also use this label for those answers where students reduce the whole solving strategy to a program. This is a use of formal programming language taken to the extreme, leading the student to express the solution in a language that can be understood by a computer. D4 - Structure: students structure their procedure, for instance by ordering a sequence of steps. These steps can be indicated by a series of numbers or a bullet list, but they can also be punctuated using expressions such as "first, then and finally", or by the use of braces and indentation. D5 - Interpreter: students include explicit references to the performer of the procedure they are devising or to their knowledge. D6 - Command: when explaining the procedure they have devised, students give instructions in the form of orders to be carried out. D7 - Action: when explaining their procedure, students describe actions they have taken or need to take to answer the question. D8 - Reasoning: when explaining their solving strategy, students explain the reasoning they have done.

Such system of dimensions can be used to analyse students' responses to a task, and to highlight different ways of using algorithms, strategies and heuristics. To illustrate this potential, we focus, as an example, on the analyses carried out on the task that is the subject of this paper. The task is instantiated in its formulation, so that the learners' possible solving approaches are almost all based

on the analysis of the single instance of the problem [A2]. This approach is a typical heuristic of the problem-solving process in Mathematics, but is not common in computing, where the computational problem, by definition, involves a (typically infinite) set of instances. The work that a student carries out on the specific instance proposed by the problem is, in some approaches, strongly anchored in the artefacts made available for the workshop [P1]: in these cases, the student acts on his/her own to solve the proposed problem, manipulating the artefacts available to him/her. Such an approach is therefore tied to the student's experience and is not effective in solving the proposed problem, because in some cases it is difficult for the student to adequately motivate the results of the work done concretely with the artefact. On the other hand, in some answers, the work done on the specific instance does not contain explicit references to the artefacts used. In these cases, answers can be found that correspond to approaches characterised by abstraction and generalisation: the learner recognises that the instantiated problem is a particular case of a more general problem and therefore tries to generalise the results found by working on the single instance [P6]. Such an approach is very effective because it combines the mathematical heuristics of working on the specific instance [A2] with heuristics based on generalisation attempts [P6]. The latter is referred to in the literature as one of the components of AT (Stephens, 2018) and is common to both Mathematics and Informatics. Finally, there are students who show an approach that is completely detached from the specific case proposed in the problem: in this case, the answers are formulated by referring to a general problem of which the proposed task is one of the possible instances [P6]. Answers of this type thus reveal an approach closer to that of Informatics, which typically deals with problems of a general nature. However, a priori, given the nature of the activity in which the task was proposed, we cannot rule out the possibility that, in order to arrive at the formulation of the answer that we analysed, the students started from the artefact and, by turning it into a tool (in the sense intended by Rabardel, 2003), arrived at the formulation of a generalisation of the proposed problem. In general, we observe that the analyses carried out on the task through the categories that emerged from the students' data allow us to describe and characterise solving approaches of different types, ranging from purely mathematical approaches to approaches that have heuristics (e.g. generalisation) in common with Informatics.

Discussion and conclusions

The process of solving a task is an interweaving of algorithmic and strategic aspects that lie on the boundary between Mathematics and Informatics. Therefore, the role of algorithms, strategies and heuristics in problem solving activities has been explored on the common ground of the two disciplines, focusing in particular on the approaches' characteristic of algorithmic thinking. In particular, the latter, which is an integral part of both mathematical and computational thinking, can be considered as a boundary object, and therefore we can say that our study is part of the strand of research that investigates the relationships between the ways of thinking of the two disciplines and seeks to clarify the ambiguities that still exist today regarding these relationships. The analyses carried out lead to the formulation of an analytical tool that allows us to characterise the possible roles that algorithms, strategies and heuristics play within the problem solving process suggesting that, in order to design and implement activities aimed at developing algorithmic thinking, it is important to understand the plurality of meanings that revolve around these concepts, which turn out to be boundary objects between Mathematics and Informatics. For what concerns the case study

presented in this paper, the categories that emerged from the data allowed us to identify and distinguish the different approaches that students use in problem solving activities. On the one hand, we have identified mathematical approaches that stimulate components of algorithmic thinking that are common to both disciplines (e.g., generalisation, differentiation of particular cases), and on the other hand, we have identified approaches that are very close to Informatics in terms of describing and designing algorithms.

From a first observation, even considering the activity proposed to the students in its entirety, a possible task effect seems to emerge: on the one hand, there are the tasks that we have defined as "calculation" tasks, i.e., tasks that propose to the student an instanciated problem (i.e., they are formulated by referring to a specific situation that could be understood as an instance of a more general problem) and lead the students to work on all three dimensions identified by our coding frame; on the other hand, there are "algorithmic computational" tasks, i.e., tasks that ask for the identification of a solving procedure, that lead learners to work primarily on the description and design dimensions of our coding frame, that encourage the creation of an algorithm and that, while not allowing heuristics specific to algorithmic design and application to emerge, allow students to use algorithmic description techniques specific to Informatics.

Although the proposed observations can be considered as preliminary and related to our case study, and therefore with a possible effect of the proposed tasks, we can say that this research can provide some general indications to be studied in further research, such as a quantitative analysis of distribution of labels identifying the categories, the study and classification of students' heuristics and their ability to work on the concepts of algorithm, strategy and heuristics, and to create interdisciplinary activities that favour the development of algorithmic thinking.

Deterministic model for objectifying the students' proving process in Discrete Mathematics

Mickaël Da Ronch[1]

[1]University of Teacher Education Valais, Saint-Maurice, Switzerland; Mickael.DaRonch@hepvs.ch

This paper presents a deterministic model for describing and objectifying the students' mathematical activity, targeting the field of discrete mathematics. This model allows to identify their proving processes in problem-solving, involving the manipulation of tangible objects, based on the audiovisual data collected. The model is described in three steps. The first one involves selecting observables relating to the actions and strategies linked to the proving process identified in the mathematical analysis that we wish to identify in the students' mathematical activity. The second one concerns the retranscription and encoding of their activity in relation to the choice of actions performed. Finally, the last one involves analysing the retranscriptions of their activity and comparing them with the strategies identified in the mathematical analysis, to find similarities in the proving processes used to solve the problem.

Keywords: Deterministic model, proving process, problem-solving, discrete mathematics education.

Background and objective of the research

The field of Discrete Mathematics is important for teaching and learning of the reasoning and the proving process. As Gravier and Ouvrier-Buffet (2022) point out, many international works on problem solving and proof use this field (e.g., Da Ronch, 2022; Grenier & Payan, 1999; Hanna & de Villiers, 2012; Hart & Sandefur, 2018; Stylianides, 2016). Discrete Mathematics encourage the students to develop an authentic mathematical activity (Lampert, 1990) similar to that mathematician, particularly in terms of the skills and know-how associated with this activity. Moreover, this field makes it easily to illustrate problems using tangible objects (see Grenier & Payan, 1999; Da Ronch, 2022). But how can we identify in students' mathematical activity and their proving processes used in problem solving when they manipulate these objects? One way of proceeding is to carry out an analysis of the traces using audiovisual data collected with the camera assistance. The audiovisual data allows to researchers to access more easily and more exhaustively to the traces of activities produced by students (Jewitt, 2012; Da Ronch, 2022). This also means that students don't have to select the traces they wish to leave behind a researcher or a teacher when it comes to submitting written work. Written traces lead to a loss of information and make the retranscription of the activity less objective. In a way, they also encourage interpretation biases in the analysis of these written traces by the researcher. The aim of this paper is therefore to propose a deterministic model for retranscribing the students' mathematical activity on discrete mathematics problems and to provide tools for analysing their proving processes. This model is a theoretical model for research in (discrete) mathematics education. It is therefore not intended to be put into practice by teachers, but rather to be used by researchers. On this occasion, we will first give some theoretical elements which will then enable us to describe the main steps in this model, particularly about the choice of observables, the retranscription method and the analysis of the latter. Several examples illustrating this model are given in Da Ronch's work (2022).

Theoretical background and research questions

Many models of problem-solving processes exist (Rott et al., 2021). The authors describe and compare existing models to characterise their potential and limitations for analysing students' problem-solving processes. Among other things, they point out that most of the models proposed are normative. They affirm that these phase models were not designed for the analysis of empirical data or to describe externally observed processes (e.g., videotaped problem-solving processes of students), which highlights the authors' need to build a descriptive model. The model developed by Rott et al. (2021) can be used to code episodes, i.e. to code "A period of time during which an individual or a problem solving group is engaged in one large task […] or a closely related body of tasks in the service of the same goal […]" (Schoenfeld, 1985, p. 292). These episodes are then coded according to a pre-defined typology (deductive approach), which is then enriched by data analysis (inductive approach). However, episodes are coded at a macroscopic level of student activity (e.g., "reading the problem; implementing a plan; verifying a solution", etc.) (Rott et al., 2021, p. 743). This model therefore does not allow us to retranscribe, at a microscopic level, the activity of the students in order to give a retranscription as close as possible to the reality observed. Moreover, this microscopic retranscription of the pupils' activity would make it possible to reduce the interpretation bias that can be induced by coding into episodes and coding the associated episode types.

If we want to identify students' mathematical activity in problem-solving, and their proving processes, one way of doing this is to identify a set of elementary actions considered relevant to the given problem. We are therefore at a microscopic level. Moreover, these actions are directed towards the environment of the situation, but do not all have the same function. The notion of environment named *milieu* in French didactic was developed by Brousseau (1997), Margolinas (1995) and Bloch (2006) in terms of structuring the environment by levels. Other researchers have proposed a characterisation of the environment in which students operate according to three spaces: micro-space, meso-space and macro-space (e.g., Berthelot & Salin, 1992). These three spaces simply allow to classify the environment according to the value of the variable concerning the size of the space. However, the characterisations given in the literature do not allow us to categorise the actions directed towards the environment of the situation in detail, especially as these actions do not all have the same functions (Da Ronch, 2022). It therefore seems more appropriate to categorise our environment according to its functionalities. This will enable us to propose a typology of actions according to the zone of interaction with the environment and their assigned function. For our research, the environment is therefore characterised in *functional zones*, while considering the social dimension of mathematical activity. The *Work Zone* ($\mathcal{W}_Z$) is the main area of the environment where the subject act to solve the problem. Therefore, the actions in this zone are linked to actions about problem-solving. The *Tooling Zone* ($\mathcal{T}_Z$) is the zone of the environment which provides to the subject(s), the objects they need to develop their actions in problem-solving. The *Information Zone* ($\mathcal{I}_Z$) is the zone of the environment which communicates information about the problem: rules of the game, instructions, examples, *etc.* (Da Ronch, 2022; 2024).

In relation to the objective formulated in the first section of the paper and the characterisation given to our environment, several questions can be formulated, namely*: what choices of observables should we make? How can we retranscribe the students' mathematical activity? And how should it be*

analysed? In the following section, we describe the steps in our model that will enable us to answer to these questions. These steps will make it possible to objectify students' mathematical activity, and particularly their proving processes based on audiovisual data collected.

Method for processing and analysing audiovisual data: a three-step model

In this section we present our model called **ORA** (**O** for observable, **R** for retranscription and **A** for analysis). The different steps of this theoretical model will be illustrated by an example based on a problem in discrete mathematics. This model has already been applied to other problems (e.g., Da Ronch, 2022) during research aimed at retranscribing and finely analysing the mathematical problem-solving activity of individuals, out of the classroom (in a context of popularisation of mathematics), with dozens of participants. In each case, coding was carried out by a single researcher based on the choice of observables made through mathematical analysis of the problem (deductive approach).

Choice of observables: typology, actions and strategies for identifying proving processes

Firstly, we have to identify elementary actions noted a_i. The mathematical analysis carried out on the problem allows us to retain only a subset $\mathbb{A}$ of this a_i-actions. Thus, these elementary actions are chosen for epistemological reasons in relation to the knowledge we have on the problem, or for didactic reasons. Furthermore, the subset $\mathbb{A}$ of these actions is finite since the corpus of audiovisual data to be processed and analysed is also finite. The characterisation of the environment by *functional zones* makes it possible to propose a typology of actions. We can therefore distinguish 4 types of specific action. The $\mathcal{W}$*-actions* which are actions that modify $\mathcal{W}_{\mathcal{Z}}$. *The* $\mathcal{T}$*-actions* that interact with $\mathcal{T}_{\mathcal{Z}}$. This may involve selecting or depositing objects in $\mathcal{T}_{\mathcal{Z}}$. *The* $\mathcal{I}$*-actions* that allow access to $\mathcal{I}_{\mathcal{Z}}$. Finally, the $\mathcal{SO}$*-actions* which are actions arising from social interactions involving exchanges between peers or to oneself. They can be actions in oral language or actions that involve gestures (Da Ronch, 2022; 2024).

To identify traces of students' mathematical activity, we need to identify actions based on the knowledge or skills we have about solving of the problem. One way of doing this is to objectify their solving strategies, which require the mobilisation of knowledge, skills or know-how, by means of ordered actions carried out on objects in order to solve a given problem **P**. These strategies will be defined in *extension* or in *comprehension* (Da Ronch, 2022). When we have access to all the strategies and can describe them as a sequence of a_i-actions, on instantiated o_j-objects, we will define them in extension. A *strategy* can therefore be defined as a *word* $\boldsymbol{\omega}$ which takes the form of a sequence $a_i o_j$. On the other hand, when it is not possible to describe all the strategies because there are too many for instance, we will describe these strategies in comprehension, *i.e.,* using a set of actions on generic objects. The example below illustrates a sequence of ordered actions (additions) performed on objects (dominoes) to prove the non-existence of tiling in this configuration (Figure 1). The proof of non-existence consists of reasoning by necessary conditions until an absurdity is reached (two non-adjacent squares that cannot be tiled by a domino). The case study provides a complete proof of the non-existence of tiling.

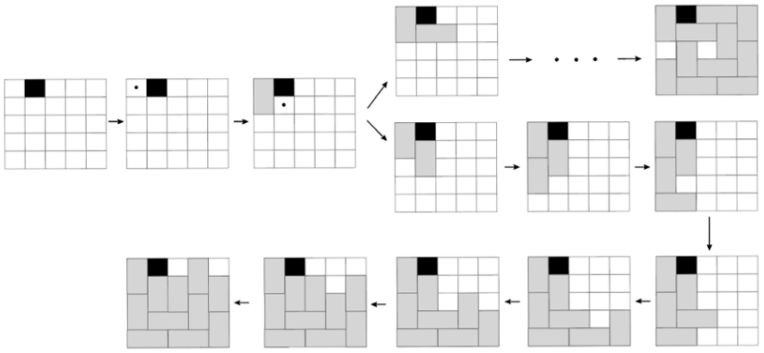

Figure 1: Strategy for proving the non-existence of this tiling

Retranscription of the experience: encoding of elementary actions and retranscription method

To retranscribe the actions that describe the strategies used by the students during the proving processes and the actions linked to the formulation of knowledge, we need to give an encoding. To make our retranscription intelligible, we bijectively encode the actions a_i of $\mathbb{A}$ in an intelligible symbolic format taken from a finite set $\mathbb{L}$ of symbols (Table 1). These symbols are built as close as possible to the observed reality.

Table 1: Examples of encoding

Type of actions	a_i-action of $\mathbb{A}$	Associated symbol of $\mathbb{L}$
$\mathcal{W}$-action	To add	+
$\mathcal{W}$-action	To remove	–
$\mathcal{T}$-action	To search	
$\mathcal{SO}$-action	To point	
$\mathcal{SO}$-action	To chat	

Now that we have encoded the a_i-actions, we propose a retranscription method. This method is completely deterministic, since it is not open to interpretation and could be carried out by a computer. The actions ($a_i \in \mathbb{A}$) carried out on objects ($o_i \in \mathbb{O}$ with $\mathbb{O}$ that could be empty) by the observed student ($s_k \in \mathbb{S}$) characterise the student's local activity. We define this local activity as a *micro-activity* characterised by a triplet $(a_i, o_j, s_k) \in \mathbb{A} \times \mathbb{O} \times \mathbb{S}$. Between each micro-activity, the time *t* and the discretised occurrence ($occ \in \mathbb{N}$) are specified by an occurrence and a time marker (Da Ronch, 2022).

$$\cdots \xrightarrow[occ]{t} (a_i, o_j, s_k) \xrightarrow[occ+1]{t'} (a_p, o_m, s_k) \xrightarrow[occ+2]{t''} \cdots$$

Between each marker, there may be one or several micro-activities starting at the same time or for which we are unable to give an order, since we do not know precisely when they were carried out. We therefore assume that they all start at the same time. We refer to all micro-activities between two markers as *phases*. Here a phase is not an episode in the sense of Schoenfeld (1985).

$$\cdots \xrightarrow[occ]{t} \overbrace{\{\text{List of simultaneous actions.}\}}^{\text{Phase}} \xrightarrow[occ+1]{t'} \cdots$$

Below is an example of a retranscription of the micro-activities of two students trying to solve the problem proposed in the previous section (the dialogue transcription is in Da Ronch, 2022, p. 325).

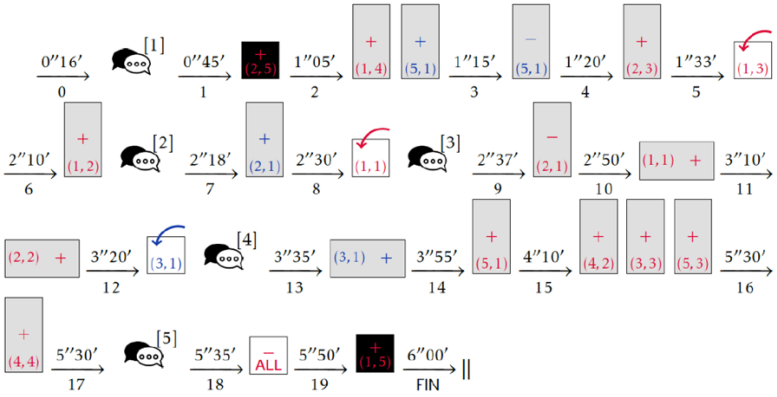

Figure 2: Example of a retranscription of the activity of two students s_1 and s_2

In this extract, two students (s_1 and s_2) are trying to tile a 5×5 grid with dominoes. This grid has a hole (black unit square) and this hole is positioned by the students. In the retranscription, the students are identified by the red and blue colours corresponding to s_1 and s_2 respectively. In addition, when a student puts (+) or removes (-) a domino on the grid, we represent this domino in the colour corresponding to the student, with the plus (+) or the minus (-) symbol and coordinates. To quickly identify the position of the dominoes on the 5×5 grid, we take the bottom left square of the grid as the origin (1,1). For example, on the first occurrence, s_1 puts the unomino (hole) in position (2,5). Then, both students simultaneously put two dominoes vertically in positions (1,4) and (5,1). This means, for example, that the south square of the domino placed by student s_1 on the grid is in position (1,4).

We then propose to enhance our transcription with a *summary*, *i.e.,* an "enhanced" photograph of the Work Zone ($\mathcal{W}_Z$) at a given moment, providing a static view of the situation at a given time. This summary allows us to retrace the students' reality at a *t* time. It also allows us to know exactly the number of $\mathcal{W}$-actions performed by the student knowing the number of $\mathcal{W}$-actions performed by the other students. This gives the number of $\mathcal{W}$-actions carried out between two effectives $\mathcal{W}$-actions and also the distribution of these actions: did s_1 perform more, fewer or as many $\mathcal{W}$-actions as s_2, for example? In the summary below, taken from the retranscription, we can see the reality of the students at a given moment in the retranscription (Figure 3). The symbols of type $\boldsymbol{a}|_{\boldsymbol{b}}$, where $\boldsymbol{a}$ and $\boldsymbol{b}$ are integers, represent the number of $\mathcal{W}$-actions of s_1 (respectively s_2) knowing the number of $\mathcal{W}$-actions of s_2 (respectively s_1). For example, during its first $\mathcal{W}$-action, s_1 puts the unit square in position (2,5), knowing that s_2 has not yet performed a $\mathcal{W}$-action (Figure 2). We thus have coded $\mathbf{1}|_{\mathbf{0}}$.

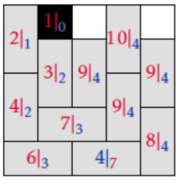

Figure 3: Example of a summary linked to the retranscription (see Figure 2)

The summary reproduces the Work Zone in which the students find themselves at a given moment, which is a perfectly complementary to the retranscription.

Analysis method of retranscription for objectifying students' proving processes

To analyse the retranscription (Figure 2) to objectify the students' proving processes, we need to remove some unnecessary information. This could be, for example, some dominoes which have been added and then removed, or some showing actions which are not significant in identifying a strategy linked to the proving process. We are therefore looking for a subword in this retranscription to highlight a strategy linked to a proving process identified in the mathematical analysis (Figure 1). This subword is shown in Figure 4.

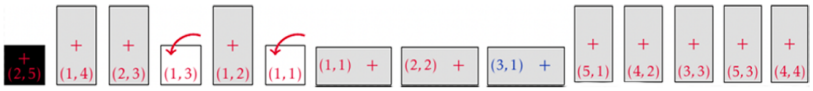

Figure 4: Subword from the retranscription sequence (see Figure 2)

This subword shows a similarity with a part of the strategy for proving the non-existence of tiling in this configuration (Figure 1). However, it does not describe the entire strategy given by the mathematical analysis. In fact, the students dealt with only one of the two cases to prove the non-existence of tiling. Moreover, it is reasonable to say that it is only s_1 who has developed a solving strategy leading to a partial proving process of non-existence. Indeed, the subword described shows that s_1 has carried out almost all the actions needed to develop this partial strategy. In addition, the transcription of the dialogue shows that s_1 reasons well, using reasoning based on necessary conditions ("we have to", see Da Ronch, 2022, p. 325) until it is no longer possible to add dominoes. Furthermore, the end of the retranscription shows that s_1 removes all the dominoes and changes the position of the hole (black unit square). This suggests that he has not realised that his strategy for proving the non-existence of tiling was incomplete. Finally, this subword shows a correct proving process but incomplete that implicitly uses a proof by non-contradiction and a reasoning by necessary conditions without an exhaustive study of the cases. Even if this proof is partial, s_1 has nevertheless developed a mathematical activity. Of course, this example of transcription is given for a particular instance; we would need to have the full transcription to be able to identify other strategies that would also be indicative of a mathematical activity.

Results and discussion

We have presented a deterministic model described in three steps: observable, retranscription and analysis. This model makes it possible to describe and objectify students' strategies in detail, and particularly their proving processes in problem-solving. We illustrated this on a tiling problem in Discrete Mathematics. This enabled us to show, on an example, that this theoretical model was

operational for describing and recognising significant elements of the proving process in problem solving. (for other examples, see Da Ronch, 2022). Moreover, in this model, we can clearly locate the interpretation part. It is precisely at the level of the choice of observables (choice of actions and strategies that seem relevant to what we want to observe). The remainder is completely deterministic, excepted sometimes at the level of retranscription analysis, since the strategies identified may be more or less close to those identified in the mathematical analysis. With this model, a single coder is sufficient, as there can be no interpretation in the coding of an elementary action, unlike episode coding (Schoenfeld, 1985), which requires at least double coding to measure reliability. This model also shows its relevance and effectiveness when it comes to solving problems using tangible objects, whose actions are similar to those carried out in "paper and pencil". Hence, Discrete Mathematics seems to be a suitable field, since a lot of mathematical objects (graphs, tiles, polyominos, *etc.*) can easily be represented in the form of tangible objects (Da Ronch, 2022; Gravier & Ouvrier-Buffet, 2022). In addition, it is probable that such problems, represented in a numerical format, facilitate this retranscription but open up the question of computer transposition. It would be appropriate to consider this type of processing and analysis in an automated way using digital tools, Artificial Intelligence and image recognition, for instance. This would make it possible to search large volumes of data, for a wide variety of users and over a very long period. By the way, recent researches is being carried out by the TWEAK team (LIRIS in Lyon, France), with the kTBS4LA (kernel for Trace Based Systems for Learning Analytics) platform. Based on *Learning Analytics*, kTBS4LA enables observable traces to be collected, stored, manipulated and analysed in order to calculate indicators of individual activity (Casado et al., 2017; Lefevre, 2018). Our model can also be used to perform quantitative analyses by mining data collected on a specific action for instance. It also has its limitations, particularly when the execution time of the actions is different, making it possible the reading and the writing of the retranscription complex. This model also raises questions about its operationality towards complex abstract objects that cannot take on a tangible format, giving an encoding more complex. Finally, it is important to specify that this theoretical model is not intended to be used by teachers, but only to provide researchers with the necessary tools to identify the traces of mathematical activity in problem solving.

Investigating the use of programming in the process of creating algebraic expressions in 6th grade

Nisa Efe[1] , Emel Özdemir Erdoğan[1]

[1]Anadolu University, Faculty of Education, Eskişehir, Türkiye; nisanuriyeefe@anadolu.edu.tr

This study was aimed at investigating students' comprehension of algebraic expressions during the transition period from arithmetic to algebra with instruction based on programming in a Scratch environment. The teaching experiment was conducted with 15 students in the 6th grade of a public middle school in Eskişehir. Data was collected from the students' Scratch project files, audio recordings, observations and clinical interviews. The data was analysed using thematic analysis. As a result of the study, it was observed that the students could easily make the transition and transform between verbal algebraic expressions and Scratch code sequences and could clearly see the dependent-independent variable relationship between the variables in the code sequences.

Keywords: Early algebra, Scratch, programming, teaching experiment.

Introduction

Algebra has historically been recognized as the most challenging area in school mathematics (NCTM, 2008; Grønmo, 2018). Research suggests that to overcome students' difficulties in learning algebra and to teach algebra more effectively, we should move away from traditional methods and provide a teaching environment and methods where students can discover and make sense of the nature of algebra (Blanton et al., 2019; Ellis & Özgür, 2024). This can be achieved by understanding the concepts correctly in the transition from arithmetic to algebra and by creating learning environments that enable students to see and understand mathematical relationships by thinking about mathematical structures (Blanton, 2008). Kieran (2007) states that performing generative and transformational activities in algebraic situations and using different representation methods is a link that enables the learning of algebraic expressions and operations. According to Papert (1993), when students create meaningful and concrete products such as a model, a computer program or a work of art in the process of learning abstract concepts, their learning becomes more permanent. For example, it was observed that students concretized mathematical concepts by drawing geometric shapes using the Logo programming language developed by Papert (Boyle,1999).

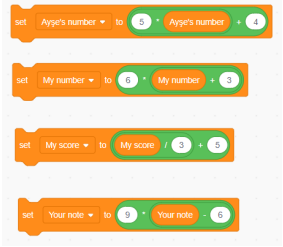
In recent years, in support of Papert's view, there are many studies showings that activities such as game development and animation creation using the Scratch 3.0 programming language developed by MIT contribute to the development of problem and equation-solving skills and a better understanding of mathematical processes by enabling students to think in more detail due to the nature of programming. Creating educational games using Scratch has been shown to positively affect students' equation generation performance (Chiang & Qin, 2018), and students' cognitive skills such as algorithmic thinking, creativity, collaboration, and critical thinking have positively changed after programming training with Scratch (Jiang & Li, 2021).

These results encourage us to investigate the effect of teaching algebra with programming on concretizing abstract algebra concepts and learning them more effectively. This study is part of a

master's thesis project that aims to investigate the process of making sense of algebraic expressions in students in the transition period from arithmetic to algebra with an instruction based on the Scratch 3.0 programming language. In the mathematics curriculum that was being implemented in Türkiye at the time this research was conducted, algebraic learning outcomes started with the algebraic expressions' unit in the 6th grade for the first time. In the Ministry of National Education (MoNE) textbooks, traditional methods are used for teaching algebraic expressions.

This study seeks to answer the following research question: How do 6th-grade elementary school students translate verbal algebraic expressions into code sequences in Scratch and vice versa? How do the students' cognitive processes required for transitioning between these two representations occur?

Method



This study is a small part of a project, which is a teaching experiment conducted over eight weeks at a public school in Türkiye. The teaching experiment aimed to help students acquire algebraic expression skills through the Scratch programming language and consisted of 14 activities. This study presents data obtained from one of these activities.

The teaching experiment was carried out in three phases: the first phase involved introducing Scratch; the second phase focused on forming algebraic expressions through activities based on Scratch; and the third phase included problem-solving activities related to algebraic expressions using Scratch. In this study, the findings from the first activity of the second phase of the teaching experiment, titled 'Let's Write a Calculating Code Sequence,' will be examined.

The teaching experiment process was designed and sequenced based on the learning outcomes specified for the algebra domain in the Ministry of National Education's (MoNE) mathematics curriculum. The skills corresponding to these learning outcomes in the Scratch environment were defined, and the activities were designed to incorporate these processes and skills. This alignment was conducted both to design the activities and to analyze the data obtained from these activities. Examples of the activity titled 'Let's Write a Calculating Code Sequence,' prepared based on these objectives, along with the themes used in data analysis, are presented in Table 1 for further clarity.

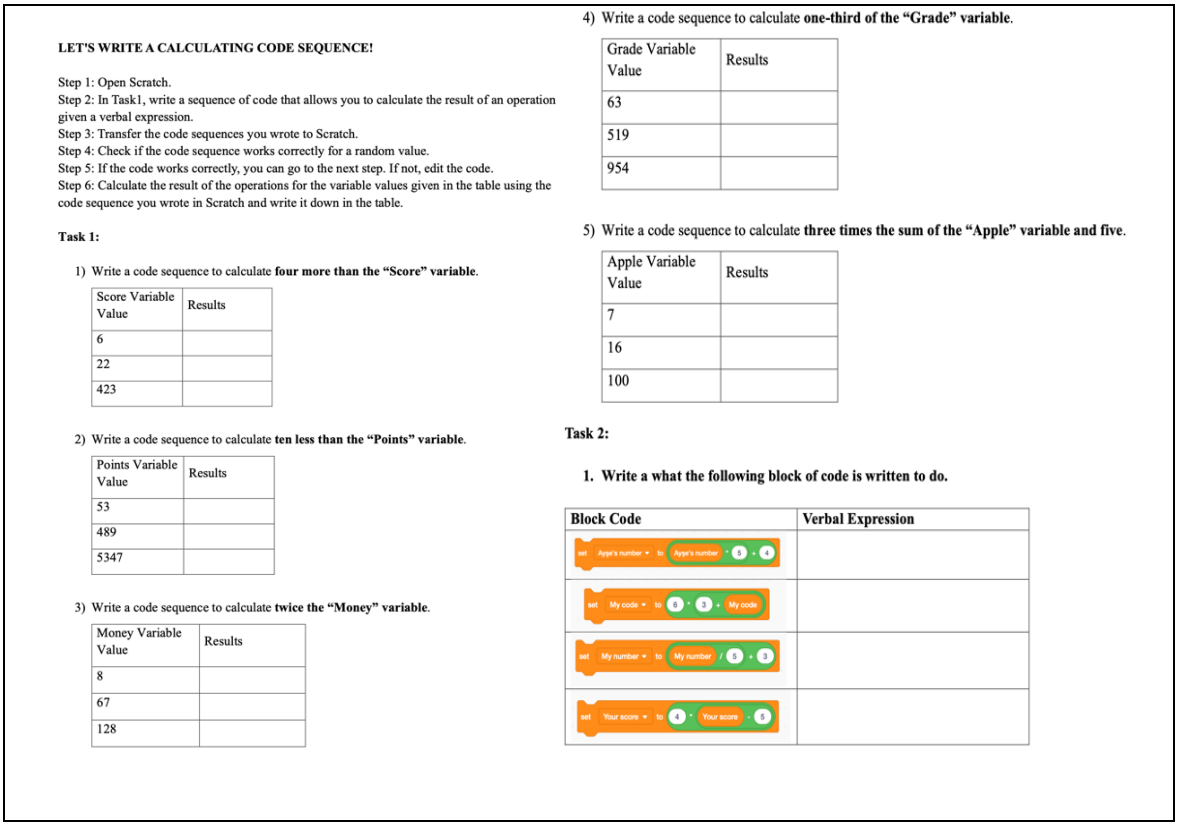
The sample of this study consists of 13 sixth-grade students. The participants were selected based on the following criteria: they were required to volunteer for the study, have no prior experience with the unit on algebraic expressions, either at school or through any external course, and have successfully completed the first phase of the teaching experiment.

To ensure the reliability of the data collected during the teaching experiment, the implementation processes were recorded both via video and through the teacher's use of a lapel microphone. Additionally, a researcher's notebook containing observational notes was maintained, and screen recordings of the students' work on computers were gathered. Furthermore, clinical interviews were conducted with the students.

Activity: Let's Write a Calculating Code Sequence



The "Let's Write a Calculating Code Sequence" activity consists of three parts, as exemplified in Figure 1. For this purpose, students were given an activity worksheet.

In the first part of the activity, students are required to define variables, define a second variable that changes based on the value of the first variable, and transfer the algebraic relationship between these two variables into the Scratch environment using operator code blocks. In the second part, students must be able to write a code sequence that calculates and displays the value of the dependent variable for every value given to the independent variable. For example, in the first task of the first part, students are expected to write a code sequence that "calculates 4 more than the score variable" and reach the correct result for different values of the score variable.

In the second part, the values that the independent variable can take are provided by the teacher in a table. Using these values, students will find the value of the dependent variable. The aim here is for students to check their code sequences against the given values and the obtained results. Having all students work with the same values and obtained results. Having all students work with the same values helps facilitate a natural control process within the classroom.

In the third part, students are asked to write the algebraic expressions corresponding to the code sequences provided on the activity sheet, which are different from those in the first part, in verbal

form. In the second task of the third part, for example, the given code sequence and the verbal expression that students are expected to write corresponds to “three more than my number multiplied the six.”

LET'S WRITE A CALCULATING CODE SEQUENCE!

Step 1: Open Scratch.
Step 2: In Task1, write a sequence of code that allows you to calculate the result of an operation given a verbal expression.
Step 3: Transfer the code sequences you wrote to Scratch.
Step 4: Check if the code sequence works correctly for a random value.
Step 5: If the code works correctly, you can go to the next step. If not, edit the code.
Step 6: Calculate the result of the operations for the variable values given in the table using the code sequence you wrote in Scratch and write it down in the table.

Task 1:

1) Write a code sequence to calculate **four more than the “Score” variable**.

Score Variable Value	Results
6	
22	
423	

2) Write a code sequence to calculate **ten less than the “Points” variable**.

Points Variable Value	Results
53	
489	
5347	

3) Write a code sequence to calculate **twice the “Money” variable**.

Money Variable Value	Results
8	
67	
128	

4) Write a code sequence to calculate **one-third of the “Grade” variable**.

Grade Variable Value	Results
63	
519	
954	

5) Write a code sequence to calculate **three times the sum of the “Apple” variable and five**.

Apple Variable Value	Results
7	
16	
100	

Task 2:

1. **Write a what the following block of code is written to do.**

Block Code	Verbal Expression

Figure 1: Activity worksheet

During the stage where students transfer the verbal expression into a code sequence, the control process in Scratch can be done by assigning values to the variables. However, the teacher needs to check the verbal expression written for the corresponding code sequences. After all students correctly complete the tasks and save their Scratch projects as required, the activity is concluded.

After the data obtained in the study was transcribed, the data was analysed using thematic analysis, one of the qualitative research methods. The themes to be used in the data analysis (Table 1) consist of the skills that students are expected to realize while preparing the activities.

Findings

Since the students had difficulty in using expressions such as more, less, multiple, one in ..., the activity was started by reminding the students which operations these expressions correspond to. While transferring the expression “4 more than the score variable” to the code sequence, students first created a score variable. Then, they wrote a code sequence that performs the score+4 operation using the addition operation block from the operator’s menu. All 13 students participating in the activity started coding by creating the variable “score”. 9 of the students used the “What is the score?” block

from the sensing code blocks and defined the answer to this question as the “score” variable. Then, they defined the variable “score” as “score+4” using operator blocks. When the code sequence is executed and the “score” variable is defined as 5, the “score” variable takes the value 9 on the screen.

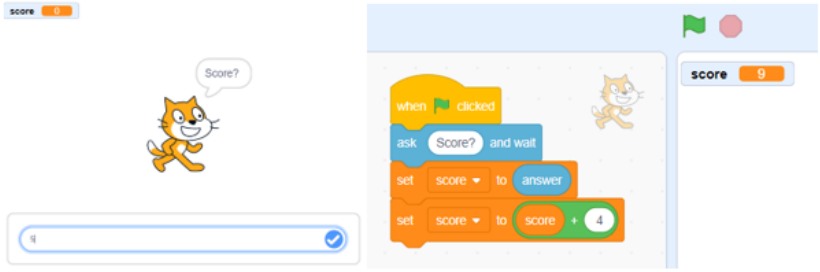


Figure 2: Code sequence using only variable code blocks

4 students first used the “make the score variable 0” block and then used the “make the score variable score+4” block. Here, the “score” variable is given a number value instead of “0” in the “make score variable 0” block in the code sequence and the code sequence is executed. In this case, when the “score” variable takes the value 5, the “score” variable takes the value 9.

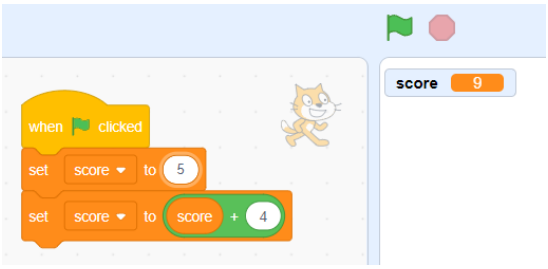

Figure 3: Code sequence using only variable code blocks

Evaluating dependent variables for various independent variable value

After completing the code sequences, the students entered the values given for the variable “score” in the activity sheet into the code sequence and ran it. In this case, two of the students thought that something was wrong and asked the teacher for help.

Yağmur: Now we want to calculate 4 more than the score. If we say score 6 in the code string, we get 10. But the result appears as score again. In this case, 4 more than the score is still the score. Isn't that illogical?
Teacher: You made a good point. What do you guys think?
Yağmur: Then we need to create a new variable and bind the result of the operation to it.

After this conversation, students reorganized their code sequences. They created a “sum” variable next to the “score” variable and defined the “sum” variable as “score+4”.

Figure 4: Revised code sequences

All the students reached the result by entering the values given in the table into the Scratch code sequence. In this first question, it was observed that the students calculated the values in the Scratch and then checked them on paper and pencil. When asked why, the answer given is as follows:

Nesli: I check it, the paper gives a guaranteed result.

Then, when it was observed that the same students calculated the values in the Scratch code sequence and did not calculate them on paper and pencil, when asked why they did not continue to check, the student's answer was as follows:

Nesli: Scratch already calculates correctly; it takes less time.

Interpreting code sequences as verbal algebraic expressions

In this section, students were given 4 code sequences. Only 1 student was able to write a correct verbal algebraic expression in all code sequences. In code sequence 1, except for one student (Zeynep), the remaining 10 students wrote a correct sentence. Zeynep wrote the sentence “4 times the sum of 5 and the number of Ayşe” instead of “4 more than 5 times the number of Ayşe”.

Teacher: Which of these is addition and which is multiplication?
Zeynep: The first is multiplication and the second is addition.
Teacher: So, what does she add and multiply Ayşe's number by?
Zeynep: (Looking more carefully) First she multiplies by 5 and then she adds by 4.
Teacher: How does it work in your sentence?
Zeynep: I added by 5 and then multiplied by 4.

After the end of the fourth code sequence, since it was observed that the students made too many mistakes based on operation priority, the activity was not terminated, and the students were asked to transfer the code sequences to the Scratch. The aim was to make the students realize that the nesting of code blocks in Scratch is related to the operation priority. Students were first asked to try the fourth code sequence. First, a code sequence was created as '4 times of 5 minus' and then '5 minus of 4 times'. Then, when the value of the variable was 9, the results were compared and discussed in class.

Ozan: Teacher, this result is wrong, but I think the code is correct.
Teacher: For example, is 5 minus 4 times of 9 equal to 4 times of 5 minus 4 times of 9?
Ozan: It seems equal... Let me try.
Serdar: No, it's not, one is 16 and the other is 31.
Teacher: This should give you a clue.
Yağmur: Teacher, the order of these jellybeans affects the result of the operation! *(At this stage, students named the code blocks symbolizing the variable as jellybeans.)*
Teacher: I thought there was a name for this... What was it?
Rain: Priority of operation, priority of operation!
Ozan: Then these jellybeans act like parentheses. Each jellybean is a parenthesis.

Results and Discussion

Many studies in the literature on algebra instruction have stated that students who correctly learn arithmetic and arithmetic rules tend to have higher success in algebra (Kieran, 2004; Blanton, 2008; Demonty et al., 2018). One of the findings of this study also indicates that, for students to develop algebraic thinking and perform algebraic operations, they must first possess a foundational arithmetic competence. During the instructional experiment, it was observed that students lacked proficiency in

the mathematical language related to arithmetic operations. It was found that students did not understand that phrases like "4 less" correspond to subtraction, "5 more" to addition, "3 times" to multiplication, and "half of" to division. However, by the end of the instructional process, the students' command of the language had improved, and they demonstrated more success both in planning code sequences and in expressing algebraic situations.

Another finding of the study is that Scratch's approach of not processing code blocks randomly or from left to right, but rather treating each block like a parenthesis, paying attention to operation precedence, indicates that Scratch can be an effective tool for teaching order of operations. Students became aware of this situation after encountering problems when first introduced to algebraic expressions that included constant terms.

Research acknowledges that recognizing and expressing relationships between quantities is a crucial step in transitioning to algebra. When writing code sequences, students must analyse the given problem, accurately express the variables, and identify the relationships between them. In this study, it was observed that this process encouraged students to think more deeply about the problem elements, as they made observations about dependent and independent variables during the activities. In fact, when faced with a code sequence where the dependent variable was not provided, students identified, named, and explained the relationship between the dependent and independent variables on their own. This finding suggests that the Scratch can be an effective instructional tool for understanding and establishing relationships between quantities. Calao et al. (2015) suggested that Scratch could be an effective tool for teaching relationships between quantities, and the results of this study support that claim.

In this study, the choice of tools was made to support students in learning programming and mathematics simultaneously. Scratch was chosen for teaching programming because it dynamically and visually represents variables and algorithms, allowing students to interact directly with the code. An alternative tool, such as spreadsheets (e.g. Excel), can also display variables and calculations. However, Scratch provides an environment where only semantic errors can occur, making it easier for students to learn by trial and error. It also reduces the cognitive load on students by removing the syntactic complexity of traditional programming. Furthermore, the visualisation capabilities of Scratch help to create a ‘mental space where the code lives’. Future studies could explore whether spreadsheets can provide a similar learning environment.

Although the data obtained in this study indicate that programming with Scratch can be an effective instructional tool in teaching algebra to students in the early algebra phase, further research is needed to examine the impact of this instructional process on students' success in algebra and the retention of their learning. The results of the study suggest that Scratch programming can be an effective tool for teaching algebraic expressions and introducing algebra. However, further research is needed to prevent misconceptions and learning difficulties.

Superfluous or meaningful integration of programming in mathematics? An analysis of lower secondary textbooks

Programming has been integrated in mathematics education in many countries, however, its relation to mathematics in education is not necessarily agreed upon. In this work, we investigate the relations between mathematics and programming in textbooks from two of the largest publishers in Norway. This analysis is inspired by, and compared to, a former study of textbooks in Sweden. Compared to the results of the Swedish study, our results indicate that in Norway there are relatively many examples of programming that have a potential for students to explore and deepening their mathematical understanding. At the same time, an introduction of basic programming is lacking. Our measures of inter-rater reliability also rises questions regarding the applicability of the theoretical framework. The need for more research in several directions is emphasized.

Keywords: Programming, secondary school mathematics, textbooks, mathematical exploration.

Introduction

In recent years, programming has been integrated into the mathematics curriculum in many countries (Oda et al., 2021). The importance and demand for programming skills and skills in information and communication technology in the digital society is high, and is expected to grow (Balanskat & Engelhardt, 2015). The inclusion of programming in school curricula over the last decade can be seen as a second wave of programming in schools. The idea of using programming as a tool for learning mathematics originates back to Papert (1980). He developed the programming language LOGO, which he argued could change the way students think of mathematics, as well as positively affect communication and collaboration between students and teachers. Programming is today introduced in school curricula in different ways. In some countries, a separate subject of programming has been created, while in other countries programming is an integrated part of other subjects. Introducing programming in school is often argued to help students learn computational thinking (Kallia et al., 2021), however, incorporating computational thinking into mathematics is not straightforward (Nouri et al., 2020).

One issue, highlighted in former studies, is that programming can delineate the mathematics towards topics that are programmable and away from other kinds of mathematics (du Boulay, 1980). Holo et al., (2023) find in their literature review that mathematics is mostly applied as a context for learning programming, and that the broad attention of exploring mathematics through programming is yet to come. Kaufmann & Stenseth (2021, pp. 16-18), argue that programming can be included into mathematics education, however, on the condition that the focus "must not be entirely on using programming". This argument is supported by Lie et al. (2017), who indicate that student may learn

about mathematical concepts, as well as practising mathematical competencies as reasoning, communication, modelling and problem solving, when engaged in programming activities.

In their analysis of Swedish and Norwegian curricula, Vinnervik & Bungum (2022) find that programming is broadly referred to as part of the digital competence, and more specifically a tool for learning content within subjects. In both Sweden and Norway mathematics is positioned with the responsibility to provide for basic programming skills. According to the Swedish mathematics curriculum (The Swedish National Agency for Education, 2024, pp. 56), one of the aims of digital tools and programming is "to explore problems and mathematical concepts, perform calculations, and present and interpret data." Vinnervik & Bungum (2022) found in the Norwegian mathematics curriculum connections between modelling and applications and programming, and between exploration and problem solving and algorithmic thinking.

In addition to mathematics, programming is integrated in the Swedish technology subject. Although programming is included in the subjects arts and crafts, music and science in Norway, programming is here intended as a tool to learn subject matter, keeping mathematics responsible for introducing basic programming concepts (Vinnervik & Bungum, 2022). In both the Norwegian and Swedish curricula, basic programming concepts are introduced in early primary school. While the Swedish curriculum explicitly states that the students shall learn visual programming languages in primary school and text-based languages in lower-secondary school (The Swedish National Agency for Education, 2024), the Norwegian curriculum does not specify this (Norwegian Ministry of Education and Research, 2019). However, the most Norwegian textbooks series take the same approach.

Kilhamn et al. (2021) created a theoretical framework for analysing lessons created by teachers in school. They later adapted this framework to analyse mathematics textbooks in the lower secondary school of Sweden (Nyman et al., 2024). In their study, they find that most of the tasks in the Swedish textbooks have a primary goal of teaching programming, and mathematics is mainly a context for the programming.

In the current study, we reproduce part of the study of Nyman et al. (2024), but apply it in the Norwegian context. We adapt their analytical framework to six lower-secondary mathematics textbooks from Norway, to compare and identify possible similarities and/or differences between these two Scandinavian countries. By investigating the textbooks, we may gain insight into how the students in the two countries meet programming in mathematics. Although analysing textbooks does not tell us what students learn, mathematics has a long tradition for being driven by the textbooks (Remillard, 2005), and thus analysing the textbooks can give us an indication of the learning opportunities given to the students. In the recent literature review, Holo et al. (2023) list understanding the potential relation between specific mathematical topics and programming as one of the two major suggestions for future research. The current paper contributes to this understanding of the potential relation between specific mathematical topics and programming.

Based on the framework and the data material in this analysis, we ask two of the same research questions (RQ) as Nyman et al. (2024), adapted to the Norwegian context:

RQ1: What is the relation between mathematics and programming in Norwegian textbooks?

RQ2: What mathematical content is visible in connection to programming in Norwegian mathematics textbooks?

These research questions are studied and discussed with respect to the findings in the Swedish context.

Method

In the current study we collect data from the 8th -10th grade (lower secondary school) mathematics textbooks from two of the largest publishers in Norway[1] (6 books in total). Both textbook series contain visual/block-based programming (Scratch), but they mainly focus on text-based programming (Python). In the analysis, only units that contain programming is included. A textbook unit is included if programming is explicitly mentioned or shows computer code, e.g., a task explicitly requesting the student to solve it using programming. As in Nyman et al. (2024, pp. 6) a textbook unit is defined as "a section in the textbook with a new heading and a coherent content containing, for example, an introduction, worked examples and tasks". In the Norwegian textbooks analysed in this work, the textbook units are often one subchapter. The size of a unit varied from 1 to 16 pages, with a median of 3 pages and an average of 4 pages. In total 96 units were analysed, 36, 27 and 33 in 8th, 9th and 10th grade, respectively.

To examine the first research question, the relations framework was applied. This "includes four types of relations between mathematics (M) and programming (P) in a growing hierarchy from MP1 to MP4" (Nyman et al., 2024, pp. 7). The relations framework was originally a framework formulated in Swedish and applied on teaching lessons (Kilhamn et al., 2021). Nyman et al. (2024) translated the framework to English and adapted it slightly to apply it to textbook units. We based our framework on these two frameworks to be able to compare our results with Nyman et al. (2024), and ended up with the following definitions:

MP1: *Programming without connection to mathematics*
Textbook units that merely consists of programming.

MP2: *Mathematics as a context for programming*
Textbook units where mathematics is mainly a context for learning programming. No new mathematics learning is intended, but programming can be used to repeat or consolidate math skills.

MP3: *Programming as a tool for streamlining calculations within mathematics*
Textbook units where the content is clearly mathematics. A computer is programmed and used in an efficient way to perform calculations.

MP4: *Programming as a tool for exploring mathematics*
Textbook units where programming is used to explore mathematical concepts or relationships. The programming adds new ways of approaching mathematics and is used to deepen the mathematical understanding at a level that is relevant for the specified grade.

[1] The Maximum series of Gyldendal and the Matemagisk series of Aschehoug.

For examples of content of the four categories, we refer to Kilhamn et al. (2021) and Nyman et al. (2024). MP1 and MP2 are described as "poor" categories for learning mathematics while MP3 and MP4 represent productive ways of learning mathematics. This does, however, not mean that all units should be MP3 and MP4. Learning mathematics through programming in an MP4 task will typically require that the students know some basic programming in the first place. Therefore, MP1 and MP2 examples and tasks might be needed as well. In the analysis, a unit is put in the highest possible category, meaning that, for example, a unit comprising at least one example of content that fits into MP4 is categorized as MP4.

The textbooks were initially analysed by three of the authors independently, without any prior discussion on how the units should be coded other than reading the relations framework. In the final unit coding presented in the results, we picked the category of the majority of the coders. For two of the units, all three coders coded different categories (MP2, MP3, MP4). For these two units, the coders discussed the units and reached an agreement. The coding framework has to some extent an ordinal relationship between the categories, from least mathematics to most mathematics. Thus, assuming ordinal data, Krippendorff's alpha for inter-rater reliability for the initial coding is 0.61. However, the categories may also be considered nominal, in which case the Krippendorff's alpha is calculated to 0.46.

To answer the second research question the mathematical content of the textbook units was analysed. Each textbook unit would typically only contain a small section about programming. Thus, to categorize the content of the units we only looked at the content of the tasks, examples, explanations, etc. that contained programming. We used the same content topic categories as Nyman et al. (2024) which were: number sense, algebra, geometry, statistics, probability, and problem solving. Both within a single task, or between several tasks in a unit there can be several different topics, thus, each unit can be categorized with multiple mathematical content topics.

Results

Each category, from MP1 up to MP4, constitute approximately 3%, 43%, 24% and 30% of the textbook units, respectively. Compared with the results from Sweden (Nyman et al., 2024), there are a relatively higher ratio of MP3 and MP4 units in the Norwegian textbooks, and a higher ratio of MP1 and MP2 units in the Swedish textbooks, see Figure 1.

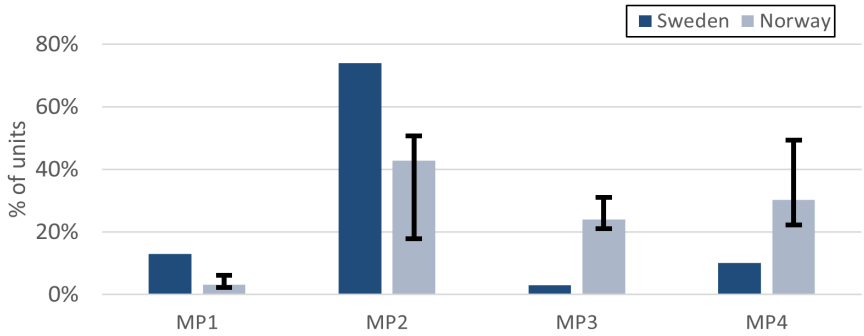

Figure 1. The percentage distribution of relations between mathematics and programming in Norway and Sweden. The Swedish data are from Nyman et al. (2024)

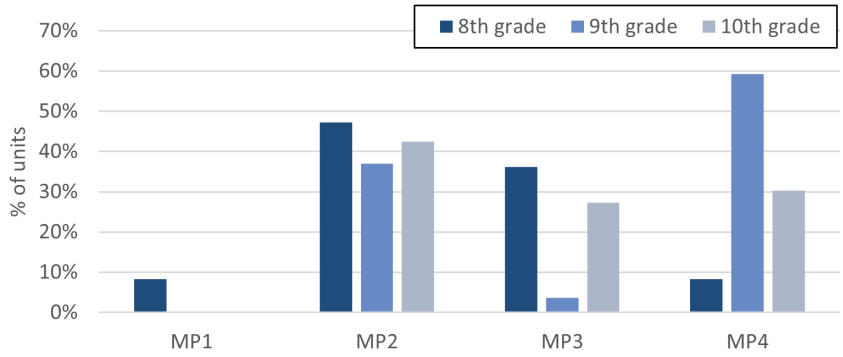

Figure 2. The percentage distribution of the relations between mathematics and programming in each age group

In addition to the distribution of relations in textbook units in Norway and Sweden, the variation between the coders is also illustrated for Norway in Figure 1. This shows the outcome of the coding if the minimum and maximum category was picked, assuming the range from MP1 to MP4 as lowest to highest. Using e.g. the minimum, would put 51 % and 22 % of the units in the MP2 and MP4 category, respectively.

The relations between mathematics and programming vary between the three grades, as shown in Figure 2. The percentage of units in the two highest categories combined are 44%, 63% and 57% for 8^{th} to 10^{th} grade, respectively. 9^{th} grade has by far the highest share of MP4 units, while 10^{th} grade almost have the same share of MP3 and MP4 units. Only 8% of the textbook units in 8^{th} grade belong to the category of exploring mathematics through programming (MP4). We find some introduction to text programming in one of the 8^{th} grade textbooks, but our first impression is that, overall, little attention is given in the textbooks to introducing the fundamental concepts of programming, such as variables, if-statements and loops.

The complete distribution of content in context of relations framework is shown in Table 1. For each mathematical content category, we find that over 50 % of the units were either an MP3 or an MP4 unit.

Table 1. The distribution of mathematical content with respect to the relations between mathematics and programming

Category	Number sense	Algebra	Geometry	Statistics	Probability	Problem solving
MP4	9	16	6	6	8	5
MP3	9	14	1	1	0	5
MP2	15	14	6	4	3	3
Total	33	44	13	11	11	13

Discussion

In the six textbooks analysed we barely found MP1 units (3 of 96), all of them in 8^{th} grade. The high share of MP2 units compared to MP1, indicates that in Norwegian textbooks, the authors try to combine the basic instruction in programming with a mathematical context. One reason for the apparent lack of emphasis on basic programming concepts alone in secondary school might be the

attention to programming concepts in primary school (grade 1-7) (Norwegian Ministry of Education and Research, 2019). In this way, the transition towards a higher share of MP3/MP4 tasks in 9th and 10th grade, compared to 8th grade, may follow a larger trend, where programming to a larger extent is used as a vehicle to learning mathematics. Further, the apparently small focus on introducing fundamental programming concepts can perhaps be due to that the largest publishers in Norway also have digital programming resources, and hence, comprehensive programming material in the written textbooks might not be necessary, if the online material is used in combination with the textbooks. In the Swedish textbooks, the units (except from in one book) were 1-3 pages (Nyman et al., 2024). In the Norwegian textbooks 52 of 96 units consisted of 1-3 pages, and 77 of the units consisted of 1-5 pages. Thus, the Norwegian textbooks have longer units than the Swedish textbooks. This can be important since the units are categorized according to the highest category within the unit, thus, units with more pages will more easily end up in higher categories. This also means that a unit categorized as, e.g., MP4 may have many tasks on MP1 and MP2 that focus on learning programming.

The inclusion of three specialised programming textbooks in the analysis by Nyman et al. (2024) can be another important reason for the high share of MP1 and MP2 units in Sweden. Furthermore, with 2 and 6 MP3 and MP4 units, respectively, their conclusion that the textbooks units with programming provide small opportunities for exploring mathematical content and deepening the mathematical understanding, is reasonable. Our study shows that in Norwegian textbooks, due to the larger fraction of MP3 and MP4 units, there are possibilities of exploring mathematics through programming, given that the learner has some prior basic programming skills.

Some of the differences between Norway and Sweden may be explained by the subtle differences in the curriculum aims in the two countries. Nyman et al. (2024) problematize that although programming is included in the algebraic core content of the Swedish curriculum, the findings of MP3 and MP4 units in the textbooks were mainly found under the content topics of probability and problem solving. However, the curriculum aims do not explicitly link programming to mathematics (The Swedish National Agency for Education, 2024), so it is left to others, e.g., textbook authors, schools and teachers, to operationalize them within mathematical topics. The Norwegian curriculum more explicitly relates programming to mathematics, as in 10th grade, where the aim is "to explore mathematical properties and relationships by using programming" (Norwegian Ministry of Education and Research, 2019). However, the implementation of formal curriculum into teaching materials must be further investigated to fully understand the impact the curricula may have in this context.

Assuming nominal relations categories, the Krippendorff's alpha of 0.46 indicates that the framework by Kilhamn et al. (2021) can be difficult to use consistently. Since the units often included more than one task or example, and the task with the highest score determined the overall unit score, we expect a higher level of agreement. Thus, it should be emphasized that these results come with uncertainties. Nevertheless, our analysis shows a relatively high number of units within MP3 and MP4, and the divergence from Sweden maintains although the minimum is used as selection criteria in the coding, as shown in Figure 1. We propose more elaborate descriptions of the apparently fluent transitions from mathematics only as a context for programming towards using programming in new ways to deepen students' mathematical understanding, as the data has been differently interpreted by the

coders. We also propose a more thoroughly examination and possibly further development of the relations framework.

We performed the mathematical content classification with the purpose of investigating the connection between the relation between mathematics and programming, and mathematical content. Thus, we accepted multiple categories of content topics in the same unit, in contrast to the analysis of Nyman et al. (2024), where each unit is only associated with one mathematical content. The Swedish study shows that number sense, algebra, geometry and problem solving have been largely used as a context of mathematics, constituting 51 of the 54 MP2 units. Looking at the MP3 and MP4 units combined (totally 8), these were found in probability (4), problem solving (3) and number sense (1). Our results show that there might be an opportunity to use programming for exploring within all content topics, which perhaps is not very surprising as the 10th grade competence aim with programming is openly formulated with respect to mathematical content. Further, programming is in 9th grade explicitly connected to statistics and probability (Norwegian Ministry of Education and Research, 2019). Thus, it is not surprising that we found several units with programming connected to statistics and probability. In 14 of 22 (6 of 11 in statistics and 8 of 11 in probability) of these units programming is used to explore mathematics (MP4). Additionally, we found one MP3 unit. Several of the units that were coded as MP4 would also fulfil the requirements of MP3. In one unit, programming is for example used as a simulation tool, but the interpretation of the simulation results moves the unit from the MP3 to the MP4 category. We suggest more thoroughly investigation on possible linkages between MP3 and MP4 content, both within statistics and probability, but also in the other content topics.

The relations framework has now been used in both a Swedish and a Norwegian context. While the Norwegian and Swedish curricula may at first glance look similar, we find that the textbooks have a different realization of programming in mathematics education where the Norwegian textbooks provide larger opportunities of learning mathematical content through programming. We find this for all content areas in the Norwegian textbooks and conclude that programming can be used as a tool for exploring mathematics in all six content topics investigated.

Towards design principles for learning environments based on theorem provers

Irene Garnelo[1], and Michael Liebendörfer[1]

[1]Paderborn University, Department for Mathematics Education, Paderborn, Germany;
ireneg@math.upb.de

Undergraduate students are faced with significant challenges in learning and producing mathematical proofs. Recent research suggests that theorem provers can support this transition by enhancing students' proof abilities. This paper derives design principles for digital learning environments based on the open-source theorem prover Lean, using a design-based research approach by integrating theories from computer science and mathematics education, as well as empirical results from a study conducted on our prototype.

Keywords: Mathematical logic, undergraduate education, computer assisted instruction.

Introduction

One of the challenges students face in in university mathematics is understanding and producing mathematical proofs. Recently, theorem provers were shown to help students to develop their proof abilities (Thoma & Iannone, 2022). However, implementing them is not straightforward, especially because students have to learn how to use theorem provers. In our project, we are developing a learning environment, which aims at supporting mathematics students' learning of proofing by embedding the theorem prover Lean, in the framework of design-based research. In this paper, we derive design principles for such a learning environment by combining theory from computer science and mathematics education as well as results from a study based on our first prototype of the learning environment. Our paper is therefore a theoretical discussion paper. First, we will present theory about proof in undergraduate mathematics, theorem provers and the challenges they pose for students. Then we will draw on other work in design-based research to establish initial design principles for learning environments that include interactive theorem provers. Our aim for this contribution is then to expand the design principles with the help of the theoretical background from Bayman & Mayer (1988) and Moore (1994) together with the empirical results we collected from the initial learning environment.

Theoretical Framework

Proof in undergraduate mathematics

Undergraduate mathematics regards a narrower definition of proof than high school mathematics. At the university level mathematics is built from axioms and definitions, that can be applied to proof theorems. Students' challenges when producing proofs can be clustered into three categories (Moore 1994): (a) mathematical language and notation, (b) concept understanding, and (c) getting started on a proof, referred to here as strategic challenges. Concept understanding includes difficulties stating definitions, lacking an intuitive understanding and failing to generate examples, as well as struggling to use one's concept images for a proof or structuring a proof based on a definition.

Theorem provers

Theorem provers are software in which mathematics can be implemented in a computer-formalized language. In particular, theorem provers have a symbolic library covering a vast number of mathematical topics, which makes it possible to check the correctness of statements and in particular proofs. While theorem provers have existed for decades, they have been gaining traction in mathematics research in recent years, including work by Fields-medallists (Commelin, 2022; Tao, in press). Theorem provers were developed for research, but their features make them promising tools for teaching as well. In particular, these tools provide interactive feedback as one produces a mathematical proof and a comprehensive overview of the mathematical concepts relevant to the topic being worked on (Massot, 2021). Bartzia et al. (2022) give an overview of different theorem provers and list their educational potential. Thoma & Iannone (2022) have reported a study in which university students used more accurate and correct mathematical language, and were better at organizing and structuring proofs after engaging with the theorem prover Lean.

The interface of the open-source theorem prover Lean (https://leanprover-community.github.io/) is divided into two columns. In the left column, the user provides their input, while the right column provides feedback from the tool. Figure 1 illustrates a proof of the commutativity of the addition over the natural numbers using Lean. The example is a proof by induction over the variable ‘b’, where the user has completed the base case and is currently working on the induction step. The Lean feedback, in the right column, includes the proof state and error messages if any mistakes occur. The dark orange area of the proof state lists all the given statements, in this case, ‘a’ and ‘d’ being natural numbers along with the induction hypothesis named ‘hd’. In the light orange area, the current goal, which is the statement to be proven, is displayed. The red area shows an error message by specifying the location and type of error. Both the given statements and the goal change dynamically as the proof is typed in.

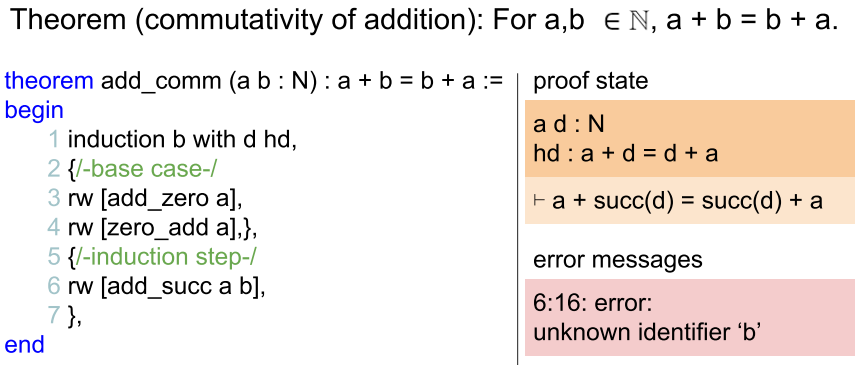

Figure 1: A proof in the theorem prover Lean

To use Lean, students must first learn the Lean language and how the program works. Hoyles (2018) discusses the dual role of digital tools as both a learning subject and a scaffold for learning mathematics, emphasizing the initial investment in learning how to use such a digital tool. Theorem provers were not developed as educational tools. They are therefore not intuitive to use without prior knowledge, and require a considerable amount of work to learn how to use them (Avigad, 2019).

The challenges of students learning Lean

To understand how students learn Lean, we use a perspective from computer science education. Bayman, & Mayer (1988) structure the knowledge needed to master a programming language into three consecutive levels: syntactic knowledge (e.g., proper use of brackets and punctuation, writing commands), conceptual knowledge (e.g., understanding variables, scopes, loops) and strategic knowledge (planning, writing and debugging code).

Iannone and Thoma (2023) have used the model of Bayman, & Mayer's (1988) to categorize students' perceptions of challenges, relying on self-reports obtained from questionnaires and interviews conducted after an 'Introduction to Proof' module that incorporated Lean. Their findings highlight students' struggles, particularly at the syntactical and conceptual levels. In particular, the challenges on these levels are intertwined with the mathematical challenges of the same nature (mathematical syntax and conceptual knowledge), as these issues are not context-specific.

Our learning environment

As learning how to work with a new digital tool requires an initial investment (Hoyles, 2018), we decided to focus the learning environment on a mathematical topic and proof strategies that students were already familiar with. The target audience of our learning environment are second year undergraduate students studying to become mathematics teachers, so we chose the natural numbers and how their properties can be derived from the Peano axioms.

As we are not aware of any existing design principles for the implementation of theorem provers, the initial design of our own learning environment was guided by design principles from other areas of mathematics education. Hein (2021), who researched on pupils verbalizing proof, concluded that students should be offered a linguistic scaffold that helps them in learning how to express mathematical proof. Wessel (2014), who studied non-native speakers learn mathematics alongside learning a language, concluded that students need exercises that link the different representations of the mathematical objects at hand.

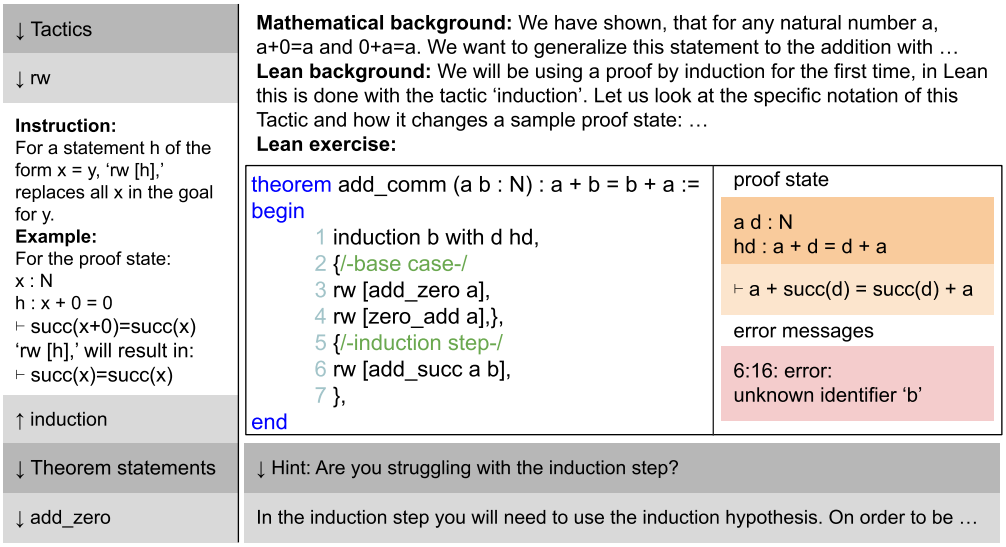

Figure 2: Digital component of the Lean-based environment

Figures 2 and 3 present a schematic depiction of the learning environment (available in German here: http://irenegarnelo.github.io/nat_zahlen_lean/), which is comprised of a digital component and written exercise sheets.

The digital component is a browser-application as depicted in figure 2. It is inspired by the 'Natural Number game' (Buzzard & Pedramfar, 2021). It incorporates exercises to be solved in Lean, featuring the aforementioned input and output columns at the centre of the figure. Additionally, the environment includes texts above the Lean exercises, introducing the mathematical and Lean-specific contents of the exercise. The column on the left contains the descriptions of all tactics and all theorems that can be applied and is meant to provide the linguistic scaffold described by Hein (2021). The environment also incorporates expandable hints to further aid students.

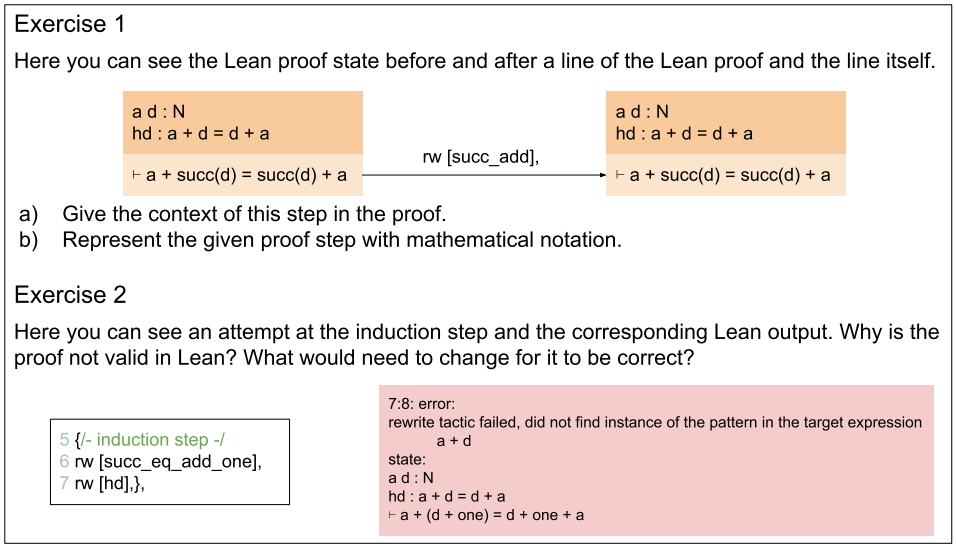

Figure 3: Written exercise sheet from the Lean-based learning environment

The written exercises, as illustrated in figure 3, aim to assist students in learning how to work with Lean, to reflect on their usage of the tool and in particular, to consider the different representations of proofs, following the design principle from Wessel (2014). The written exercises are provided on digital pdf-documents that are linked in the learning environment.

The environment was designed to be used over two 90-minute sessions, in which students are first familiarized with computer-assisted proving, theorem provers, Lean, and the learning environment through a live demonstration. The majority of the time is dedicated to students working in pairs with the learning environment. The working phase concludes with students discussing their experiences and opinions in pairs during a reflection phase.

Empirical results regarding our learning environment

In (Garnelo and Liebendörfer, in press) we presented a study conducted on the learning environment, which was implemented in the lecture 'Mathematics with a Computer' conducted at our university for preservice high-school mathematics teachers in their second year. Our goal in particular was to uncover challenges that need to be further considered in the design of the environment. We documented the work of a subgroup of students and analysed it with regards to the research question:

"At which level of programming knowledge (Bayman & Mayer, 1988) do students face challenges when working with the learning environment and how do the challenges relate to those identified in the process of learning how to proof highlighted by Moore (1994)?". The results that are relevant to the design principles we derive for this work are summarized here.

The challenges encountered when working with Lean occurred at all three levels of knowledge described by Bayman & Mayer (1988). Initially, the majority of problems were related to syntax, which gradually decreased until conceptual and then strategic problems predominated.

Students had trouble with the Lean output. Oftentimes they only looked at whether there was an error message or if the proof state had changed without actually reading them and other times they attempted to read it but fail to understand it. Students reported having trouble with the error messages in particular.

Students oftentimes skipped the written exercises. They were mostly focused on the Lean task, and once it provided the "Proof complete!" message, they moved onto the next Lean task and did not solve the exercises on the sheets. Oftentimes they did not even open the sheets, despite them being linked directly within the environment.

Developing new design principles

Providing a scaffold for the different levels of knowledge

When working with Lean students are learning multiple skills, both on an interdisciplinary level (Hoyles, 2018) and on the level of Lean itself (Bayman & Mayer, 1988). We need to choose the order in which we want students to acquire these new skills. In the first iteration, guided by Hoyles (2018), we had decided to focus on learning Lean as a tool as opposed to adding new mathematical content. (Bayman & Mayer, 1988) present a further subdivision of the skills required within learning how to use a programming language. In particular, they argued that these skills are developed in a specific order (syntax, then concepts, then strategies). In our study, we confirmed that working with Lean also leads to these results. Therefore, we propose designing a scaffold along the learning environment, which provides the levels (syntactic, conceptual and/or strategic) that the student has not acquired yet, so that students are able to focus on the level of knowledge they are currently learning. To this end, the concept of the exercises was changed. While in the initial learning environment, students always had to provide a full proof, we propose that the first exercises consist of reading, completing or correcting given proof attempts in order to focus on understanding and using the Lean syntax initially, before working on tasks related to conceptual and then strategic knowledge. Similarly, once students have mastered the Lean syntax, we recommend exercises where the strategic knowledge needed is given (e.g. in the form of a proof structure), so that students can focus on their conceptual knowledge.

Increasing students' attention to the Lean output

As seen in figure 2, the digital component of the learning environment provides a variety of elements, that students could turn their focus to. When designing such an environment we must decide which of these elements we want students to focus on and how we can achieve this. In our initial design**,** we intended to make use of the advantage of Lean providing interactive feedback as mentioned by

Avigad (2019). To this end, we set the focus on the Lean components of the environment, namely the user input and Lean output, which was achieved by making the left column with all the details on theorems and tactics, as well as the hints collapsible. The only component in the left in the foreground other than the Lean interface, was the introductory text, which was intended to be focused on by the students primarily before work on the task started. Becker et al. (2019) highlight the challenges that students face when confronted with diagnostic messages generated by compilers and interpreters, such as syntax error messages. In Lean, in addition to the error messages, the tool also provides the proof state as an output. In our study**,** we found that Lean is not an exception to the findings of Becker et al. (2019) and that the results also extended to the proof state. We propose introducing instructions and exercises targeted at increasing students' attention to the Lean output. To this end, the instructions both in class and in the digital learning environment on how to understand the output were expanded. A cheat sheet with an overview of how to interpret these outputs was created. Additionally, students received exercises whose sole focus was on reading and understanding the Lean output.

Guiding students' attention to the connection between different representations of proof

Students are faced with the challenge of learning a new language in which to express mathematics as they work on the proofs. This raises the question of whether it would be beneficial for the students to focus on how the proofs they are working on are expressed in a traditional mathematical context or with Lean. As suggested by Wessel (2014), in our first iteration we focused on students connecting these different representations of proof by introducing written exercises. These exercises were posed as a reflection after completing Lean proofs. Lutfianto et al., (2013) showed that pupils prematurely consider a task complete when they reach a mathematical solution, disregarding the intended reflection after obtaining their result. In their case, the reflection consisted in relating the mathematical results back to the context in which they were posed. In our study we also found that students disregarded the exercises that we provided as a reflection after the proof was achieved. We propose that the exercises need to be interweaved better with the Lean-tasks, as opposed to being offered as a final step after proof completion in order to guide students to the connection of different proof representations. To this end the exercises are given in the text introduction, preceding the proofs within the digital environment and are posed in a way, in which they helped the student resolve the Lean proof. For example, an exercise of this type could consist of providing the proof or a proof step in traditional mathematical language for students to translate into its Lean-representation. Similarly, one can set the focus on translating Lean language into regular mathematical language by providing students with the goal states that one will achieve throughout the proof, for them to use as a guideline to develop their mathematical strategy for the proof.

Discussion

In our work we focused on how Lean, or more generally interactive theorem provers, can be incorporated into learning environments for undergraduate students. Interactive theorem provers are complex, but they are have gained increased attention both for mathematical research and education. There are many ways in which a theorem prover could be incorporated into a classroom, which is why design principles are needed. In our work we have started to derive possible design principles from theory in mathematics and computer science education as well as from our empirical results.

The first design principle we derived was designing a scaffold which offloads the higher level of Lean knowledge, so that students can focus on attaining the lower levels of Lean knowledge first. To this end we propose introducing exercises in which students focus on parts of a proof instead of the full proof. The second design principle we derived is to increase students' attention to the Lean output by introducing instructions and exercises targeted at working with the Lean output. The final design principle we derived was to interweave the written exercises with the Lean-tasks in order to guide students' attention to the connection of the different representations of proof. To this end we propose embedding the written exercises within the introductory text preceding Lean tasks and to conceive them in a way that supports students during their Lean task as opposed to serving as a reflection conducted after the Lean task.

Apart from some small structural changes, the design principles described above translate mainly into developing new types of exercises to support the learning journey and in which order these exercises could be posed in order to accompany the different levels of knowledge. The design principles derived in this paper were applied in the development of a new version of the learning environment (available in German here: https://ireneupb.github.io/lean_umgebung/), which we hope to use to get insights on how our design principles affect the learning with the environment.

Further research in the field of theorem provers should study the effect of interactive theorem provers on learning proof. As discussed in Hoyles (2018), digital tools, and in our case Lean, play two roles in the classroom. In particular mastering Lean requires an initial effort, that is exclusively directed at Lean in the role of learning subject. We have analysed the challenges students encounter when learning how to use Lean and tried to mitigate some of them with our design principles. Nevertheless, learning the language will always require some additional effort, even with improved versions of the learning environment. By showing whether mastering challenges with a theorem prover supports learning the analogous challenges in mathematical proof, future research will show whether the initial learning effort is worthwhile.

Programming in the primary mathematics curriculum in Norway

Trond Stølen Gustavsen and Suela Kacerja

University of South-Eastern Norway, Drammen, Norway; trond.gustavsen@usn.no

This study examines the integration of programming into primary school mathematics in Norway, which the new LK20 curriculum emphasises. Through a qualitative case study across four schools, we analysed teachers' reflections through focus group interviews over three years. Findings indicate initial enthusiasm by teachers and their students. However, programming tends to be treated more as an add-on to mathematics rather than being integrated into the mathematics curriculum. Despite faithful implementation, teachers highlight challenges and a need for more knowledge. We recommend enhanced professional development, further research and ongoing curriculum development to support the integration of programming into the mathematics curriculum.

Keywords: curriculum implementation, programming, primary school mathematics.

Introduction and theoretical framework

The integration of programming into compulsory school curricula has gained significant traction, driven by a recognition of the importance of digital literacy (Bocconi et al., 2018). In Norway, these trends can be seen in the 2020 national curriculum (LK20), mandating the inclusion of programming in Mathematics, Science, Music, and Arts and crafts (Vinnervik & Bungum, 2022). There are varying approaches to integrating programming into school curricula, from having it as a separate subject to integrating it into mathematics and other school subjects (Bocconi et al., 2018). In Finland, Sweden, and Norway, programming is integrated into existing subjects (Vinnervik & Bungum, 2022).

Programming is the process that goes from identifying a problem and proposing solutions to translating these into a computer program, which is then refined and improved through testing and debugging (Sevik, 2016). Computational thinking (CT) is a broader notion including "formulating problems in a way that enables us to use a computer and other tools to help solve them" along with aspects such as data practices and modelling and simulation practices (Bocconi et al., 2016, p. 21). A growing body of research investigates how CT can be integrated with mathematics (Ye et al., 2023).

The LK20 mathematics curriculum for primary school has one competence aim each year, addressing programming. In years 1–3, students create and follow rules and step-by-step instructions during play and games, in years 4–6, they create (year 4) and program (year 5) algorithms using variables, conditions, loops, and functions (year 6). In years 6–7, they apply programming to explore geometric patterns (year 6) and tables and datasets (year 7) (Ministry of Education and Research, 2019). In the same curriculum, the process of breaking down problems and solving them systematically is presented as an aspect of CT, thus linking CT to problem-solving. However, in this study, we focus more narrowly on programming, as this was most prevalent in the interviews. Kaufmann and Stenseth (2023) pointed out that even though programming has been given a prominent position in the LK20 mathematics curriculum, its role in mathematics remains unclear.

For implementing LK20, the Directorate of Education in 2018 commissioned 13 science centres to develop an educational program to strengthen teachers' and students' foundational programming

skills with courses for teachers and schools. They also offer programming teaching resources that they link to the competence aims in LK20 explicitly addressing programming. Using programming as a tool for learning mathematics seems not to have been emphasised (Superbit, n.d.).

There are few studies addressing the preparedness of teachers for the integration of programming into the mathematics curriculum. Kravik et al. (2022) interviewed eight Norwegian teachers in grades 5–7 to investigate their understanding and teaching approaches to programming and computational thinking and their professional development needs. While teachers were generally positive about incorporating programming into mathematics and science, they had a narrow understanding of programming and limited teaching methods. Similarly, Kaufmann et al. (2023) found that prospective mathematics teachers, despite considering themselves "digital natives," had minimal experience with programming. They stressed the need for further research on how programming can contribute to deepening students' mathematical understanding. In Sweden, it was found that the adoption of programming in mathematics education was unclear and challenging for teachers, often focusing on reinforcing previously learned mathematics rather than developing new skills (Stigberg & Stigberg, 2020). Previous studies have thus shown challenges concerning the preparedness of teachers to integrate programming into mathematics education. However, how teachers adapt their understanding and approaches over time remains a crucial yet uncertain aspect of the LK20 reform.

Following Remillard & Heck (2014), we distinguish between the official and the operational curriculum where the official curriculum consists of the designated curriculum, curricular aims and objectives**,** and the content of consequential assessments, while the operational curriculum consists of the teacher-intended curriculum, the enacted curriculum and student outcome (Remillard & Heck, 2014, p. 709). The teacher-intended curriculum refers to the ways the teachers interpret the official curriculum and additional resources, as well as the decisions they make to transform it into practical instructional strategies (Remillard & Heck, 2014). It is the teacher-intended curriculum, rather than official documents themselves, that shapes how teachers facilitate student learning, and several factors are known to influence the teacher-intended, and hence the operational curriculum, including teachers' practices, beliefs, knowledge, access to resources and support and understanding of students need (Remillard & Heck, 2014, p. 714). In addition, the enacted curriculum and student outcomes contribute to additional influencing factors of the operational curriculum, such as contextual opportunities and constraints and students' attitudes and motivation. Given this, our research question is as follows: *What are primary school teachers' reflections about programming in the operational mathematics curriculum and what factors influence it?*

Methods

We use data from a qualitative multi-case study with a longitudinal design, 'EvaFag2025', investigating the implementation of the LK20 National curriculum in Norway (Burner et al., 2022) focusing on Mathematics, English, Music, and the Social Sciences. We report from the first three data collections. Four primary schools representing variations in urban or rural settings, economy and school size were included. Nine mathematics teachers (respectively 2, 3, 3 and 1 teachers from School 1, 2, 3 and 4) took part in focus group interviews lasting 60–105 minutes in 2022, 2023 and 2024. The teachers represented a variation in age and experience and were teaching across grades 1–7.

Among several aspects of the LK20 implementation, the teachers were asked open questions on how they integrate programming into mathematics, if and how they worked with it and about support and hinders in that work. For instance, an initial question could be: "Programming and computational thinking has entered the curriculum. How did you work with this?". Follow-up questions were often more specific, like: "Do you think that programming in mathematics affects students' learning in mathematics in any way?". In subsequent years, we typically started by briefly referring to the previous year and asking for updates.

For the present paper, all interview extracts related to programming in mathematics were identified and coded thematically (Braun & Clarke, 2006). Codes sharing a common meaningful unit were grouped into subcategories, which were then merged into broader categories shaped by our theoretical lenses. The resulting categories are presented and explained in the following section.

Findings and discussion

We identified four main categories and several subcategories (in italics) related to programming in the operational mathematics curriculum. The categories, while distinct, are inherently interconnected, each aligning with specific aspects of the curriculum enactment process.

Category 1: Teachers' knowledge for teaching programming in mathematics

Category 1 includes teachers reflections on their knowledge for teaching. This is known to be a factor influencing the teacher-intended curriculum (Remilard & Heck, 2014). Category 1 contains two subcategories: *Sources of knowledge about programming in mathematics* (coded 11 instances) and *Gaps in knowledge* (9 instances).

The interviewed teachers refer to three *sources of knowledge about programming in mathematics*: courses, self-study, and support from a resource person within the school staff. In the first year, some of the teachers reported attending programming courses at the Science centres. These seem to have played a role in introducing teachers to concepts and tools for teaching programming. However, much seems to rely on self-study as a significant and implicit aspect of professional development.

Teachers also mentioned the importance of resource persons within their schools, and one of the interviewed teachers had such a role. The municipality organises courses for resource persons who then share with colleagues. Other schools report on different practices, less organised at the start, counting more on interested individuals. This changed in 2023 when a group of teachers at one of the schools, focusing on digital aspects of teaching, was "organising a [course] in programming … over two afternoons [...] focusing on mathematics and science" (Teacher 1, School 2, 2023).

Despite teachers' efforts to integrate programming into mathematics and their participation in various courses, several of the teachers still *identify gaps in their knowledge and areas where they need additional support*. One teacher expressed that while they can manage technical aspects, they struggle with explaining and facilitating deeper learning of concepts like "conditions, loops and variables", stating: "I don't feel that I learn that from being able to program them myself" (Teacher 2, School 1, 2022). This reflects a need for professional development that also addresses didactical aspects of teaching programming in mathematics. This sentiment seems to have persisted and developed over time and was expressed by a teacher in a later interview: "… we're not really programmers…"

(Teacher 1, School 4, 2024). This teacher pointed to a lack of competence, rather than a lack of resources, as the root of the problem, indicating a desire for a more comprehensive and detailed understanding of programming, as well as clarity in integrating it into the curriculum, particularly regarding its connection with mathematics. On the other hand, another teacher (Teacher 1, School 1, 2024) emphasised that they do not need to know everything since students themselves should explore and find out. Kravik et al. (2023) also reported a lack of knowledge for teaching programming. After implementing and experiencing the curriculum over three years, our findings suggest that there is still a lack of knowledge and teacher uncertainty about the connections between mathematics and programming.

Category 2: Programming in the teacher-intended mathematics curriculum

Category 2 encompasses teachers' interpretations of programming within the mathematics curriculum, organised into three subcategories: *The importance of programming* (7), *Placement of programming during the school year and at levels* (7), and *Integration of programming and mathematics* (24).

Concerning the *importance of programming,* teachers generally support integrating programming into the mathematics curriculum, recognising its growing importance. One teacher remarked: "The world is heading in that direction, and programming and digital skills are currently much in focus» (Teacher 2, School 1, 2024). Despite the initial positivity, there are indications of a slight decline in motivation over time. One teacher mentioned Micro:bit and not having used it much (Teacher 2, School 3, 2024).

Concerning *placement of programming during the school year and at levels* in line with the designated curriculum, the teachers see programming as relevant across all seven grade levels of elementary school. However, there are challenges in maintaining continuity. One teacher noted: "You kind of start over again each time ..., and you might not fully manage to connect it to the goals you're supposed to link it to" (Teacher 1, School 4, 2024). The teacher highlights challenges in establishing a natural and coherent place for programming in the curriculum and in connecting it to the mathematical part of the learning objectives in the designated curriculum. On a practical level, another teacher struggles to find a natural place for programming based on the progression of the learning in the subject, instead relying on practical considerations, such as doing programming before Christmas.

Concerning the *integration of programming and mathematics*, teachers recognise the potential but do not always emphasise the integration of programming in the traditional mathematical curriculum: "There's a lot of mathematics in it ... It's not like I go around thinking, 'Oh no, now they have to see the connection to programming as well'" (Teacher 3, School 2, 2024). However, some teachers do integrate programming with traditional mathematics content, such as using the terms right, left, forward, and backwards in early grades or exploring areas and rectangles with robots: "We've used the robots to work with area and rectangles, in relation to centimetres with rulers" (Teacher 1, School 1, 2022). However, overall, there were few reflections on the integration of mathematics and programming, and it seems that programming has an unclear role in the traditional mathematics curriculum, as also remarked by Kaufmann and Stenseth (2023). The limited application of

programming in mathematics learning in the primary grades may to some extent, be a consequence of a slow, spiralling progression for programming, which contrasts with a departure from a spiral progression for traditional mathematical topics (Ministry of Education, 2019). This may also be a possible explanation for the lack of reflections on programming in problem-solving, even if this aspect is used as an argument for CT in compulsory education and mentioned in connection with problem-solving in the curriculum documents (Ministry of Education, 2019; Directorate of Education, 2019).

Category 3: Teaching programming in mathematics

Category 3 includes teachers' reflections on how they teach programming in mathematics in practice. This category is divided into three subcategories, focusing on specific aspects of enacting programming: *Tools and curricular resources* (35), *Teaching approaches* (13), and *Interdisciplinary dimensions of teaching programming* (7). All teachers place a significant emphasis on *tools and curricular resources*, a focus that persists across the first, second, and third interviews, as one teacher noted: "What I think about programming is that you need quite a few tools ... you need quite a bit of equipment to get things up and running" (Teacher 3, School 2, 2022). Tools like Micro:bit, BitBot, Arduino, Sphero Ball, Lego Robots, and Edison Robots are mentioned, in addition to block programming platforms like MakeCode and Scratch. Robots are generally associated with programming in mathematics.

Concerning resources for teaching programming, the teachers commonly use ready-made curricular resources such as the adopted textbooks or Superbit (n.d.) (with Micro:bit) that seem to have influenced several of the teachers. There is a danger that an extensive focus on a variety of gadgets, tools and elementary coding tasks may divert the focus from understanding underlying principles and in-depth learning.

In the *teaching approaches,* teachers emphasise starting with simple, hands-on programming activities without computers, focusing on planning and precision, aligning with the lower-grade competence aims in the LK20 mathematics curriculum and the adopted textbooks. Progressing from these unplugged activities to digital programming is seen as beneficial for both younger and older students. One teacher further acknowledges a contrast between traditional mathematics teaching and including robots, "…they have tasks where they need to do a certain amount in the math book, but it's a bit different when they have a robot or something in front of them because then they can actually see it moving physically" (Teacher 1, School 1, 2024).

Teachers see programming as facilitating exploration, as one teacher observed: "It doesn't take long before [the students] are out there trying something" (Teacher 1, School 4, 2022). However, there is a developing concern that while students are actively engaged in hands-on activities, this may not always lead to in-depth learning, thus recognising its limits and stagnation after a while. Also, Kravik et al. (2022) found that the teaching approaches in 2021 were limited, a challenge that seems to persist, with some teachers expressing uncertainty about how best to facilitate exploration. The Nordic approach of implementing programming in compulsory education (Bocconi et al., 2018) integrates programming into various school subjects rather than treating it as a standalone subject. As a result, programming is inherently taught *interdisciplinary,* particularly in mathematics and science

(Vinnervik & Bungum, 2022), though it also extends to creative activities in Music and Arts and crafts. Some of the mathematics teachers reported on interdisciplinary teaching efforts or teaching programming in subjects other than mathematics, mostly connected to Science.

Category 4: Programming and students

Category 4 includes teachers' reflections on the effects of programming on students, resulting in two subcategories: *Students' level of engagement and motivation* (9), and *Challenges and opportunities they experience* (8). The teachers report a high *level of engagement among students* when implementing programming tasks: "[The students] were very inspired […] When we had an activity week, they decided for programming" (Teacher 1, School 2, 2022). The teacher further described a week of programming activities, where students built cars, held competitions, and invited parents to participate.

Teachers also highlighted how programming can be particularly motivating and provide a sense of achievement for students struggling in other academic areas. One teacher observed that "students who might struggle academically in other contexts find joy in this" (Teacher 2, School 3, 2022). Most of the resources used, like Micro:bit, Bit:bot and Scratch, are rooted in international trends and designed to make knowledge accessible and engaging for young students. However, by the last interview, it was clear that the initial motivation might not be sustained over time. One teacher remarked: "[The motivation] is probably very, very high at the start, and then […] it might kind of stall a bit" (Teacher 1, School 4, 2024). This evolution in student motivation suggests that there may be a need to move beyond making programming fun and engaging. Future efforts should also focus on sustaining long-term engagement and fostering deeper understanding.

Teachers reflect on *achievements, opportunities and challenges for students*, pointing out the success many students experience in programming: "there were loops and variables, and they created a lot.... the ones growing up now are so good at these things. They pick things up so quickly" (Teacher 1, School 2, 2024). However, as one teacher acknowledges, some students struggle with programming or lack the necessary patience. Interestingly, it was also observed that students who otherwise struggle can, in some cases, find a sense of achievement in programming. These observations indicate a need for further research on how programming, as part of the mathematics curriculum, may cater to diverse learner profiles.

Contrasts in teachers' perspectives over time and between schools

The transcripts do not reveal strong longitudinal trends; however, the data suggest a gradual waning of initial enthusiasm, an evolving awareness of challenges such as facilitating in-depth learning related to programming, and an increasing desire for pedagogical knowledge among some teachers. In the first interview, teachers spoke more about knowledge and its sources, while in the final interview, one teacher, in particular, shifted focus to the types of knowledge needed, emphasising challenges and the integration of mathematics and programming. No clear differences were identified that could be attributed to the schools' characteristics, such as rural or urban location, size, or budget. Interestingly, teachers at schools with smaller budgets reported no lack of equipment for teaching programming in mathematics.

Conclusion and implications

The interviewed teachers report multiple sources of knowledge about programming, with the Superbit (n.d.) initiative as the most prevalent. Even though teachers seem to have a good basic knowledge of programming, some report a desire for deeper technical and pedagogical knowledge. Teachers view programming as a natural part of the mathematics curriculum, though it appears more as an add-on or as isolated blocks, with few examples of synergies between learning to program and learning mathematics. They often use ready-made curricular resources utilising robots, Micro:bit, and block programming. Exploration is reported as an important teaching approach, although some report lacking approaches for advancing learning beyond the fundamentals. The Nordic model of integrating programming across multiple subjects is seen as beneficial by many teachers, although mathematics is often not a central focus in their implementation of programming. Teachers report engagement, even among struggling students, although this engagement is not universal or sustained over time.

In the official LK20 curriculum, there is only a singular competence aim related to programming for each grade. The Super:bit educational program links these competence aims (for grades 5, 6 and 7) to proposed activities. While it is helpful for teachers to connect activities to the programming competence aim, this is not enough to be able to see further connections between programming to mathematics. Although there is a growing body of research on CT-based mathematics instruction (Ye et al., 2023), more research and curriculum development are needed. In the Norwegian context, one should further explore and map out connections and opportunities for using programming as a tool for learning mathematics. Furthermore, research should also focus on sustaining long-term engagement and fostering deeper understanding while catering to diverse learner profiles.

In the Nordic approach to introducing computational thinking (Bocconi et al., 2018), much of the responsibility falls on teachers. In the authors' view, insufficient efforts have been made to adequately support and prepare teachers. Professional development initiatives need to provide, as they become available, research-based examples of how programming can be integrated into the teaching of various mathematical topics, highlighting both the connections and distinctions between mathematical and computational thinking as well as facilitating sustained engagement and in-depth learning for all students. The aim should be to equip teachers with enough understanding of programming's potential in mathematics to enable them to develop their own teaching resources and strategies. Teachers should also be prepared to teach programming as an integrated component of mathematics, avoiding its perception as a mere add-on. Integrated approaches should enhance mathematics learning while also fostering the development of computational thinking.

Relationship of computational thinking and spatial reasoning when programming educational robots

Laura Heibeyn[1] and Carina Büscher[1]

[1]University of Cologne, Germany; laura.heibeyn@uni-koeln.de

Many studies see potential in the use of educational robots in primary school. On the one hand, the potential is seen to promote students' Computational Thinking (CT) as early as possible. At the same time, a connection between CT and spatial reasoning is often assumed. On the other hand, further research is needed into how exactly CT and spatial reasoning are used in programming processes. In a qualitative study with sixteen second grade students from Germany, this is examined in more detail. This article uses a best case to show how CT activities and aspects of spatial reasoning can be linked in a successful programming process. Consequences for teaching practice are discussed and an outlook on the next steps is given.

Keywords: Educational robots, programming, computational thinking, spatial reasoning, primary school.

Introduction

As early as 1980, Papert had the idea of promoting mathematical skills by programming robots. In this context, he used the term Computational Thinking (CT) to capture the cognitive processes involved (Papert, 1980). Today, CT is seen as an increasingly important skill for responsible movement in today's digitalised world. Wing (2006) even equates the relevance of CT with the basic skills of reading, writing and arithmetic and describes it as a fundamental skill for everyone - regardless of whether they are computer scientists or not.

Teaching spatial reasoning (SR) as interdisciplinary task is also one of the main objectives of general schooling. The sub-component of spatial orientation in particular plays a central role in everyday life. For example, it is constantly necessary to distinguish between right and left - whether driving a car, describing a route or following instructions on which side the doors open on a train. For spatial orientation, however, it is not only important to be able to distinguish between right and left, but also to be able to put oneself in the spatial situation, either mentally or physically, to be able to orient oneself. Only then can children describe routes flexibly by including the directions forwards and backwards in addition to right and left. Among others, the study by Uttal et al. (2013) show that SR can be trained.

Several studies have examined the beneficial impacts of SR and robotic interventions in educational settings (Francis et al., 2022). However, not much research has been done on this current topic. Francis et al. (2022) emphasise that future studies should investigate how exactly the programming of moving robots supports the learning of mathematics. This article therefore examines the extent to which CT and SR demands are placed on children when programming educational robots as the Blue-Bot.

Theoretical background

Framework for the capture of computational thinking

According to Wing (2006), CT is the reformulation and representation of a seemingly difficult problem in a way that makes it manageable and solvable. Wing emphasises: “Thinking like a computer scientist means more than being able to program a computer. It requires thinking at multiple levels of abstraction” (2006, p. 34). That means, students should not only use computational tools but also construct them themselves, which requires many competences. However, there are different views on which activities belong to CT (Brennan & Resnick, 2012; Selby & Woollard, 2013; Angeli et al., 2016; Büscher, 2025). Büscher (2025) subdivided CT in six activities: Reusing and Modifying, Decomposing, Testing and Evaluating, Algorithmitising, Abstracting and Generalising. As there are only three of these activities observed in the case to which this study refers to in the empirical part, only these are explained in Table 1.

Table 1: Important CT activities for this paper (following Büscher, 2025)

Decomposing	Learners break down a complex problem into smaller subproblems.
Algorithmitising	Learners plan a series of several steps.
Testing and Evaluating	Learners test their codes and change them and investigate the effect.

Framework for capturing spatial reasoning

SR includes “the capacity to relate and navigate the world and the ability to imagine objects and their movement” (Francis et al., 2022, p. 928). There are different models of SR, but this paper uses the model of Davis et al. (2015). Davis et al. (2015) identify six different sub-processes that take place during SR and thus, at least in part, during spatial orientation. They break these down into sub-processes, as shown in Table 2. To avoid the impression of conceptual scaling, Davis et al. (2015) presented the categories in their work in a circular model. For reasons of space, this paper uses a tabular representation, as this is sufficient in terms of content, but it should be noted here that the order of the aspects does not matter. In addition, Davis et al. (2015) emphasise that the individual sub-processes often do not take place independently of each other, but that there is an interplay between them. According to Davis et al., both “’mental’ understanding” (2015, p. 141) and “’physical’ transformations” (2015, p. 141) are necessary in SR, whereby these merge into one another and cannot be clearly assigned to the different aspects. The fact that this definition and categorisation includes both mental and physical activities, which is rarely the case (Francis et al., 2022), is important in the context of this paper as it is relies primarily on the physical reasoning tools that the children use, because only these can be observed.

Table 2: Aspects of SR (following Davis et al., 2015)

Mental understanding	Sensating	Perspective-taking, Visualising, Propriocepting, Imagining, Tactilising
	Interpreting	Diagramming, Modelling, Symmetrising, Comparing, Relating
	(De)constructing	De/re/composing, Un/re/packing, Re/arranging, Sectioning, Fitting
Physical trans-formations	Altering	Dilating/Contracting, Distorting/Morphing, Scaling, Folding, Shearing
	Moving	Sliding, Rotating, Reflecting, Balancing
	Situating	Dimension shifting, Locating, Orienting, Pathfinding, Intersecting

Related research

There are already several studies that deal with programming in elementary school. In their meta-analysis, Lye and Koh (2014) found that programming in the primary school context is primarily taught using the programming languages LOGO and Scratch, but educational robots like the Blue-Bot are also used, even at lower school levels. In the study by Caballero-Gonzalez et al. (2019), for example, first graders were asked to steer an educational robot to a specific target field on a floor mat divided into squares. They were able to show in their pre-post study that the exercises with the educational robots led to an increase in learning, for example in the activities *Testing and Evaluating* and *Algorithmitising*. Thus, they investigated the influence of the use of learning robots on learners' CT activities.

The study by Francis et al. (2022) examines the malleability of SR in robotic interventions. Francis et al. (2022) therefore also transferred the categories for SR according to Davis et al. (2015) to the robotic intervention and tested them there. They found that the *Visualising* and *Imagining* subcomponents of the *Sensating* supercategory were identified in all items of the spatial imagination test and in all robotics tasks. Additionally, elements of the *Interpreting*, *(De)constructing* and *Situating* categories could also be found in the tests and robotics tasks. The elements of *Altering* and *Moving* were also integrated in the robotics tasks. However, it was not possible to investigate whether there were positive effects in the children's spatial imagination regarding these categories, as the spatial imagination test did not cover these elements. In their previous study, in which nine to ten-year-olds were asked to program EV3 robots with LEGO Mindstorms, Francis et al. (2016) were able to observe almost all the elements of SR described by Davis et al. (2015). Only the sub-elements of *Altering* were not used by the children. However, the extent to which this robotics task shapes SR was not investigated here, as the change in orientation skills was not examined using a pre-post-test.

Further research is needed on how CT and SR are related when programming educational robots. This paper therefore addresses the following research question:

RQ: What are the demands for programming educational robots regarding CT and SR and how are they connected?

Methods

For exploring the demands, an explorative case study was carried out (Yin, 2002). It is important that the selected cases are comparable on the one hand, but diverse enough to cover as many different outcomes as possible on the other. Therefore, the sample consisted of 16 learners from Germany aged between 7 and 9 who had no previous experience of CT in the classroom and had not worked with robots. The sessions were videotaped, and relevant scenes were transcribed. A qualitative content analysis according to Kuckartz (2019) was used to evaluate the data, as it enables a structured and rule-based evaluation of the data, makes the interpretation of the data verifiable and allows the results to be transferred to other subjects. To illustrate the results, a child who reached the goal the fastest was selected below to better understand her successful process. We decided to take a closer look at Lisa's case because her example clearly shows how many CT activities and how much SR are required for this process to run successfully. This also illustrates the complexity of the programming process. In other cases where the process is not effective, only a few aspects of the CT and SR that Lisa uses are observed. Using Lisa as an example, we can see what the programming process ideally looks like, which allows us to highlight key aspects of CT and SR in programming.

Empirical insights into the case of Lisa: systematic decomposing and use of diverse aspects of spatial reasoning

In the task focused on in this paper, the learners were asked to move the robot from starting field B4 to target field A1 (Figure 1). However, the exact path was left up to them to keep the task as open as possible and to encourage the children to act independently. In contrast to most of the other learners in the survey, Lisa succeeds in programming a path from the start field to the target field on her first attempt. She programs the path marked in grey (Figure 1).

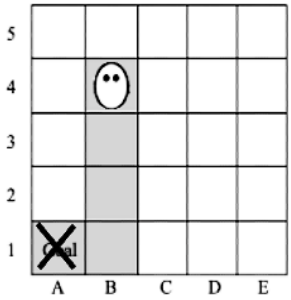

Figure 1: Path of Lisa

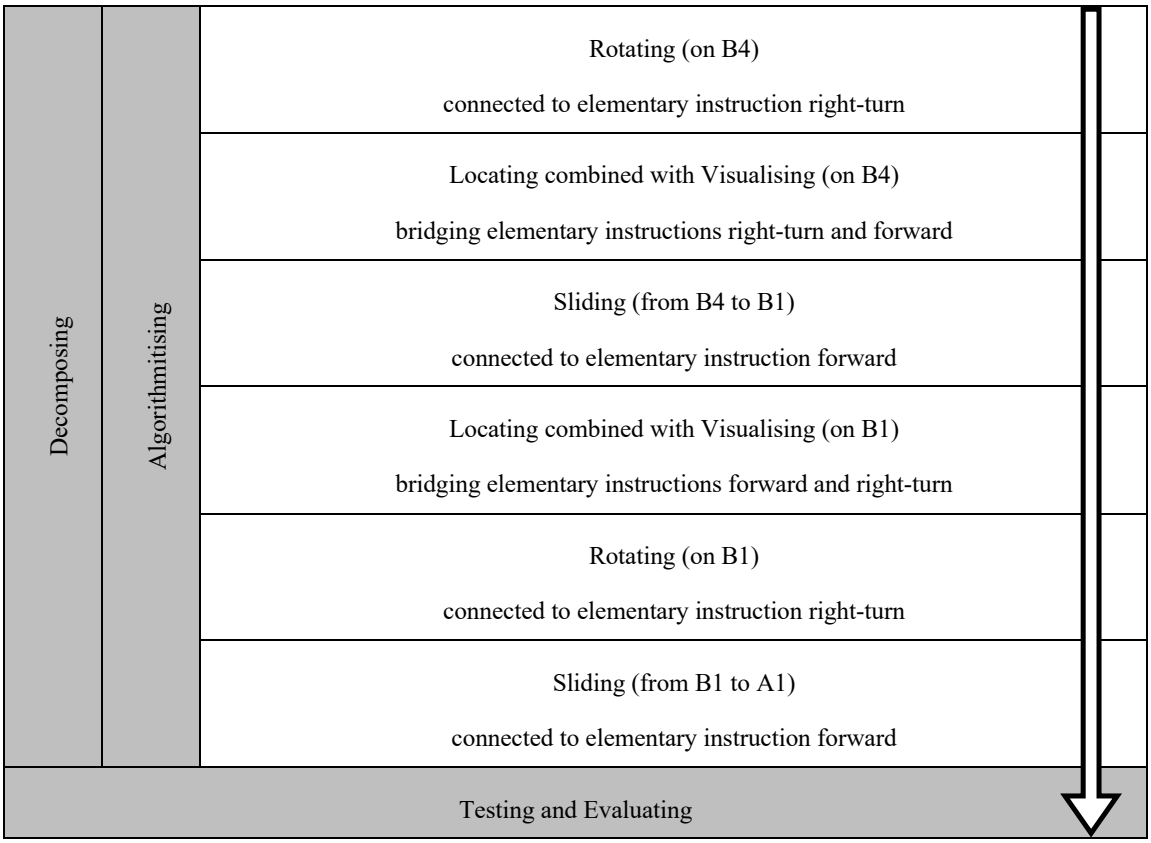
118.1	Lisa	So. You could once, erm twice like this. [presses “right” twice] and then it would look like this [puts her hand over the robot and turns it 180° to the right].
118.2	Lisa	Then you could one, [points to B3] two, [points to B2] three [points to B1] fields forward. One, [presses “forward”] two, [presses “forward”] three [presses “forward”].
118.3	Lisa	Erm, then this is how it stands. [puts her hand over B1 in the same way as over B4 in 118-1] … Then to the right again [points to B1] and then he goes there [points to A1]. Right [presses “right”] and then one forward [presses “forward”].
119	Teacher	Okay, try!
120	Lisa	[presses “go”] This could work. [robot moves the intended path] It worked out!

Lisa says: “you could once, erm twice like this” (#118.1) and presses the button for right-turn twice. She then holds her hand over the robot and turns it 180° to the right. In this way, she visualises the position of the robot including its orientation according to the previous programming. In terms of CT, this shows *Algorithmitising*, as she enters the first two elementary instructions. In terms of SR, it shows *Rotating* (*Moving*) when she plans and implements the rotation of the robot. *Locating* (*Situating*) also occurs when she describes how the robot would stand after the movement. This occurs together with *Visualising* (*Sensating*) when she gesturally represents the movement with her hand. It is possible that the visualisation helps here for locating and thus for further planning.

Lisa then points to the fields B3, B2 and B1 one after the other and counts from one to three. She then presses the forward-button three times and counts from one to three simultaneously (#118.2). Regarding CT, *Algorithmitising* is again evident here, as she enters the next three elementary instructions. In terms of SR, Lisa uses *Sliding* (*Moving*) to plan and implement the forward movement by pointing her hand to the fields along which the robot should move straight ahead. Here, Lisa does not use *Moving* to determine the current orientation of the robot, but to plan the forward movement.

Lisa then visualises the position of the robot again, including its orientation according to the previous programming, by aligning her hand in the same way over the field in which the robot would stand after all the previous programming, as she had done before the forward movement over the corresponding field (#118.3). She says: “Then to the right again” (#118.3) and points to field B1 again. However, before she presses the right button on the robot, she says “and then it goes there” (#118.3) and points to the target field A1. Only then does she enter the right-button and the forward-button, saying “right” (#118.3) and “and then one forward” (#118.3) at the same time as pressing the buttons. Regarding CT, this is therefore *Algorithmitising*, as she enters the last two elementary instructions together. Lisa may not need to move her hand here, as she knows that the robot has not been rotated, and the orientation of the robot has therefore not changed. To plan the entire path, she again uses *Locating* (*Situating*) when she describes how the robot would stand after the movement, which occurs together with *Visualising* (*Sensating*) by gesturally representing the orientation of robot with her hand.



Lisa always proceeds in the same way. First, she plans the turning movements in the sense of *Rotating* (*Moving*), then the forward movements in the sense of *Sliding* (*Moving*), then the next turning movement in the sense of *Rotating* (*Moving*) and finally the last forward movement in the sense of *Sliding* (*Moving*) again. After each of these blocks - except for the last one - Lisa shows *Locating* (*Situating*) combined with *Visualising* (*Sensating*), supported by matching gestures. At the same time, Lisa breaks down the entire path into movements of one kind in one direction according to systematic *Decomposing*. This enables her to divide the planning into smaller blocks for a better overview to successively algorithmicise the path.

After the robot has travelled the path according to Lisa's instructions (#120) and arrived at the target field, she says: “And it worked.” (#120). After testing the planning, Lisa briefly evaluates it. *Testing and Evaluating* is thus shown here as a CT activity.

As can be seen from this excerpt, Lisa is able to plan the route and program the robot correctly with the help of various CT activities and spatial orientation aspects. Overall, Lisa shows the CT activities

summarised in Table 3 (grey) and, in addition to *Orienting* (*Situating*), the aspects of SR (white), whereby *Decomposing* is also part of the spatial orientation processes and here specifically *(De)constructing*. This case study illustrates how complex the process is when both areas of challenge are successfully mastered and how they can be connected.

Table 3: Activities of CT and aspects of SR shown by Lisa

Summary and Discussion

The process summarised in Table 3 shows how complex the programming of the robot is and how many sub-steps it can require, involving CT activities and aspects of SR. Lisa's example represents well that almost all categories of the Davis et al. (2015) model are applied when programming the robot. This applies to other robotic interventions according to the study by Francis et al. (2022). Only the *Altering* component, which was also the only one not founded by Francis et al. (2016) in the programming tasks in their study, did not appear in any of the tandems in this sample, including Lisa. Regarding the sub-processes, not all possible sub-components that are essential for programming the robot are covered. The other interviews have to be examined more closely for these categories.

In addition to *Testing and Evaluating*, Lisa also shows the two activities *Decomposing* and *Algorithmitising*, whereby the first is the central building block in her approach, as it enables structured planning, and particularly the use of aids for planning specific movements. Caballero-Gonzalez et al. (2019) also observed a learning growth in the *Testing and Evaluating* and *Algorithmitising* activities in their exercises with the robots.

It has been shown that, in addition to CT activities, SR can also be important for a successful programming process. The consequence of this for teaching practice is that CT activities as well as SR should be stimulated and supported in a more targeted way. However, to provide students with structured support in the future depending on their individual learning level, further research needs to be carried out with larger samples to determine which demands are placed on children with regard to CT and SR when programming educational robots, in particular investigating which orientation aids are useful in which case.

Conclusion

Studies indicate great potential for the use of educational robots in mathematics classrooms (Zhong & Xia, 2018). The use of educational robots can, for example, promote CT (Hong, 2023) or SR (González-Calero et al., 2019). However, more detailed insights into the actual learning processes are needed to describe the associated demands more precisely and to develop support approaches.

As part of this study, it was found that CT activities as well as SR is repeatedly demonstrated when programming educational robots. When programming educational robots, CT and SR seem to go hand in hand (as in Table 3). To prove whether CT activities must always be carried out before and during the application of SR for a successful process, it is meaningful to analyse more cases. Regarding the groups in this study, it can be stated that those in which both CT and SR activities were used by the students often were more successful than other groups. However, to be able to make a generalised statement, a specific look at other examples would be necessary, but this is beyond the scope of this paper.

The case presented here was an example of a very successful process. This paper has not yet investigated possible difficulties in the use of CT activities and SR. This should be researched further in the future. But the results here can provide a starting point for what the processes could look like in a best-case scenario. Support options for weaker learners can be derived from this. For example, the planning of the route with elementary instructions could be decoupled from the direct implementation on the robot to reduce complexity. And gestures could also help with spatial orientation. This potential should also be investigated in more detail in the future.

Dragon flights, an unusual introduction of tournament

Eszter Bóra[1] and Péter Juhász[1]

[1]Alfréd Rényi Institute of Mathematics, Budapest, Hungary; juhasz.peter@renyi.hu

Discovery learning is considered as an important way of learning and doing mathematics. The Pósa method is a Hungarian instructional method of mathematical guided discovery through specifically designed problem threads. This paper presents how this method makes it possible for students to discover tournaments. A tournament is a directed graph with exactly one directed edge between each two vertices. In relation to tournaments, we can present many interesting problems to students that cater to their interests, allowing them to encounter fascinating applications. Besides introducing tournaments, the key didactic goal of the problem thread is to highlight a typical misapplication of mathematical induction. This is achieved by the teacher deliberately setting a trap for the students, into which most of them fall, resulting in incorrect solutions to the problem. This creates a memorable moment for them, significantly reducing the chances of them repeating this mistake in the future.

Keywords: Discovery learning, Pósa method, tournaments, mathematical induction.

Introduction

The Pósa method, which developed on the foundation of Hungary's long-standing problem-solving traditions in mathematics education (Gosztonyi, 2016), embodies a significant advancement of mathematical didactics (Győri & Juhász, 2017) incorporating inquiry-based elements (Artigue & Blomhøj, 2013). In the late 1980s, Lajos Pósa began to work with mathematically talented children during weekend camps, and over the years, he designed a specialized method for nurturing talents. To date, more than 400 of these weekend camps have been organized for students in grades 7-12.

The teaching method, devised specifically for talented students, was examined by Juhász and colleagues through a high school experiment to see how it fares among students who are not exceptionally talented (Urbanski et al., 2022). It is worth mentioning that the Pósa method shares many similarities with the Hejny method (Hejný, 2012), while also exhibiting notable differences. A significant portion of Pósa's problems is too difficult for high school students following the standard curriculum, but many of them are accessible, exciting for these students, and can endow them with skills beneficial for their later life. In normal high schools, it is more challenging to implement the parallel running of threads, which is a key feature of the Pósa method. But the experiment demonstrated that this approach also works well. Within the constraints of the usual school environment, there is less time for discovery, so the method can be adapted with appropriate modifications for use in high schools.

The tournament is a special concept in graph theory, not part of the high school curriculum, but it arises naturally in interesting situations for students. The topic is timely for talented students in grades 9-10 and in “normal” high school in grades 11-12. It is important that students must already be familiar with basic graph theory concepts and perspectives.

Problem thread (Gosztonyi & Varga, 2023) - in the Pósa method, we refer to a longer sequence of problems over time this way - is aimed at introducing and thoroughly exploring tournaments, but we also use it to create important didactic situations (Artigue et al., 2014).

Problems and their solutions in this problem thread

The tasks of the problem thread are embedded in a story, which goes as follows:

In Fairyland, dragons transport passengers between any two cities in both directions. However, one day the dragons rebel because the inhabitants of Fairyland do not appreciate them enough. In their anger, they cancel many routes, but still ensure sufficient service, meaning that between any two cities, traffic continues in exactly one direction. This rebellion changes the previously idyllic situation, raising various questions.

P1. Does there always exist a city in Fairyland that can be reached from any other city with at most one transfer, in other words with at most two connecting flights?

At the beginning of the problem thread, we use this story, and we do not yet talk about tournaments, edges, vertices, or paths, but rather about cities, dragon flights, and transfers. As we progress through the thread, this context gradually fades into the background, and we begin to introduce and use graph theory terminology. Exactly when and how this transition occurs depends on the group; we make the switch when everyone feels comfortable using these concepts.

S1. During the solution of the task, students can apply the previously learned method of 'starting from an extreme' (Bóra & Juhász, 2022), as choosing the city where the most dragon flights arrive will be appropriate. The proof is straightforward, so we will not elaborate on it here.

Following this, students are given the opportunity to ask interesting and intriguing questions. In the Pósa method, great emphasis is placed on encouraging students to ask good questions.

For the sake of simpler terminology, let us call a city where one can reach from anywhere with at most one transfer a good city from now on.

The following questions tend to arise:

Q1. Is there always a second good city?

Q2. What can we state about the minimum number of good cities?

Q3. What happens if there are infinitely many cities?

The first question always comes up. It is very easy to answer in this form, so we ask it right away as a lightning round question. Here, too, the idea of examining an extreme situation helps, because if there is a city (C) that only has incoming flights, it is clear that there cannot be two suitable cities, as it is impossible to reach another city from C with just one transfer (in fact, it is impossible to reach it at all). We have now reached an important moment. For a significant number of students, it seems that this thread has come to an end, as there is always one city, but not necessarily two.

In discovery learning, it is worth emphasizing that mathematics is a science that seeks the boundaries between what is possible and impossible (Lützen, 2022, pp. 263-264), and often these

boundaries are more subtle than we initially imagine. This moment is not the first of its kind in our students' experience, so there is a good chance that the following question will arise:

Q1. If there is no city with only arriving dragon flights, does there always exist at least two cities that can be reached from anywhere with at most one transfer?

We set this as a task, meaning this question also becomes P2. The solution of this problem is not as simple as it was for P1.

S2. Let A be a good city. (We know that at least one good city exists.) This city can be reached from anywhere with at most one transfer. Let K be the set of cities that can be reached directly from A. According to the problem's condition, this set is not empty. In the subgraph induced by K, there is also a good city, let us call it B. In this case, B is a good city in the larger graph as well. This is because B can be reached from any vertex in K with at most 2 flights. B can be reached directly from A. From all other vertices outside K, there is a flight going to A, so we can reach B with two flights through A.

After this, interested students can work on question Q2. If we examine the solution to the previous problem more thoroughly and pay attention to the details, it turns out that there are always at least 3 good cities. It is not difficult to construct a general example where there are exactly 3 good cities. With this, we have solved this problem, as we have shown that there are always at least 3 good cities, but 4 is not necessarily guaranteed.

At this point, we ask the students to return to the original story and pose questions that go a bit beyond the initial problem.

A relatively natural question arises:
Q4. Is there always a journey that goes through every city exactly once?

Some of the students already know that in graph theory, this is called a Hamiltonian path, but from now on, we will also introduce this concept in the camp.

We usually receive two different solutions from our students:

S4a. Let us prove the statement using mathematical induction. It is clearly true for two cities. Then, let our induction hypothesis be that the statement holds for n cities. Take a graph with n+1 vertices and remove P from it. In this graph, there is a Hamiltonian path, let it be $S \to T$. If there is an edge from P to S, the path can simply be extended with P at its beginning. If there are two consecutive cities in this path such that an edge leads to P from the first, and another edge from P to the second, then P can be inserted into the path, and we are done again (see Figure 1). If this is not the case, then there is certainly an edge from T to P, thus the $S \to T$ path can be extended with P at its end.

S4b. We can apply a special form of mathematical induction, where we use the statement for all previous values of *n*. Again, choose a vertex, let this be P. Divide the remaining vertices into two sets: the first set contains the vertices that have an edge going to P, and the second set contains those to which there is an edge from P. Both sets have at most *n* vertices, so the induction hypothesis holds, meaning there is a Hamiltonian path in each set. Using this, there is also a Hamiltonian path in the entire tournament (see Figure 2).

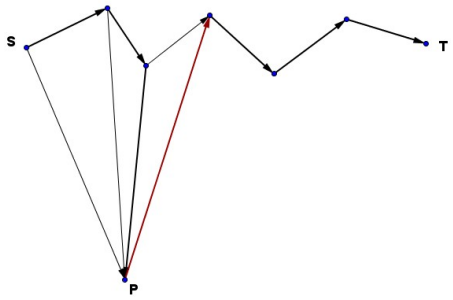

Figure 1: Proof of S4a

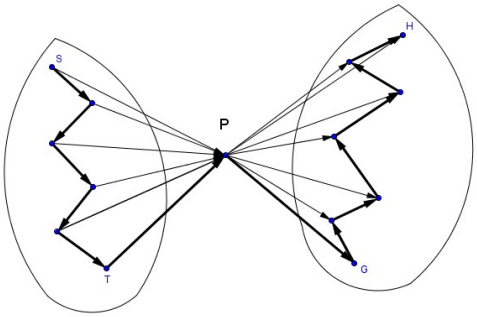

Figure 2: Proof of S4b

The following question arises naturally: instead of a journey that goes through every city, is there also a round trip that goes through every city? Our observations show that students immediately respond that there is not, since if there is a city with only outgoing edges or only incoming edges, a round trip is not possible. However, based on previous experiences, they do not stop there; the next question that arises is: what if we do not allow this, meaning there are flights departing from and arriving at every city? At this point, we introduce the concept of a Hamiltonian cycle for those who are unfamiliar with it. The question then becomes:

Q5. (P5.) Assuming that in a tournament every vertex has both an outgoing and an incoming edge, is it true that there is a Hamiltonian cycle in the tournament?

This question arises for tournaments with at least 3 vertices, and students quickly see that the first step of mathematical induction holds, as the condition is only satisfied for 3 vertices if the tournament is a directed cycle. In this case, there is indeed a Hamiltonian cycle in the tournament. Students can generally be divided into two groups based on how their reasoning continues from here. One group consists of those who thoroughly understood the previous solution (S4a.) and recognize that they can apply the same idea here. Their proof is as follows:

S5. Remove P from the tournament with n+1 vertices. In the remaining graph with n vertices, there is a Hamiltonian cycle due to the induction hypothesis. Given the conditions of the problem, there are edges going both into and out of P, so there will certainly be two consecutive vertices in the Hamiltonian cycle where one has an edge going to P, and from P, there is an edge going to the

other. This means that P can be inserted into the Hamiltonian cycle of the n-vertex graph, so there is a Hamiltonian cycle in this case as well.

The second group consists of students who found the previous reasoning difficult and don't feel a strong sense of ownership over it, so they do not think that the previous method would help here.

This second group can also be divided into two parts: one part includes students who, after this, cannot make meaningful progress on the task, with no advancement toward solving it. The other part includes students who begin examining small cases, and a significant portion of them realize they can find a counterexample, meaning the statement is not true. At this point, we ask them not to share this discovery with the others. (Of course, there is a third group as well, students who understand the solution to the first problem, recognize that this is a similar situation, but also notice that the previously used method does not work properly here. Our experience shows that there are relatively few such students.)

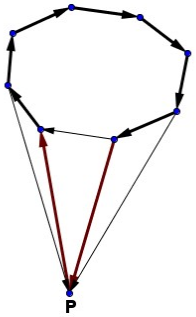

Figure 3: Possible proof of Q5

The most exciting moment in this thread is when students learn that the proof for S5 is incorrect. Not only is the reasoning incorrect, but the statement itself is also false. (We only tell them the first claim.) There is, in fact, a tournament with at least 3 vertices where every vertex has both outgoing and incoming edges, but there is no Hamiltonian cycle. We do not reveal the error to the students; it is their task to find it. This is a task even for those who solved the problem correctly, they also need to find the mistake in the reasoning. For those who believed the statement was true, it is also their task to determine whether only the proof is wrong or if the statement itself is false. After this, many students find the counterexample, and a possible example is shown in Figure 4.

However, it is harder to spot the error in the flawed proof, even when the counterexample is known. The mistake lies in assuming that if the condition holds for a tournament with $n+1$ vertices, it also holds when one vertex is removed. It is possible to find a tournament where every vertex has both outgoing and incoming edges, but if you remove any vertex, this condition no longer holds (the tournament in Figure 4 is an example for this).

We deliberately make this mistake in S4a and S4b as well when we discuss the problem in plenary, increasing the chances that the students will also make this mistake. Later, we explain that, formally, the proof was not correct there either, but it can be easily fixed, because when we remove

a vertex, the original condition is still obviously satisfied. Thus, with this correction, those proofs are correct, because we only need to check that the reduced graph is still a tournament.

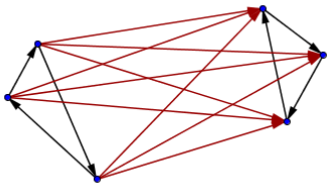

Figure 4: Tournament without Hamiltonian cycle

In this case, the teacher deliberately led the students into a trap. The intention, of course, is not to make the students feel bad. The teacher explicitly points out that this was intentional and done for their benefit. This situation vividly illustrates the importance of the step that was overlooked in the flawed proof. While it often doesn't cause problems, as they have seen before, in certain cases it does. This approach is not unique in the Pósa method. It is crucial that students feel free to think openly about the problems and understand that it is okay to make mistakes. Errors and mistakes can be used as springboards for explorations. (Borasi, 1987) They should also know that sometimes more can be learned from an incorrect solution than from a correct one, because it draws attention to a detail that might not even be mentioned during the discussion of the correct solution.

After the insightful discussion, we ask the students to try to find a condition – preferably one that is relatively easy to verify or at least elegantly formulated – that guarantees the existence of a Hamiltonian cycle in the tournament.

This is a difficult task, and due to its unusual nature, those who typically excel at problem-solving may not necessarily be the ones to find the right condition. The simply stated condition (though not easy to verify) is that it should not be possible to partition the vertices of the tournament into two disjoint sets such that all edges between the two sets have the same direction. We call such a partition a 'malicious division.' In the tournament shown in Figure 4, the vertices can be divided into two 3-element sets, and the direction of the red edges is the same, meaning this is a malicious division of the tournament.

P6. Prove that if there is no malicious division in a tournament, then it has a Hamiltonian cycle.

We will not go into the solution to this question here. The solution is not too difficult, but given the previous tasks, it cannot yet be considered a practice problem.

From the very first opportunity students have to ask questions, it frequently arises whether we can make any claims if we replace a finite tournament with an infinite one.

Q7. Is there always a good city in an infinite tournament?

S7. This task is very useful and, among other things, once again demonstrates how difficult it is to understand the concept of infinity. The answer is no, it's possible to find a counterexample. The solution is particularly simple in the sense that every student has 'seen' this structure before, but it is quite challenging to recognize that this structure can be thought of as an infinite tournament.

Consider the vertices of the graph as the natural numbers, with edges pointing to the greater number between any two vertices. After presenting this example, it's worth asking students to think about why this is a good counterexample and why the proof found for the finite case does not work here. This helps them gain a deeper understanding of infinity and the previous proof.

After solving P6 and answering Q7 the following question often arises:

Q8. If there is no malicious division in an infinite tournament, is there a good city?

Surprisingly, even this seemingly strong condition is not enough, as a counterexample can be found in this case as well. Those who have progressed this far in the thread often succeed in finding the counterexample, as they now understand the situation and can create a counterexample by slightly modifying the one seen in the previous solution.

Students who like this topic raise other interesting questions as well. These questions often arise:
Q9. For every n, does there exist a tournament where every city is a good city?
It is easy to see that for 2 and 4, such a tournament does not exist. For odd values of n, it is not too difficult to construct one. For even values of n greater than 4, the task becomes quite challenging.

Q10. Let P(n) be the probability that in an n-vertex tournament, every city is a good city. (The direction of each edge in the complete graph is determined by the flip of a fair coin.) As n approaches infinity, does the sequence P(n) have a limit, and if so, what is it?

This question also comes up regularly, although only one or two students in each group usually articulate it. Surprisingly, the limit is 1, meaning that in large tournaments, it is almost certain that every city will be a good city (Saile & Suksompong, 2020).

Conclusion

Many years of experience show that this thread is very popular among students. After mastering the basic concepts of graph theory, they have no difficulty handling the concept of tournament. Many students immediately see that tournament perfectly describes a single-round robin tournament in many sports, making the concept seem useful to them. Through problems related to good cities, students become familiar with the fundamental properties of tournaments, so when they encounter significantly more difficult questions related to Hamiltonian paths and Hamiltonian cycles, they are already comfortable using the concept. Years of experience show that those who fall into the trap when trying to prove the existence of a Hamiltonian cycle have a memorable experience, and they remember both the statement, the counterexample, and the faulty reasoning years later. These students are careful to ensure that all logical elements of their proof by mathematical induction are correct. Those who do not immediately recognize the error gain an even deeper understanding of how mathematical induction works.

Identifying isomorphism in combinatorial tasks

Anna Kuřík Sukniak

Charles University, Faculty of Education, Prague, Czech Republic; anna.sukniak@gmail.com

The goal of this paper is to describe how 6th-grade pupils (aged 11-12) solved combinatorial tasks with a focus on how they identified isomorphisms between C(5,2) and C(5,3) type problems. Through video-recorded sessions where pupils solved a series of isomorphic tasks, the research showed that pupils could recognise isomorphism between tasks even when this isomorphism was not easily apparent. This awareness emerged gradually. Key factors included group discussions, moderated discussions, an iterative solving process, and a series of isomorphic tasks. The study introduces an approach to support isomorphism perception as a strategy, suggesting that fostering this skill can enhance mathematical reasoning.

Keywords: Combinatorics, isomorphism, lower secondary school pupils.

Introduction

Despite some reports of success indicating that even young children can exhibit strong combinatorial thinking (English, 1991; Maher et al., 2011), most of the research suggests that pupils generally face significant challenges in the domain of combinatorics (Hadar & Hadass, 1981; Fischbein & Gazit, 1988; Batanero et al., 1997; Eizenberg & Zaslavsky, 2004; Maher et al., 2011; Lockwood & Gibson, 2016). Although problems presented in these studies are often isomorphic, pupils frequently fail to recognise this and instead apply different strategies to solve them (Batanero et al., 1997; English, 2005; Janáčková & Janáček, 2006; Maher et al., 2011). This research aims to trace how lower secondary school pupils aged 11–12 acquire and expand their mathematical reasoning skills by solving C(5,2) type problems. While isomorphism is apparent in some word problems, it remains hidden or difficult to recognise among others. This paper reports how pupils identified isomorphism between problem types C(5,2) and C(5,3).

Literature review

Pupils at all levels face problems even when solving elementary combinatorial problems (Hadar & Hadass, 1981; Fischbein & Gazit, 1988; Batanero et al., 1997; Eizenberg & Zaslavsky, 2004; Maher et al., 2011; Lockwood & Gibson, 2016). Among them is an inability to see two isomorphic combinatorial problems as equivalent (Batanero et al., 1997; English, 2005; Janáčková & Janáček, 2006; Maher et al., 2011).

In mathematical cognition, Greer and Harel (1998) perceive isomorphism as elements within mental representations that individuals construct while assimilating and addressing specific situations. In this context, they introduce three fundamental models:

1. Surface-level isomorphism involves mapping a given problem onto an easier one, employing surface considerations, such as using "friendly" numbers or specific formulas, without necessarily grasping the deeper mathematical structure.

2. Deep isomorphism emphasises a higher quality of mapping formation. Under this model, an individual with advanced reasoning forms mappings beyond surface-level considerations.

3. Mediated isomorphism introduces S as a mediator in constructing an isomorphism between two situations, S1 and S2. This model involves seeing S1 and S2 as specific cases of S, establishing an isomorphism between them through the intermediary S.

An example of isomorphism from the combinatorics field is found in Martino and Maher's (1999) research. Brandon, the 4th grader, solved the tower problem tasking pupils to construct as many towers as possible of height four using cubes in two available colours, and the pizza problem tasking pupils to enumerate all possible pizzas allowing the customer to choose from four ingredients. He proceeded to establish a one-to-one correspondence between each pizza and its analogous tower of height four (Figure 1), explaining how the red cubes in each tower correlated with the "zeros" and the yellow cubes with the "ones" on his pizza chart. He matched each of the sixteen towers to the corresponding sixteen pizzas.

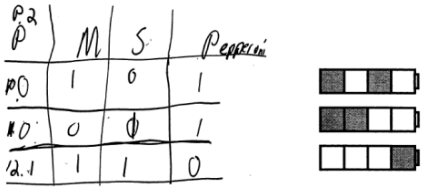

Figure 1: Brandon's one-to-one correspondence between towers and pizzas (Martino & Maher, 1999)

Research questions and methods

This study investigates the effects of engaging 6th-grade pupils in solving multiple tasks of type C(5,2). It addresses the following research questions:

1. Can pupils identify isomorphism between two tasks even when they are not immediately apparent due to differences in numbers or objects?

2. What processes and supports help pupils recognize isomorphisms among combinatorial tasks?

Pupils from 6th grade were selected in the first half of the school year to increase the likelihood that they had not yet encountered similar combinatorial tasks in their mathematics classes. There were no other characteristics required among pupils to be selected. The researcher had not encountered selected pupils before. Pupils split into groups of two to four according to their time possibilities. The experiment was conducted at their school after regular teaching hours. It involved three to four 90-minute sessions during which the pupils progressively solved 24 tasks. Pupils always received a paper with one task, solved it and shared the results and thoughts. Among tasks, 22 were part of one group of isomorphic tasks, while the remaining two belonged to another group. All of them led to the same result - 10. The experimenter did not reveal or mention the possibility of isomorphism. Since a pupil showed some isomorphism between tasks, the experimenter sometimes drew the pupil's focus to possible isomorphism among other tasks. Pupil’s discussions and individual explanations of the solutions were video recorded. Data analysis was done by the author alone using the method of decomposing the solving process of each word problem into three parts:

1) Understanding the problem, 2) Grasping the task, and 3) Problem-solving strategy[1]. This paper focuses on analysing the part with a group of three boys — Evan, William, and Jay. During the first session, the boys solved five isomorphic tasks, including Towers, Stones and Cups relevant to this paper (Table 1). Two days later, during the second session, they solved another six tasks, including the Lines and Triangles tasks, which are being focused on for this paper (Table 1).

Table 1: Series of isomorphic tasks relevant to this paper

Towers (2nd task)	We build towers from 5 cubes as shown in the picture. Two cubes are coloured blue, the rest grey. How many different towers can be built? 
Stones (4th task)	In the table, the number 102 is formed using 3 stones. How many different numbers can be created using 3 stones? 
Cups (5th task)	Tom has two identical cup stickers and five differently coloured cups on which he can place them. He does not want to place more than one sticker on the cup. How many ways can he place the two stickers on the cups?
Lines (9th task)	A regular pentagon *ABCDE* is given. How many different lines are formed by its vertices?
Triangles (10th task)	A regular pentagon *ABCDE* is given. How many different triangles are formed by its vertices?

Results

The first five tasks analyses are described in detail in Kuřík Sukniak (2024), for this paper, a summary of tasks Towers, Stones and Cups follows. When solving the Towers task, boys manipulated with cubes. Jay and William recorded towers on paper as horizontal rectangles. Evan stored individual cases in his mind. Jay combined several methods to find all the cases. William used a "looking for what is missing"[2] strategy, reaching 9 cases. Evan used a two-step organisational principle to identify all the cases and his insight into symmetry led him to find the 10th missing case of William's solution. In the Stones task, Jay used the table to record individual cases. He gradually shifted the stones and found 11 cases, missing the 1-1-1 combination and repeating 2 cases. William grasped the task using numerical values and his strategy was "looking for what's missing". He found 10 cases, counting the case 300 twice and overlooking the case 102, which was the number from the assignment thought. Evan quickly grasped the task without making notes, found the missing 1-1-1 case from Jay's solution, and noticed symmetry in the arrangement of stones. In the Cups task, William recognised an isomorphism between this and the Towers task and solved it using this conceptual isomorphism. Jay identified an isomorphism through the coding system he used when solving the Desk task. Evan probably suspected the isomorphism at a conceptual level and verified it processually.

1 A method I have used several times under the guidance of Professor Hejný.

2 It involves identifying possibilities by focusing on potential cases that have not yet been explicitly listed, relying on intuition or observation rather than a formal or structured system of enumeration.

The following part focuses on an episode when the group of boys approached the Lines and the Triangles tasks, decomposing their solving process as mentioned in the section above. Jay: 1) Jay misunderstood the Line task. 2) He drew a pentagon on a whiteboard, and roughly labelled the vertices. He assigned each vertex two half-lines and labelled these with numbers (Figure 2a). 3) He wrote a pair of numbers for each vertex in turn (1 and 2, 3 and 4 ... 9 and 10).

Other students had no comments. I decided to refine the task. I drew the five vertices of the pentagon, labelled them A through E, and commented that every time two vertices are connected, they form a line. I drew line AB as an example (Figure 2b). Then I asked again how many lines like this were there.

Jay found the task similar and said that the solution was still 10. Evan asked if lines AB and BA were the same. I confirmed. I asked again about Jay's solution. Jay explained in his own words that each vertex is always formed by a pair of lines (half-lines determined by adjacent vertices) and gave a concrete example – vertex C is formed by lines BC and DC (Figure 2c).

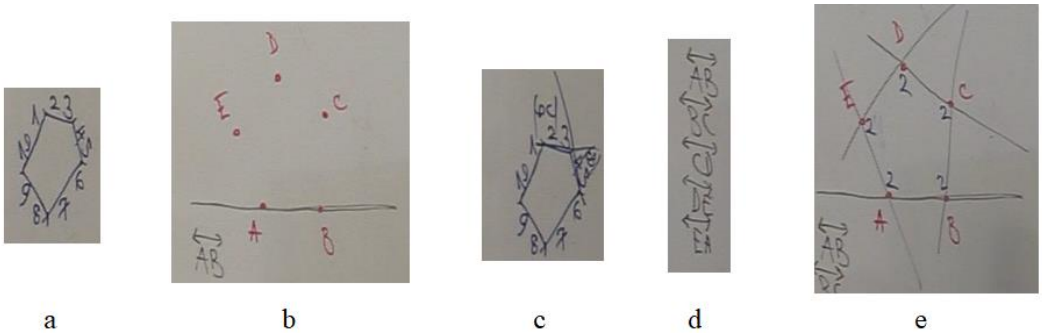

Figure 2: Process of solving the Lines task

Evan: 1) He understood the Lines task after additional input from the experimenter. 2) He used the picture of the five points $A, B, C, D,$ and E. 3) Successively read pairs of adjacent vertices of a pentagon and added the lines $BC, CD, DE,$ and EA to the line AB (Figure 2d).

Jay did not proceed with Evan's alternative solution. The solution offered by Evan made sense to him, but it still seemed to him that five lines were not enough, because each point has two lines in it, there are five points, so there must have been ten lines. However, he could not yet answer where the other five lines are.

William: 1) He didn't understand the Lines task. 2) He numbered the vertices and the sides of the pentagon and the sum of 5+5 gave him the desired ten. He laughed when presenting this idea and said it was just an idea.

Jay verbalised the idea that each vertex was formed by two lines again. He drew twos next to each vertex (Figure 2e) and argued that there must have been ten lines but he didn't know where they were. I suggested moving on to the next task with the possibility of returning to the task with the lines if someone thinks of something.

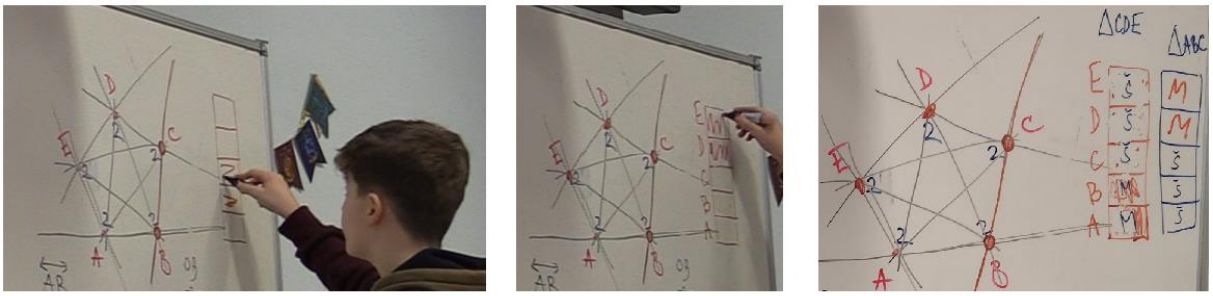
The boys started to solve the Triangles task. None of them wrote or drew the triangles on their paper. Jay came to the whiteboard to present his solution.

Jay: 1) He understood the Triangles task. 2) He used the triplet of letters (vertices) to list triangles. 3) Even though he said there was no system in his solution the first five triangles were based on the principle of rotation: ABC, BCD, CDE, DEA, EAB. Then Jay stopped and looked for another principle. He chose two adjacent points and looked for a third one. He had already assigned point C to AB (1st solution), so he added point E to AB and wrote ABE. Neither he nor the others realised this was the same triangle already written down the last time (EAB). Then he added D to AB as the next point and wrote ABD. He moved to points BC and looked for a third point. He found E and wrote BCE. He seemed to find the remaining two triangles CEA and DBE using the "looking for what is missing" strategy.

Then William offered him one more triangle DAC and Jay listed it on a whiteboard.

William and Evan: 1) They understood the Triangles task. 2) They used triplet letters (vertices) to list triangles. 3) They probably used the "looking for what is missing" strategy.

The boys found it suspicious that the result was now eleven. In previous tasks, the result was always ten. The list of triangles passed their eyes, but they could not see whether it was complete. I asked if there was some system in the notation that would allow us to be confident, we had all the triangles. Jay said there was no system, he was looking for what had not yet been written down.



After a while, Evan came up with an idea and pointed to point A, on the whiteboard, which he connected to points B, C, D, E. He counted 1,2,3,4. Then he pointed to point B which he connected to three points C, D, E, and counted 5, 6, 7. Then he pointed to point C and connected it with points D and E. He counted 8, 9. Finally, he connected D to E and said 10. I asked if the boys understood what Evan said. Jay said he did not understand it much. I added that I did not get how it was related to the triangles. Evan himself said he did not understand it either and went to sit down. I asked Evan if he could describe what he showed us, but he could no longer answer.

I navigated the conversation to the Triangles task, but the group did not get further. The task remained with 11 solutions without certainty whether it was everything or whether there was something twice.

I then asked the boys to look again at the Lines task. Now they could see other vertex connections. Jay went to the whiteboard and added lines DB and AC. Jay stated that this was all, but immediately Evan dictated line EB and William line DA, and again Evan line CE. They were happy that they already found 10 lines.

Pupils have already found isomorphisms between some of the previous tasks. I asked whether the Lines or the Triangles task also seemed the same as some of the tasks they had already solved. William speculated the Lines task seemed the same as the Cups or Towers task. He pointed out that all three tasks had numbers 2 and 5. However, he was not sure if this connection was enough. Then Evan came to the whiteboard and revealed the repeating triangle ABE. The number of solutions of the Triangles task was since this point also ten. That made the boys happy. I turned their attention again to the similarities of the tasks. I took William's hypothesis that the Lines task seemed the same as the Towers task and, as in previous cases, challenged the boys to defend this potential similarity. I chose a particular line BC, drew a tower of five cubes next to it, and asked William if he could somehow explain the connection. William assign vertices to the cubes: the cube on the 1st floor

represented vertex A, the cube on the 2nd floor represented vertex B, etc. He coloured the cubes on the 2nd and 3rd floors (Figure 3a). He added another example and associated the DE line to the tower with the coloured 4th and 5th floors (Figure 3b). Evan and Jay confirmed that this made sense.

a b c

Figure 3: Process of uncovering isomorphism

I asked if they could connect the Triangles task to some of the tasks they have already solved. William suggested the task was the same as the Stones task because there were three stones and now, we had three letters (pointing to the names of triangles). He tried to find a specific connection but was unsuccessful. About two minutes later William suggested the Triangles task is the same as the Towers task. He assigned a tower to triangle ABC, where he coloured the first three floors, and then created a tower for triangle CDE, where he coloured the top three floors. Jay argued that for the triangle CDE floors 3, 4, and 5 should be empty and floors 1 and 2 should be colored. I recalled that in the original task with the towers, there were two blue and three grey cubes, but since they didn't want to colour everything, they coloured only the two blue cubes and left the grey cubes uncoloured. I asked if they could connect the triangles and towers of the 3 grey and 2 blue cubes. I wrote Š in the blank boxes (3rd, 4th, and 5th floor) as grey (šedá) and M in the coloured ones (1st and 2nd floor) as blue (modrá) and asked which triangle this tower corresponded to. Jay answered CDE (Figure 3c). I asked if we could rewrite each triangle into the towers using this system. William was not sure if this would always work. Jay and Evan, both thought it would always work this way. William came to the board and drew into the tower what a triangle ABC looks like (Figure 3c). I was ready to move on to the next task and if necessary, return to this one, when William declared another thought. He described that blue cubes from towers represent the lines and grey cubes represent triangles.

In the described session, the pupils identified isomorphisms between given tasks. After moderated discussion and further exploration, the pupils started drawing parallels between the Lines and Towers tasks, later between the Triangles and Towers tasks, and finally between the Lines and the Triangles tasks. The process by which pupils recognised isomorphisms included re-examining previous tasks, collaborative discussion, and identifying shared characteristics. William, for example, began to suspect similarities based on the recurring numbers 2 and 5 and later successfully made connections between the Lines and the Triangles tasks by relating them to the Towers task. The pupils needed multiple steps and cues to finally recognise the isomorphism, such as when Evan re-examined the Triangles task and corrected the initial error of counting eleven triangles, realising that one triangle was counted twice, or as Jay after reviewing the Lines task again realised that also non-adjacent vertices of pentagon can form a line. The pupils frequently discussed their thought processes with

each other. The experimenter asked for explanations of pupils' problem-solving processes, moderated the sharing of ideas to help focus on the tasks, and gave explanations of the assignments when needed. In the *Lines* task, for example, the researcher clarified task instructions and provided concrete examples to help pupils resolve misunderstandings. While the researcher avoided explicitly revealing the possibility of isomorphisms, she occasionally prompted pupils to consider connections between tasks[3]. The researcher, for example, encouraged William to defend his hypothesis that the *Lines* task was similar to the *Towers* task, leading him to map vertexes to cubes.

Discussion and conclusion

This experiment explored how 6th-grade pupils identified isomorphisms between C(5,2) and C(5,3) task types. A unique feature of this experiment was that all tasks shared the same numerical result—10, which noticeably influenced pupils' reasoning. Findings revealed pupils could recognise similar mathematical structures in the Lines, Towers, and Triangles tasks but required collaborative problem-solving, moderated discussion, and task re-examination. It aligns with previous research by Batanero et al. (1997), Janáčková and Janáček (2006), and Maher et al. (2011), suggesting pupils often miss deeper structures when solving by themselves without collaboration. Pupils compared characteristics from earlier tasks to identify isomorphisms. For example, William connected the Lines and the Towers tasks by mapping similarities after realising both involved combinations of two elements. Martino and Maher (1999) and Maher et al. (2011) described a similar iterative problem-solving approach, where pupils used analogous reasoning to solve combinatorial problems. Tasks Lines and Triangles were recognised as isomorphic thanks to the Towers task that functioned here as a mediator. According to the theory of Greer and Harel (1998), mediated isomorphism describes a mediator as some general case. However, the Tower task does not fit this category, which could lead to the refinement of this theory. This study highlights that students do not always immediately recognise isomorphisms but can develop this awareness over time through repeated exposure to similar tasks. The paper illustrates how the iterative nature of problem-solving, combined with moderated discussions, gradually led to students recognising isomorphic structures.

The small sample size and dependence on specific types of tasks limit the generalisability of this study. Future research focuses on the perception of isomorphism among other tasks still of this type and observes other pupils in this age group. Further research could observe how different types of combinatorial tasks or age groups affect the recognition of isomorphisms.

In conclusion, promoting isomorphism recognition through moderated discussion and peer collaboration improves pupils' combinatorial reasoning. Developing these skills can contribute to mathematical thinking in a broader context.

3 The researcher asked for these possible connections even when the two tasks were not isomorphic.

Generalizing in combinatorial problem solving: Processes-based or numerical-based approaches

Elise Lockwood[1] and Zackery Reed[2]

[1]Oregon State University, United States; elise.lockwood@oregonstate.edu

[2]Embry Riddle Aeronautical University Worldwide, United States

In this paper, we present two cases in which undergraduate students engaged in generalizing activity as they solved combinatorial problems. We note a contrast in what the students generalized (numerical regularity versus process), and we frame these distinctions in terms of Harel's (2008) result pattern generalization versus processes pattern generalization, and in terms of Lockwood's (2013) model of students' combinatorial thinking. We intend these cases to facilitate discussion about what kinds of patterning and generalizing activity is desirable in combinatorics – whether numerical-based pattern generalizations are sufficient, or whether we desire students to engage in patterning and generalizing activity that is based in processes or other aspects of combinatorial thinking. We also connect these ideas to technological advances in generating sets of outcomes with the computer.

Keywords: Combinatorics, Discrete mathematics, Generalization, Counting

Introduction and Motivation

Generalization is a fundamental aspect of mathematics (e.g., Ellis 2007), and students often engage in searching for and identifying patterns as they seek to solve problems involving combinatorial enumeration (Maher et al., 2011; Reed & Lockwood, 2021). In combinatorics, students might employ qualitatively different generalizations, and the content of the generalizations may have an impact on the students' combinatorial thinking and activity. In this paper, we intend to raise the question for readers and participants about what the goal of generalizing in combinatorics can and should be. On the one hand, we see a case in which a student successfully solves a problem in combinatorics, engaging in activity that generalizes a counting process. On the other hand, we see a case in which a student (also successfully) generalizes to solve a problem, but the generalizing activity is centred around numerical regularity. We want to raise the question of what the aims of engagement with generalization and patterning should be in combinatorics and discrete mathematics education. We seek to answer the research question: *When solving counting problems, what kinds of generalizations do students make and use, and what does this imply for the teaching and learning of combinatorics?*

Relevant Literature and Theoretical Perspectives

A Model of Students' Combinatorial Thinking

We frame our findings in this paper on Lockwood's (2013) model of combinatorial thinking. When solving counting problems, students might attend to *formulas/expressions, counting processes,* and *sets of outcomes*. Formulas/expressions are expressions that involve numbers, operations, or variables that yield the cardinality of some outcome set. Counting processes are procedures of enumeration (the procedures students engage in as they solve the problem), and set of outcomes are the set of elements being enumerated by a counting problem. We focus on the ways that students drew upon

(or did not draw upon) these components while solving counting problems. Aligned with Lockwood's model is the notion of a set-oriented perspective (Lockwood, 2014), which is a way of thinking about the mental act of solving counting problems; this construct builds upon Lockwood's model. Other studies have made the case for the value of focusing on sets of outcomes and a set-oriented perspective and have leveraged the model as a way of framing students' combinatorial thinking (e.g. Medova et al., 2020; Soto et al., 2022; Wasserman & Galarza, 2019).

Generalizing with Numerical and Process-Oriented Foci

Students often engage in patterning and generalizing activity as they solve counting problems. In their longitudinal study, Maher et al. (2011) report on students' noticing of patterns across problems and representations as they solve many types of combinatorial problems over the years. In light of such work, we highlight a distinction reflected in students' engagement with counting problems that relates to the focus of their combinatorial activity. In solving counting problems, one may emphasize the cardinality of the sets, and may further emphasize or explore the numerical properties, relationships, or patterns in those cardinalities. For example, Lockwood et al., (2015) reported students creating lists of outcomes among several small versions of a problem and noting numerical patterns among them. This suggests what we call a *numerical focus* as they engaged with generalizing activity. In contrast, students may focus not on numerical patterns, but rather on the counting processes that they employ. For instance, students in Reed and Lockwood (2021) generalized based on processes they employed rather than on numerical patterns and regularity. This distinction between focusing on numerical patterns versus *regularity in processes* is one way we analyzed and interpreted our data.

Related to this distinction, we also consider a distinction between Result Pattern Generalization (RPG) and Process Pattern Generalization (PPG) (Harel, 2008). Harel describes RPG as a way of thinking in which one attends solely to regularities in the result. For example, determining the number of options for flipping a coin n times, someone may notice that the first few cases are 2, 4, 8, 16, etc., and they may suggest the number of options for n flips is 2^n because they notice the numerical pattern of powers of two. RPG is often the type of generalization in which the identification of a pattern is based on empirical evidence alone. In contrast, PPG entails attending to regularity in a process – in our case, a counting process. To extend the above example of coin flips, someone might use PPG to determine that there is a process of doubling to justify the expression of 2^n, noting that by appending an H or a T to the previous sequence, one can double the previous total. Here, the generalization is based not strictly on a numerical pattern, but on regularity observed in the counting process.

Methods

The data presented in this paper comes from a series of task-based clinical interviews (Hunting, 1997) conducted with nine students at a large university in the United States. The interviews were part of a study exploring students' uses of equivalence in counting. We present results from interviews with Ewan and Brian (pseudonyms), two undergraduate students who had taken or were taking discrete mathematics at the time of the interview. They thus had exposure to counting problems in these discrete mathematics courses, although we do not have further information on the specific instruction they received in these courses. In the United States, combinatorics is not consistently part of the high school curriculum. Ewan and Brian majored in computer science and mathematics, respectively.

The students solved various counting problems on an iPad and described their work. During and after their problem-solving activity, the interviewer frequently asked questions to clarify aspects of their thinking and activity. If the students were unsure of a solution, or if the students were unable to proceed after some initial work on the problem, the interviewer often encouraged them to try a smaller-sized example of the same problem (we call such problems smaller-sized problems or smaller-sized instantiations of a problem). In an effort to provide opportunities for students to engage with sets of outcomes, the interviewer would at times suggest exploration of a pre-generated outcome set (of a smaller instantiation). For instance, at times the interviewer provided a pre-generated set of arrangements of 1, 2, 3, and 4, and the student could use the GoodNotes app on an iPad to select and drag outcomes on the screen, creating their own organizations of the provided outcome set.

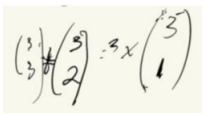
To identify the ways in which students engaged with patterning activity, the second author reviewed all of the interviews and recorded episodes in which students specifically engaged in patterning activity in their problem-solving process. This researcher articulated broad themes and categories for these kinds of engagements, drawing upon a numerical versus process-oriented distinction. The first author then also reviewed these episodes and themes. Together, via discussion, the first and second authors chose representative episodes to highlight illustrative distinctions among students' engagement with processes and numerical regularity in their solving of counting problems.

For this paper, because of space constraints, we limit ourselves to presenting just two contrasting cases of students' generalizing and patterning activity. We seek to offer points of contrast in students' generalizing activity to facilitate discussion of what kinds of generalizing might be beneficial for students and useful to emphasize in research and instruction in combinatorics education.

Results

We provide two contrasting cases in which students produced patterns as a result of their work with sets of outcomes. We aim to demonstrate a qualitative difference in the kinds of patterning students use in solving these combinatorial problems, and to raise questions about possible limitations and affordances of different approaches.

First, we examine the case of Ewan in solving the Committees problem: *There are 8 females and 10 males. How many different committees of 6 people can you form if there needs to be more women than men on the committee?* On this problem, Ewan began by noting, "Is this addition or multiplication?" Ewan wrote out some expressions – writing specifically C(8,4), C(8,5), and C(8,6) and C(10,2), C(10,1), and C(10,0), as seen in the top of Figure 1; he stated that these expressions represent choosing 4, 5, or 6 from the 8 women and 2, 1, or 0 from the 10 men.



However, Ewan did not write operations and was unsure of whether he should add or multiply to combine these terms. In thinking more, Ewan did see that the "cases corresponded" in some way, so that C(8,4) and C(10,2) would be connected. That is, he understood these expressions in terms of what they did combinatorially – such as selecting 4 females and selecting 2 males. The rest of Figure 1 indicates that he wrote some specific outcomes in reasoning about this process and these expressions. As was typical in our interventions, we then asked Ewan to consider a smaller-sized

instantiation of the Committees problem: *There are 3 females and 3 males. How many different committees of 3 people can you form if there needs to be more women than men on the committee?*

Figure 1: Ewan's initial work on the original Committees problem

Ewan noted immediately that there were two cases, either picking 3 or 2 women. He solved this correctly by writing C(3,3)+C(3,2)*C(3,1), as seen in Figure 2a. He recognized that C(3,3) was the case of selecting 3 women, and as he multiplied the C(3,2)*C(3,1) he noted there were "three possible choices for a different male" that could go with the choice of two females. We interpret that he could justify both cases (of 3 females and 2 females) and could justify the multiplication in the second case.

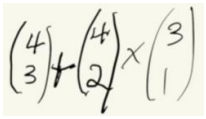


Figure 2a and b: Ewan's solutions for the two smaller instances of 3 and 4 females

We then increased the total number of females to 4: *There are 4 females and 3 males. How many different committees of 3 people can you form if there needs to be more women than men on the committee?* In solving this problem, Ewan recognized that there were again two cases, that he needed 3 or 2 females (and can't have a committee with just one female). He wrote C(4,3) as the case of 3 females, and the exchange below shows his reasoning on the second case.

> Ewan: In this case [C(4,2)*C(3,1)], uh, I have males left over to choose. Right? So, I need to account for all of the different groupings of males that I have leftover to choose, for each one of these scenarios. Right? […] And we're adding here because, in this case, just like I said, this didn't affect the males in any way. But we also don't need any of the males. So, this is kind of like, almost like a separate problem. … If you pick 3 females, the committee's already formed…the males have no dependence on that group.

We thus note that he was making sense of each formula/expression in terms of the counting process it was representing. Specifically, C(4,3) meant choosing 3 women from 4, and that was the case where the committee was all women. The other possible case was when there were 2 women and 1 man, and he understood that as a separate case. He added the terms together because they represented "separate problems," which we interpret as different cases for the number of women on the committee. We interpret that he understood the processes, and he understood the expressions/formulas as representing those processes.

Finally, we asked him to consider the original problem in light of his work. He thought about it, and we see again that he was extending to the larger original problem by generalizing the process, not just the numerical pattern. He said, "All of the situations where I have no males is going to be when I have 8 females and I'm choosing 6 of them (writes C(8,6)), and that's going to be added to something." Ewan established that there was first the problem with all eight females, and he needed to choose 6 of them, and he wrote C(8,6). He noted that was one case, and he needed to consider another case.

Ewan:	[…] I have eight females, I'm choosing six of them [C(8,6)]. Right. So that is going to be added to something. And I think that does scale just fine. […] I mean, it's going to be kind of a similar thing, right? So, it's going to be like what was it? How did they do it? Ten choose or sorry, no, I did the females first. That's right. So it was like plus eight choose five times ten choose, one [writes C(8,5)*C(10,1)]. But that's not all in this case. So that's where it doesn't scale, at least like at least not immediately. It doesn't scale because there's also one more thing where we need four females. Right?
Interviewer:	Right, exactly.
Ewan:	Is that just added or is this like a sum overall, does it is it just like eight choose, four and 10 choose, two? So this is some sum over all? Actually, that that does make sense to me. That does make sense to me. That feels this [8C4*10C2] is a fundamentally different problem than this [C(8,5)*C(10,1)] in my mind. So, I think that addition, since there is not any interdependency between the things at play here [C(8,4)*C(10,2)] and the things at play here [C(8,5)*C(10,1)], but we need to account for both of them. So, yeah, yeah. I think it's just a sum of all of them. Right.

In this case, we see that Ewan was able to arrive at a solution for the main problem, understanding and interpreting the processes he was laying out and the expressions that reflect the process. First, he noted that there was the case of six women, which he could find by using the process of choosing 6 of 8 women, which was reflected in the expression C(8,6). Then, he realized that there was a case of five women and one man, which he saw as reflected in the expression C(8,5)*C(10,1). Then, he noted a distinction between this larger problem and the previous 3 and 4 person problems, namely that an additional case was needed (where four females are on the committee). He calculated that by noting it would be C(8,4)*C(10,2), and then he reflected on how he was using addition in the problem. He correctly operated on the binomial coefficients he had written down initially, coming to make sense of how to combine them in a way that made sense combinatorially. Notably, he had not been initially sure how to combine the terms to reflect a desirable process, but after his work and connection back to previous smaller-sized problems, he was able to successfully solve the original problem.

We interpret that he extended the counting processes he had used on the problems, and he had a solid understanding of the choosing processes and the different cases in forming the committees. Further, he demonstrated understanding of how the processes he used were represented by the expressions and formulas. So, the binomial coefficients and expressions represented the counting processes he engaged in. Thus, Ewan' work on this problem is an example both of a generalization based on processes (PPG) and also one that leveraged multiple components of Lockwood' (2013) model – namely processes and formulas/expressions.

Second, we contrast with the case of Brian, who solved the Decreasing Sequences problem: *How many ways are there to form decreasing sequences of 3 numbers from the numbers 0-9?* Brian began by considering cases for which number could be first, noting that the sequence could not start with

a 0 or a 1. Brian then engaged in some listing of partial outcomes, noting that, for example, if the sequence started with 4, they had 3 options for what the second digit could be (1, 2, or 3), and then for each of those they had 1, 2 and 3 choices for what was next, respectively (Figure 3a). As Brian write down these numbers, he said, "So we're going to keep going, and see if I start noticing any patterns," and, later, "let's see if we can start extrapolating." We thus infer that Brian's overall approach was to try and identify some regularity in patterns from which they could extrapolate something more general. Brian reflected back on the case so far and in Figure 3b wrote the 1, 3, and 6 corresponding with each row; he then said, "those are triangle numbers" and wrote the triangle of dots in the upper right of the figure. Brian noted that they did not know the formula for triangular numbers but proceeded to try to identify patterns.

Brian then had a shift in his work. As he completed values for 5 and 6, rather than continuing with the process of thinking about options, he noted a numerical pattern and added the numbers to each case. He said, "For five, there should be, um, 6 plus 4 is 10. For six, there should be, 10." He wrote out the sums he observed in each one, as seen in Figure 3c. Ultimately, he summed these numbers are came to the correct answer of 120.

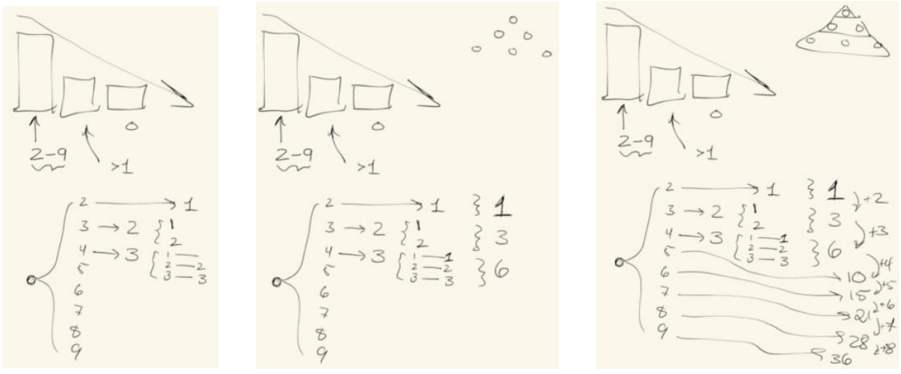

Figure 3 a, b, and c: Brian's work on the Decreasing Number Task, highlighting triangular numbers

The interviewer asked Brian how he went from choices to thinking about triangular numbers (and sums of triangular numbers), and he said "I think I noticed that you're adding a one bigger number every time, and that is the growth pattern here [of the triangular numbers]." Upon reflection, Brian also noted that "I guess there's also a recursive way of thinking about it." He noted that, in the case of starting with 4, the 3 were "new" while the 1 and 2 were repeated from the previous situation. This also helped Brian reason about why the triangular number pattern made sense.

In Brian's case, we appreciate the effective patterning in which he engaged, and we see an efficient and effective use of an appropriate numerical pattern. But, in contrast with the previous case, it raises some questions for us about the overall use of patterning and what was used to develop and justify the patterns. We explore these questions in the Discussion and Conclusion Section.

Discussion and Conclusion

In this report, we see two students engage successfully with patterns to solve combinatorial problems. In both cases, students engaged with multiple smaller-sized problems to arrive at an answer for a larger problem. We claim, though, that there is a distinction between the cases – namely, what

students generalized and what the content of the generalizations were. Ewan engaged in Process Pattern Generalization (Harel, 2008) and carried forward the counting process he had observed in the smaller cases to the bigger case. The numbers and results were not the focus, but rather different aspects of the counting process itself were generalized. Indeed, Ewan focused on the choosing of the people to be on the committee (as seen in the binomial coefficients), the separation into cases, and the use of multiplication to combine male and female committees. In terms of Lockwood's (2013) model, the processes Ewan articulated were closely related to the expressions he wrote, and it seemed clear that his expressions were underpinned by the counting processes, which were the content of his generalizations. We claim that Brian engaged in Results Pattern Generalization (Harel, 2008), as the generalizing activity was based on numerical patterns. Indeed, Brian generated numerical results in observing that larger numbers were added to each case of a starting number, and he leveraged his familiarity with Triangular Numbers to carry that pattern forward.

We intentionally provide two cases in which the students arrived at correct answers, because we do not wish to paint RPG as strictly ineffective or inferior to PPG. Clearly proficiency with numerical patterns may be efficient and effective. These are both correct, but we highlight differences in the nature of what is involved in the patterning. And we raise the question which is more desirable in students' engagement with counting and why. What are potential implications for the teaching and learning of combinatorics as it relates to fostering patterning and generalizing in combinatorics?

Although we do not focus on computing in our data, this discussion (and in particular the phenomenon of numerical patterning we highlight in the case of Brian) is also potentially related to computational solutions and to the role and function the computer might play in generating numerical answers and entire sets of outcomes. Researchers have shown students using the computer to generate large sets of outcomes and to notice numerical patterns (e.g., De Chenne & Lockwood, 2022). Moreover, modern computationally-oriented data analysis methods similarly find and leverage patterns in data that are useful but not always clearly explainable. We consider such activity as providing an important opportunity for researchers and teachers to elaborate appropriate curricular roles that both numerically-based RPG and process-based PPG play in curricula orienting students towards computational mathematics. More research is needed to explore the kinds of generalizing activity such approaches may afford or inhibit, particularly given this distinction between RPG and PPG.

Ultimately, we value patterning and generalizing in students' combinatorial problem solving, and we acknowledge that students tend to leverage patterns, numerical or otherwise, in their combinatorial work. We think this phenomenon opens up important questions for us as discrete mathematics educators – what kinds of engagement with patterning and generalization do we want to foster in students, and how might we practically support hem in such desirable thinking and activity? We hope to engage with such discussions with the field, with the overall aim of continuing to inform and improve the teaching and learning of combinatorics and discrete mathematics.

Integrating computational thinking in the learning of functions in the 8th grade

Andreia Mateus[1], Hélia Oliveira[1] and João Piedade[1]

[1]UIDEF, Instituto de Educação, Universidade de Lisboa, Portugal; hmoliveira@ie.ulisboa.pt

As computational thinking is being included in the mathematics curricula in different countries there is a need to design tasks that support an integrated approach to learning computational thinking and mathematics. Recognizing some common obstacles in the learning of functions, this exploratory study intends to analyse what practices of computational thinking 8th grade students develop in solving a task on affine functions and how this task supports them in distinguishing linear and nonlinear affine functions. A qualitative methodology was adopted, within a teaching experiment, with data collected through observation, and the analysis of students' written work on the task. Findings suggest that the task provided opportunities to enact practices of computational thinking and simultaneously to support first development of students' knowledge about nonlinear affine functions, providing a starting point for discussion on computational thinking and mathematical functions integration.

Keywords: Computational thinking, task design, functions, proportional reasoning, middle school.

Introduction and background

Acknowledging the significance of fostering students' computational thinking (CT), many countries have incorporated CT into their curricula in various ways in recent years, either through dedicated subjects or across multiple disciplines (Bråting & Kilhamn, 2021). In line with this trend, Portugal has introduced CT into its basic education mathematics curriculum (Canavarro et al., 2021). CT may be characterized as a way of thinking in face of problematic situations that involves the enactment of practices such as those outlined by different authors (Kallia et al., 2021), and in the Portuguese mathematics curriculum for basic education: (i) abstraction, which involves extracting the essential information from a problem; (ii) decomposition, which is based on simplifying a problem by breaking it down into more manageable parts; (iii) pattern recognition, which implies recognizing or identifying patterns and regularities when solving one problem and applying them to similar problems; (iv) analysis and definition of algorithms, which involve solving a problem through a step-by-step procedure, often resorting to technology; and (v) development of debugging and process optimization habits, which encourages testing to identify and correct errors and subsequently refine a given solution.

One central issue that emerges when planning the inclusion of CT in mathematics classroom concerns the pedagogical approaches (plugged and unplugged) that best promote its development (Caeli & Yadav, 2020). Plugged approaches are mostly focused on programming and are recognized as a strong pedagogical approach to developing CT, given the importance of the cognitive aspects behind programming (Kallia et al., 2021). However, also several potentialities have been highlighted for unplugged approaches, namely, helping students to construct and outline their reasoning (Caeli & Yadav, 2020), and helping to ease fears of programming among teachers and students, and meaningfully engaging the latter with the big ideas of computer science (Bell & Vahrenhold, 2018). Kotsopoulos et al. (2017) suggest that students should start with less demanding experiences in terms

of understanding (*unplugged* and *tinkering*) and progress to more cognitively demanding ones *(making* and *remixing*). Those authors also note that *unplugged* experience should be the initial approach to promote computational thinking, as it introduces concepts without using computers. This approach requires less cognitive load and does not require knowledge of programming languages. In the *tinkering* experience students modify existing objects, analysing the implications of these changes on the results and correcting possible errors, with a focus on applying concepts and simulation. In the *making* experience, students solve problems by planning and selecting tools, as well as establishing connections between concepts. Finally, in the *remixing* experience, students modify an object to adapt it for a different purpose.

Effectively merging computational thinking with the mathematical topics in the curriculum remains a significant undertaking (Israel & Lash, 2020). Still there is a need to develop studies in less studied mathematical topics, such as functions, to fully understand in which domains of mathematics it is suitable to include computational thinking (Ye et al., 2023). In the case of functions learning, several challenges have been identified within the literature, namely the conversion between different representations of functions, the development of knowledge that becomes connected over time and that is not only context-specific (Wilkie & Ayalon, 2018), and more recently, with introduction of computational thinking, the different meanings variables may assume in the context of algebra and in programming (Bråting & Kilhamn, 2021). Furthermore, it is important to consider the well-documented and widespread students' tendency to make use of proportional reasoning in situations where it does not apply (Van Dooren et al., 2005) and how that may affect the learning of functions when they move from studying linear functions to nonlinear affine functions, an important topic in mathematics curriculum. Hence, there is a need to understand how to integrate computational thinking practices in the learning of functions, namely by conceiving tasks that combine unplugged and plugged activities. This exploratory study, which comes from a teaching experiment aimed at integrating computational thinking into the learning of affine functions in the 8th grade, intends to answer the following two research questions: RQa) What practices of computational thinking do students develop in solving a task on affine functions?; RQb) How did this task support students in distinguishing linear and nonlinear affine functions?

Methods

Task design

The task was the first one in a teaching experiment on the topic of affine functions carried out with two 8th grade classes. In its design, the specific objectives for learning affine functions outlined in the mathematics curriculum (Canavarro et al., 2021), and the characteristics of tasks to promote conceptual mathematics understanding by Swan (2014), namely representing and translating mathematical concepts in their various representations and identifying and analysing structure within situations, including studying relationships between variables, were considered. This lesson was the starting point to support students in building the notion of nonlinear affine functions ($f(x) = ax + b$, with $a, b \in \mathbb{R}$, and $a, b \neq 0$) against linear functions ($f(x) = ax$, with $a \in \mathbb{R}$), they had already studied in the previous school year, in different representations. Targeting the learning goal of interpreting and modelling real-life situations, the task's context presents different plans of gas consumption in

Portugal and it is divided into four parts in connection with the experiences in computational thinking described in Kotsopoulos et al. (2017). The use of Scratch was promoted in this task since it is suggested as a resource in the Portuguese mathematics curriculum and the teacher-researcher (first author) already had successfully explored it previously with these classes. In other tasks in the teaching experiment was also used Geogebra, namely for the graphical representations of functions.

The first part of the task corresponds to the *unplugged* experience, aims students to analyse a situation that can be modelled by a linear function, through out three items where students are asked to: i) explore an example of a direct proportionality situation using specific values of gas consumption; ii) construct a flowchart that identifies the inputs/outputs related to the described situation and outlines the reasoning from the previous item in a more abstract context; and iii) to advance to symbolic language relating objects (x) and images (y) to write an algebraic expression representing the linear function.

In the second part of the task (Figure 1), that corresponds to the *tinkering* experience, students are expected to interpret situations modelled by a nonlinear affine function, make predictions, and correct errors. In the first two items, students should interpret a pre-written code, contextualize some of its instructions according to the given situation, and make a prediction about an output (image) resulting from a specific input (object). In a third item, students are prompted to compare codes and identify errors, using, for example, the rules of mathematical operation priority to justify their reasoning. Finally, they are asked to translate the situation, relate objects (x) and images (y), and arrive at the algebraic expression of a nonlinear affine function.

2. Due to convenience, safety and price, in recent years piped natural gas has reached more and more homes. In the natural gas bill, there is a variable component, associated with gas consumption in cubic meters, and a fixed component, relating to several fees, namely the fixed term, access to the network and occupation of the underground.
For the gas company to automatically issue gas invoices, it is necessary to enter the number of cubic meters that were consumed in a month, real or estimated. The following program was built in Scratch to depict this situation:

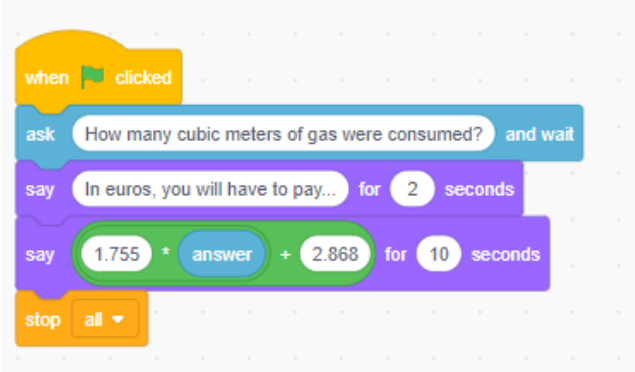

Figure 1: Statement of the task (Part 2)

The third part of the task, the *making* experience, aims to address more problematic situations involving the nonlinear affine function and to establish connections between concepts, through out three items where students are expected to: i) to determine an object corresponding to a given image, using, for example, reasoning with inverse operations or solving equations which were studied in previous years; ii) generalize the reasoning from the former part by completing lines of a code

presented in the task; and iii) build the program in Scratch to validate the obtained result. Thus, both plugged and unplugged approaches are expected from students.

Finally, in the *remixing* part of the task, students are required to build, in a less guided manner, a program in Scratch to model a real-life situation involving percentages, which is associated with a linear function.

Data collection and analysis[1]

This study followed a qualitative methodology within a teaching experiment carried out by the teacher-researcher (the first author). From the two classes that participated in the teaching experiment, eight pairs (four from each class) were selected to represent the heterogeneity of students. To ensure the collection of comprehensive data, these were chosen to optimize the benefits of their interaction during task-solving. For the teaching experiment different data collection methods were employed, including participant observation, with video recordings and the collection of students' written work. In this paper we focus on the analysis of these students' written work which represents the range of solutions from the target groups.

The analysis framework focuses on the five practices of computational thinking mentioned before (Canavarro et al., 2021) and on the evidence of students' use of proportional reasoning or non-proportional reasoning in the context of affine functions. For this study we rely only on the analysis of students' solutions to the items of parts 2 and 3 of the task (the *tinkering* and *making* experiences), where students were expected to understand the difference between a linear and nonlinear affine function.

Findings

The *tinkering* part of the task

The first item in this part of the task asked students for the meaning of the two values (1.755 and 2.868) displayed in the coded representation (Figure 1), in the context of the problem. All students correctly interpreted these values and exhibited the intended *Abstraction*. Differently to most groups, that mentioned the two values as the "price of gas by m^3" and "the value of the fees", one pair interpretated them strictly from the mathematical point of view ("1.755 is the fixed component and 2.868 is the variable component") in connection to what was presented in the task statement.

In the second item of this part, most students were able to determine the values of the input and output values for a gas consumption of 10 m^3, showing that have understood that coded representation translated the situation depicted in verbal language in the statement (Figure 1). In their initial solution (17.55), however, one pair overlooked the fixed rate, focusing solely on the variable component of the gas price. After testing the value in Scratch, they were able to identify and correct the error (*Depuration*), as depicted in Figure 2.

[1] Data presented in this paper is part of a research published by the authors in the paper: https://doi.org/10.48489/quadrante.37041.

Figure 2: Solution to item 2 from Part 2 by one pair of students

In item 3 (Figure 3) all pairs provided a correct answer, accurately identifying and explaining the differences between the two code blocks (*Depuration*). One pair first converted the codes into symbolic language and then justified their response using natural language in the context of the situation (*Abstraction*), showing proficiency in converting different representations (Figure 4).

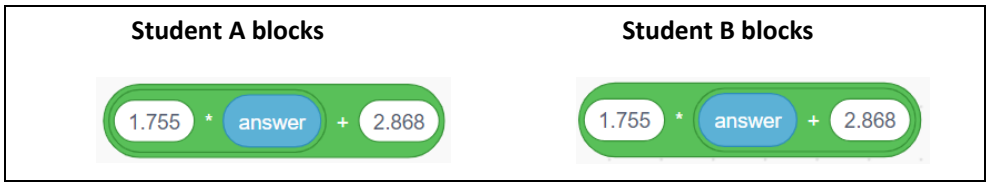

Figure 3: Blocks of code for students to choose (item 3 from Part 2)

This pair of students explained that the correct block of code is the first one: "The idea is to do the price of one cubic meter x (times) the consumed gas + (plus) the fee and not the consumed gas plus the fee x (times) the price of one cubic meter" (Figure 4).

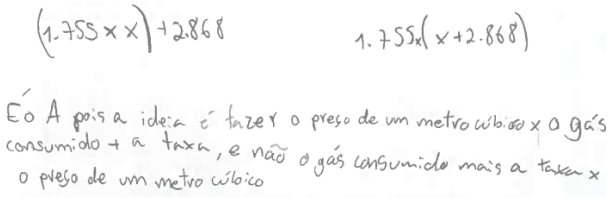

Figure 4: Solution to item 3 from Part 2 by a pair of students

In the last item of this part of the task, students were asked to make a flow chart reflecting the situation depicted by the program (Figure 1), using the variable *x* to represent the amount of natural gas consumed in a month. All students successfully elaborated a flowchart, defining an algorithm where most of them correctly identified the input data, procedures, and output data (*Algorithm analysis and definition*). This is evident from the geometric shapes used in the flowchart construction, where they use parallelograms for input or output data and rectangles for procedures (Figure 5).

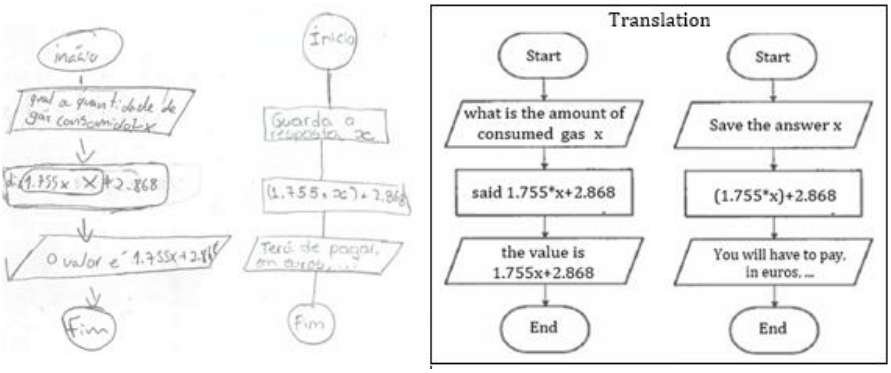

Figure 5: Flowchart by two pair of students

In the solution on the left, one pair of students (Figure 5, left) identifies the input data in the flowchart as a question, using the context of the described situation, and associates it with the variable *x*. For the procedure, it indicates the calculations to be performed in a generalized way, using the variable *x*, and they mention the output data as a response associated with the result of the previously performed procedure. In the solution by another pair (Figure 5, right), there is a reference to the need to store the value of the variable *x*, although this is not identified in the flowchart as an input data.

The *making* part of the task

In the first item of this part, where students were asked to determine the amount of natural gas for a given monthly value (39.95 euros), the pairs that arrived at the correct solution used the inverse operations reasoning. However, several students solved the question incorrectly, some of them by using the direct proportionality reasoning without considering the fixed rates. In these cases, students mainly recurred to the simple rule of three, a procedure quite common in mathematics classrooms.

In the second item, where students were required to fill the blanks in the Scratch blocks (Figure 6), most of the solutions presented by them are generalisations of the correct or incorrect reasoning used in the previous item, allowing for the identification of input and output data and the calculations to be performed (*Algorithm analysis and definition*). Contrary to what was expected, one pair (Figure 6), who had used the simple rule of three without considering the fixed rate in the previous question, was not able to directly translate the rule of three reasoning into code. Instead, these students used the context of the described situation to correctly solve this question, although they did not define the meaning of the variable *x* in their solution, which would prevent the program from working correctly.

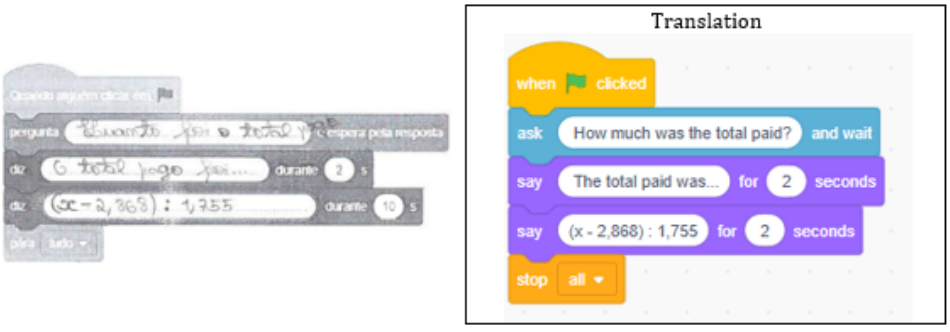

Figure 6: Solution of item 2 from Part 3 by one pair of students

In the third item, students were asked to access Scratch website and to create the above program. Most students managed to test their reasoning by building the program according to the blocks they completed (*Debugging and process optimization habits*). Interestingly, the same pair of students, when constructing their program, noticed something was wrong and managed to solve this by creating the variable *x* to store the value of the response.

Conclusion

Addressing the need to understand how to integrate computational thinking practices in the learning of functions, this exploratory study shows that the chosen approach for the design of the first task in the teaching experiment has allowed students to reveal consistently several practices of computational thinking. Thus, concerning RQa), besides the main practices envisioned for each item of the task, mostly abstraction, pattern recognition and algorithm analysis and definition, students often recurred to debugging for adjusting their solutions. In what regards RQb), we observed that in the *Tinkering* part of the task, students managed to analyse a new way of representing a function, different from the usual representations, a *coded representation*, contributing to the understanding of the concept of a nonlinear affine function. In *Making* part of the task, most students, starting from the analysis of a concrete example of the described situation, managed to advance their reasoning to reach a contextualized generalization of the situation. That was achieved by constructing a program to determine an object given an image in a nonlinear affine function and performed testing and validation of their reasoning. Thus, during parts 2 and 3 of the task, analysed in this paper, students moved between unplugged and plugged experiences which seem to have supported their work.

As documented in the literature, we also observed some instances of overgeneralisation of the proportional model (Van Dooren et al., 2005). However, computational practices practices assisted some students in reflecting on their solutions and made them progress to a non-proportional model, as the one depicted in the *making* part of task. In sum, it seems that the task provided students a good understanding of the two variables involved in the situation (amount of gas consumed and what to pay) and about the relationships between those variables, a key issue in leaning of functions (Wilkie & Ayalon, 2018).

Further analysis of the students' learning during the teaching experiment will allow us to have a deeper understanding of the potentialities of the adopted approach and adequacy of tasks' structure to promote students' knowledge of affine functions. One key point will be to study how students deal with the different meaning variables may have in algebra context and in programming environment (Bråting & Kilhamn, 2021), in the domain of functions. Nevertheless, these findings already provide a platform to discuss the tasks' nature that may support the integration of computational thinking in the learning of mathematics, in regular classrooms, in a connected way.

Use of re-coding strategy while solving problems related to Catalan numbers by undergraduate student

Janka Medová[1] and Antonín Jančařík[2]

[1]Constantine the Philosopher University in Nitra, Faculty of Natural Sciences and Informatics, Department of Mathematics, Slovakia; jmedova@ukf.sk

[2]Charles University, Faculty of Education, Department of Mathematics and Mathematics Education, Prague, Czech Republic; antonin.jancarik@pedf.cuni.cz

This study explores the use of isomorphism, specifically re-coding, in solving combinatorial problems involving Catalan numbers. According to previous research, isomorphism, or recognizing equivalent problems with similar structures, can improve problem-solving success. Through a lesson study with undergraduate students, we examined how one student used re-coding during a diagnostic interview. Despite his high programming skills but low combinatorial proficiency, Alex effectively translated Dyck words and paths into familiar representations like parentheses. These findings highlight that re-coding can simplify problem-solving by reducing cognitive load and suggest that promoting isomorphic strategies can enhance students' problem-solving efficiency in combinatorics.

Keywords: Mathematics education, problem-solving, combinatorics education, problem-solving strategies, undergraduate students.

1 Introduction

Problem-solving in combinatorics presents a challenge for students, often due to the absence of clear verification methods and multiple correct strategies. Studies (e.g., Batanero et al., 1997) show that students face uncertainty when deciding on a solution method, and incorrect estimations frequently arise in counting problems (Fischbein & Grossman, 1997). This reflects the need for effective problem-solving strategies, especially those that facilitate structured approaches to complex combinatorial tasks. One promising strategy for addressing combinatorial problems is the recognition of *isomorphism*, the one-to-one correspondence between equivalent problems that share the same underlying mathematical structure despite differing superficially (Siegler, 1977 in Zenkl and Vondrová, 2023). This problem-solving approach allows students to transform a problem into another equivalent situation that they are more familiar with, which can lead to a correct and more efficient solution (Lamanna et al., 2022). The ability to recognize and apply isomorphism is central to developing a deep understanding of combinatorial concepts.

Research supports the effectiveness of isomorphism as a strategy for solving combinatorial problems (Maher et al., 2010). Lamanna et al. (2022) observed that students who utilized isomorphism were more successful in solving combinatorial problems. In the study by Lockwood and Gibson (2015) students who began solving tasks by enumerating or referencing an isomorphic problem demonstrated a statistically significant improvement in their problem-solving success. Despite its proven benefits, students rarely employ such strategies unless

explicitly guided (Lamanna et al., 2022). This highlights the need for teaching methods that emphasize isomorphism as a problem-solving tool in combinatorics.

Zenkl and Vondrová (2023) identified three distinct ways in which students employed the strategy based on isomorphism: (1) **Re-coding**: Students replaced letters from the problem with numbers or other symbols, or used different letters (e.g., substituting letters from the beginning of the alphabet) to simplify the task and facilitate understanding; (2) **Solving an isomorphic combinatorial task**: Students drew on their knowledge of a previously encountered isomorphic combinatorial problem, either due to familiarity with the solution or a more comprehensible context, to successfully solve the current problem; and (3) **Solving an isomorphic problem from a different mathematical domain**: Students applied concepts or skills from a different area of mathematics beyond combinatorics to address the problem, leveraging their broader mathematical knowledge for the solution.

In this paper, we focus on the application of isomorphism as a problem-solving strategy in problems leading to Catalan numbers, defined as $C_n = \binom{2n}{n} - \binom{2n}{n-1}, n \in \mathbb{N}_0$ (Stanley, 2015). They appear in a variety of combinatorial problems, such as counting valid parenthetical expressions, grid paths not crossing the diagonal, mountains consisting of slashes and backslashes non-descending under the given level, non-crossing pairings of vertices placed on the circle, or polygon triangulations. Catalan numbers provide students with opportunities to explore recursive structures, patterns, and connections between problems (Cofman, 1997).

2 Material and Methods

The findings reported in this paper are from a broader study focused on the affordances of Catalan numbers in undergraduate courses of combinatorics, particularly in courses for pre-service mathematics teachers. The study is designed as a lesson study (Lewis et al., 2019) when two mathematics educators from two different universities (authors) designed the series of lessons in four steps: study – plan – teach – reflect. Besides future mathematics teachers, the designed lessons are also used for students of applied statistics and applied informatics at the university in Nitra. More than 20 task-based interviews (Maher & Sigley, 2020) with students were conducted; most of the sessions and the lessons were (audio- or video-) recorded.

The designed activity consisted of three lessons, 90 minutes each. The first lesson was focused on isomorphisms between eleven combinatorial situations leading to Catalan numbers. As homework after this lesson, students were asked to find as many bijections between the given combinatorial situations as they were able to. The list of the situations, as well as the first categorization of students' strategies to find the bijection, can be found in Medová and Jančařík (2024). During the second lesson the students were divided into groups of 2-4 students. Each group re-discovered one of the three various formulas for Catalan numbers and their proofs in thinking-classroom settings (Liljedahl, 2020). In the non-compulsory homework, after the second lesson, students were asked to write a procedure to list all Dyck's words or valid parenthetical expressions for given n. During the third lesson, students presented their solution strategies and proofs from lesson two to the whole classroom. The lesson three was led by

students and facilitated by the authors. Several instances of students using isomorphism were observed at various stages of the lessons.

In order to deeper understand how students use and switch between different representations and terminology when reasoning about Catalan numbers, and what challenges arise from this recoding during problem-solving we analyzed one of the interviews. As Lockwood and De Chenne (2021) suggested that computer programming might support solving combinatorial problems, we chose a person submitting the non-compulsory coding assignment and, based on our observations from lesson three tending to use a re-coding strategy.

The diagnostic interview was conducted one week after the third lesson, in front of the whiteboard, because the students in the course were used to work with vertical non-permanent surfaces as suggested by Liljedahl (2019), and video recorded. The student provided informed consent with the interview and its use in scientific publications as well as for further educational purposes. The interviewee, Alex (pseudonym), studied applied informatics in his second semester. Based on the fact he got an A mark in the programming course in the previous semester, we can assume his programming competencies were very high. On the other hand, according to the pre-test given at the beginning of the course (the same test as in Melušová & Vidermanová, 2015), his proficiency in solving combinatorial problems was quite low, he solved correctly only two problems and used enumerative strategies.

3 Findings

During the 60 minutes of the diagnostic interview, we identified four instances where Alex used isomorphism between the combinatorial situations. We will now describe the stances and then provide a short analysis. The session started by revising the coding homework. Then, he explained the proofs of the three formulas re-discovered during the second lesson. In the last phase, we focused on isomorphism between the given combinatorial situations.

3.1 Coding

The first instance where the re-coding was observed was the solution of coding homework. The assignment was as follows: “Write a code producing a list of valid parenthetical expressions or Dyck’s words. Input is n (number of characters X in the Dyck’s word), output is the list of the words.” A Dyck word is a string consisting of n X's and n Y's such that no initial segment of the string has more Y's than X's (Stanley, 2015).

The code provided by Alex mixed the use of English and Slovak language. The name of the procedure (GenerateDyckWords) is in English, and the instructions for the user are in Slovak. It can be seen that he does not distinguish between valid parenthetical expressions and Dyck’s words. Although the procedure is called GenerateDyckWords in the source code, it prints the parenthetical expressions. Also, the instructions for the user are written confusingly. The input is supposed to be n, the number of X characters in Dyck’s word, and the user dialogue says "Number of parentheses:". The number of elements in the working set is printed with the comment "Number of words:". It doesn't seem that Alex cared what two characters the Dyck words consist of, whether it's AB, XY or (). In fact, English Wikipedia uses square brackets

when defining Dyck words for the entry Dyck language. Alex claimed that while coding, he also looked up information about Dyck words on the Internet.

When asked why he preferred parentheses to any other character, he answered, “I don't know, but I'll think about it...” (app. 2 minutes later). “Maybe because the parentheses are simpler? Faster to understand? I can see right away if they [generated strings] are okay.”

```
public static void main(String[] args) {
    Scanner scanner = new Scanner(System.in);
    System.out.println("Pocet zatvoriek:");
    int n = scanner.nextInt();
    List<String> result = generateDyckWords(n);
    for (String s : result) {
        System.out.println(s);
    }
    System.out.println("Pocet slov: " + result.size());
}

3 usages
public static List<String> generateDyckWords(int n) {
    List<String> result = new ArrayList<>();
    if (n == 0) {
        result.add("");
    } else {
        for (int i = 0; i < n; i++) {
            List<String> left = generateDyckWords(i);
            List<String> right = generateDyckWords( n: n - i - 1);
            for (String s1 : left) {
                for (String s2 : right) {
                    result.add("(" + s1 + ")" + s2);
                }
            }
        }
    }
    return result;
}
```

Figure 1: The code provided by Alex as the solution of the coding assignment

Note: “Pocet zatvoriek:” means “Number of parentheses:”, “Pocet slov:” means “Number of words:”

3.2 Proving the formula for mountain ranges

The unconscious re-coding can also be observed when Alex proved this solution to the problem about Dyck paths as mountain ranges. Dyck's path is a series of up-and-down steps. The path will begin and end on the same level, and as the path moves from left to right, it will rise and fall, never dipping below the height it began on (Stanley, 2015).

While pointing at the mountain ranges (Figure 2), he described “the way it's divided up is that there's one group where there are three **brackets** down, two brackets down, one bracket down, zero brackets down” and he fluently continued with the description of the bijection used in the proof (Figure 3) “from one form to another, this is adjusted by taking one **step down**. The **stick** is transferred upwards. And when we go the other way around, we take those chopsticks from the bottom”.

Throughout the whole proof, he interchangeably used the terms “parentheses”, “step up”, and “stick” again, in a very unconscious way.

Figure 2: Alex pointing on the whiteboard while describing grouping of Dyck paths

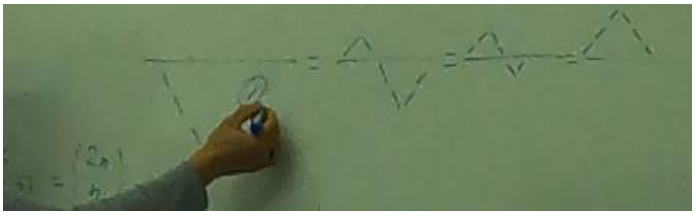

Figure 3: Alex pointing on the whiteboard while describing the bijection

3.3 Proving the formula for Dyck words

While proving the formula for Dyck words using the cyclic lemma, Alex again uses the two words "parentheses" instead of characters, even when reasoning about the Dyck word consisting of characters X and Y.

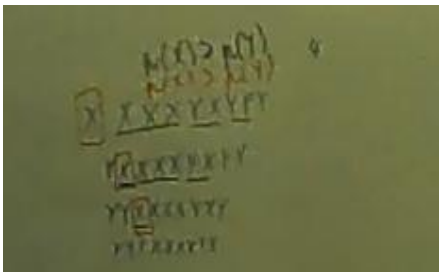

Figure 4: Whiteboard while explaining the cyclic-lemma proof

Alex:	This one doesn't fit because I'm starting with the left parenthesis [pointing to Y in row 4].
Interviewer:	Why won't any new word I get by cyclic rotation satisfy this condition?
Alex:	Because there's always one extra parenthesis, and there's no parenthesis to close that word.
Interviewer:	But that's a different condition we're talking about.

3.4 Explaining the bijections

The last stance when Alex used the re-coding was when he was asked to explain the bijection between the non-crossing pairing of $2n$ vertices and the Dyck words.

Interviewer:	Why does it always have to work like this? Why does the condition of not having multiple ends before the **beginning** always fit?
Alex:	Well, because those **parentheses** can't be like that.
Interviewer:	Well, but does it fit with this picture?
Alex:	(silence for the 40s)

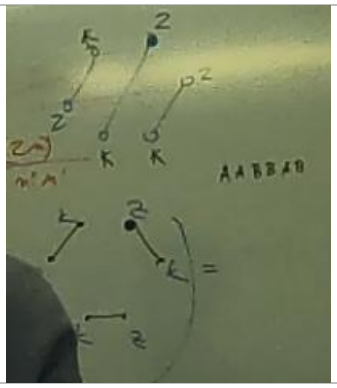

Figure 5: Whiteboard while reasoning about the bijection

Figure 6: Alex showing the gesture "parentheses can't be like this"

Note: character Z states for "začiatok", i.e. beginning, the character; K for „koniec", i.e. end.

This vignette demonstrates the unconsciousness of the usage of the re-coding strategy. After the direct question of the interviewer "Well, but does it fit with this picture?", Alex was looking at the whiteboard for more than 40 s. It seemed that he was really confused as there were no parentheses on the whiteboard. Also, the word proposed by teachers consisted of letters A and B and not Z/B and K/E, as used for the diagrams of the graph. Then the interviewer recoded the given Dyck work into the ZK notation used for graphs and asked.

Interviewer:	Why does the word I get from such a listing have to be Dyck's? Why can't I get the word KKZZKZ [using English notation EEBBEB]?
Alex:	Because we coded it that way, and it's right.
Interviewer:	Why can't I get this out of a picture like this? ZKKZKZ [BEEBEB]
Alex:	Because we go like this (writes a circle around the vertices of the graph with his finger) and write down the letters (looks at non-Dyck's word ZKKZKZ/BEEBEB). I don't know why you went like that. How did you get this?
Interviewer:	It's not from this picture. I'm asking why I can't get a word like that from the matching graph. Or vice versa: why can't I make a pairing for this word?

Alex looked at the whiteboard and then translated Dyck word into the form of parenthetical expression and underlined the parentheses that made the expression incorrect and looked at the interviewer questioningly.

Interviewer:	I know it's not Dyck's word. The question is why there can't be a non-crossing pairing to such a word.
Alex:	Because the **parentheses** can't be like this (gesture: he crossed his arms in front of his chest, hands were curved into the shape of parentheses, Figure 6). There the edges cannot cross and the beginning must be less than the end and in such a word the end would be before the beginning.

In this turn, Alex used several situations simultaneously: parenthetical expressions, pairings, and Dyck words. They appeared to be three representations of the same concept for him. He seemed to think in the language of parentheses and speak according to the situation. When the question was more cognitively demanding, he switched the code to the language of parentheses. During the whole interview, he did not mention that he switched the representations or used the isomorphism.

4 Discussion and conclusions
