At line 81 we found F3, since the inconsistency of the new functionality with the original one is presented at 82 we have F2, T3, as DT1 argued that it makes sense to demonstrate the functionality simulation to introduce the trainees to the FP functionality. At 83 we have F2 to a lesser degree and perhaps T2, as it was discussed how the tradition can be continued (to simulate the particular functionality of FP), but taking into account contemporary possibilities and overcoming the "barrier" of F3; yes, indeed, one cannot copy a functionality of a tool with another, but maybe it makes sense to adapt it using novel technological possibilities. The coding of these units is indicative of the analysis, since there were more units and data related with each code.

In the second case we studied, two educators wanted to leverage a simulation of tossing an ordinary (fair) coin. The special feature of this case is that in the previous phases of training there was no corresponding artefact like the one they wanted to create. Although there are ready-made simulations, they decided to design a new one, with the help of GeoGebra (figure 3): by manipulating the slider, the user sets the number of tosses and sees how many times heads and tails appear. The red points correspond to the head appearances, while the blue ones to tails.

The following excerpt shows part of the designers' dialogue before proceeding with the design:

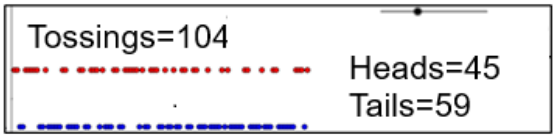

Figure 3: Simulating the flip of an ordinary coin, in GeoGebra

187	DT3:	I suggest that we don't use a ready-made simulation by putting a link, because I don't even know if we can. Does it have any copyrights?
188	DT4:	Maybe we can, but the ready-made one may one day be "offline" and its URL no longer valid. It is also good to design it in GeoGebra, because this is also the philosophy of our training program: "the teacher as designer".
189	DT5:	But we should show them other simulations, because some of the trainees may have difficulty with such designs, which are demanding, in terms of technical knowledge and competencies. We mostly want them to cultivate a designer culture, rather to design everything one can think of!

190 DT6: Okay, but in order to be able to adopt designer culture should they also have some capabilities at a technical level? These go together!

The above excerpt is indicative of the coded meanings that emerged from the analysis we did throughout the design process of this artefact. We categorized line 187 to D1 and 188 to D2, while 188, 189 and 190 discuss the "teacher as designer" issue, while the meaning of lines 189 (Ph1) and 190 (Ph2) corresponds to a tension on the correlation between the technical skills and the acquisition of designer culture by a teacher which would be trained to the use of digital media for mathematics teaching and learning.

Discussion

In the second stage of our analysis, we classified the units of meaning into AS elements, by classifying the corresponding codes (table 1). This classification is the main subject of our discussion. In table 1 it is shown which code corresponds to which elements of the AS. Since all codes of stage 1 were related to the digital medium (GeoGebra as a digital authoring system), the subjects (the teacher educators) and the object (to design digital artefacts, to be used at the end of training) of the activity, we focused on classifying the codes that were also related to the remaining elements of the AS, the community, the rules, and the division of labour.

Table 1: The result of the second stage analysis. The X in each cell means that the code of the same column corresponds to the element of the respective row, i.e. T3-T4 correspond to the community, while E3-E4 correspond to all three elements of the AS, which are listed in the table

AS elements	T3-T4	E3-E4	F2-F3	Ph1-Ph2	D1-D2
Community	X	X	X	X	
Rules		X	X	X	X
Division of labour		X	X	X	X

On the one hand, codes with the same letter but different numbers conceal a contradiction and a possible tension, while on the other hand, the appearance of the same code in more than one AS element of table 1 (i.e., an X in more than one cell of each column), may conceal an interaction between these elements. Since we are looking for tensions between the AS elements, we will focus our discussion primarily on the codes E3-E4, F2-F3 and Ph1-Ph2 of table 1, where there is an X in every cell of the corresponding column. Thus, table 2 shows the tensions that we identified between the AS elements, as we interpreted them based on the corresponding units of meaning.

For example, we noticed that E3-E4 appear in the rules, the community and the division of labour. So, we could say that the process of deciding what and to what extent trainees would participate in the design of artefacts was related to interactions between the educators and themselves, the rules of training and the "position" of the educators compared to the trainees during the training (the division of labour). Another tension also emerged in the discussion about whether it is appropriate or not to replicate the functionalities of digital tools with new ones, as shown in column F2-F3 of table 2. This tension seemed to be resolved by the end of educators' collaboration, while the first one remained

unresolved. Finally, we identified a tension related to the educators' perspective on "the teacher as a designer" concept. It seems that this tension was related to codes Ph1-Ph2, especially when the discussion was about trainees (community) and "to what extent a lack of fluency in creating artefacts is a barrier to acquisition of designer culture?". Moreover, it was also related to D1-D2 when the educators mainly discussed issues of rules that affect the decisions of a teacher as a designer, in general. This tension remained unresolved, as well.

Table 2: Starting from Table 1, we listed the tensions we identified between the elements of the AS

AS elements	E3-E4	F2-F3	Ph1-Ph2
Community	Who is supposed to design?	Replicate functionalities or artefacts or not?	What does 'teacher as designer' mean?
Rules	To what extent should a trainee design artefacts?	Designers/educators argue on transformations that occur when the functionalities of one artefact are duplicated.	Is technical fluency prerequisite or strongly correlated to designer culture acquisition?
Division of labour			

Conclusions

In this study we proposed a method for identifying and analyzing tensions that appeared in the design activity of the educators in the context of our research. Some of these tensions remained pending, while a tension about whether it is acceptable or not to replicate the functionalities of digital tools with new ones, appeared to be smoothing out as educators reached a consensus. However, the normalization of tensions, in the context of CHAT, is a process that is accompanied by significant changes in the subjects' activity, which was not evident from our data. This raises some questions: Did some significant change occur that we did not detect? Has this tension indeed been resolved or is it still pending? Were there factors that favored a temporary "solution" to this tension, which will resurface in the future? Were there factors that allowed the other two tensions to remain unresolved? That is, perhaps training can continue even if the discussion between the educators about the role of a teacher as designer remains open. Perhaps training was designed to allow for such different approaches. On the other hand, a decision had to be made about whether and how they would replicate the functionality of the digital tool to move forward, so perhaps this is why this tension seems to be resolved. Since this is a large-scale training activity, the environment is changing dynamically (e.g., emerging technologies, etc.) and such tensions lurk. By enriching one's data and by studying additional cases one can describe tensions in even more detail, possibly answering some of the previous questions, or new ones that will arise.

Generative AI in Mathematics Teaching: lessons from spreadsheets through the lens of double instrumental genesis

Eirini Geraniou[1], Manolis Mavrikis[1], Uffe Thomas Jankvist[2] and Morten Misfeldt[3]

Teachers often integrate new digital tools into their practice for pedagogical reasons, even when these tools have not been designed for mathematics education in particular. In this paper, we discuss how lessons learned from the use of spreadsheets in teaching and learning can potentially support us in the use of generative artificial intelligence (GAI) tools in mathematics teaching practice. Through the lens of the double instrumental genesis and two illustrative cases, we look at the didactic use of these two tools and put forward arguments for the GAI tools' genesis and potential challenges and implications for mathematics teachers.

Keywords: Instrumental genesis, double instrumental genesis, spreadsheets, generative artificial intelligence, mathematics teachers.

Introduction

Upon the arrival of a new (digital) technology, the field of mathematics education research often proposes new theoretical constructs and notions specifically targeting that technology. Needless to say, this has led to a plethora of theories, theoretical frameworks and constructs targeting just as many functionalities embedded in various digital tools. However, as illustrated by Jankvist and Misfeldt (2021) in the case of computer algebra systems (CAS) and dynamic geometry environments (DGE), having a look at our field's back catalogue may very likely offer something that can be used as an outset for describing and understanding aspects of our current situation and observations. With the recent introduction of generative artificial intelligence (GAI) we face a similar situation as the field did some decades ago with the introduction of CAS and DGE. Hence, the hypothesis we have is that some of the theories and constructs developed around previous technologies may have something to offer in relation to a (constructive) use of GAI in the teaching and learning of mathematics.

Any digital tool becomes a mathematical instrument in the hands of a learner, through a process of instrumental genesis (e.g., Drijvers et al., 2013). Besides the need for teachers to consider their orchestrations for using digital tools in their practice (instrumental orchestrations, Drijvers et al., 2014), we acknowledge the need for teachers to go through a professional genesis during which the digital tool in question becomes an instrument in their practice. These two different processes are what Haspekian (e.g., 2014) termed as *double instrumental genesis* (DIG). With GAI in mind, this dual process becomes particularly relevant considering also that recently policy and scholarly work puts increasing emphasis in teacher competencies for AI (e.g., UNESCO, 2024). In the context of mathematics education specifically, our previous work suggests that teachers would need to develop their Mathematical Digital Competency (MDC) (Geraniou et al., 2024) when using a digital tool and

in fact to ensure that they continue to develop *mathematical and digital competencies so as to select and implement various tools in their practice in pedagogically productive ways* or in other words develop their Mathematical Digital Competency for Teaching (MDCT) (Geraniou et al., 2024). Considering GAI as a digital tool, we are interested in teachers' mathematics teaching with the use of such. We wonder what may be different, new, challenging and potentially beneficial with GAI, and subsequently what the professional development needs of teachers are to teach mathematics with GAI. We take our departure point in Haspekian's (2014) argumentation about the use of spreadsheets:

> […] the spreadsheet provides a good amplification of the phenomena that play in the development of ICT practices […] Firstly, the spreadsheet is a professional tool without any *a priori* didactical functionality. In this case, the instrumental distance is not negligible and plays a considerable role in the difficulties surrounding the integration of spreadsheets. Secondly, the teacher has to turn this non-educational tool into a didactical instrument through a process of professional genesis, a process made more complex by this instrumental distance. (Haspekian, 2014, p. 253)

Our aim is thus to consider GAI as tools that can be turned into didactical instruments through mathematics teachers' professional genesis and thereby explore, using two illustrative examples, *to what extent the DIG framework suffices to explain teachers' use of GAI tools, although originally developed for spreadsheets.*

Double instrumental genesis - Lessons learned from spreadsheets

The mathematics education research community has increasingly focused on the use of technology in learning and teaching of mathematics. Theoretical frameworks, such as the **instrumental approach** (Guin et al., 2004) which focuses on the concept of instrumental genesis, have emerged and have been widely applied to different studies involving different digital tools (CAS, DGE, etc.). Under the umbrella of the instrumental approach, there are several theoretical frameworks and constructs used in mathematics education, e.g., instrumental genesis, instrumental distance, instrumental orchestration and DIG, which we present below.

The instrumental approach (e.g., Trouche, 2005) focuses on how students interact with digital technologies (DT) and the impact DT have on their mathematics learning. As Trouche (2005) defined it, **instrumental genesis** is "a complex process, linked to characteristics of the artifact (its potentialities and constraints) and to the subject's activity, her/his knowledge and former work methods" (p. 144). There are two main processes involved when a student goes through an instrumental genesis. The first one is termed as *instrumentalization*, which entails the process when the subject shapes and modifies an artifact; and the second one is termed as *instrumentation*, and it involves the process during which an artifact shapes and influences the subject.

Lagrange (2005) highlighted that DT demand new teaching strategies and that "push-button" approaches challenge traditional paper-and-pencil methods. The concept of **instrumental distance** (Haspekian, 2014) considers the gap between the educational potential of paper-pencil mathematics and that offered by specific digital tools. This notion extends beyond the usual concept of "computer transposition" (Balacheff, 1994) to encompass various shifts—cultural, epistemological, or institutional—brought about by incorporating a tool into mathematical practice.

The theory of **instrumental orchestration** (e.g., Drijvers et al., 2014) was developed to analyse teachers' orchestrations when supporting students' learning when interacting with DT. Haspekian (2014), though, considered the necessity for teachers to also professionally develop by going through a process of instrumental genesis, before they are to further develop their teaching practices to pedagogically support their students' learning when interacting with DT. This process was termed as **double instrumental genesis** (DIG) and was inspired when Haspekian looked at the use of Spreadsheets, a tool that is not specifically designed for mathematics teaching and investigated its integration in mathematics teaching practices. Her research led to the idea of the spreadsheet becoming an "instrument for teachers' didactical activity" (Haspekian, 2014, p. 253) through professional instrumental genesis that, in addition to a process where teachers instrumentalize the tool in order to serve didactic objectives, another process of instrumentation takes place to enable the teacher to "incorporate within her (already stable) teaching schemes some new schemes that integrate the use of the tool" (p. 253). Haspekian (2014) presented the case of an experienced mathematics teacher, Ann, who integrated the spreadsheet tool within her teaching practice and who was observed for how she used it for the first time, but also for how her practice evolved as she continued to use it for two years. DIG was used to analyse Ann's actions during the integration in question.

In our experience, the way a teacher uses a tool depends highly on the lesson's objectives and the learning goal and outcomes for her students. Similarly, Ann's activity with the spreadsheet was tailored to the goal of teaching algebraic concepts, such as variables and formulas, as she used the copy function, for example, or reflected upon the numerical feedback of the tool to check the equivalence of two formulae. Such actions reveal the teachers' utilization schemes, which are related to the material aspects of the tool (e.g., Rabardel & Bourmaud, 2003), as opposed to the schemes of instrumented action, which relate to the overall task goals and intentions (e.g., Rabardel, 1995) and their organisational decisions. Ann had to decide how to orchestrate the usage of other tools, such as the data projector to make collective explanations for example. In Ann's case, her professional genesis with spreadsheets was closely intertwined with her personal experience using them, as observations indicated that these aspects influenced each other in a relational way. This interplay became more complex because she wanted her students to use the spreadsheet independently and learn mathematics through the activity, rather than just based on her demonstrations. As Haspekian (2014) continued her argumentation, the students' instrumental genesis in using the tool also became part of Ann's professional genesis with it, leading to further interference.

Ann had to also consider which spreadsheet functionalities her students needed or were ready for, at each stage in their learning journey. For example, Haspekian (2014) mentioned that Ann had decided not to involve or talk about a specific functionality in the first spreadsheet session "as it was above the level of instrumentation she wanted for her pupils at that moment" (p. 257). Such decisions interfere with students' instrumental genesis, but on the other hand showcase that Ann had not "yet turned her personal instrument into a mathematics-teaching instrument" (Haspekian, 2014, p. 258) and revealed how complex these processes are. So, she did use the spreadsheet as a "*calculation-oriented* instrument", but she also had to use it as a "*didactic-oriented* instrument", which evolved her own instrumental genesis with spreadsheets, and further developed her professional genesis (Haspekian, 2014). As Haspekian (2014) summarised, mathematics' teachers professional genesis is

constrained by their own aims and shaped by the way they support their students' instrumentation and instrumentalization processes. Generalising the above, a teacher would have to go through an instrumentalization process, as they would have to instrumentalise the tool to achieve the didactic objectives for their teaching practice, but also an instrumentation process, as they would have to integrate 'new' usage schemes in their existing schemes to ensure a successful integration of the tool in question. As also argued by Haspekian (2014), turning any such tool into a didactical instrument, and therefore go through this DIG process, is a lengthy and complex process and that has implications for teacher training in ways that support teachers through both aspects of tool integration.

Double instrumental genesis in the case of a Large Language Model (LLM)-enabled notebook

In this section, we explore the applicability of the notion of DIG through an example of the Wolfram chat notebooks[1] that integrate GAI, and specifically Large Language Models (LLM) such as OpenAI's and Anthropic's models, that allow for both natural language interaction and coding to interact with mathematical entities and data. Let us consider a scenario where a teacher wants to engage her class in mathematical modelling projects such as "renting vs. buying a house" or "investigating referee bias"[2] while leveraging the chat and LLM functionalities of the notebooks. A teacher would be expected to solve the problem first herself using the AI notebook. We leave aside for now some of the technical challenges that might be encountered.[3] Wanting first to explore the notebook herself, a teacher could simply type "*explore the financial implications of renting a flat versus buying a house over 10 years*" into the notebook. The notebook would respond with a detailed financial comparison between renting and buying. The LLM would automatically define key variables, such as interest rates, property appreciation, and inflation, and would make reasonable assumptions about mortgage terms, and maintenance costs. It would then calculate the total costs for both options over a 10-year period, providing step-by-step explanations along the way. A teacher would be expected to explore further these features and test the current capabilities of AI to gain confidence in effectively integrating this as a tool into her own practice. One noticeable aspect is that through this process a teacher would notice how different GAI is from a calculator, or a spreadsheet. A teacher may feel a lack of autonomy if in the process she does not engage with any mathematical formulas. The AI can do all the work, which may lead her to question whether she would have approached the problem differently on her own. Following her own interactions with the GAI tool, the teacher should wonder how best to approach this issue in a way that supports students develop their problem-solving skills.

---

[1] https://reference.wolfram.com/language/tutorial/ChatNotebooks.html

[2] We took inspiration from Wolfram's Computer-Based Maths https://www.computerbasedmath.org/project-repository/

[3] Such challenges could include managing LLM API keys or adjusting model parameters, which, of course teachers should not be expected to have to do. We assume here that such tools could be integrated seamlessly with the school's systems, with costs and infrastructure managed by learning technologists. A big assumption perhaps but this would allow teachers to focus on pedagogy, though ongoing training will still be necessary as these tools evolve rapidly, much like spreadsheets.

Drawing parallels to Ann's journey with spreadsheets, as described by Haspekian (2014), she recognised the importance of actively engaging with the mathematical content to transform digital tools into effective didactic instruments. The teacher using a GAI tool may be worried that the students might bypass some important problem-solving steps, simply inputting questions in natural language and receiving complete solutions. A way forward would be to break the problem down into smaller, more manageable parts that would not only help her students develop a systematic approach, but also require them to engage with the underlying mathematics in each part (e.g., following Polya's problem solving cycle and the well-known DISUM modelling cycle, see Blum and Leiß, 2007). As such, the teacher could structure the notebook into different parts (e.g., understanding the problem, searching and using mathematics and explaining the results) to help the students. A second, equally important way forward would be to realise that LLMs are not aligned with our values and practices 'out-of-the-box'. For example, even if breaking the problem into steps, if asked to identify factors an LLM would respond: "Here are three major cost factors to consider when comparing renting a flat versus buying a house," followed by explicit descriptions of these factors (initial costs, ongoing monthly costs, etc.). Such a response would bypass the students' opportunity to engage in their own thinking. In later steps for calculating ongoing maintenance costs for a home, an LLM would most likely respond directly providing the formula: "You can calculate ongoing maintenance costs using the formula: Annual Maintenance Cost=Home Value*Maintenance Rate".

Therefore, to turn GAI in a true didactical instrument, a teacher would have to (at a very minimum) craft a prompt to ensure the AI's responses would support, rather than undermine, her learning objectives. To achieve this, in the case of the GAI-enabled notebook, the teacher should revise the 'context' of the notebook to include more specific instructions, explicitly directing the LLM to not provide complete solutions and instead guide students to explore the problem. Such an adjustment is crucial in aligning the tool with the pedagogical goals of fostering critical thinking and deeper understanding in mathematics.

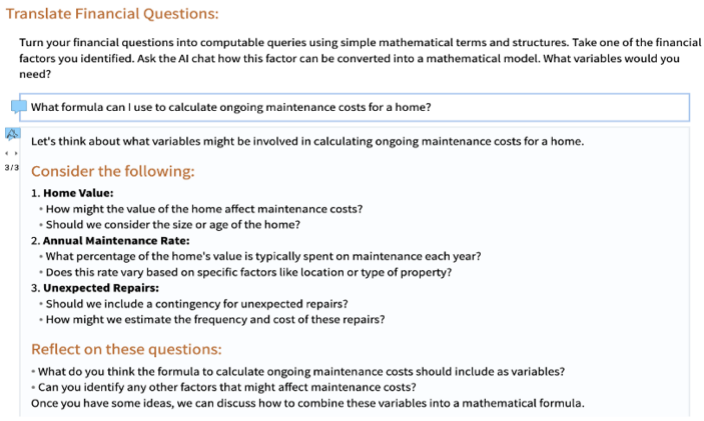

Figure 1: An example of an interaction with an LLM-enabled notebook that is prompted to guide students to specify a formula for home maintenance costs during a mathematical modelling project.

Figure 1 shows an example where the GAI employed by the notebook has been prompted in order to guide the student within the specific context of each step of the mathematical modelling process

instead of providing the answers. Careful crafting of the prompt will shape how the students engage with the tool. If a teacher were to take such actions, then GAI could become an instrument not just for solving problems, but for cultivating problem-solving and modelling skills that were the teacher's intentions in this case for example.

Discussion

We now return to our aim and summarise *to what extent the framework of DIG suffices to explain teachers' use of GAI tools, although originally developed for spreadsheets.* The framework of DIG does offer a useful although limited explanation for teachers' integration of GAI tools in the classroom. While the framework highlights the processes by which teachers transform digital tools into instruments for teaching and learning, the unique features of GAI introduce new challenges and opportunities that require extensions to the original framework. One critical difference between traditional tools like spreadsheets and new AI-based tools is that AI is not a fixed entity. Whereas tools like CAS and DGE have predetermined, static functionalities, AI systems are dynamic, constantly evolving, and capable of regenerating content based on new inputs and interactions. This presents both new opportunities for employing AI but also introduces complexity in the pedagogical process, as teachers must navigate and manage AI's autonomous problem-solving capabilities.

The process of teachers adopting GAI tools involve similar steps to those described in Haspekian's (2014) case study of Ann, who used spreadsheets to teach algebra. Ann underwent a process of DIG, wherein she transformed spreadsheets from mere tools into instruments that supported her teaching objectives and pedagogical strategies. This transformation required her to personally learn the tool, experiment with its functionalities, and make decisions about which features would benefit students' learning and how. The same is true for teachers integrating GAI tools into their lessons. The rapid emergence of AI has generated discussions and scholarly work on AI competencies for teachers and the emergence of frameworks that emphasize the need for teachers to develop both technical and pedagogical skills in working with AI (UNESCO, 2024). However, the process of double instrumental genesis highlights how teachers must develop their own competency with AI tools while simultaneously supporting their students' learning journeys—a dual challenge that is particularly acute with new layers of complexity due to the rapid evolution of GAI and its non-predictable nature and autonomous capabilities.

As argued earlier, one of the core issues with both spreadsheets and GAI tools are that they are not specifically designed for pedagogical use, leaving teachers without clear guidance on how to implement them effectively in the mathematics classroom. While teachers are undergoing such a professional instrumental genesis, they must not only learn the tool's functions but also understand how to guide its outputs in ways that align with their teaching objectives, carefully choose what to present and what to withhold; all of which are decisions that subsequently impact students' learning. In the case of GAI, this is particularly relevant because the AI's ability to autonomously generate answers may tempt teachers to prioritise efficiency over understanding, potentially undermining students' deeper learning, and making the teaching process harder to predict and control. This mirrors Haspekian's (2014) notion of "interference between the personal and professional instrument," where the teacher's use of the tool may unintentionally impact how students engage with it.

The evolving aspect of GAI means that teachers need continuous professional development, not only to refine their MDC (Geraniou et al., 2024), as they did with past tools like CAS, DGE and spreadsheets, but also to stay updated on the constantly changing landscape of AI tools. This implies the need for developing the necessary MDCT (Geraniou et al., 2024). As such, MDCT professional development should emphasize the importance of aligning AI usage with pedagogical values that mathematics education research and practice has demonstrated to be conducive to promoting problem-solving and critical thinking or whichever learning objectives the teacher aims to achieve.

Conclusion

Reflecting on the above points, we can argue that DIG indeed offers a solid foundation for understanding teachers' integration of digital tools. But it may require modification to fully account for the unique challenges posed by GAI. Instrumental distance—the gap between the tool's potential and the teacher's use of it—needs to be expanded to consider the new dimension of alignment that AI introduces. Teachers must develop new competencies to shape AI interactions to support their pedagogical goals, ensuring that AI serves as a means of fostering deep mathematical understanding rather than merely automating problem-solving. In other words, teachers must not only refine their MDC and MDCT but also engage in ongoing professional development to keep pace with the rapid advancements in AI, ensuring that they can effectively integrate these tools into their teaching practices.

Many have expressed both great concerns and high hopes about the impact of chatbots and AI on education (Giannakos et al., 2024). Some may argue that it is best to discard these tools from our education system. But they can be seen as opportunities to enhance learning and focus on mathematical concepts rather than calculation skills, as showcased in the two illustrative cases. We hope that the maths education research community continues to research the new possibilities offered by AI, bearing in mind the lessons learned by past research on digital technologies.

Preservice teachers and their computational thinking perspectives

Khaled Ben Latief Jemai, Toril Eskeland Rangnes, Shipra Sachdeva, Odd Tore Kaufmann and Marianne Maugesten

Østfold University College, The Faculty of Teacher Education and Languages, Norway; khaled.jemai@hiof.no

This study aims to provide teacher educators with valuable insights into preservice teachers' (PTs') perspectives on computational thinking (CT). We analyse three PTs' notes from their process and reflections when solving mathematics problems with programming to identify their CT perspectives. We employed Brennan and Resnick's CT framework focusing on CT perspectives and applied Warshauer's concept of productive struggle to gain deeper insight into what the PTs see as struggle and how they valued it. Our findings suggest that the PTs' positioned themselves as novices in programming, focusing on learning programming and making something useful for their students to support their students' learning. They chose well known mathematical problems claiming that programming was the main challenge. Their struggles with programming were valued as part of their learning process.

Keywords: Computational thinking, preservice teachers, productive struggle, programming.

Introduction

In this paper we investigate how preservice teachers (PTs) conceptualize computational thinking (CT) and learning programming in mathematics. Since Wing (2006) promoted CT as a fundamental skill, essential for solving complex problems across disciplines, researchers have emphasized different aspects of CT activities (Nordby et al., 2022a). One aspect is to see CT as a skill that needs a good common definition to accurately evaluate student performance, as mentioned in Shute et al. (2017). They defined CT as the "conceptual foundation required to solve problems effectively and efficiently (…) with solutions that are reusable in different contexts" (Shute et al., 2017, p. 151). Brennan and Resnick (2012) see CT more as a process, incorporating the dimension *CT perspectives* that include the designer's view of the world and themselves in the design process, an understanding of CT we adopt in this paper. Additionally, we apply the concept of productive struggle (Warshauer, 2014), which emphasizes that difficulties encountered while solving mathematical problems can be beneficial and promote learning. Our aim is to provide teacher educators with knowledge about PTs' CT perspectives and how productive struggle is communicated when they solve self-chosen problems in mathematics by using programming. The data analysed are PTs' notes from a mandatory assignment in their final year[1].

Yadav et al. (2014) highlight that it is important to develop the teachers' (and therefore also PTs') understanding of CT in the context of their subject to prevent an overly abstract comprehension that may impede CT integration. However, merging CT with mathematics can be challenging for teachers. Nordby et al. (2022a) note that problem-solving serves as a bridge between CT and mathematics in

[1] Norway has mandatory five years master education for all new teachers in primary to higher secondary school.

schools, providing a rationale for incorporating CT into math education. In a study on primary teachers introducing CT into mathematics (Nordby et al., 2022b), two main approaches were observed: integrating CT into the existing mathematics curriculum, and focusing on programming, sometimes at the expense of mathematics. Teachers play a pivotal role in either facilitating or hindering the integration of CT in mathematics. These researchers advocate for further studies to identify effective strategies for fully integrating CT into mathematics teaching.

Some countries have introduced programming as a new school subject (Nordby et al., 2022a), while others, such as Norway, have integrated programming across multiple subjects, including mathematics. Mathematics is a key subject for incorporating programming in compulsory schooling in Norway (Vinnervik & Bungum, 2021). The Norwegian mathematics curriculum emphasizes that CT should be utilized as a problem-solving method. Consequently, teacher education must align with this curriculum, and CT and programming have become essential components that the PTs must learn. In this context, PTs in their final year of master's studies were given a mandatory assignment to solve a mathematical problem using programming and to document their problem-solving process and reflections. The research question guiding this study is: *What perspectives related to CT and traces of productive struggle can be identified in preservice teachers' notes when solving a mathematical problem through programming?* Analysing and describing PTs' perspectives and struggles, and how they overcame them, can provide teacher educators with valuable insights into the challenges and needs of PTs when applying CT and programming to solve mathematical problems.

Theory

Solving problems and applying CT can often lead to struggles. In mathematics, Warshauer (2014) introduced the concept of productive struggle, describing mathematics as "a dynamic discipline that involves exploring problems, seeking solutions, formulating ideas, making conjectures, and reasoning carefully" (p. 377). Warshauer's productive struggle framework includes 1. getting started, which includes the students' struggle with interpreting the task and how to approach it, 2. carrying out a process, which includes to encounter an impasse, struggle with implementing a process, or being unable to carry out an algorithm, 3. uncertainty in explaining and sense-making, as when they struggle with explaining their work, express uncertainty or are unclear about reasoning their choice of strategi, and the last one, 4. expressing misconceptions and errors related to mathematics topics (p. 385). These aspects of struggle are not only pertinent to problem-solving in mathematics but also extend into the domain of computational thinking. As Herheim and Johnsen-Høines (2020) suggest productive struggle can be linked with programming through computational thinking, which involves systematic steps to solve problems and find solutions, often requiring programming to execute these solutions. Thus, we perceive productive struggle as an integral part of the learning process when practicing CT in conjunction with mathematics. For struggle to be productive, learners must be appropriately challenged. However, their efforts to solve tasks should ultimately lead to a solution, whether achieved independently or with support from others. If struggles lead to students abandoning the problem with a feeling of failure, we see these as non-productive struggles. Brennan and Resnick's (2012) framework for CT encompasses three key dimensions: *computational thinking concepts, computational thinking practices, and computational thinking perspectives. CT concepts* refer to the fundamental ideas in programming, such as sequences, loops, parallelism, events, conditionals,

operators, and data. They demonstrate how these concepts can be applied in Scratch. *CT practices* are described as the skills developed during the programming, such as being incremental and iterative, testing and debugging, reusing and remixing, as well as abstracting and modularization. They explain *CT perspectives* as the perspectives designers form about the world and themselves in relation to technology, identified through; 1) expressing, which includes how learners can express themselves by using programming, 2) connecting, which includes cooperation with others, and 3) questioning, which involves what the students see as opportunities and limitations.

Both the Brennan and Resnick (2012) and Warshauer (2014) frameworks were developed from classroom observations, focusing on learners working through problems, whether in programming or mathematics. Both frameworks emphasize the problem-solving process learners engage in. The CT perspectives focus on learners' reflections on their experiences with CT while working on programming tasks, whereas the productive struggle framework highlights how learners' struggles in problem-solving can foster learning and growth. We see these frameworks as relevant also when PTs are the learners.

Method

The participants in the study were master's students from teacher education programs for grades 1-7 and 5-10, as well as in-service teachers pursuing a master's degree in mathematics education. They had two days of programming instruction, but their all experience with programming from teacher education remained limited. Data was collected from a course titled "Exploratory ways of working in mathematics, problem-solving, and modelling", which all three groups attended together. For simplicity, we will refer to all participants as preservice teachers (PTs).

As part of an assignment in their 5th year, the PTs were asked to select a mathematical problem, solve it using CT and programming, and document the process using screenshots and including reflections on their learning. They were required to explain their choice of the mathematical problem, describe their problem-solving approach using programming, and discuss any coding errors encountered along the way. They worked independently; however, they received some guidance from the teacher educators when requested.

The data set consists of 39 notes from PTs who consented to participate after completing the course. To delve deeper into and further develop our framework inspired by Brennan and Resnick's (2012) CT perspectives and Warshauer's (2014) concept of productive struggle, we decided to examine one randomly selected paper (by drawing lots) from each group. Coincidentally, all three participants reported limited programming experience and chose to use block programming tools like Scratch.

Our preliminary analyses aim to provide insights into the participants' perspectives on CT and mathematics and how they communicate struggle as productive. The process of identifying categories was iterative, starting with theoretical frameworks and then adjusting after the initial readings. Given that our data consists of notes written by PTs rather than observations of school students, we needed to adjust Brennan and Resnick's CT perspectives and Warshauer's productive struggles to fit our context. Due to the limited space, we have chosen here to focus on two of the three elements of the CT perspective: *expressing* and *connecting*.

Expressing: Brennan and Resnick describe "Expressing" in terms of students sharing stories about how they express themselves through programming. We broaden this definition to include: (a) *PTs' notes on how they understand CT,* (b) *their self-reflection on their own learning process*, and (c) *their choice of problem to solve*. We see a connection between (b) and productive struggle, as both are integral to the learning process. As we primarily focus on the reflections in the PTs' notes rather than screenshots due to space limitations, it can be challenging to directly identify their programming struggles. However, our initial examination revealed that PTs openly described their struggles in their learning process. We, therefore, searched for mentions of difficulties or obstacles connected to learning or understanding. Expressing these productive struggles might involve describing uncertainties with implementing a process and detailing the efforts made to solve problems.

Connecting: Since the data consists of individual written notes, there is no observable collaboration between students as in Brennan and Resnick (2012) or interaction with teachers as in Warshauer (2014). Instead, we redefine *Connecting to include input from peers, colleagues, course literature, and other resources* that PTs mentioned as helpful in their process. We also expanded this category to include *connecting mathematics and programming*.

Our analyses in this paper are preliminary. The insights provided can inform us about PTs' reflections and perspectives when learning CT through problem-solving and programming. Incorporating productive struggles helps us identify where PTs comment on their struggles and whether they perceive these challenges as productive in the learning process.

Results

A short summary of the three PTs' assignments

PT1 is in the master's program for grades 1-7. PT1 understands CT as "the process of developing a recipe, the overall thinking and process in developing a systematic approach to problems." They mentioned limited experience with programming and chose to solve the problem: "Create an algorithm that calculates the area of a rectangle with varying length and width" using Scratch. PT1 also tried the program with students during practicum and described the computer as a discussion partner. They expressed enjoyment in mastering and solving mathematical problems. However, PT1 did not explicitly connect programming activity with mathematics.

PT2 is in the master's program for grades 5-10. PT2 described CT as starting with big problems, breaking them into smaller parts, and solving them. They described their programming skills as not good but gained new insights from a student assistant, who suggested viewing the task not just as a programming exercise but as a problem-solving exercise. They initially chose to construct geometrical figures (a rectangle and a right-angled triangle) and used Microbit, a block-based program language like Scratch, to program a BitBot car to trace their perimeter. Due to technical issues with the BitBot car, PT2 shifted focus to creating a game to help students memorize the multiplication table. PT2 noted that the aim was to learn programming rather than create the multiplication table.

PT3 is a teacher pursuing a master's degree in mathematics education. PT3 chose a previously solved problem: visualizing "A bacterial culture doubled every 20 minutes. How many bacteria are there

after 10 hours?" using programming with Scratch. They thoroughly presented the CT practice developed and reflected on different perspectives of CT and mathematics. PT3 detailed description of struggles with programming, such as making the bacteria move and split, providing insights into these challenges. PT3 noted that using programming as a digital tool to learn mathematics offers various opportunities to present models, illustrations, and figures.

Computational thinking perspectives and productive struggles

All three PTs wrote about their perceptions of CT, which we categorized under the CT perspective of Expressing, *(a) notes about how they understand CT*. They are referencing the description of CT from the Norwegian Directorate for Education and Training's website as well as the course literature. For instance, PT1 wrote:

> PT1: Computational thinking I understand as the process of developing a recipe, or in more academic language; the overall thinking and process in developing a systematic approach to problems. […] the process of solving a problem, where the focus is on the development, reflection and execution of knowledge one has or acquires along the way.

PT1's focus is on developing the recipe, the learning gained through systematic approach, the development, reflection, execution and use of knowledge one brings in or acquires during the process. This is a description of CT practice where the practice develops through doing programming.

When analysing *Expressing (b) Self-reflection on learning*, we searched for mentions of programming and/or mathematics, and learning-related terms. PTs primarily reflected on learning programming. For instance, PT2 wrote: "In my case, the goal is not the multiplication table itself but the programming and the journey towards it." This highlights that the aim is learning programming and the process of creating a program, not merely learning mathematics. PT3 also noted that programming is the main challenge, describing the process on a general (1st quote) and specific (2nd quote) level and connecting the struggles to a problem-solving process.

> PT3: (1st quote) Programming is something I find difficult, but from my experience with the previous assignment, it is in the problem-solving process that you really face challenges and learn skills to keep going, even when the task seems impossible.

> PT3: (2nd quote) In this phase of the task, I believe the concepts of decomposition and debugging more clearly describe the process. I continuously fix the program, delete commands, and improve the code. It is a time-consuming process, but I find that I gain a deeper understanding as I continue programming.

What PT3 describes about facing challenges as part of the learning process in 1st quote, is what we identified as a description of being in productive struggle. The 2nd quote begins by describing computational practices such as decomposition and debugging and then shifts to PT3's self-reflection on the learning process. PT3 mentioned that the time-consuming programming efforts led to a deeper understanding. They described a continuous cycle of fixing, deleting, and improving the code, indicating that they encountered struggles and errors that needed correction which we see in connection to productive struggle framework point 2, carried out a process which include encountering impasses (had to delete commands), implementing a process or struggling with carrying out codes. PT3's experience illustrates productive struggle, as it resulted in what they described as deeper understanding, although it was not specified what exactly they understood better.

In *Expressing (c) their choice of problems to solve*, we find that they selected tasks focused on creating something for their students—for instance, a learning program (PT1), a multiplication game (PT2), and a visualization tool (PT3)—rather than solving their own mathematical problems. This choice likely influenced their self-reflections, leading them to emphasize learning programming. Their selections might stem from what they described as a lack of competency in programming, but it can also be seen as an expression of their identities as teachers through the programs they create.

When examining the PTs' reflections on *connecting*, we identified two distinct themes: *connecting with others* and *connecting mathematics and programming*.

In the theme of *connecting with others*, the PTs referenced various sources of interaction and inspiration. PT2 mentioned seeking assistance from a student assistant, while PT1 highlighted interaction with school students and even described the program or PC as a "participant". All PTs drew inspiration from literature. Additionally, PT1 noted connections to wider society.

The shift in perspective, inspired by a student assistant, illustrates how connecting with others can provide new insights and approaches. For PT2, this guidance helped refocus on programming as a tool to solve problems rather than just the tool itself. PT1 noted that the assignment was individual, limiting opportunities to share ideas and reflections. However, inspired by an article from the course literature, PT1 found that the program provided ongoing feedback, acting as a "third participant." PT1, specializing in grades 1 to 7, argued for using Scratch due to its appropriateness for primary school students. PT1 also involved students in practicums to test the program, showing that students were important both as receivers and responders of the programming product.

For all three PTs, their students significantly influenced their choice of programming language, and the mathematical problems selected, even though the primary aim of the assignment was PTs' own problem-solving and learning, in mathematics.

PT1 also connecting to society, stating:

> PT1: Another advantage of working with programming is the practical experience you gain. Society is changing and increasingly moving towards a society that demands knowledge and programming skills. Therefore, these skills can be seen as important for developing into a valuable and good citizen.

This expands the idea of connecting beyond the classroom, linking programming skills to societal needs and emphasizing the role of education in preparing students for a technology-driven world.

Connecting mathematics and programming was not frequently mentioned in the PTs' assignments. However, as current or future teachers, they recognized the potential to link their programming with possible mathematics activities for their students. PT3, for instance, highlighted the opportunity to visualize the mathematical problems they were working on. They also connected this assignment to previous tasks involving mathematical modeling and problem-solving in their reflections.

> PT3: Using programming to solve a mathematical problem gives the impression of combining skills in both modelling, problem solving and CT. ... I model, reflect, argue and prepare solutions using all elements from previous tasks. It is in this assignment that I really get to explore on my own and learn about myself as a problem solver.

PT3 recognized the process of mathematical problem-solving and modeling with CT. While PT1 and PT2 also mentioned this connection, PT3 articulated it more clearly. The linkage between the mathematical problem of exponential growth and programming is evident in this quote from PT3: "This assignment (the note) shows my reflections, processes, and descriptions when I use programming to illustrate a bacterial culture that grows exponentially." Here, PT3 effectively connects a mathematical model with its representation through programming, offering alternative ways of understanding mathematical problems. PT3 noted, "For me, it was about understanding what the different codes and commands did, and a deeper understanding of the process can result in greater cognitive benefits, both in mathematics and in other contexts." This indicates there can be cognitive benefits when integrating mathematical modeling with programming.

Discussions and concluding remarks

As future teachers, the PTs will play a crucial role in introducing CT in mathematics to their students. As Norby et al. (2022b) noted, they can act as gate openers or gate closers for CT. Therefore, it is essential to understand their CT perspective and views on struggles with programming.

We used CT perspectives from Brennan and Resnick (2012) and productive struggles from Warshauer (2014) to develop our analytical framework. With some adaptations, we identified CT perspectives in their notes. The PTs described CT as a method for problem-solving and saw connections between struggling with programming and solving mathematical problems. They viewed problem-solving as a commonality between mathematics and CT. PT3 chose an assignment related to exponential growth, indicating a strong link between programming and mathematics. Creating visual representations of a mathematical model is closely associated with understanding mathematical expressions.

Brennan and Resnick (2012) emphasized that students express themselves through programming, which we adapted to focus on PTs' self-reflections in their notes. PTs expressed their identities as mathematics teachers through the programs they created for students' mathematical learning. Choosing a mathematical problem to solve, using programming, is challenging for novices, so PTs opted for familiar concepts and focused on games or visual representations over new problems. This shows that integrating CT into mathematics may cause the mathematical aspect to shift to the background (Norby et al., 2022b). Yadav et al. (2014) stressed learning CT within the subject context to avoid abstract understanding, which is crucial for integrating CT into mathematics teaching, and this is an area that needs further exploration in teacher education. Designing mathematical programs for didactic purposes is different from solving a mathematical problem for oneself and defends its own place in teacher education. Creating something for students was motivating for the PTs, and such motivation should also be nurtured.

We incorporated the concept of productive struggle into our framework. This decision was based on reflections in the PTs' notes about their struggles and learning. Their documented struggles indicated uncertainty in implementing and carrying out processes (Warshauer, 2014). They showed persistence and engagement in sense-making during programming, demonstrating productive struggle. However, we believe there is further potential in this concept that we have not yet fully explored in our data analysis. We realized that screenshots with PTs' explanations might offer better insights into their sense-making, error searching, and program improvements. Future analyses will include these

screenshots to better capture productive struggle. Additionally, interviews with participants could deepen our insights into productive struggle and enhance our understanding of CT in education.

The research question was: *What perspectives related to CT and traces of productive struggle can be identified in PTs' notes when solving a mathematical problem through programming?* The findings indicate that the CT perspectives chosen by the PTs were primarily related to programming when tasked with solving a mathematical problem through programming. They expressed themselves by creating didactic programs for their students. The process they described we associate with productive struggle. The fact that they themselves go through such a process can help them to support their students through similar processes. To support PTs in using CT to solve mathematical problems, we suggest that a programming course could be introduced before applying CT in mathematics.

3DMP and TPACK in professional development: Combining actions and knowledge

Tim Läufer[1] and Matthias Ludwig[1]

[1]Goethe University, Faculty for Computer Science and Mathematics Education, Frankfurt (Main), Germany, laeufer@math.uni-frankfurt.de

3D-printing is more present than ever, with new advancements made constantly. Teachers can use 3D-modelling and print tailored learning objects for their students, simultaneously fostering their own TPACK knowledge, making this context very suitable for student teacher education. Still, research on student teachers, 3D-modelling and printing and TPACK is lacking. Therefore, we present our seminar for mathematics teacher education, and how we use our model to describe the 3D-modelling and printing process in combination with TPACK to gain insight into the knowledge needed for the individual steps of the process. This is needed to efficiently develop teacher training and empower teachers with 3D-printing. The qualitative study is presented, and first indications of the combination of 3DMP and TPACK are shown.

Keywords: 3D-Printing, TPACK, Manipulatives, Interview, 3DMP

3D-printing and education

Gone may be the days when teachers cannot realize their wish for a tailored manipulative (Stigberg et al., 2022) for their classroom. Through 3D-printing, educators are empowered and do not need to rely on commercial solutions for their learning object wishes, but can instead create their own.

Advances in 3D-printing make the technology viable for private and educational use, yet their implementation in schools is hindered still due to a lack of teacher education among other reasons (Ford & Minshall, 2019; Pearson & Dubé, 2022). Therefore, we have created a seminar for teaching student teachers on how to use 3D-printing to create their own manipulatives (Läufer & Ludwig, 2023b; Stigberg et al., 2022), such as the one in figure 1:

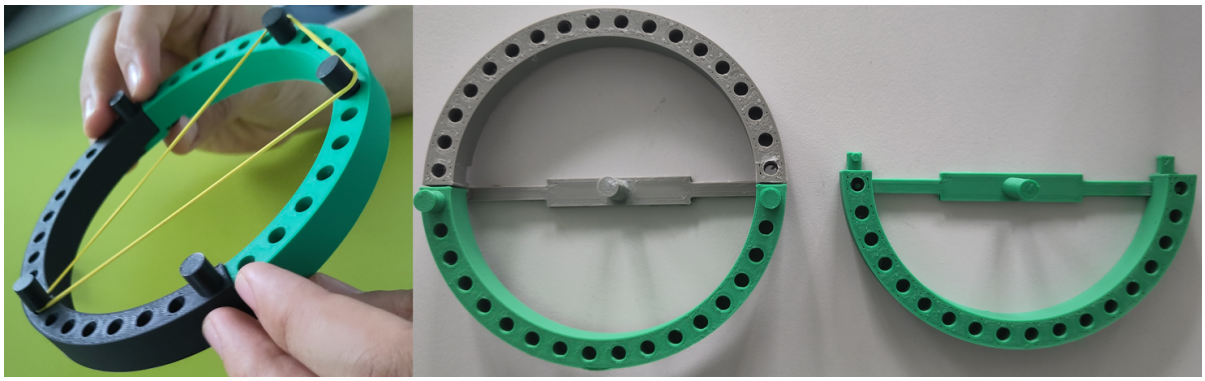

Figure 1: A 3D-printed manipulative made by a student teacher aimed to show Thales' Theorem and the theorem for the peripheral angle and the central angle using a rubber band. The black pieces where the rubber band sits can be inserted into the holes.

The seminar

The target group for our elective seminar is mathematic education students, who already completed the two basic courses, “how to teach algebra” and “how to teach geometry”. We have about 10–12 students every semester, which spans 12–15 weeks. At first, we have an input section (4-5 weeks), outlining the general process, didactics, the tools, and including videos and assignments to learn basic 3D-modelling. Afterward, we have the hands-on section, where the students work on their own projects alone (9-11 weeks). During this phase, we have a first presentation of prototype 1. At the end of the semester, we have presentations of a second prototype (1-2 weeks). The phases are also shown in figure 2. The assignment given to the student teachers is: “Fabricate your own manipulative for a fictional mathematics education lesson, that (1) cannot be bought, (2) is suitable for mathematical education, (3) is complex to some degree, and (4) is 3D-printed.” The example in figure 1 cannot be bought anywhere (criteria 1), but must be fabricated by oneself. It can be used to teach the circumferential angle theorem and more (criteria 2). There is complexity in the design and modelling (criteria 3), and it is 3D-printed (criteria 4). The presentation of the second prototype determines if the students pass or fail. An optional graded 10-page essay can be written for additional credit points.

Theory: Process and knowledge

Research regarding educators (teachers and student teachers alike) 3D-printing and the needed competencies is lacking. The 3D-modeling and printing process (3DMP, (Läufer & Ludwig, 2023a) can be used to describe the steps taken to fabricate a manipulative for mathematical instruction. This model is split into phases (concept, model, prepare, print), tool usage and interim results.

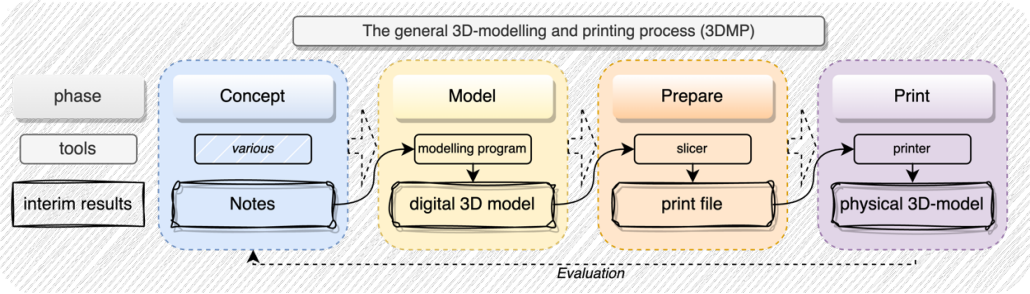

Figure 2: The 3DMP-Process (Läufer & Ludwig, 2023b)

At the beginning, the students have an idea which they want to realize. For that, they need to come up with a **concept** of how they intend to achieve it, answering questions like “What should it look like?”, “What can the students learn?”, “What are the dimensions?” and “What do the students do with it?”. Afterward, they begin **modelling** their concept in a 3D-modelling program. Our student teachers use a programming environment (OpenSCAD) to explicitly require pre-set notes, calculations and thoughts because, in our experience, programming makes it harder to “discover” a manipulative, skipping the concept phase, although this has not been researched yet.

Once the 3D-model is to our expectations, we need to **prepare** the model for printing. This is done in a so-called slicing program, which divides our 3D-model into layers (“slices”; therefore the program is called a “slicer”) and precise directions for our 3D-printer. In the **printing**-phase, the students prepare the printer, the print bed, the filament, and then print their manipulative themselves.

Due to the origin of the process model being a seminar for student teachers, which can pass or fail the seminar, the **evaluation**, which happens anywhere in the process, is only added for completeness but not considered in this paper. Students' evaluation of their manipulatives in a fail/pass seminar does not resemble in-service teacher behavior. Therefore, we focus on the concept, modelling, preparation and printing.

While knowing what the teacher's action are and how to relate them to each other is needed to describe and conceptualize professional development for mathematics (student) teachers, the competencies and knowledge needed during these actions taken is not yet researched. To accommodate for this, we use the TPACK-Framework (Mishra & Koehler, 2006) in this explorative study, which concerns itself with the qualitative description of teacher knowledge and has been used to investigate student teacher tool use (Akkoç & Hangül, 2023; Engelhardt et al., 2023; Rocha, 2023).

Research Question

Teachers want to have good learning materials for their students, while teacher *educators* aim to provide teachers with education resulting in the best possible competencies needed for teaching. Currently, when teaching 3D modelling and printing, we don't know which actions or phase corresponds to which area of TPACK. To fill this gap, especially to accommodate the growing need for teacher education, studies are needed that investigate the connection between these two models. Therefore, we combine the two mentioned theories into the following research question:

What phase of the 3DMP process corresponds with which area of TPACK?

Due to the technical nature of the seminar and the used tools, as well as the mathematical contents that are to be used in and with the manipulative, we expect to see the Modelling, Slicing and Printing phases as mainly technological, and that especially the Concept phase is mathematical and pedagogical.

In the winter semester 2024/2025 this study will be repeated to provide additional data.

Method

To answer this question, we are performing a qualitative study with guided interviews. The first is at the very beginning of the seminar to gain insight on the motivation of the students and if they arrive at the seminar with a goal in mind, which is not included in this paper. We then hold interviews during the semester every time they are to present a prototype (see figure 4). After every prototype, the students have gone through the 3DMP process at least once per prototype. The interview sections are

(a) "Topic and Introduction", which serves as an introduction to the interview
(b) "Concept", where we ask questions on what the students did before 3D-Modelling
(c) "Modelling", where questions regarding the use of the modelling program are asked
(d) "Slicing", where questions regarding the use of the slicing program are asked
(e) "Printing", where questions regarding the printing process are asked
(f) "Feedback", with which we want to see how much influence the instructor and the assistants have on the way the students work on their own manipulatives, and

(g) "Self-locating on TPACK", in where we intend to gain additional insights on how the students view their own work and where they locate each phase of 3DMP. The students have not been taught TPACK but were only shown a very reduced figure of a typical TPACK Venn-diagram.

For this paper, we focus only on (a) – (e). The interviews are not held by the authors (who also grade the students), but by an assistant that has no influence on the grade of the students. The study was piloted and the guided interview, as well as the following methods, were tested (Läufer & Ludwig, 2023b). The interviews are on a voluntary basis.

Overall, they present two prototypes, which do not have to concern the same topic:

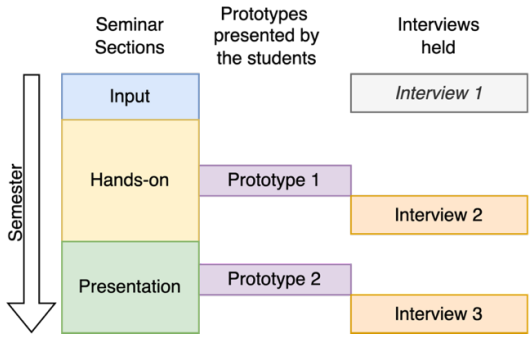

Figure 4: The phases of the seminar, the prototype presentations, and the interviews being held.

After the semester, once the students' grades have been entered, the authors get access to the transcribed, anonymized interviews, ranging from 45 min to 1h 20 min. The answers of the students are then numbered and, if they are very long, split into semantic parts, which are commonly between 1 and 6 sentences. These parts are then rated by 2 raters according to a piloted rating manual for TPACK and 3DMP respectively (see Läufer & Ludwig, 2023b). Due to the *overlap* of the 3DMP ratings and the TPACK ratings, we can then draw conclusions of the connections between the two theoretical models.

First they were rated into the base categories of TPACK (CK, TK, PK) whenever they showed mathematical (CK), pedagogical (PK), or technological (TK) knowledge. We are using the base categories of TPACK to not get lost in details and to avoid an overly complex construct of the 3DMP phases with TPACK, which happened during the piloting phase. In this study, CK is rated when the student uses or mentions explicit mathematical content (i.e. rotation, angles, formulas, …). We rate PK whenever a student references school, education, pedagogy or didactics. TK is rated whenever technology is referenced, like the programs used, research done with computers, and other digital resources.

Afterward, they were rated into the phases of 3DMP every time the actions that the students describe can be attributed to a phase of 3DMP, especially if they reference a tool or an interim result. Every semantic part can be attributed to all phases, if the students talk about their actions in this phase. An example of the rating is shown here (translated from German):

Interviewer: "What notes or preparation did you make during conceptualization?"
Student: "(…) I would use the edge of a semicircle and its diameter, and I would simply construct a semicircle, have it printed, and then I imagined using triangles. I thought

> of printing the triangles separately—some right-angled, some acute-angled, and some obtuse-angled. My first idea was that students, like very young children, would insert the triangles into the semicircle and see which ones fit. (…)"

This is one semantic part that has been agreed on by both raters to be **CK**, **PK** and **Concept**, due to the mathematical shapes (CK), the direct reference to students (PK), and the actions described that can be attributed to the concept phase.

To have methodological solidness, we calculated the inter-rater-reliabilities (IRR) not only in the form of Cohen's Kappa for every category (TPACK) and phase (3DMP), but also calculated Moon's Kappa, which is an abstraction of Fleiss' Kappa (Moons, 2023). Through this, we gain insight not just into the general agreements (Moon's Kappa), but also which agreement is difficult (Cohen's Kappa). The "Self-locating on TPACK" section is only rated during the TPACK rating because the questions are not focused on the ***actions*** that the students have taken, but with their own ***views*** on 3D printing. Therefore, we also don't include it in this paper, and it is not included in table 1.

Results

Every students' 2nd and 3rd interview with the respective IRRs in form of Cohen's and Moon's Kappa values (Moons, 2023) is listed in the following table. The value ranges are 0.2-0.4 (slight), 0.41-0.6 (moderate), 0.61-0.8 (substantial) and 0.81-1(almost perfect) according to Landis & Koch (1977 cited by Moons, 2023).

Table 1: Descriptive Data on the interviews and the agreements of both raters in TPACK and 3DMP. Bold IRR values are >= 0.6. All names are anonymized. *n* refers to the amount of overall ratings over both interviews. The numbers behind the names describe the sum of all semantic parts in interview sections (a)-(e).

Student **(# of semantic parts over both interviews without (f) and (g))**	IRR TPACK				IRR 3DMP				
	Cohen's Kappa			Moon's Kappa	Cohen's Kappa				Moon's Kappa
	CK (n)	PK (n)	TK (n)		Conc. (n)	Mod. (n)	Slice (n)	Print (n)	
Tamino **(111)**	0.35 (15)	**0.67 (12)**	**0.64 (34)**	**0.67**	**0.65 (20)**	0.51 (12)	**0.66 (10)**	0.58 (14)	**0.79**
Sare **(85)**	0.38 (10)	0.44 (9)	0.57 (20)	**0.60**	0.45 (13)	0.45 (6)	**0.82 (5)**	**0.70 (13)**	**0.79**
Jonathan **(99)**	0.49 (25)	0.52 (15)	**0.72 (35)**	**0.63**	0.54 (19)	**0.62 (13)**	**0.76 (8)**	0.46 (14)	**0.72**
Omar **(131)**	**0.75 (27)**	**0.81 (27)**	**0.70 (46)**	**0.75**	**0.75 (29)**	**0.65 (24)**	**0.84 (14)**	**0.69 (18)**	**0.84**
Jürgen **(110)**	0.51 (18)	**0.68 (18)**	0.54 (29)	**0.71**	**0.60 (17)**	**0.70 (16)**	**0.8 (9)**	0.49 (9)	**0.82**

Robin **(122)**	0.31 (21)	**0.60 (27)**	0.55 (27)	0.51	0.45 (24)	**0.69 (17)**	**0.66 (9)**	0.53 (8)	**0.77**
Emily **(93)**	0.48 (14)	0.53 (10)	**0.65 (23)**	**0.70**	0.57 (19)	**0.77 (12)**	**0.86 (9)**	0.49 (10)	**0.80**

For TPACK, the interview with the highest agreement is Omar, while the one with the lowest is Robin. For 3DMP, it is Omar (highest) and Jonathan (lowest). For 6 out of 7 interviews, CK (mathematical knowledge) was the lowest, indicating that this was the least clear to identify. Looking at 3DMP, no such negative trend is visible, but in 6 out of 7 cases, **Slicing** was the one with the highest agreement. For every student, we also generated activity diagrams (Albarracin et al., 2019), as shown here for the students Omar and Robin:

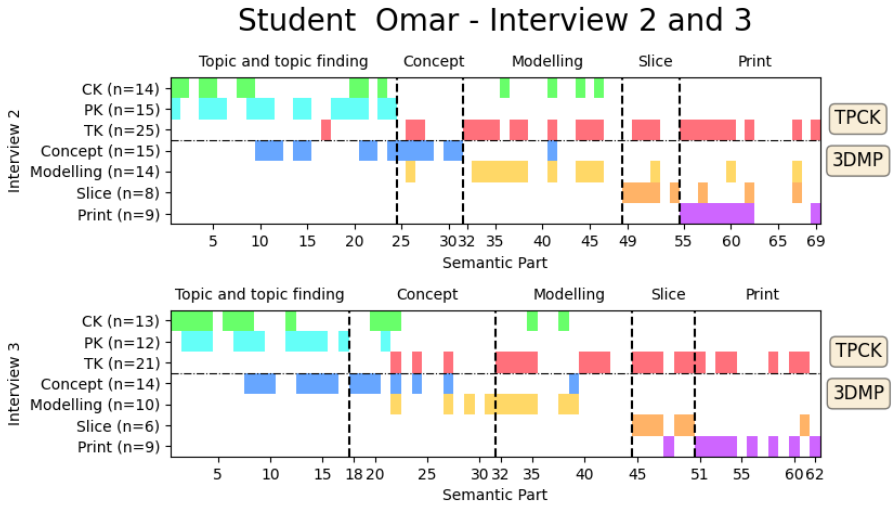

Figure 5: The Activity Diagram of Omar interview 2 and 3, split into TPACK and 3DMP coding. The top sections (vertical splits) divide the interviews into the parts (a)-(e). The x-axis shows the semantic parts (like the one in the interview above, it can span multiple sentences), while the y-axis shows the agreement of both raters for one semantic part. Each row has its own color to help distinguish itself.

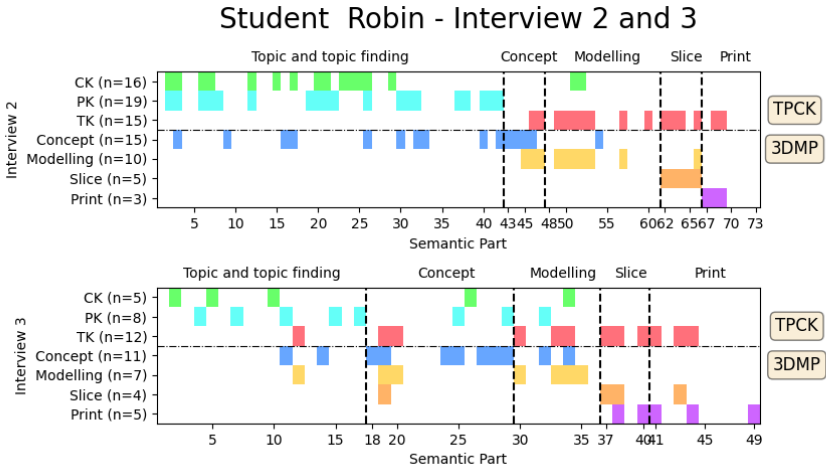

Figure 6: The Activity Diagram of Robin interview 2 and 3, split into TPACK and 3DMP coding.

The diagrams show, that the sections of the interview and the answers of the students are fitting with each other in the sense, that i.e. the student's answers are rated for Modelling inside the Modelling section. Still, the sections are heterogeneous, meaning that the students also mention other phases of 3DMP than the one that's currently the topic of the interview.

In the diagrams (including the 5 not shown in this paper), we can see clear trends that begin to answer the research question:

1) The Concept-phase is not easy to locate in TPACK, since the start of the interview "Topic and topic finding", where the students describe what their manipulative is about, already brings out a lot regarding the concept phase. A small link between CK, PK and TK to the Concept Phase can be seen.
2) The Modelling-phase seems to be linked to CK and TK.
3) Additionally, in all interviews, no semantic part is attributed to Modelling and PK, indicating that the modelling phase may have no pedagogical content.
4) Slicing and Printing are mainly connected to technological knowledge. There is no semantic part that is rated as Printing and CK/PK, while Slicing has a small connection to CK. This is mostly when the students rotate the objects in the slicer or change the size.

Limitations and Discussion

In this paper, we have presented our study on 3D-Modelling and Printing and how we combine our Model describing this process with TPACK to investigate mathematical student teachers' actions through retrospective interviews. Due to the small number of students and the limited space, only basic trends can be surmised, as the detailed investigations of the student's actions are yet to be done.

While the agreement rates, especially with Moon's Kappa, we well and acceptable, the individual categories seem difficult to rate consistently for some students. This can be explained due to the retrospective interviews. The 3DMP model is not yet proven or investigated fully. Still, shows promise in being able to describe the student's actions appropriately for qualitative investigations. This is also since the phases directly relate to the tools and interim results, and the interview was sectioned into (among others) the usage of the tools. The research question is not yet fully answered, as additional interviews should still (and will) be held, and an analysis of additional data taken during the seminar is yet open.

Acknowledgements

The doctoral study "3D-printing in mathematics student teacher education" by Tim Läufer is funded by the Hans and Ria Messer Foundation.

Pedagogical framework for AI literacy integration: Applications for mathematics teaching and learning

Irina Lyublinskaya[1], Xiaoxue Du[2]

[1]Teachers College, Columbia University, United States; il2369@tc.columbia.edu

[2]Media Lab, Massachusetts Institute of Technology, United States

This theoretical paper proposes pedagogical framework for AI literacy integration into curriculum with focus on K-12 mathematics. This framework was developed based on the guidelines provided by the Five Big Ideas in AI initiative, essential components of human-centred design approach to problem-solving, and fundamental principles for creating optimal learning environments in schools and other settings suggested by the Science of Learning and Development (SoLD) framework. Possible applications of the proposed pedagogical framework to teaching mathematics are illustrated through several examples across different grade bands and curriculum topics.

Keywords: Artificial intelligence literacy, Human-centered design, Five big ideas in AI, Instructional strategies, Integration methods, Mathematics education.

Introduction

In the rapidly evolving landscape of education, the Artificial Intelligence (AI) is reshaping the way we teach, learn, and prepare the next generation for the challenges of the 21st century (Dwivedi et al., 2021; Ng et al., 2023). Growing influence of AI in schools require teachers to have essential knowledge and skills to use, design, and adapt AI literacy curriculum (Kreinsen & Schulz, 2023). It is critical to ensure all students have equal access and resources to achieve success in the era of AI (Pedro et al., 2019).

This paper proposes a pedagogical framework for integrating AI literacy into curriculum with focus on K-12 mathematics. In particular, we suggest strategies for integrating AI literacy across different grade bands and mathematics disciplines, and demonstrate the application of the proposed framework for designing an algebra lesson that integrates AI's concepts of representation and reasoning.

Background

Recent advancement in learning technology and learning sciences helped to expand the range of concepts students can explore with different robotic systems and machine learning platforms (Castro-Alonso et al., 2020). Research also shows that Generative AI could serve as peers, partners, mentees, or tutors to improve cognitive and affective learning outcomes (Mogavi et al., 2024). In particular, Mogavi et al. (2024) demonstrated that ChatGPT helped students to improve their reading, writing, grammar, sentence-building, and conversational language skills; tailored learning experiences for individual students; provided home assistance with assignments; and provided accessible learning resources for students with disabilities.

In the past, students learned about AI in school from their computer science teachers. Thus, the majority of early AI resources and curricula were developed for teachers who had prior training and experience in programming. However, as AI-powered experiences and applications become an

increasingly important part of everyday personal and professional life, being AI literate becomes an important component of K-12 digital literacy and digital citizenship (Bender, 2024). As a result, more recent AI literacy curricula have begun to expand beyond computer science to include interdisciplinary approaches and perspectives (Su et al., 2022). These new AI literacy curricula do not only provide students with a comprehensive understanding of AI, but also include discussions of its impact on society, covering a broad range of topics, from the use of AI in civic engagement and scientific inquiry to the exploration of AI applications and their ethical implications. (UNESCO, 2020).

International AI literacy initiatives have underscored the importance of developing teaching capacities in local regions across the globe (Pedro et al., 2019). Research studies across the world emphasize the need to prepare teachers to integrate AI literacy into their classroom settings, as this can help cultivate students' critical awareness of AI's societal impact and promote responsible use of the technology in different scenarios.

Pedagogical framework for integrating AI literacy

The theoretical foundations for the pedagogical framework for AI literacy integration included Five Big Ideas in AI (AAAI & CSTA, n.d.) that define AI core concepts, essential knowledge, and skills, human-centred design approach (IDEO, 2015) that provides a structure for teaching with AI, and Science of Learning and Development (SoLD) framework (https://soldalliance.org/) that supports inclusiveness and accessibility of a curriculum.

The five big ideas in AI were developed by the AI for K-12 initiative to provide United States national guidelines and resources for K-12 AI education. The five ideas are: perception, representation and reasoning, learning, natural interaction, and social impact, all of which are essential for understanding how AI operates and its impact on society (Touretzky et al., 2022). Perception refers to how computers perceive the world by gathering data from various sensors. Representation and reasoning refer to how agents maintain representations of the world and use them for reasoning. Computers construct representations using data structures, and these representations support reasoning algorithms that derive new information from what is already known. Learning (or machine learning) refers to a way for computers to find patterns in data and explains how computers can learn from data and make predictions. Natural interaction refers to communication between humans and machines that feels intuitive, effortless, and similar to how people interact with each other. Societal impact refers to how AI can impact society in both positive and negative ways.

Human-centred design is an iterative problem-solving approach that prioritizes the needs and experiences of the end-user. It involves deeply understanding those users through empathy, involving them throughout the design process, and generating creative solutions tailored to their specific contexts. This is achieved through cycles of research, ideation, prototyping, testing, and refinement (IDEO, 2015).

Finally, the SoLD framework consolidates evidence from the learning sciences and various educational research fields on proven strategies that foster the necessary relationships and learning experiences to enhance students' health, development, and transferable skills (Darling-Hammond et

al., 2020). The SoLD framework outlines five fundamental principles for creating optimal learning environments in schools and other settings: positive developmental relationships; environments filled with safety and belonging; rich learning experiences and knowledge development; development of skills, habits, and mindsets; and integrated support systems.

The development of the pedagogical framework for integration of AI literacy was guided by Jabareen's (2009) multi-phase iterative process. This included identifying and mapping literature sources; initial categorization of sources to identifying core AI concepts; deconstructing and categorizing these concepts; integrating foundational AI concepts with design thinking and learning science; and synthesis of AI core concepts and core literacy indicators into initial framework. The framework was then refined through iterative cycles of expert validation and pilot testing, ensuring alignment with learning science principles and real-world applications. This process resulted in a practical, evidence-based tool that comprises three fundamental components: *design*, *create,* and *reflect.* Design component focuses on positioning school students as designers and encourages student-led initiatives in student-centred, authentic learning experience. Create component emphasizes development of learning experience for students to become active problem-solvers and apply the knowledge to solving real-world problems. Finally, reflect component fosters development of critical awareness of AI with its societal innovation, while encouraging students to cultivate digital citizenship and actively use AI to solve real-world problems. Table 1 shows school student competencies, learning outcomes, and theoretical basis for these three components:

Table 1: Summary of competencies, learning outcomes, and theoretical basis for the pedagogical framework

	Competencies	Learning outcomes	Theoretical basis
Design component	D1. Applying design thinking process	Students demonstrate proficiency in a deliberate design process, including generating and refining ideas, testing theories, and creating innovative artifacts or solutions to authentic problems.	Human-centred design
	D2. Evaluating AI applications	Students critically evaluate and apply AI technologies, including assessing their effectiveness, accuracy, perspective, and credibility in various applications and contexts.	Five big ideas in AI
Create component	C1. Applying AI to solve real-world problems	Students identify problems that can be effectively addressed with AI technologies, such as data analysis, abstract models, and algorithmic thinking, and develop solutions using a contextualized approach.	Human-centred design Five big ideas in AI
	C2. Decomposing complex problems into manageable parts	Students break down complex problems into manageable parts, extract essential information, and	Human-centred design Five big ideas in AI

		develop descriptive models to understand complex systems and facilitate problem-solving.	
Reflect component	R1. Developing ethical awareness in AI	Students think critically about the ethical implications of AI technologies and evaluate their impact on society, including issues such as bias, discrimination, and privacy.	Five big ideas in AI
	R2. Responsible use of AI technologies with real-world application for the community through collaboration	Students use AI technologies in a responsive and intentional manner, including strategies for managing personal data, maintaining digital privacy and security, and sustaining a culture of innovation and change.	SoLD

In our book (Lyublinskaya & Du, 2025) we further unpacked these competencies for different domains of knowledge, e.g., cognitive, psychomotor, and affective, in order to define performance-based objectives for assessment purposes (not shown in this table). For teachers, the design–create–reflect process naturally leads to effective pedagogical practices such as project-based, inquiry-based, and collaborative learning, discussions and debates, etc. engaging students in real-world practices, brainstorming diverse solutions, and being prompted to think outside the box.

Strategies for AI literacy integration into mathematics education

There is a natural connection between mathematics and Big Ideas in AI, which provides us with many opportunities to effectively integrate AI's concepts into mathematics teaching and learning. Mathematics serves as the language through which AI concepts are formulated, analysed, and implemented. Concepts from linear algebra, calculus, probability theory, and statistics form the foundation of AI's algorithms. Vectors and matrices are used to represent AI features and parameters, while operations such as matrix multiplication, differentiation, and integration enable computations that drive machine learning and decision-making processes.

The following examples illustrate connections between AI concepts and school mathematical practices. These examples suggest strategies for integrating AI literacy into mathematics teaching. We conclude the paper with a lesson plan that demonstrates how to apply the proposed pedagogical framework to integrate AI concepts of representation, and reasoning into an algebra unit on the structure of algebraic expressions.

Example 1. Properties of operations: True or false

In this elementary school lesson, students explore properties of operations by creating and identifying true and false statements. They then train and test AI to recognize these properties, reinforcing their own understanding in the process.

The lesson begins with students exploring properties of multiplication through hands-on activities and discussions. They discover how changing the order of factors doesn't affect the product

(commutative property), how grouping factors in different ways leads to the same result (associative property), and how multiplying a number by a sum is equivalent to multiplying by each addend and then adding the products (distributive property). As they learn these concepts, students individually or in pairs develop verbal statements about multiplication, clearly labelling them as true or false. In the activity that follows, these verbal statements become a training dataset for AI to understand and apply the commutative, associative, and distributive properties of multiplication and to make decisions about the truth of mathematical statements. Students can use Machine Learning for Kids platform (https://machinelearningforkids.co.uk) to set up a text classification model with "true" and "false" labels, and use their true and false statements as training examples. They can also use the trained model to create a simple Scratch game where players input statements and AI classifies them.

Example 2. Statistics in digital photography

In this middle school lesson, students analyse a dataset of brightness values from a digital grayscale photograph (Figure 1), calculating measures of centre and variability. They interpret these statistics to understand the image's overall brightness and contrast, mirroring how AI perceives and processes visual data.

a)

49	57	212	189	34
206	54	70	108	192
222	218	55	61	56
63	89	227	206	28
215	57	65	212	209

b)

c)

Figure 1: Digital (a) and numerical (b) representations of a photograph of stairs (c)

Teachers can introduce students to the concept of thresholding in image processing to show how computers can make binary decisions based on continuous data, which is a fundamental concept in many AI algorithms. Students can choose a threshold value based on their analysis and convert their grayscale image to a binary image (black and white only) based on this threshold.

Example 3. Comparing linear, quadratic, and exponential models

In this high school lesson, students use technology to construct, compare, and analyse linear, quadratic, and exponential functions. They will apply their understanding of these functions to discuss the role of AI in model selection, analysis, and its broader societal implications.

Teachers can provide students with three datasets, one for each function type, are related to various societal issues, e.g. income by education level, health risk factors by age, spread of viral content over time, etc. Without telling students which model is the best fit for each dataset, let students use graphing calculators, online tools, or spreadsheet software to plot data and fit models. For each dataset, ask students to compare and evaluate the fit of each model and the predictive power of each model within a specific context. After students share their models and analysis, teachers can introduce

an AI-powered data analysis tool (e.g., Tableau or Gen AI) and demonstrate how AI can automatically select the best fit model. Let students compare AI models with their models. The discussion could be guided by the following questions: How might AI-driven predictions affect decision-making in societal issues? What are the potential benefits and risks of relying on AI predictions? What is the importance of understanding the underlying mathematics when using AI tools? What are potential biases in AI models and their real-world consequences? While the lesson focuses on constructing and comparing linear, quadratic, and exponential models, this mathematical content is framed within the larger context of AI's growing role in data analysis and its societal implications.

Example 4. Multiplying polynomials

This example demonstrates a high school lesson structured as a design-create-reflect process according to the pedagogical framework for AI literacy. This lesson is part of a larger instructional unit on structure of algebraic expressions which is typically taught in first year algebra course. The key learning activities in this lesson integrate both disciplinary and AI literacy instructional goals. This integration is based on the following key insights from the five big ideas in AI framework (AAAI & CSTA, n.d.):

- AI representations are data structures. The two major types of knowledge representations are symbolic and numerical representations.
- Reasoning methods are algorithms. Representations support reasoning; reasoning methods operate on representations.
- "Knowing" something means the ability to both represent it and reason with it.

The larger performance task for the whole instructional unit places students in the role of transportation coordinators for a school district, who need to optimize school bus routes to minimize transportation costs, fuel consumption, and student travel time. Students are also expected to create detailed schemas and knowledge graphs to represent data in the school bus routing problem, explaining the reasoning behind their chosen representations, and justifying the connections between different data elements.

During the design component of the lesson students identify factors that affect transportation (e.g. travel time, distance, fixed cost, etc.). They then explore how these factors can be represented mathematically using polynomials. Working in small groups, students create mind maps to visualize routing systems and apply polynomial multiplication to calculate combined route costs. This process culminates in the development of draft knowledge graphs for their transportation networks. In the next part of the lesson representing the create component students prototype their AI routing system. Using polynomials to represent different school bus routes, student develop algorithms for route classification. To facilitate prototyping, students can utilize tools like MIT App Inventor (https://appinventor.mit.edu/). Students can also use Scratch (https://scratch.mit.edu/), a block-based programming language to create simplified simulations of transportation systems. The product of this step is a visual representation of their transportation system, highlighting the application of polynomial multiplication in their prototype. Finally, they present their AI routing system and knowledge graphs to the class for feedback. The reflect component is the conclusion of the lesson in a form of a whole class discussion to reflect on student learning emphasize these key points:

- How polynomial terms represent different factors in transportation problems
- The role of polynomial multiplication in combining and comparing routes
- How AI uses structures similar to polynomials for data representation and reasoning
- The connection between mathematical operations and AI decision-making processes

Developing mathematical thinking and problem-solving skills are crucial for understanding and developing AI systems. By integrating mathematical practices, educators can help students not only excel in mathematics but also comprehend the fundamental concepts driving AI technologies and their impact on society. This alignment facilitates a deeper understanding of how mathematical principles underpin AI advancements and how AI systems can be ethically and responsibly developed and deployed.

Conclusion

We need AI-literate teachers who can help all students to prepare for the complex world they are entering, and meet the societal demands for problem-solvers who could use AI responsibly, ultimately widening the AI access for everyone. That means educators need to be familiar with AI technologies and be able to integrate AI literacy into classroom teaching. Moreover, we need teachers who can overcome cultural and financial barriers and limited resources to support the implementation process, especially for students with limited financial resources and access. There is still much work to be done for widespread adoption of AI literacy in classrooms across the world. This includes the development and evaluation of teacher professional development materials that prepare educators with essential knowledge and pedagogical practices necessary to adapt and integrate AI literacy into their teaching (Pedro et al., 2019). Teachers need more resources and support to effectively use AI in order to create student-centred learning environments. The availability of resources, curricular materials, and ongoing professional development opportunities are all core factors that contribute to teachers' self-perceived readiness to integrate AI literacy into their curricula (Milliken et al., 2019).

Integrating Computational Literacy into Primary Mathematics Education:
Opportunities for developing mathematical ideas and relationships

Siri Krogh Nordby[1], George Gadanidis[2]

[1]Oslo Metropolitan University, Faculty of Education, Oslo, Norway; sikno@oslomet.no

[2]Western University, Faculty of Education, Ontario, Canada; ggadanid@uwo.ca

In recent years, computer programming has emerged as an important skill in curricula worldwide, including mathematics curricula. In this paper, we explore how computer programming may contribute to mathematical ideas and relationships in primary mathematics classrooms. Using diSessa's principles of computational literacy, we examine 32 classroom activities. The results reveal that only one activity fulfils the principles of computational literacy. By showcasing this activity, we present an example of how computer programming can transform classroom conversations in primary mathematics. However, we argue that more research is needed to identify how (and if) computer programming can be used to develop new ways of learning primary mathematics.

Keywords: computational literacy, computer programming, mathematics, primary school.

Introduction

As far back as the 1970s and 1980s, computer programming was shown to be an effective tool for mathematical education (Feurzeig et al., 1970; Papert, 1980). In his work, Papert (1980) demonstrated how the programming environment, Logo, could be integrated into classroom activities to enhance students' ability to engage with and manipulate mathematical ideas. Today, we see a new and different wave of integrating computer programming into education, based on the assumption that computer programming is necessary to navigate technological environments in our society (Wing, 2006). These new ideas are not rooted in mathematics, but rather seen as fundamental skills and concepts from the field of computer science (Shute et al., 2017). Consequently, the integration of computer programming in education today takes a more general approach that often overlooks the benefits of designing and understanding teaching and learning in specific domains, such as mathematics (Kafai et al., 2020).

At the same time, many jurisdictions have revised curricula, including mathematics curricula, to integrate computer programming across grades (Bocconi et al., 2022). For example, in 2020 and 2021, Ontario, Canada added specific computer programming expectations for grades 1-8 and grade 9 mathematics curricula, respectively (Ontario Ministry of Education, 2020, 2021), with the goal of representing mathematical concepts and relationships dynamically. Another example is Norway, which, in 2020, included computer programming as a central part of mathematics, focusing on variables, algorithms, conditionals, and loops (Directorate of Education, 2020). However, recent research studies show that when primary teachers integrate computer programming into mathematics classroom activities, they struggle to maintain a mathematical focus (Feng & Yang, 2022; Nordby et al., 2022; Nordby et al., 2024).

There is an interest amongst mathematics researchers in how computer programming can be useful and aid in mathematical ideas and relationships. For instance, diSessa (2000, 2018) claims that computer programming can be viewed as a computational literacy because it has infused the field of education (and many other fields of study) changing the structure of "domains of knowledge" (p. 7). diSessa (2018) conceptualizes that new literacies disrupt fields that adopt them through remediation, reformulation, reorganization, and revitalization. In essence, using mathematics education as an example, new literacies change the nature of mathematics education, by disrupting how it is done (taught and learned), who can do it, and when. Noss and Hoyles (1992) note that "there are tasks that children can do with a computer that would be impossible without one" (p. 455). In addition, Borba & Villarreal (2005) suggest that digital media in mathematics education should not be seen simply as tools that serve our purposes, as they may also reorganize our mathematical thinking.

Based in the above-mentioned ideas, more research is needed to highlight the potential for exploring mathematical ideas and relationships when in-service teachers integrate computer programming into their classroom activities. Such understanding will aid in better creating opportunities for using computer programming in learning mathematics. In this context, we are interested in the following research question: *How may the integration of computer programming contribute to the development of mathematical ideas and relationships in primary school classrooms?*

Computational literacy

We recognize that there are different conceptions of computational literacies (Guzdial, 2019; Kafai, Proctor & Lui, 2019). We chose to use diSessa's (2000, 2018) idea of computational literacy as a conceptual framework as it provides 4 explicit categories for identifying the disruptive potentials of computer programming in classroom teaching and learning: remediation, reformulation, reorganization, and revitalization. We illustrate this through a grades 3-4 mathematics and computer programming example (Gadanidis et al, 2024).

Remediation

Computer programming remediates ideas through its ability to dynamically represent concepts and relationships through a new medium. For example, consider the following puzzle:

1. *In the Scratch code (Figure 1a) a bug walks a square path. Run the code at https://scratch.mit.edu/projects/1055180217/editor/*
2. *How does the code work?*
3. *How might we alter the code so that the bug walks a spiral like the one shown in Figure 1a?*

Scratch allows us to remediate this puzzle from a paper-and-pencil activity to a dynamical modelling of a bug "walking" on the computer screen.

Reformulation

In the process of solving this puzzle, students learn about shapes and angles, and encounter a new idea: a variable. A variable is needed so that we can repeat the process walking and turning while changing how far we walk in each stage. The variable "steps" is shown in Figure 1b. This code is available at https://scratch.mit.edu/projects/1055189920/editor.

A traditional approach for engaging grades 3-4 students with a variable may be by solving equations of the form X + 5 = 12 and 2X – 3 = 9. The problem with such approaches is that X in these cases does not vary. X is an unknown constant. X = 5 in the first case and X = 6 in the second case. By dynamically walking a square and then a spiral, Scratch reformulates the mathematics experience so that students may encounter the real meaning of a variable in the spiral walk of a bug. In their work, Kilhamn et al. (2022) show how the variable in the computer program makes it possible to highlight the role of variables as generalized numbers. Hence, reformulation is possible using Scratch as a computer program, due to what diSessa (2018, p.26) calls "cognitive simplicity" that is offered through dynamic modelling of variable.

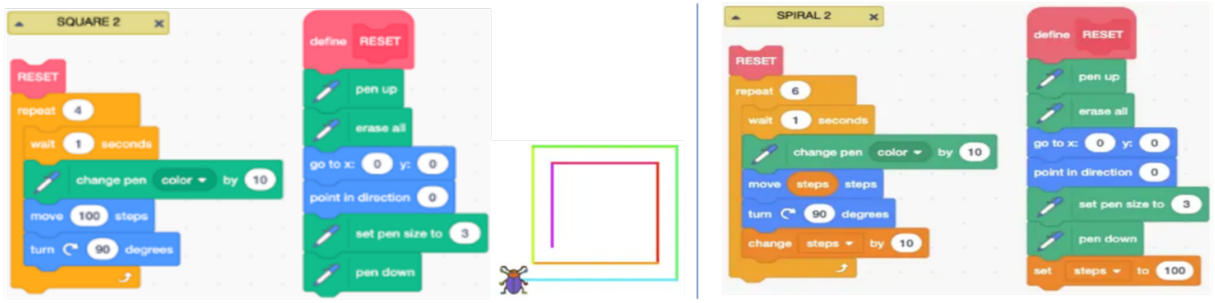

Figure 1: Scratch codes: A bug walks a square path (1a, left) and introducing a variable (1b, right)

Reorganization

diSessa (2018) suggests that computer programming causes a reorganization of the conceptual framework of a field of study, changing what we can do and who can do it (diSessa, 2018). The remediation and reformulation we discussed above reorganizes what mathematics may be done, who can do it and when.

Revitalization

When a field of study makes pervasive use of computer programming, it leads to a revitalization of the field, and how and what teachers teach and how and what students learn (diSessa, 2018). For example, in solving the puzzles in Figure 1a and 1b, students recognize that for the bug to walk a spiral, it needs to take an increasing number of steps. That is, the number of steps need to *vary*. As students in grades 3-4 typically do not know how to define and use a variable in Scratch, the teacher offers them the link to the Scratch code in Figure 1b and poses this new puzzle: *Edit the code to create each of the spirals shown in Figure 2a, 2b and 2c.* This helps mathematics come to life in new ways, offering students access to playful engagement with dynamic representations of the nature and function of variables in a meaningful context.

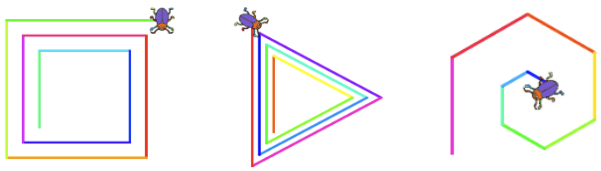

Figure 2a (left), 2b (middle) and 2c (right): Using Scratch to model different spirals.

Methods

The study context is derived from activities conducted in primary mathematics classrooms (grades 1 – 5) in Norway. This study focuses on classroom activities designed by four different primary school teachers from three different schools over a period of one and a half years. In total, this paper draws on data from 27 classroom observations where the teachers integrate computer programming into their primary mathematics teaching practices. Data were collected through video-recorded classroom observations, with audio being recorded via a wireless microphone attached to the teacher.

In our analytical approach, we were interested in identifying how the activities contributed to the development of mathematical ideas and relationships. Drawing on diSessa's (2018) ideas of computational literacy, we used a deductive approach when analysing the data material. First, all the transcribed video-data were analysed using a table in Word capturing all the activities conducted (we view an activity as a range of tasks derived from engagement with similar mathematical concepts). This initial analysis resulted in 32 identified classroom activities (some lessons included more than one activity). Second, we identified the activities where computer programming was used to engage in mathematical ideas and relationships. For instance, if the computer program Scratch was used to engage in mathematical content, the activity was included for further analysis. On the other hand, if the activity was based on students working in programs such as LightBot[1], with no mathematical focus, the activity was removed from further analysis. This step resulted in reducing the activities from 32 to five. In the third and final step, we used the 4 disruptive potentials of computer programming identified by diSessa (2018) to categorize the activities. For instance, we looked for examples of remediation within the activity to determine whether it dynamically represented mathematical concepts and relationships. We also looked for reformulation to ascertain if the activity offered opportunities for students to encounter mathematical ideas in new ways. Ultimately, only one activity fulfilled these criteria. We will present this activity in the result section.

Results

By focusing on how computer programming may contribute to develop mathematical ideas and relationships in primary school classrooms, we will in this section first present three different tasks happening in the classroom activity before we discuss these tasks in terms of the disruptive potentials of computer programming (diSessa, 2018). Moreover, we will also discuss opportunities for potential improvements of the activity.

Task 1

The teacher begins the lesson by introducing the activity as an "exploration of geometrical figures and patterns" (teacher grade 5). Scratch is used as the programming environment, an environment where students can drag and drop different blocks to solve different problems[2]. After a brief introduction to how Scratch works, the teacher asks the students to create a rectangle. In the whole class conversation, the students and the teacher agree that they can use the block called "repeat": "if

[1] https://lightbot.com/
[2] https://scratch.mit.edu/

you want to make a rectangle, you can take one [side] and one [side] and twice – repeat" (student grade 5). The result of their conversation is shown in Figure 3.

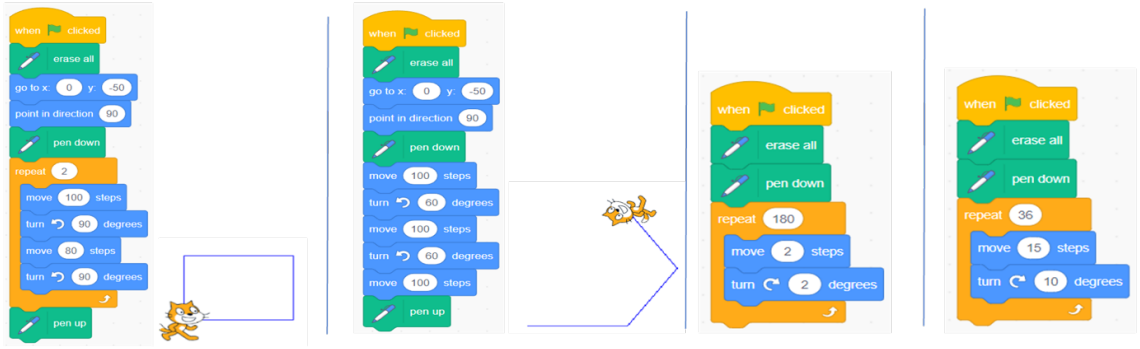

Figure 3 (from left to right): 3a - Code shown on the whiteboard, 3b - Code resulting in the problem, 3c - Code of student 1, 3d - Code of student 2

Task 2

After the whole class conversation about rectangles, the teacher introduces another task, asking the students to create a triangle. When the students start working on creating triangles, a problem arises about what angle to insert in the turning block (see Figure 3b).

Teacher:	what is the problem?
Student:	how many degrees should it turn?
Teacher:	ok, if we have a regular triangle, what are each angle if they are 180 in total [the teacher draws the triangle on the whiteboard]
Student:	60.
Teacher:	yes, but when you are here in the figure in Scratch [points at the right corner of the triangle], you need the opposite of 60 degrees.
Student:	minus 60?
Teacher:	[draws the external angle with dots] How many degrees are here [pointing at the angle with dots].
Student:	120
Teacher:	yes

Task 3

In the third and last task in this lesson, the teacher asks the students to use Scratch to model a circle. While the students are working on the task, the teacher finds that the students are using different sets of numbers in the step and turning block: "you are using different numbers" (teacher grade 5) and asks the students to show their work in front of the class (the students connect their tablet to the whiteboard). The upcoming extract show the whole class conversation:

Student 1:	I took, walk two steps, and turn two degrees and repeat 180 times [see Figure 3c].
Teacher:	great, why 180 and not 170?
Student 1:	because two times 180 is 360.
Teacher:	yes, now we are using mathematics, do you see that? Is there any other way we can create a circle?
Student 2:	[showing his/her work, see Figure 3d]
Teacher:	but 36, repeat 36 times and 10 degrees and move 15 steps? Is that right?
Student 2:	yes, 36 times 10.
Teacher:	yes, because 36 times 10 is 360.

Meaningful moments for developing mathematical ideas and relationships

According to diSessa (2018), computer programming can provide new ways of engaging in mathematical learning. In all the tasks in the activity above, we can identify *remediation*, because Scratch is used to represent mathematical ideas through a new medium (code). For example, in Task 1, students explore the relationship between the side lengths of a rectangle by interacting with codes that dynamically depict a model of the rectangle on the computer screen. We also identify *reformulation,* due to dynamically representing concepts and relationships of angles and how to create different geometrical shapes. This allows for the discovery and discussion of mathematics in new ways that were not previously possible.

Remediation and reformulation combine to *reorganize* the concepts of angles and polygons into a playful investigation with immediate feedback, *reorganizing* mathematics concepts and relationships. This reorganization makes the playful exploration of polygons and their properties more easily accessible than with paper and pencil for younger students. For example, by looking at the conversation in Task 2, we can identify that the students are visually meeting a challenge, when the drawing appears not to be a triangle. The immediate feedback on the students work, *reorganizes* the mathematics, by visually promoting for a discussion of internal and external angles in a triangle in a dynamic representation, in contrast to what can be done with static paper and pencil representations. Thanks to the flexibility of changing the blocks and numbers in the code, students are able to engage with the mathematics from their own starting point by testing and visually seeing the result. An analogy may be the difference between learning about how a bicycle worked by reading a book versus riding a bicycle. The above changes create novel experiences that are mathematically meaningful and deep, *revitalizing* what mathematics is, what it means to do mathematics, and who can do it and when.

Task 2 may be further enhanced by using repeat to automate the repetitive process of drawing polygon sides, as is the case in Task 3. Task 2 may be altered to draw a square rather than a rectangle with different side lengths. This would allow an easier extension to other regular polygons, by altering the repeat number and the angle size. For example, repeat 3 with a turn angle of 120 degrees would result in an equilateral triangle. This automation through code of drawing regular polygons by repeating a number of steps followed by a turn angle helps reduce cognitive load and offers what diSessa (2018) calls *cognitive simplicity.* Additionally, ability to add a wait 1 second code block allows students time to observe the changes as the polygon is drawn.

An extension of this activity could be to include other tasks, such as creating pentagons and hexagons. In that way, by first introducing the square and the repeat, the students can play and test how they can use this starting point to discover other geometrical shapes. In Task 3, the students extend the automation for drawing regular polygons to draw a polygon with many more sides: 180 sides in Figure 3c and 12 sides in Figure 3d. This can help students realize that as we increase the number of sides by reducing the turn angle, we get closer and closer to approximating a circle. In essence, students are taking initial playful steps for investigating ideas of infinity and limit, which are foundational concepts of calculus. That is, as we decrease the turn angle, as the turn angle gets closer to zero, the polygon's "limit" is a circle. However, one constraint with this idea is that the Scratch environment does not allow reducing the step size less than 1 (as the step of 1 = 1 pixel and you

cannot draw ½ a pixel). Nevertheless, introducing the idea will contribute to a conversation about important concepts and relationships in primary mathematics.

Discussion and concluding remarks.

Computational literacy represents a powerful way of seeing the potential of computer programming in primary mathematics education. Findings from this study show that the computer program Scratch, can contribute to the development of mathematical ideas and relationships in primary school classrooms. Using diSessa's (2018) computational literacy principles allows us to discuss and discover how computer programming can be used to identify new ways of engaging with and discussing mathematics. Our findings, in line with Noss and Hoyles (1992), demonstrate that the computer program offers mathematical activities in the classroom that would be difficult to conduct without it. Particularly, how Tasks 1-3 provide students with immediate feedback on their work, leading to discussions about mathematical ideas and relationships of geometric shapes.

However, there are some issues to consider. Our analysis reveals that only one out of 35 activities in our study was considered powerful enough for computer programming to remediate, reformulate, revitalize, and reorganize content in primary mathematics. This finding aligns with both Feng & Yang (2022) and Nordby et al. (2024) who state that teachers struggle to maintain a mathematical focus when computer programming is integrated into classroom activities. Therefore, at its current state, we can argue that computer programming has not contributed to develop new ways of teaching primary mathematics in general. This study contributes to showing how computer programming may develop mathematical ideas and relationship, and that more attention is needed in primary mathematics research to discover ways in which computer programming can support mathematical activities. Developing such knowledge may lead to substantial and powerful changes in how we perceive the teaching and learning of primary mathematics.

Teachers' challenges integrating technology into teaching problems they have posed: Through the lens of instrumental approaches

Tikva Ovadiya

Oranim College, Tivon, Israel; tikva_o@oranim.ac.il

An area of interest for educators today is how technology can support teachers' problem-posing for their teaching needs in mathematics. Teachers often face significant challenges when attempting to incorporate technologies such as applets, and software effectively, in particular for pedagogical practices. By examining these challenges using the theory of "instrumental approaches," that is, the interactions between the user (teacher or student) and technology, we can better understand the complexities involved, which is crucial for addressing specific challenges and improving technology's integration into education. This article highlights three significant challenges identified in a project where teachers used a digital tool to pose problems for teaching purposes.

Keywords: Problem posing, digital literacy, instrumental approach, instrumental orchestration, orchestration types

Introduction

In the last two decades, there is increasing focus on the knowledge teachers develop regarding digital tools (DT) and how DTs can elevate the teacher's role by replacing traditional methods and also to explore concepts, improve techno-mathematical literacy, cultivate knowledge (Jacinto & Carreira, 2023), and promote teachers' problem-posing (PP) processes for teaching needs (Ovadiya, 2023). Cognitive mathematical technology, including digital mediums, motivates learning in diverse ways, sparks curiosity, and opens up new areas for education such as delving into mathematical concepts and operations that were previously beyond reach without technology (e.g., Smith et al., 2017).

Understanding Instrumental Approaches. The concept of "instrumental approaches" assumes that technological tools are useless without specific schemes or cognitive tools to operate them effectively. When that happens, "instrumental genesis" occurs, meaning that the user has adapted their thinking and the tool's function to suit their goals. In education, this involves using technology for effective learning, particularly for complex tasks such as mathematical PP to achieve specific pedagogic goals, which necessitates a profound grasp of the goals of the mathematical task and the skills to adapt the mathematical content to achieve the didactic and pedagogical objectives. Further research in this area is necessary; there is limited research on how teachers pose mathematical problems using DT for specific teaching purposes. This study focuses on understanding the challenges teachers encounter in this area and tries to interpret the teaching process (of the posed problems) through the lens of instrumental approaches by observing the teaching process using the "instrumental orchestration" types specified by Tabach (2013), who consolidated the terms from several studies.

Theoretical background

How Teachers Pose Problems

Research into how teachers pose mathematical problems has explored various aspects, including professional development (PD) workshops to enhance PP practices (e.g., Ovadiya, 2021, 2023).

Studies reveal that teachers struggle to design problems that engage substantive or logical-mathematical ideas rather than just the "calculate" or "find" types (Kozakli Ulger et al., 2022). There are positive indications from studies by Ovadiya (2019, 2021, 2023) that teachers are open to learning how to innovate PP and PD programs that include teacher discussions have led to improved PP skills for specific pedagogical goals, such as understanding graph properties (Ovadiya, 2021) or applying inquiry-based approaches in geometry (Ovadiya, 2023). However, the existing literature often overlooks the practical steps required for effective PP for teaching. This method described herein tries to bridge this gap by describing how teacher educators can leverage PP training to enhance teachers' abilities to pose problems that meet instructional needs.

Teachers' use of DTs in problem posing

Integrating DTs into PP adds complexity to an already challenging task. Since the mid-1990s, research has shifted from focusing on learners to exploring how digital technologies impact teachers (Sinclair et al., 2023). The consensus is that teachers often find problem-posing more challenging than problem-solving, particularly when creating complex problems requiring high-level thinking (Yao et al., 2021). Ovadiya (2019, 2021, 2023) suggests that designing problems with specific pedagogical goals can enhance teachers' techno-mathematical literacy and pedagogical knowledge. Also, when teachers experimented with integrating technology into PP, they discovered – as a result of the technology – properties of concepts, mathematical operations, or geometric theorems that they had not been formerly aware of. In other words, the tools led the teachers to deepen their mathematical knowledge. Indeed, tools such as Desmos, GeoGebra, Phet, Traker (and so on) facilitate the exploration and understanding of mathematical concepts, operations, and phenomena. However, teachers must develop their techno-mathematical skills to use such tools effectively (Ovadiya, 2023).

Problem posing during professional development for teaching it in the classroom

Most studies dealing with how mathematics teachers pose problems, even recent ones, focus on teachers in PD programs or academic courses and not on actual classroom situations. However, successful PP during a training program does not guarantee that the teacher can pose appropriate problems to foster classroom learning. There are many reasons for this, but the main one is the ability (or not) to define the mathematical pedagogical relevance, which differs between the two. In the current study, there was an effort to address this gap as well. Therefore, as part of the course syllabus, the teachers were to design and pose problems that used DT and would abide by the curriculum.

A theoretical framework to understanding the findings: Instrumental approaches

The instrumental approach is based on the idea that the use of instruments by learners (whether physical, mathematical, or technological) does not only involve performing specific actions but also involves integrating these tools into the cognitive structure of the learner. Through this process, the learner appropriates the tool and it is transformed into an instrument that the learner adapts to serve their own purposes and contribute to their mathematical thinking (Revillon & Rabardel, 2004). The instrumental approach focuses on how tools evolve into cognitive learning instruments through user interaction. This concept is also called “instrumental genesis.” This process involves a “dynamic interaction between the learner and the tool, which goes beyond the simple use of the tool and leads to the tool becoming integrated into the cognitive structure of the learner, aiding in the construction

of mathematical knowledge" (Vergnaud, 1994, p. 150). Artigue (2002) emphasized the concept of instrumental genesis, which describes how a tool becomes an instrument for thinking and learning mathematics. She distinguished between "instrumentalization," that is how learners adapt the tool to their needs by modifying and shaping it, and "instrumentation," which is how the tool influences learners' thinking and shapes their mathematical activity. This dual process highlights the dynamic interaction between the user and the tool and reshapes views on how technological and other mediating artifacts may be integrated into mathematical practices.

As part of developing research about teaching and learning using DTs, additional concepts have been developed. For example, "instrumental orchestration" is a term introduced and defined by Trouche (2004) in the context of mathematics education. Trouche's work (2004) emphasizes that the teacher actively mediates the learning process to ensure that the DT is not merely used passively but becomes an instrument that enhances mathematical thinking and engagement. The key elements of instrumental orchestration are didactical configuration (arranging tools, tasks, and the environment for learning activities), exploitation modes (strategies to guide tool use, such as demonstrations, group work, or individual tasks), and orchestration types (context-dependent approaches, including whole-class, small-group, or individual activities). In the years since Trouche, a number of orchestration types have been defined, for example, as presented by Tabach (2013). Recent studies, for example, Artigue et al. (2020), emphasize the need for teachers to adapt their orchestration strategies to integrate DT effectively by developing appropriate skills in classroom management.

Method

Research question: Can the theory of instrumental approach help identify, understand, and interpret the challenges teachers face when using DTs to teach mathematical problems they pose to meet their teaching needs? **Participants**. Twenty in-service high school mathematics teachers participating in a professional development at a teachers' college. They taught grades 7–12, either in Arabic or in Hebrew. Their seniority ranged from 3 to 21 years. All had experience teaching with technological tools, some for 8 to 12 years and some for two.

Procedure. Teachers independently posed mathematics problems using DTs, taught them to their college peers, revised the problem if necessary to better meet their teaching goal, and then taught the problem to their students in school. They then selected an event from the lesson to discuss in the course and then adjusted the problem as necessary. Every stage was fully documented in their journals. Each teacher underwent this procedure six times (total, 120 math problems)**. Data sources.** The teachers' journals, video documentation of their teaching, video and audio recordings of the college lessons and mentoring meetings, and the author's journal. **Data analysis.** Documents underwent inductive analysis driven by the research question: (1) analysis of teachers' journals to identify challenges they recognized and reported; (2) similar analysis of researcher's journal; (3) identification of specific technological challenges; (4) categorization of technological challenges (these include didactical configurations such as understanding the role of the tool(s) as active mediators of learning, using technology to create new ways to think about mathematics and new opportunities for exploration and interaction, or exploitation modes that encourage students to interact with group work or individual problem-solving; (5) associating examples for each challenge; (6)

analysing the challenging events by "orchestration types" and identifying the teacher's instrumental orchestration actions (Technical-demo, Sherpa-at-work, Discuss-the-screen, Work-and-walk-by, Spot-and-show, Not-use-tech, Explain the screen, Link-screen-board. For explanation see table in Tabach, 2013); (6) determining and choosing challenges that reflect the dynamics between the teacher, the acts of teaching, students learning, the math problem, and the DT.

Findings and discussion

The assumption is that a teacher who identifies a challenge in teaching will try to manage it through specific teaching actions. In the present article, the author addresses the challenges teachers identified when teaching the problem they posed using DTs and identifies their orchestration actions to manage that challenge. Below are three examples and their interpretation using instrumental approach theories

Challenge 1. Teaching how to illustrate a mathematical phenomenon graphically

The posing process: Challenges. The teacher posed a problem about local and absolute extrema while finding the shortest distance between the graph of a quadratic function and a specific point. She wrote: "While solving the problem, I encountered a mathematical conflict: differential calculus indicated a specific maximum point, but the graph showed more distant points. This raised the question of how to mathematically explain to students that an internal maximum point is not necessarily an absolute maximum, especially in an open domain, and how DT can mediate it."

The problem. Find the shortest distance between the graph of function $F(x) = \frac{1}{4}x^2$ and point (0,3) (Use digital drawing tools for investigation).

The teaching process: Orchestration types. The teacher opened the lesson by presenting the problem on the general board of the class (Technical-demo). She allowed the students to solve the problem independently in any way they saw fit and emphasized that they were welcome to check on their computers or the application on their cell phones. A discussion about the distance function developed, and a student went to the board to write the solution (Sherpa-at-work). Another student suggested looking at the graph on the board (Discuss-the-screen), noting that the maximum point can be identified without investigation using a derivative, meaning, according to him, that the point on the original graph indicates a maximum distance. Another student suggested both referring to the algorithm for comparing the derivative to zero and drawing the graph of the derivative function, which he did on his cell phone (Work-and-walk-by) to learn about the types of extrema. Another student suggested drawing a graph of the distance function and investigating it (Work-and-walk-by). The teacher encouraged all suggestions and used the ideas to promote discussion (Spot-and-show). A conflict arose over the graph in the applet (distances greater than the maximum distance were found). A student suggested drawing it in another widget; perhaps there would be details about the graph that Desmos and GeoGebra did not reflect. He did this in OneNote and claimed that the maximum point was local (Sherpa-at-work). The teacher and students together investigated the graphs of all the functions suggested for drawing and concluded that the point they found was a local maximum (Discuss-the-screen). (An example is at https://www.geogebra.org/m/e5enuzv4)

The gap. Examining the function's graph in the applet and identifying the maximum distance based on the algorithmic solution raised the question: "… the graph displays greater distances." The students

explored this conflict by plotting distances greater than (d = 3) in the applet, discussed how that was possible, and realized that the algorithmic solution revealed a local maximum, not an absolute one. As their discussion deepened, they concluded that distances larger than that indicated meant that the maximum they had found was local. To confirm this, the students decided to graph the distance function with GeoGebra. They identified two local minima and observed infinitely large distances that they believed represented the maximum. This changed their understanding of "local extrema."

Explanation using instrumental genesis theory. In this lesson, the teacher helped students grasp the concepts of local and absolute maxima by highlighting a conflict between the graph in the application (Discuss-the-screen) and the algebraic solution (Not-use-tech). The lesson included various orchestration activities that facilitated transitions from general discussions to independent or paired explorations. The teacher's approach to leading the lesson to identify the mathematical phenomenon by incorporating drawing and engaging dynamic actions within it led to interaction between the learner and the tool and to the tool becoming integrated into the cognitive structure of the learners, aiding in the construction of mathematical knowledge about "local extrema" as did the diverse orchestration activities and her flexibility in listening to and evaluating each student's ideas, whether expressed verbally or digitally.

Challenge 2. Managing discussions on digital problems to illustrate the parameter phenomenon

The posing process: Challenges. The aim was to pose a problem that incorporates a parameter and then discuss with the students the concept of the graph as a general representation.

The problem. Use a wire of length "*a*" to construct a picture frame with three sides of a rectangle and a semicircle whose diameter is the fourth side of the rectangle. What should the circle's diameter be to obtain the maximum area within the frame? Log in to https://www.geogebra.org/m/djgdvtxn.

The teaching process: Orchestration types. The teacher read the problem aloud (Not-use-tech) and invited the students to work in pairs to send a sketch of the solutions via WhatsApp (Work-and-walk-by). The teacher provided an explanation on the board about GeoGebra, focusing on the data it presents (Technical-demo), and then facilitated a class discussion to find a "target function" while observing the graph (Explain-the-screen). The teacher encouraged questions about the solution without using algorithmic investigation tools (Not-use-tech). Students interacted with the app and asserted that essential features of the graph had changed but were not sure what had happened (Work-and-walk-by). Some students overlooked essential traces in the graph (Discuss-the-screen). The students arrived at a final answer but did not understand the role of the parameter (Not-use-tech). The teacher attempted to revisit the graph to explain the parameter, but the students deemed it unnecessary since they believed the parameter did not represent a central feature (Explain-the-screen, Discuss-the-screen). Students suggested graphing the "target function" graph, and one of them came to the board to do it (Sherpa-at-work).

The gap. After reflecting on the discussion, the teacher felt disappointed that the students concentrated on extracting information from the graph related to size rather than features. One student had suggested drawing the "target function," which was not part of the teacher's original plan. However, this suggestion led to a valuable discussion about the meaning of the parameters in the target function, the graph representing it, and the comparison between the two graphs.

Explanation using instrumental orchestration theory. Here, we can see the reasons for the breakdown in effective orchestration. i) The teacher may not have developed the necessary orchestration schemes to facilitate a class discussion around a general parameter using the DT. Orchestration schemes are ways of structuring tasks to use the tool most effectively and guide the class discussion. If the teacher cannot handle the complexity of general discussions around the parameter, they may be forced to revert to specific cases, which are easier to manage and explain. ii) The teacher's technical fluency with the tool (e.g., handling symbolic or parametric inputs) might not have met the technical-pedagogical goal of discussing the general problem. This mismatch led to simplifying the problem by focusing on specific cases. Nonetheless, the teacher's flexibility in discussing a student's suggestion to draw a different graph led them to a meaningful discussion of the concept of parameter. (See the student's graph: https://www.geogebra.org/classic/agbk5km8).

Challenge 3: Teaching students to create dynamic objects (as "traces") to extend the understanding of mathematical phenomena

The posing process: Challenges. "We never talked in class about the object of the graph of the "target function" in an extrema problem. I expect this to be the most interesting part of the problem by showing the students that when you drag point C, you get the graph of the target function, in this case the graph of the area. … After building the app and talking to my fellow teachers, I realized it was important to teach the students to build the object's 'traces,' as this sharpens understanding of the relationship between the infinite possible triangles and the parabola function. That is, the parabola is a geometric place for all the triangles that meet the conditions of the problem. But how do I teach this without giving explicit instructions on what to do?"

The problem. There is an L-shaped building behind Sammy's school. Sammy wants to build a garden in the shape of a right-angled triangle. Two sides of the triangle will be adjacent to the building. Sammy has a 6-m length of fencing for the hypotenuse of the triangle**.** Log in to https://www.geogebra.org/m/xmnxxhn6 and answer the following question**:** What are the maximum and minimum areas of the garden that Sammy can build? In GeoGebra, we will construct point D together, which describes the target function of the problem. (See https://www.geogebra.org/m/hsm4w92g to see the results after building the trace).

The teaching process: Orchestration types. The teacher presented a problem on the board (Technical-demo) which the students followed on their cellphone app (Link-screen-board). The teacher explained how to understand the graph. The students tried this on their cell phones and those who solved the problem shared their solutions with and without technology (Discuss-the-screen, Not-use-tech). The teacher responded to students who identified an error between the algorithmic solution and the solution they identified, inquiring about the app (Work-and-walk-by). One student led a discussion (Not-with-tech) about target functions and an algorithmic solution to the problem. The teacher told the students to add components and operations to the app to construct traces for the problem to describe a geometric locus of the solution set (Technical-demo). Investigating the app included the traces and an attempt to understand the traces by describing mathematical phenomena. Both independently and by observing what was written on the board, the students understood that the parabola created (through the traces) is a geometric locus that represents the collection of solutions

(Work-and-walk-by, Discuss-the-screen). A discussion and summary around the question “Do we have to understand and draw the locus to solve the problem?” took place that combined the non-technological solutions (Not-use-tech) and ideas from the trace graph (Discuss-the-screen).

The gap. The student's understanding of the problem and solution without the DT preceded their understanding of the graph with the DT. To them, building a target function to describe the infinite areas of the triangles as a parabola using the DT did not resemble the algorithmic solution. The insights from an algorithmic solution differed from those they obtained when required to build an app describing the problem and the solution.

Explanation using instrumental orchestration theories. Building traces in software requires mathematical insight behind the technical operation to understand that they are components in the graph of the solutions of the objective function. The visual graph that emerges dynamically while changing the sizes of the triangles explains the collection of solutions and their relationship. The teacher's orchestration actions led the students, time and time again, to move from an algorithmic to a dynamic solution. This explains the teacher's challenge, which was to teach how to build a digital object that the students do not seem to need because they have settled for the procedural solution. Understanding the digital solution led to the tool becoming integrated into the cognitive structure of the learners, aiding in the construction of mathematical knowledge about how a parabola created (through the traces) is a geometric locus, and this process is reflected as an instrumental genesis.

Summary

The instrumental approach helps the researcher identify and interpret the challenges. The three examples above demonstrate the challenges a teacher may have when teaching a concept or phenomenon by solving a mathematical problem when a gap occurs between how students understand the problem and its solution without technology and understanding using a dynamic tool. To bridge the gap, the orchestration actions moved from a state working without technology to one where they understood the dynamic solution and compared the two solutions simultaneously. The orchestration continued until the dynamic solution of the problem explained the algorithmic solution of the problem and vice versa. In the current study, the researcher implemented orchestration actions defined by other researchers (Tabach, 2013) to clarify the teacher's challenge. It often stemmed from the gap in students' understanding of the concepts and actions required to digitally solve the problems posed by the teacher. Not all orchestration types were suitable for the lesson's analysis. The next step for the researcher is to focus on more precise definitions of orchestration types specific to problem-solving instruction that teachers have posed, especially in challenging situations.

Teaching computational thinking in a collaborative context: A case study

Gláucia Pinto Rama, João Pedro da Ponte and Marisa Quaresma

Universidade de Lisboa, Instituto de Educação, Lisboa, Portugal; glauciarama@edu.ulisboa.pt

This paper aims to address the knowledge of the teaching practice regarding computational thinking (CT) of Lara, a grade 8 mathematics teacher, through her participation in a lesson study. Scratch supports this study as a working tool to promote CT practices. The research is a qualitative and interpretive case study with participant observation design. The participants are four mathematics teachers and the first author, as a facilitator. The results show that the collaboration carried out in this lesson study led to the mobilization of the teacher's CT knowledge regarding planning and leading the research lesson. Her actions and those of the students contributed to effective learning.

Keywords: Computational thinking, Scratch, teaching practice, collaboration, lesson study.

Introduction

Bocconi et al. (2022) published a study in which, among 29 European countries, 18 EU member states and 7 other countries, introduced basic computer science concepts into their mathematics curricula in primary and secondary education. With great emphasis on the development of Computational Thinking (CT) knowledge, the authors suggest Scratch as one of the main ways for students and teachers in this context to explore and develop themselves in this regard. Bocconi et al. (2022) also show great concern in preparing teachers to integrate CT development into their educational practices, pointing out this challenge to ministries and teacher education institutions. Considering the questions raised by Bocconi et al. (2022), it is necessary to take into account the various aspects of mathematics teachers' professional knowledge. When teachers exercise their teaching practice, it is especially relevant to consider their didactic knowledge (Ponte and Oliveira 2002), which a form of knowledge in action (Schön, 1983).

In this study, we use Scratch to promote the development of CT and its integration into mathematics teaching. As a teacher education process that seeks to meet this demand, a lesson study was conducted. The participants were four experienced mathematics teachers, from the grade 8, who sought to include CT teaching in their practice. We consider in particular Lara's participation, as she evidenced her knowledge in action, manifested by her actions and decisions when planning and conducting an exploratory lesson. This communication aims to answer two questions: 1. How was Lara's didactic knowledge mobilized in teaching CT to plan a task in an exploratory lesson and leading that lesson? 2. How did the collaboration between the participants during the lesson study favor Lara in mobilizing the development of CT in her class?

Theoretical framework

Ponte and Oliveira (2002) designate professional knowledge that directly intervenes in teaching practice as didactic knowledge. Knowledge of teaching practice can be evidenced by the manifestation of knowledge in action by teachers, when considering their actions and decisions in the exercise of their profession (Schön, 1983). Knowledge of teaching practice allows teachers to have

confidence in making choices in accordance with their professional identity, establishing their preferences and priorities (Ponte & Oliveira, 2002). Collaborative work may interfere with teachers' choices in planning, designing and conducting tasks (Ponte, 2012). In this sense, Ponte (2012) states that acting collaboratively implies "assuming common goals, in a context of personal trust, in which everyone has something to teach and something to learn, as a pragmatic perspective, as a solution found by a group to solve common problems, which would be difficult to solve individually" (p. 10).

The materials that can be used to design tasks are relevant factors that also influence the choices of teachers when expressing their knowledge in action. Among them, there are a variety of technological resources that support mathematical teaching. Cobb et al. (2017) emphasize that the type of technology is less important than the functionality it provides and, therefore, teachers need to have a deep understanding of how technology and tools can be used to investigate mathematical ideas, generate multiple representations of a mathematical construction, and solve mathematical problems. Only then can these materials used in teaching be integrated into the curriculum in a meaningful way. Teachers need to know criteria for selecting textbooks and teaching materials that include the regular use of tools and technologies, in addition to improving the skills to use them effectively in the classroom to support students in mathematical learning.

Wing (2006) presents CT as a skill with great potential to be explored in mathematics teaching due to its close relationship with mathematical problem-solving. This skill involves five fundamental practices: abstraction, decomposition, pattern recognition, algorithmizing, and debugging (Wing, 2006). For their part, Moreno-León et al. (2017) mention that Scratch allows working on CT practices through its commands, serving as a bridge for the development of this ability. Developing knowledge of CT practices, specifically when using Scratch, has become a relevant topic in mathematics teacher education processes. In this sense, it is important to expand knowledge of teaching practice, which substantiates the teacher's actions in designing or selecting tasks and in their enactment in the classroom, which is the manifestation of their knowledge in action relevant in this study (Schön, 1983). In this communication, we are interested in analyzing the mobilization of didactic knowledge for the design and leading of a task, specifically when using Scratch as a technological tool to support CT learning in the context of teaching mathematics. It's also part of the study to consider the influence of the collaborative context of professional teaching training in which the activities were developed.

Methodology

i) Participants and context

The participants are four lower secondary mathematics teachers from a public school in Lisbon, where the first five work sessions and research lessons also took place, with the remaining sessions being conducted via Zoom. The object of study of this paper is the mobilization of Lara's didactic knowledge. Lara has 26 years of teaching but had no experience with CT, as neither did the other participants in the lesson study. Lara has a master's degree in Mathematics for Teaching. This study takes place in the context of a lesson study with the aim of promoting the development of the teaching practice of the participants. The lesson study took place in the 2023/2024 academic year and followed the steps indicated by Ponte et al. (2016): definition of the study aim, planning the research lesson, teaching the lesson, and post-lesson reflection. Twelve work sessions were held, each lasting around

2 hours. The group planned 3 tasks that were taught by Lara and analyzed by all participants in the post-lesson reflections. This study focused on the third planned task applied to fifteen grade 8 students attending the mathematics class under Lara's responsibility. In the research lesson, the students sat in a U-shape and worked collaboratively for 45 minutes.

The sessions sought to promote the development of CT knowledge to enable the mobilization of didactic knowledge, with greater attention to the aim of the proposed tasks and collaboration among participants (Ponte & Oliveira, 2002). Fujii (2018) states that lesson study supports teachers in developing knowledge on how to teach students not only content but also thought processes so that they become independent thinkers. Paying great attention to the processes of preparation, analysis, and reflection on teaching practice, this author especially values problem solving in the tasks proposed in research lessons. Fujii (2018) emphasizes that promoting teaching through problem solving cultivates students' mental habits in terms of the way they think and their attitudes towards arriving at a mathematical solution. Given that problem formulation and solving is a strong characteristic for the development of CT, it became perfectly compatible with the tasks proposed in the lessons of this formative context. As teaching material for CT development, Scratch was used due to the good results that research, such as that of Moreno-León et al. (2017), recommend in this regard.

ii) Data gathering and analysis

The methodology adopted is a qualitative case study, which follows the interpretative paradigm and the design of a case study, being the first author a facilitator. For data gathering, the following procedures were used: two semi-structured interviews, one before and one after the lesson study; direct observation of the lesson study sessions, including the research lessons; collection of documents of the tasks produced during the lesson study. Information from direct observation was collected through notes in a research journal, audio recordings of all lesson study sessions, and video recordings of the research lessons.

Using content analysis (Bardin, 1979), data were explored inductively, especially in situations that reflected the professional knowledge that Lara mobilized to design and lead the third research lesson, evidencing the manifestation of her knowledge in action (Schön, 1983). Lara was chosen for the case study because she taught the three research lessons, participating intensively in events that were relevant to the analysis of the results that evidenced the manifestation of her knowledge in action. However, in this communication, data analysis takes place within the scope of the planning and design of the third research lesson, as well as the post-lessons reflections and final interviews, as they evidence results of the entire teacher education process promoted by the lesson study.

Based on the video and audio recordings and their transcripts, as well as the lesson plans, episodes were selected focusing on three activities, from which three sub-activities emerged: (i) Planning the research lesson – selection and design of a task (sub-activities: declaration, blocks ordering, representing categories in blocks); (ii) Research lesson (sub-activities: presentation, independent work, whole-class discussion); (iii) Post-lesson reflections (sub-activities: collaboration between teachers before the lesson, collaboration between students and Lara during the lesson, collaboration between teachers after the lesson). This study follows the relevant ethical principles and guidelines, and all names are pseudonyms.

Results

As this is the culmination of the lesson study, we pay special attention to the mobilization of Lara's professional knowledge in the planning, enactment and reflecting of the third task.

i) Planning the research lesson – selection and design of a task

The aim of the task that the group planned was for the students to build a program so that they could calculate their final weighted average in mathematics, according to the real evaluation criteria established for this subject. The following variables of the algebraic formula already known by the students in the paper and pencil solution for this calculation should be created and inserted in the operator blocks: "TestsAverage", "MiniTestsAverage", "TestsCounter", "MiniTestsCounter", and "FinalGrade". Likewise, the grades of the Tests, Mini Tests, Lesson Observation (LO) and Oral Assessment (OA) would determine variables of: "TestsSum"; "MiniTestsSum". The grades of Lesson Observation (LO) and Oral Assessment (OA) always range from 5 to 25. The number of Mini Tests was always twice the number of Tests, requiring specific variables for these parameters. Each assessment was graded from 0 to 100, requiring a calculation to satisfy the 25% proportion that the average of the Tests and Mini Tests made up in the final average. There were two sets of blocks in the statement: in the first cluster, the final weighted average was calculated; next to it, it was converted into levels from 1 to 5.

Using their knowledge in action (Schön, 1983), Lara and the teachers decided that the program should be fully constructed but divided into blocks that followed a similar algorithmic pattern to the blocks immediately above, with the aim of inducing students, through problem-solving (Wing, 2006), to learn how to use the appropriate variables in Scratch. In order to challenge as many students as possible to enjoy every moment of the lesson, those who completed the blurred part of the set of blocks positioned on the left side of the script had to do the same on the right side (figure 1):

> Lara: Because you have groups at different speeds. The fact that we have a plan of a more complex degree of difficulty and a more reasonable plan, so to speak, allows you, because you have the complex one, to then fine-tune it in real time and move on to the next one. Ah, if the whole class needs it, the class needs it. That's it. If only a few need it, then only a few need it. (session 10)

The statement (figure 1) went through three versions, adapted by the facilitator with options to choose from, to meet the objectives of the task determined by the teachers, arriving at the final representation. By using Scratch commands to design the task (Ponte, 2012), Lara had the opportunity to promote the knowledge of CT practices (Moreno-León et al., 2017): i) pattern recognition: the order of the statement was organized so that students recognized that the variables they had to create in the blank blocks ("MiniTestsSum", "MiniTestsCounter", "MiniTestsAverage", and LO) had the same purpose as those immediately above these gaps ("TestsSum", "TestsCounter", "TestsAverage", and OA) and, therefore, the excluded blocks should also be structured like their upper blocks in order to obtain the final weighted average representative of the real evaluation criteria; by using "repeat" to ask the user questions so that they could enter the different evaluation scores; ii) algorithmic: by using "repeat", "question" and the "operators"; organizing these commands with the information that the user provides in "question and wait for answer", so that they are correctly inserted in the "variables" created for the "operators" to calculate their averages; using "if... then... else" to classify the final

average obtained in an organized level from 1 to 5; iii) abstraction: using "says", as it does not interfere with the functioning of the code; focusing on the organization of the algorithm to solve the problem, without worrying about irrelevant information; iv) decomposition: calculating the average independently of the grades of Tests, Mini Tests, Lesson Observation (LO) and Oral Assessment (OA) to obtain the final weighted average of these results; and v) debugging: checking by "clicking on the green flag" to see if the code executed the task correctly.

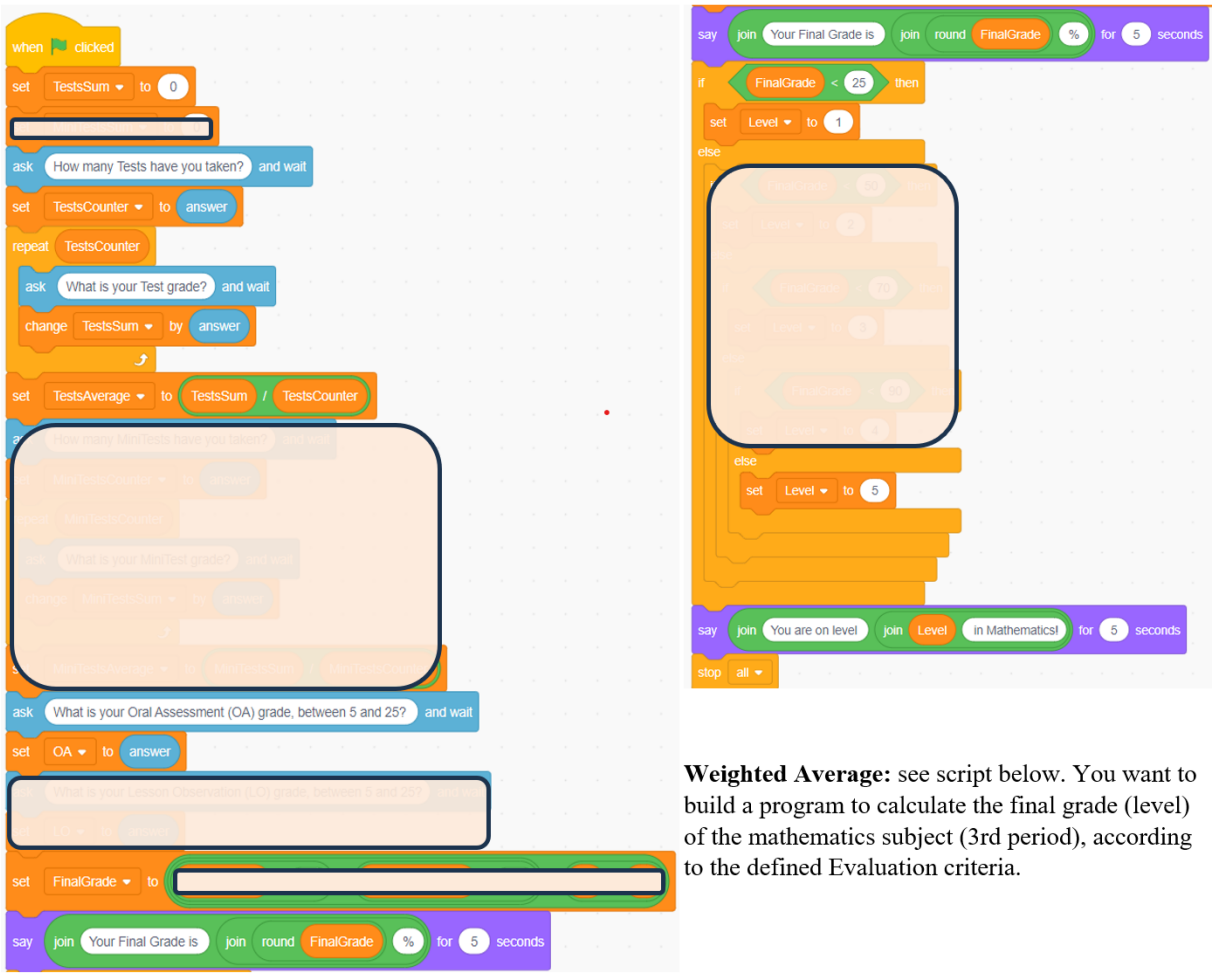

Figure 1: Task for the 3rd research lesson

At this stage, the teachers planned questions (Ponte, 2012) for Lara to lead the students to participate in the lesson in its three stages, as described in the next section.

ii) Research lesson

The research lessons followed the structure: (i) task introduction; (ii) students' independent work; (iii) whole-class discussion (Fujii, 2018). When introducing this planned task, Lara gave each pair of students the statement, explaining the aim of the task. Lara used her professional knowledge (Ponte, 2012) about the dynamics of an exploratory lesson to guide the students through this phase, using the questions provided to participate with information about the calculation of the final math average.

During the students' autonomous work, Lara also used her knowledge in action (Schön, 1983) about leading exploratory lessons (Ponte, 2012), asking them individually: what variables make up the average and how is each of them calculated. These questions, planned in advance, helped the students to identify the variables that should be created to represent all the evaluation criteria necessary to calculate the final grade (Wing, 2006). They also recognized patterns among CT practices (Moreno-León et al., 2017) when they realized that the variables "MiniTestsAverage", "MiniTestsSum" and "MiniTestsCounter", had the same purpose as the variables "TestsAverage", "TestsSum" and "TestsCounter". The same occurred with the variables Lesson Observation (LO) and Oral Assessment (OA). The students also built the blocks containing the operators that calculated the final weighted average, using the variables created to represent all the evaluation criteria used (Wing, 2006).

In the whole-class discussion, led by Lara according to the plan, three students presented different solutions, concluding with a summary by her of the main ideas discussed and the aims achieved. Lara followed the plan by asking challenging questions (Ponte et al., 2016), so that more students would participate in this phase. They analyzed different solutions that address the correct use of pattern recognition applied to the calculation of the weighted average and the mathematical rigor necessary for the algorithm to debug correctly (Wing, 2006):

Lara: So, we've created two routines, one for the Test average and one for the Mini Test average. Would it make sense to make a single routine for the average of the Tests and Mini Tests?
John: I don't think so, but if I had the same number of Tests and Mini Tests, it could be done.
Lara: But for those who did the final operation with all the calculations, was it different from the numerical expression we studied for calculating the average? In other words, what are the priorities in a numerical expression?
Peter: Multiplications and divisions.
Lara: Is the program respecting that?
James: Yes, so I did multiplication first and then addition.

iii) Post-lesson reflection

In the final interview, Lara emphasized how collaboration among teachers contributed to planning the task of supporting the teacher efficiently (Ponte, 2012), helping her to recognize the importance of this context:

Lara: The group made all the difference when it came to choosing the tasks and I'm extremely proud of the work we did because of its coherence. I think it was thought out and consistent. When we had the task-solving sessions, it had a purpose, it was to give us some comfort, ideas, possibilities for what would later be the construction of these tasks. I'd never have achieved this on my own. There was an evolution, even in the codes we used, in the programming routine itself. I couldn't build a set of tasks of this quality, with this consistency. I think things had a logical direction with a purpose, in the right measure, at the right time, and it was something built in a group, which always works out better than one person thinking alone. Even though I like working in groups, sometimes I find that I learn faster on my own. However, I recognize that when we are forced to share, the work is much better.

In her final interview, Maria, who observed the lessons in person, also valued Lara's approach to promote collaboration among students, thus reinforcing the didactic aim of this assignment:

Maria: The questions and the way Lara handled things were a guiding thread for the rest to develop and for the children to complete the tasks they were doing. Any question that came up during the course of the program, the children eventually understood. Those who had not finished the first stage got there. I think that was important and that was what brought all the groups together to get to the final program. Because there were some who had a little thing that they had not done [or] another little thing that they had not finished. And I think that was important.

Discussion

The definition of the learning aim of the task indicates the development of Lara's knowledge about CT practices, as they relate the blocks used in the Scratch categories to abstraction, decomposition, pattern recognition, algorithm, and debugging (Moreno-Leon et al. 2017). In these aspects, the knowledge of teaching practice, referred to by Ponte (2012), was developed in relation to the teaching of CT practices, since Lara and the teachers did not have this competence before the teacher education process. Lara and the participants mobilized the acquired knowledge to develop the aim of the task and integrate the technology in a meaningful way in the teaching of mathematics (Cobb et al., 2017). In turn, Lara's and the teachers' didactic knowledge about task design was mobilized during planning (Fujii, 2018), when they organized the order and appearance of the blocks in the task statement, to boost learning.

The structure of the research lesson (Fujii, 2018) favored student participation so that they could develop CT practices: when the teacher presented the task with an explanation of the procedures involved in the solution; when the students solved the task autonomously; when the teacher guided the classroom discussion on the different solution methods; and, finally, when the teacher summarized the content studied, emphasizing how students constructed their ideas for the different solutions discussed. Different solutions for this task were presented by students in the class discussion (Fujii, 2018), motivated by challenging questions asked at each stage of the lesson, as provided by the respective planning. Lara mobilized her knowledge in action (Schön, 1983) when she planned this lesson structure collaboratively and conducted it rigorously, demonstrating the didactic confidence mentioned by Ponte and Oliveira (2002).

Conclusion

Given the need for teachers to have consistent knowledge of CT practices (Wing, 2006) for their teaching, the different phases of this lesson study contributed to Lara's in-depth study on how to develop this competence (Cobb et al., 2017). Through the tasks solved and analyzed in the problem identification and lesson planning sessions, Lara and the teachers explored Scratch for tools: movement, appearance, sounds, events, control, sensors, operators, variables, and blocks. This allowed Lara to understand how useful these resources are for the development of CT practices, as they are directly related to problem solving. From this developed knowledge (Ponte, 2012), Lara and the teachers planned and Lara conducted a research lesson with the same aim, set up to be engaging for students. This reinforces and extends the perspectives of Moreno-Leon et al. (2017) on the usefulness of Scratch for developing CT.

Lara's and the teachers' reflections helped them to understand that collaboration at all lesson study stages was essential for the success of the research lesson, as it was based on planning aimed at

improving student learning (Ponte, 2012). The collaborative context favored the mobilization of knowledge in action (Schön, 1983), for improving the planning of the task and Lara's actions when leading the lesson and her reflections on effective teaching and learning of CT practices with the support of Scratch. Further studies may lead to understand how to develop the competence of teachers at other school levels to work with CT with their students.

Teachers' knowledge and technology: the global model

Helena Rocha

CICS.NOVA, Faculdade de Ciências e Tecnologia, Universidade NOVA de Lisboa, Portugal;
hcr@fct.unl.pt

The teachers' central role in technology integration and the challenges of that integration emphasize the need for a deeper understanding about the teachers' knowledge required to teach with technology. Based on previous work and a systematic literature review, we identified three knowledge models often used: TPACK, KTMT and PTK. The goal of this paper is to discuss the similarities and differences between these knowledge models and present a Global Model. This Global Model is not a new model. On the contrary, it is a model developed based on the existing models and intending to integrate in a single model the knowledge domains considered in the different existing models. The Global Model highlights the common domains considered and the common roots for the three models, but it also makes explicit the differences, mostly related to the understanding of the domains or even to the domains considered, and also to the way how the knowledge's development is conceived.

Keywords: Teachers' knowledge, knowledge model, technology, Global Model.

Introduction

The integration of digital technology has been recognized for its potential to promote mathematical learning (Tabach & Trgalová, 2019). However, achieving that potential has proved to be quite a challenge (Rocha, 2020). Teachers have a central role in technology integration and their professional knowledge is one of the influences over that integration (Clark-Wilson et al., 2020).

The PCK – *Pedagogical Content Knowledge* construct developed by Shulman (1987) is a significative mark in the research on teachers' knowledge. Since then, several authors have developed refinements of PCK (e.g., *Mathematical Knowledge for Teaching* [MKT] by Ball et al., 2008) and even developed new frameworks (e.g., *Knowledge Quartet* by Rowland et al., 2005). The integration of technology as raised new questions and conducted to the development of new knowledge models. These models, with a focus on technology, included a model inspired by the PCK construct (*Technological Pedagogical Content Knowledge* [TPACK] by Misha and Koehler, 2006, 2019), a model intending to promote the inclusion in a knowledge model of aspects related to instrumental genesis (Rabardel, 1995) (*Pedagogical Technology Knowledge* [PTK] by Thomas and Hong, 2013), and a model intending to integrate the research on professional knowledge and the results from studies in technology integration (*Knowledge for Teaching Mathematics with Technology* [KTMT] by Rocha, 2013, 2020).

Although we generally refer to these models as knowledge models, some of them encompass more than just teachers' knowledge within their conception. That is the case of PTK, that includes the teachers' personal orientations, and also the case of KTMT, that globally considers all influences on the teachers, originating from themselves or from the context in which they are inserted.

The goal of this paper is to discuss the similarities and differences between the existing knowledge models with focus on technology. Based on this work, we intend to present a *Global Model*. This

Global Model is not a new model. On the contrary, it is a model developed based on the existing models and intending to integrate in a single model the knowledge domains considered in the different existing models.

Methods

According to Radford (2008, p. 317), "a network of theories can be conceived of as a semiosphere, (…) such a networking space revolves around two different and complementary 'themes' – integration and differentiation". As so, we will base our work on an analysis of the similarities and differences of the existing knowledge models.

Inspired by Jablonka et al. (2018), we started from a literature review (Rocha, 2023), to identify the existing models and the understanding ascribed to each of the knowledge domains considered. We then used all the knowledge domains, their conceptualization, and the relations among the domains to conceive the *Global Model*.

To align with our objective, we adopted the following categories for analysis:

- Domains of knowledge included;
- Other dimensions besides knowledge;
- Characterization of the knowledge development.

In each of these categories, we tried to identify similarities and differences, looking for a way to include them in the visual representation of the *Global Model*.

The knowledge models

According to the systematic literature review conducted in the time frame of 2018 – 2022, using the database Scopus, there are several knowledge models being used in research in Mathematics Education (Rocha, 2023). The results of this study point to the TPACK as the most used model, although there is some diversity in the way how the model is being used. Other models identified in this review were the KTMT and the PTK. As so, in the present work we consider these three models: TPACK, KTMT and PTK.

TPACK

As addressed before, the integration of technology in teachers' practice has raised new challenges. It was clear that teachers need some knowledge about technology, but very soon it was clear that some additional knowledge would be needed. Inspired by the work of Shulman and his PCK construct, Misha and Koehler (2006) developed a new model focused on technology integration. This model emphasizes technology while remaining general, lacking a specific focus on the teaching of mathematics.

Domains of knowledge included

The TPACK model considers the *Content Knowledge* and *Pedagogy Knowledge* domains, assuming PCK as the intersection between these. To these domains the authors add the one on *Technology*, considering then the intersections among each pair of domains: *Content and Technology*, *Pedagogy and Technology*, and the intersection among all the domains – the TPACK. The *Context* is also

considered, although in different ways over time, only recently being assumed as a knowledge domain (Mishra, 2019).

Other dimensions besides knowledge

All the domains in this model are knowledge domains, except for context. In the initial representation of their model, Misha and Koehler (2006) did not include the context, although in the discussion they include some references to it. Later, the model changed to include what the authors call *Contexts*, even if they do not describe what that could be (Harris et al., 2009). Finally, more recently, the model evolved to include *Contextual Knowledge* (Mishra, 2019). This change is clearly based on the recognition by Mishra that *Contexts* is not conceptualized as knowledge, resulting in some inconsistency in a knowledge model. So, the author changed the designation to align it with a knowledge domain. And this new domain of knowledge is assumed as being "everything from a teacher's awareness of available technologies, to the teacher's knowledge of the school, district, state, or national policies they operate within" (Mishra, 2019, p. 76) or, in a shorter way, knowledge about the school reality where the teacher is teaching. The result of this change is that all the domains in TPACK are indeed teachers' knowledge.

Characterization of the knowledge development

The conceptualization of the TPACK model is not so clear about how the knowledge development is conceived. Some authors interpret the model in an integrative perspective and some others in a transformative one (Angeli & Valanides, 2009). As so, it is not clear if knowledge in two base domains (Content, Pedagogy, or Technology) results straightforward in knowledge in the intersection of these domains, but this is the perspective assumed in some studies.

KTMT

The KTMT model recognizes the contribution of the work of authors such as Shulman (1987), and Mishra and Koehler (2006). However, the model intends to go beyond TPACK, integrating in a single model the research conducted so far in teachers' knowledge and in technology integration. With a specific focus on the teaching of Mathematics, this model developed by Rocha (2013, 2020) includes several types of domains in a pyramidal structure.

Domains of knowledge included

KTMT includes three types of knowledge domains: base knowledge, inter-domains knowledge, integrated knowledge.

The base knowledge domains are four: *Mathematics*, *Teaching and Learning*, *Technology*, and *Curriculum and Context*. *Curriculum and context* are regarded as a transversal domain that influences all other domains. It encompasses all influences on teachers' choices, including personal factors (such as teachers' beliefs) and external factors (such as the school context).

Inter-domain knowledge is a distinctive key component of this model that differentiates it from other knowledge models. The KTMT model considers two inter-domain knowledge: the *Mathematics and Technology Knowledge* (MTK), and the *Teaching and Learning and Technology Knowledge* (TLTK). MTK focuses on how technology influences mathematics, enhancing or constraining certain aspects,

and TLTK focuses on how technology affects the teaching and learning process, enhancing or constraining certain approaches.

Integrated Knowledge (IK) is the last type of knowledge in the KTMT model, resulting from the articulation between all the knowledge domains.

Other dimensions besides knowledge

As previously noted, *Curriculum and Context* are viewed as a transversal domain that influences all other domains. It encompasses both external influences on teachers—such as the official curriculum and available school resources—and internal influences, including their beliefs about the potential of technology for teaching mathematics and their self-efficacy. Therefore, this domain extends beyond mere knowledge.

Characterization of the knowledge development

KTMT has a pyramidal structure. Instead of intersections as in TPACK, the inter-domain knowledge is a new knowledge developed from more than one base knowledge and integrating in its characterization results from the research on technology integration. And the *Integrated Knowledge* develops from the base and the inter-domains knowledge in a similar way. This is an on-going process with a continuous development of the knowledge in all the domains of the model.

PTK

According to Thomas and Hong (2013), the PTK model can be useful to promote understanding about how the teachers use technology to teach Mathematics. As so, and as in the case of KTMT, this is a model specific to the teaching of Mathematics. Even so, the authors adopt a very different perspective from the ones in previous models, highlighting the use of technology and how the technological tool can be transformed in different instruments (in line with Rabardel, 1995). However, it is possible to identify in this model, as in the previous ones, the influence of the work of Shulman and his notion of PCK.

Domains of knowledge included

With its roots in the work of Shulman, this model considers as domains the *Mathematical Content Knowledge* and the *Pedagogical Knowledge*. However, instead of PCK, it considers the work of Ball et al. (2008) and their MKT. Besides these, the authors assume as important two domains that are not knowledge domains. That is the case of the *Technology Instrumental Genesis*, assumed as highly relevant, and of *Personal Orientations* also with a strong impact recognized by the authors. All these domains contributing to the PTK.

Other dimensions besides knowledge

As already mentioned, the PTK model includes two domains that are not knowledge domains. This is a difference in comparation to TPACK, but a similarity with KTMT. The inclusion of instrumental genesis, a framework usually not articulated with knowledge models, results in a significative difference of this model when compared with the other two.

Characterization of the knowledge development

The model seems to be based on the MKT model from Ball et al. (2008), to which the technology is added. This resulted in the transformation of the artefact in an instrument, influencing simultaneously the teachers' MKT and the PTK. The *Personal Orientations*, in turn, influence the teachers PTK.

The *Global Model*

The three models are very different in the way they conceived the development of the knowledge. For TPACK we have intersection and, in the integrative perspective, knowledge resulting straightforward from there; for KTMT we have new knowledge developing from the previous level of knowledge, conceived like layers continuously developing; for PTK we have domains influencing other domains.

However, despite the differences, there are also similarities between the three models, with a base on the work of Shuman and his notion of PCK. With nuances, but there are domains of knowledge common to all the models considered. Some kind of context, with differences across the models (and even including it as knowledge in TPACK and as a different type of domain in the other two models), is assumed to be important in all the models.

As a way to highlight the similarities and differences between the models, we start by adopting a similar way of representation. And we adopt boxes and arrows to represent the domains and the relations among them. In the representation of the *Global Model* presented here, we use different colors to represent the relationships between the knowledge domains of each of the knowledge models considered – TPACK, PTK and KTMT – and we resort to partial overlap between the representation of domains in different models when it seems to us there is some relation between the domains of knowledge considered.

The analysis presented here in a very synthetic way, led to the *Global Model* represented in figure 1.

Different colors in the arrows allow the identification of each of the original models. As so, parallel arrows offer the identification of similarities among two of the models. That is the case of TPACK and KTMT, a situation that was possible to anticipated, given the influence of TPACK on KTMT conceptualization.

Partial overlap between the representation of domains is also important, revealing some connections between models. These overlaps can however be of two different types. In one of the types there can be different names to represent basically the same domain of knowledge. That is the case of *Mathematical Content Knowledge* in PTK, of *Content Knowledge* in TPACK, and of *Mathematics Knowledge* in KTMT. In the other type of cases the domain is entirely different, although it is possible to see some relation. That is the case of *Technology Knowledge* in KTMT and TPACK, and Technology Instrumental Genesis in PTK.

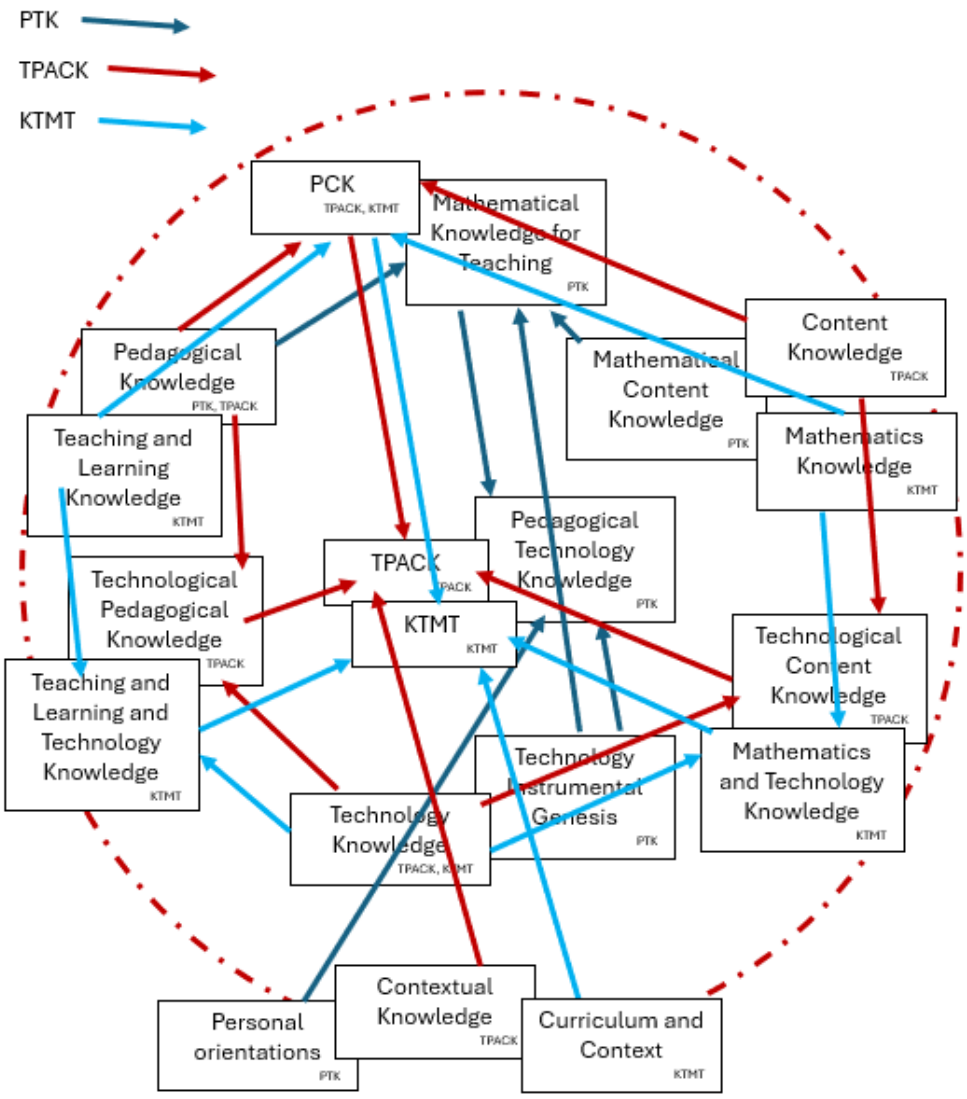

Figure 1: The Global Model (Rocha, 2024 – in press)

Conclusion

The conclusions achieved point to some similarities, essentially related to the mathematics knowledge and to the pedagogical knowledge, with a strong value given to PCK. But the conclusions also point to some differences. Some related to the name given to the domains (e.g., mathematical knowledge, mathematical content knowledge), but mostly related to the understanding of the domains (e.g., PCK vs MKT) or even to the domains considered (e.g., curriculum, context), and also to the way how the knowledge's development is conceived.

It is now important to refine the model, based on its use in the analysis of teachers' professional knowledge, and analyze whether this *Global Model* can make contributions to understanding teachers' knowledge and to promoting their professional development.

Resonance of instrumental functions in geometric constructions: Unpacking teacher and student artifact use

Zahida Sayadi and Maha Abboud

CY Cergy Paris Université, LDAR, France; zahidasayadi@gmail.com

This ongoing research investigates the didactic potential of using multiple artifacts in the teaching and learning of geometric constructions. It aims to explore the interactions of instrumental functions by accounting for the diverse perspectives of the user(s) and the object(s) of their activities. We hypothesize that the same artifact can give rise to multiple instruments when integrated into the activities of different subjects, owing to their unique processes of instrumental genesis. In addition to examining the synergy of instrumental functions, we introduce the concept of 'resonance' which emerges when instruments mediate the activities of different subjects engaging with 'paired objects of activity'. It also applies to the set of semiotic resources activated within such context. To illustrate these emerging concepts, we present a case study highlighting their application and relevance.

Keywords: Instrumental genesis, instrumental functions, interaction of artifacts, semiotic bundle.

Introduction

Integrating multiple tools in mathematics education reflects a didactic need that underpins this diversity (Drijvers et al., 2016). Digital artifacts offer unique affordances compared to their non-digital counterparts, emphasizing the importance of understanding how technologies are used in technological environments and how both technological and non-technological artifacts interact to enhance the forms of mathematical teaching and learning in the classroom (Clark-Wilson et al., 2020). The teacher's decision to integrate an artifact into their teaching is shaped by its perceived didactic affordances and the anticipated obstacles students might encounter (Abboud-Blanchard, 2014). In this paper, interactions between artifacts are examined in terms of their functionalities within the different activities observed in the classroom. Beyond the synergy of instrumental functions (Rabardel, 1995), we introduce the concept of *resonance*, which can further be extended to the set of semiotic resources activated by different subjects within the same teaching and learning context. We explore and characterize this conceptual tool throughout a case study of a teacher conducting a sequence on the construction of parallelograms.

Theoretical frames and research questions

The study we present in this paper is structured around the following research questions: Why do teachers integrate multiple artifacts within their teaching? How do the functions of selected artifacts relate? How does the interaction of different semiotic resources leverage students' learning experience?

The overarching theoretical framework is *the instrumental approach*, which provides a solid foundation for examining how teachers and students adopt and adapt artifacts through the intertwined processes of instrumentation and instrumentalization, transforming them into instruments (Rabardel, 1995). This approach enables the analysis of an artifact's appropriation, both in terms of mastering the artifact itself - which involves technical proficiency independently of its context of use - and

mastering the use of the artifact enabling the subject to mobilize its functionalities in alignment with their object of activity. The dynamics of instrumental functions depend on whether a single artefact or multiple artefacts are mobilized, and whether one or several subjects are involved. A single artefact may serve multiple functions within a subject's activity (Rabardel, 1995), while the use of multiple artefacts can create synergies, with each activity enhancing the potential of the others (Faggiano et al., 2018). Furthermore, different subjects may be engaged with coexisting similar *paired objects of activity*. These are not identical since they are approached from distinct perspectives such as those of the teacher and the students. We introduce the *resonance of instrumental functions* that emerges when identical or distinct artifacts are used simultaneously by multiple subjects engaging with *paired objects of activity* (Figure 1).

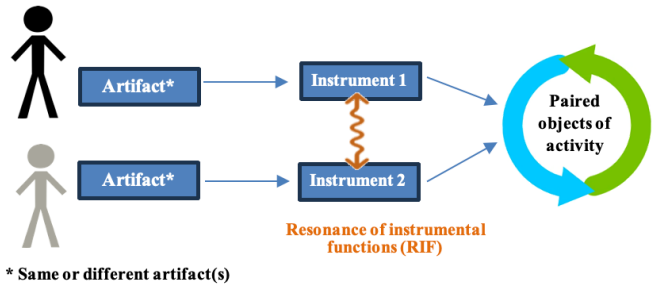

Figure 1: Resonance of instrumental functions

With this approach, we define *the resonance of semiotic resources* as the interaction within the set of semiotic resources mobilized by different subjects - including artifacts, utterances, gestures and inscriptions - when engaging with paired object of activity.

A second framework that offers analytical concepts to investigate teachers' practices in the context of digital tool use is the *Double Approach applied to Technology* (DAaT) (Abboud, 2024). It examines teachers' practices through three principal axes - cognitive, pragmatic, and temporal - while accounting for social, institutional, and personal factors as key determinants shaping them (Abboud-Blanchard, 2014). Our focus lies on the reasons underlying teachers' use of different artifacts within the classroom setting, the tensions they encounter in striving to achieve their teaching objectives and how they manage them (Abboud & Rogalski, 2021). As for aids provided to students, Abboud (2024) identifies two types: *manipulatory aids*, which involve using the artifact itself without explicit connections to mathematics, and *mathematical aids*, which establish direct links between the artifact and mathematical concepts.

We also refer to the *semiotic bundle* developed by Arzarello (2006) to explore the interaction of artifacts and different semiotic resources at play - utterances, gestures, and inscriptions – within teachers' and students' instrumented activities.

Methods

In our ongoing research, we study three cases of French teachers at lower secondary school designing and implementing parallelogram sequences using technological and non-technological artifacts. To illustrate our methods and analysis, we present the case of Nina, one of these three teachers.

Data were collected through naturalistic observations conducted in Grade 7 mathematics classes with students aged 12 to 13 years. Nina, has approximately 20 years of professional experience. She provided us with her detailed lesson plan that relates to the sequence of parallelograms. We conducted a pre-interview with her, comprising two phases. The first phase provided valuable insights into her overarching motivations for selecting artifacts in her teaching, both on a general level and within the context of geometric constructions. In the second phase, the focus shifted to a more detailed exploration of the mathematical content, investigating the interplay between her teaching objectives and the use of selected artifacts. Subsequently, we observed how artifacts' use was implemented within the classroom setting; seven teaching sessions were videotaped. Finally, we had a post-interview with Nina to reflect on whether the use of artifacts aligned with her stated intentions, to uncover challenges she faced and to point out any changes she would like to make.

To better organize our class observations, we initially categorize the teaching-learning classroom environment into three distinct types: (a) *Non-Technological Environment (NT)*, where no technology is involved; (b) *Techno-Latent Environment (TL)*, where technology is present but not directly engaged in mathematical tasks, instead serving to display textual documents or support the organization of the teacher's work (Clark-Wilson et al., 2020); and (c) *Techno-Operant Environment (TO)*, which fosters innovative ways of performing and representing mathematical activities.

The analysis was carried out under a three-tiered approach, encompassing macro, meso, and micro levels. The macro level analysis provides us with a synthetic view of artifact use by both the teacher and students. It highlights the overall synchronic and diachronic articulation of technological and non-technological artifacts, taking into account the mathematical task under study and the type of teaching and learning environment. At the meso-level, we focus on teaching episodes within TO environment. We closely examine the dynamics of instrumental functions. The fine-grained micro-analysis of key moments explores the resonance of semiotic resources activated by both the teacher and the students.

Teacher motivations for artifact selection and use

At a global level, Nina integrates multiple artifacts into her teaching practices for cognitive reasons directly tied to the mathematical domain itself - Excel for probabilities, Geogebra for geometry, Scratch for algorithms, etc. Her selection of artifacts aligns with institutional requirements including those for official examinations and accommodations for students with special needs. She also prioritizes accessibility by leveraging artifacts that are readily available to students, such as iPads. Pragmatic considerations play a predominant role in her choices, shaping the didactic strategies she adopts to best serve her teaching objectives. These choices help her overcome anticipated student difficulties, foster motivation, provide opportunities for consolidating knowledge beyond the classroom, manage the learning environment, and ensure access to instructional resources. The temporal dimension further influences her use of artifacts, as she adapts their selection to the different phases of a lesson - for instance, incorporating flash questions during the introduction. She also resorts to specific artifacts in response to time constraints, whether to compensate for delays in her overall annual progression or to manage limited time within a particular session.

At a local level, regarding geometric constructions, pragmatic reasons are prevailing. Nina emphasizes artifacts that help students overcome difficulties, particularly videos and animations that demonstrate the manipulation of geometric tools. She prioritizes online exercises with detailed feedback for construction tasks. Nina adapts Geogebra to her teaching goals, using projection mode for whole-class instruction and active mode on students' iPads for individual or collaborative work. She identifies Geogebra as a key artifact for generating conjectures about parallelogram properties, thereby making these properties more tangible for students.

Macro-level analysis

Classroom observations are synthesized in the macro-synoptic diagram illustrated below (Figure 2). The teaching and learning environment, along with the artifacts mobilized by both the teacher and students, underpins teacher practices along the pragmatic axis of the DAaT. The generic tasks related to the mathematical knowledge involved highlight the cognitive axis. The main contribution of this diagram lies in its integration of a temporal dimension, enabling a dual reading perspective – both diachronic and synchronic – regarding artifact use.

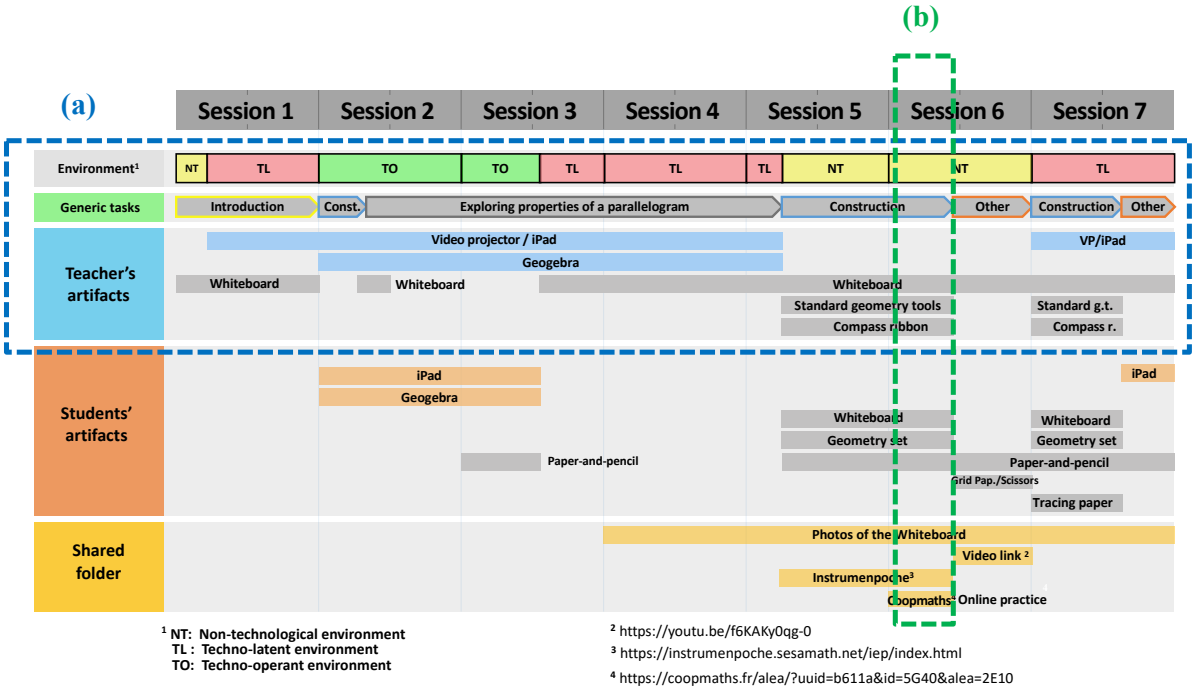

Figure 2: Macro-synoptic diagram. (a) Diachronic analysis, (b) synchronic analysis

The diachronic analysis at the teacher's level (Figure 2a) might initially suggest a mere juxtaposition of artifacts; however, this is not the case. The choice of artifact serves as a strategic means to support Nina's teaching objectives. For instance, Geogebra is used in parallelogram construction tasks based solely on the parallelism of its opposite sides, while it is also deployed to explore the properties of the parallelogram. When proving these properties, it is projected to display a pre-constructed figure without drawing upon any of its functionalities. As a result, three distinct instruments emerge from this artifact, each corresponding to a specific object of activity.

Conversely, a synchronic analysis offers a perspective on Nina's teaching approches, emphasizing three key dimensions: knowledge delivery, students' anticipated engagement with the assigned tasks, and the provision of resources to support learning and practice beyond the classroom. For instance, during the construction tasks in session 6 (Figure 2b), both the teacher and the students use standard geometry tools. Additionally, the teacher has developed her own personalized compass using a ribbon. Although no technology is integrated into the classroom setting, animations illustrating detailed construction procedures and online exercises with step-by-step corrections are made available on the shared folder for students' use outside the classroom. This approach aligns with the rationale behind artifact use, as previously discussed in the pre-interview with the teacher. However, in the post-interview, Nina notes that the animations were not particularly helpful to her students, despite accurately replicating the task assigned in the video - which did not correspond to the task she had given her students. In fact, the positioning of the missing vertex with respect to the given vertices of the parallelogram (Figure 3) was not the same - which ultimately required challenging adaptations from students. This highlights the importance of considering different subjects' perspectives when engaging with paired objects of their instrumented activity.

Figure 3: (a) Teacher-assigned task, (b) task as illustrated in the animation

Meso-level analysis

We investigate the dynamics of instrumental functions within the second teaching session (Figure 4). The teacher shares her iPad screen displaying Geogebra, while students work on the online version using their iPads. The first dynamic concerns the functional versatility of the dragging tool. Nina anticipated its use across different tasks (Figure 4a): checking the robustness of the construction in the construction task and developing conjectures while investigating the properties of parallelograms. For students, the functions of dragging varied within a single task (Figure 4b): adjusting constructions, validating conjectures, and revealing unexpected configurations. These observations highlight the instrumental functions shift according to the user's perspective and to their object of activity. The second dynamic is illustrated through the synergy between the *distance tool* and the *dragging tool*, each contributing a distinct dimension to the conjecture-making task (Figure 4c). While some students formulated the conjectures solely based on the displayed measurements, others used the dragging tool to explore covariation, demonstrating a more advanced level of reasoning. In this interplay, each artifact enhances the functional contribution of the other, fostering a more comprehensive learning experience.

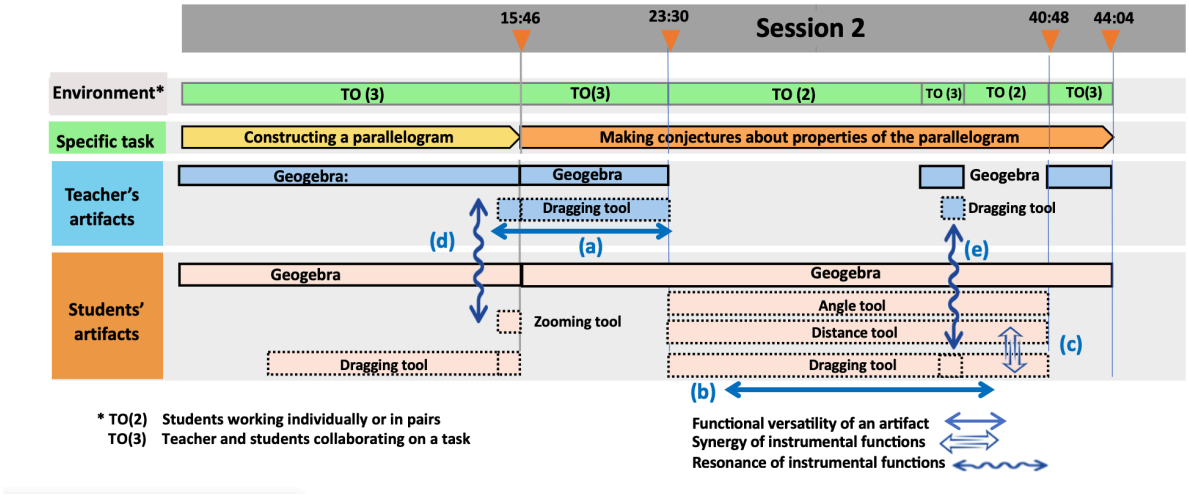

Figure 4: Meso-synoptic diagram

The third dynamic concerns the teacher and students collaborating on a construction task (Figure 4d). While the teacher was demonstrating how to use the dragging tool to check the robustness of a construction, a student simultaneously used the *Zoom tool*, believing he was engaging in the same process. This instance of resonance reveals a divergence in tool use and understanding that went unnoticed by the teacher and remained unresolved for the student. A second example involves the identification of an anomalous configuration (Figure 4d): the student shared his screen and dragged point A to check on the measures of opposite angles (Figure 5); however, the display of angle measures appeared abnormal. To illustrate the expected dynamic behavior of the construction, the teacher shared her own screen and performed the dragging test. The resonance of the dragging tool functions as a strategic means of making the student's difficulty explicit and supporting the teacher's intervention.

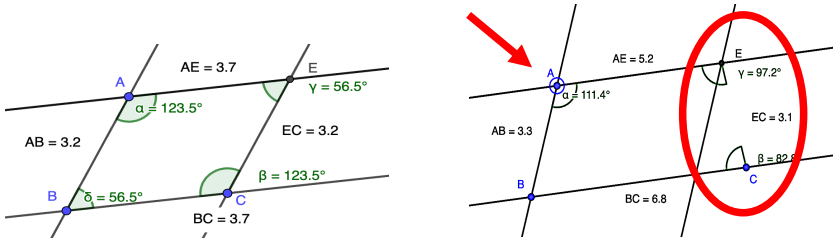

Figure 5: Meso-synoptic diagram

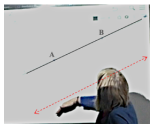
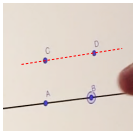
Micro-level analysis

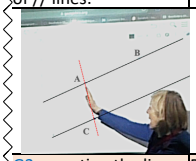
We are interested in a student's interpretation of the teacher's gestures in two episodes within the second session and how he implemented them within his construction procedures (Figure 6). The first one relates to constructing a parallel line to (AB). Nina first pointed to (AB), then to the expected location for the parallel line. The student, independently exploring the parallel tool, touched (AB) on point A. Consequently, he obtained point C when pointing to the position of the parallel line as indicated by Nina. When the intended parallel line still did not appear, he undid his actions and, on his third attempt, successfully drew it - albeit accidentally - by touching (AB).

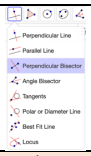
The second episode relates to drawing (AC) by joining points A and C, a situation not identical to drawing (AB) on an empty screen, even though the same artifact line is being used. The student linked the teacher's vertical hand movement to the perpendicular bisector icon, which depicts a vertical line and two connected points. The negative visual feedback prompted him to select the perpendicular icon instead, as it produced a visually similar configuration on his screen for the given position of point C. He then deemed his objective achieved.

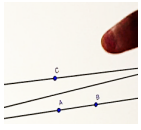
The resonance of semiotic resources activated in these two episodes highlights the importance of considering the distinct perspectives of the subjects involved, as well as the crucial role the teacher plays in an open, dynamic technological environment (Abboud & Rogalski, 2021). Differentiated instrumental interventions by the teacher are necessary to foster meaningful learning experiences and to support students' instrumental genesis of the artifact in use.











Timing	03:41	03:45	07:25	07:27	07:30	07:40

Subject	Teacher	Student	Teacher	Student	Student	Teacher/student
Utterances	Find out how you can draw the parallel line to this one (G1), which is located approx. here (G2).		Draw the line passing through points A and C (G3) then draw the //line to (AC) passing through B (G4). We'll get by then two pairs of // lines.			Teacher: When you make a mistake and you try to clear it, you know well this tool "going backwards"(G5). You do all master it.
Describing gesture and/or inscriptions						Student 
	G1: pointing to (AB) - her index is between points A and B G2: enacting the parallel line position	Picking the // tool. Touching (AB) on A, then touching the screen: Point C is displayed. Selecting point B. touching the screen so that (CD) appeared parallel to (AB)	G3: enacting the line passing through points A and C. G4: enacting a line // to (AC) passing through point B.	Picking the perpendicular bisector tool.	Picking point C, then point A. Then undoing his work.	G5: Teacher pointing to the "undo" S1: Picking the perpendicular tool, picking point A, then touching (g) *nearby* point C.
Teacher's tensions and students' difficulties		By touching line (AB), the student accidently picked point A.	The teacher limited students' strategies by imposing a construction procedure.	Misinterpreting the perpendicular bisector icon for it shows two connected points.	Direct manipulation feedback prompts S1 to undo his work.	Particular position of point C was behind S1 choice to draw a perpendicular line. The icon shows a vertical line as well.
Resonance of semiotic resources	**Resonance 1:** (Teacher; gesture) – (S1; parallel tool)- **Resonance 2:** (Teacher; board) – (S1; iPad screen)- **Resonance 3:** (Teacher; utterances) – (S1; screen touch gesture) **Paired objects of activity:** Drawing a line // to (AB)		**Resonance 1:** (Teacher; gesture) – (student; perpendicular bisector icon) **Resonance 2:** (Teacher; gesture) – (student; perpendicular tool) **Paired objects of activity:** Drawing a line passing through two existing points			

Figure 6: micro-synoptic diagram for selected episodes

Conclusion

The integration of an artifact into teaching practices is intrinsically linked to the teacher's objectives and contingent upon the specific function the teacher intends to leverage through its deployment. Three key points emerge when investigating the dynamics of instrumental functions. First, the necessity of accounting for the uniqueness of instrumental genesis, which relates not only to the artifact *per se* but also to the subject engaging with it, to ensure that actions effectively align with objectives. Second, when identical artifacts are activated by the teacher and students within a task, they are interpreted and implemented from distinct perspectives, leading to divergent procedural

approaches. Third, when teachers integrate an artifact without sufficiently recognizing its didactic potential and semiotic affordances, their ability to address emerging students difficulties is compromised, thereby hindering students' instrumental genesis and impeding their learning.

Within our ongoing research, two other case studies are in progress. Using the same methods and layers of analysis, we look forward to a broader exploration of the articulation of artifacts in mathematics classrooms. In particular, by introducing and testing the concept of resonance in various contexts, we aim to highlight its potential. Our goal is to enhance insights into teaching and learning experiences within these contexts and, hopefully, demonstrate its potential contribution to supporting teachers' professional development.

Mathematical problem-posing according to defined educational needs utilizing generative AI as a lever to enhance pre-service mathematics teachers' TPACK

Ruti Segal[1,2] and Yaniv Biton[2,3]

[1]Oranim Academic College of Education, Faculty of Advanced Study, Tivon, Israel; rutisegal@gmail.com

[2]Shannan Academic College of Education, Faculty of Mathematics Education, Haifa, Israel

[3]Center for Educational Technology, Tel-Aviv, Israel

This study was conducted during a course entitled Teaching Advanced Secondary School Mathematics. Fifteen pre-service teachers solved various mathematical problems and then were asked to pose additional problems and improve them to meet precise educational goals by furnishing "prompts" to a generative artificial intelligence environment and refining them as necessary according to predefined steps. They then answered a questionnaire (ten Likert-type statements; six open-ended questions). The study shows that this process contributed to the pre-service teachers' body of technological, pedagogical, and content knowledge (TPACK), exposed them to the pros and cons of the environment itself, and showed them how to generate effective prompts to obtain relevant responses. Overall, the teachers expressed satisfaction with using this environment and indicated they would use it in the future.

Keywords: Problem-posing, generative AI, ChatGPT, TPACK, pre-service high school mathematics teachers.

Introduction

The emergence of artificial intelligence (AI) technology environments have yielded new opportunities in all spheres of life. Its integration into the education system is still in its early stages, but it has reached a point where it can be effectively utilized to address specific challenges faced by teachers. One area is that of posing mathematical problems.

In the current study, 15 pre-service high school mathematics teachers were asked to pose mathematical problems that meet their pre-defined educational needs. To this end, they conducted dialogues with an AI "assistant" (in this case, ChatGPT). Through the use of mixed-method questionnaire, we aimed to identify how such a process can contribute to teachers' technological, pedagogical, and content knowledge (TPACK).

Literature review

Mathematical problem posing

In mathematics education, the twin processes of problem solving and problem posing (PP) stand as cornerstone objectives. These intertwined activities, as highlighted by scholars such as Polya (1954) and Silver (1994), are not just educational goals but also pivotal methodologies. Mallart et al. (2018)

suggest that PP may serve as a complementary approach to problem-solving, enriching the overall learning experience.

PP encompasses a wide range of opportunities, such as creating a new mathematical problem or re-formulating given ones (Silver & Cai, 1996). This may be done by implementing inquiry strategies such as the "what if not" approach proposed by Brown and Walter (1983), which has been implemented and explored in various studies (Lavy, 2015; Segal et al., 2018; Silver & Cai, 1996). This technique encourages learners to modify given problems, fostering a deeper engagement with mathematical concepts.

Posing mathematical problems is a challenging task for teachers (Cai & Jiang, 2017; Chan, 2023; Lim et al., 2023), who often too closely follow the mathematics textbook. This shapes the tasks and examples they choose to present in class (Johansson, 2006; Lepik et al., 2015). As a result, they often fail to recognize the opportunities textbook tasks can provide for exploratory mathematical investigation. The results of a study by Mallart et al. (2018) emphasized the challenges teachers encounter when posing problems related to educational needs, such as a specific educational level or problems that enable students to realize the connection between mathematical content and their everyday lives. Often, teachers require support that provides opportunities to broaden their mathematical and pedagogical approaches to posing mathematical problems.

Cai and Rott (2024), based on a comprehensive review, proposed a four-phase model for PP processes, namely, orientation (understanding the PP task); connection (linking the mathematical concept and developing ideas); generation (creating the actual problems); and reflection (evaluating and refining the posed problem).

Utilizing generative AI (ChatGPT)

The advent of digital technologies, especially the emergence of artificial intelligence (AI) technology environments have yielded new opportunities to support teachers in their endeavors (Baidoo-Anu & Ansah, 2023). Although its integration into the education system is still in its early stages, it has now reached a point where AI can be effectively utilized as a lever to address specific challenges faced by both pre-service and in-service teachers, particularly in areas where teachers may struggle, such as in posing mathematical problems.

The recent emergence of generative AI (GenAI) has aroused special interest among the education community. GenAI is a type of AI technology that is capable of performing actions that usually require human intelligence, such as creating new content, producing images, and more (Baidoo-Anu & Ansah, 2023; Chan & Hu, 2023). ChatGPT is a form of GenAI that involves discourse between the computer and the human. It can serve as a "partner" and offer personalized and interactive learning. It can understand the meaning of basic prompts and collect available online information, analyze data (either provided or gathered), and generate texts with meaning (Deng & Lin, 2022; Kasneci et al., 2023). GenAI can provide personalized feedback and specific support for learning mathematical subjects or understanding complex content (Jia, 2015). It can facilitate solving various mathematical problems (Rane, 2023; Wardat et al., 2023).

Researchers estimate that ChatGPT, among other things, may affect traditional teaching methods (Rudolph et al., 2023). However, along with the advantages that come with integrating AI, teachers have also noted disadvantages in its use. For example, using AI may create an emotionless learning environment, may threaten the security and privacy of its users, and may make learners passive, thus preventing the development of inquisitive thinking (Lee et al., 2024).

Teacher's technological pedagogical content knowledge (TPACK)

The TPACK framework serves as a cornerstone for understanding the complexities of integrating technology into educational practices. As highlighted by Caniglia and Meadows (2018) and Nantschev et al. (2020), TPACK outlines the knowledge that teachers need to effectively incorporate technology into their teaching.

Building upon Shulman's (1986) work, Koehler and Mishra (2009) conceptualized TPACK as a synthesis of three primary knowledge domains: Technological Knowledge (TK), Pedagogical Knowledge (PK), and Content Knowledge (CK). The TPACK model implies that all three bodies of knowledge intersect at various levels of complexity. For example, Technological Content Knowledge (TCK) is the knowledge teachers need to use technology for presenting mathematical objects and complex mathematical processes. It requires employing varied representations of mathematical concepts to facilitate the development of their students' content knowledge. Technological Pedagogical Knowledge (TPK) is knowledge of how to use technology during teaching and learning, such as to foster inquiry-based learning (Jahangiri et al., 2021; Segal et al., 2021).

Research goal

This research focused on how integrating GenAI – specifically ChatGPT – for mathematical PP contributed to pre-service teachers' knowledge. The TPACK model was used as a lens by which to examine and describe the knowledge acquired by them. The research question we aimed to answer was the following: how does utilizing ChatGPT to pose mathematical problems with defined educational needs enhance pre-service high school mathematics teachers' TPACK?

Method

Participants

Fifteen pre-service high school mathematics teachers participated in this study. They were studying in a preparatory course entitled Teaching Advanced Secondary School Mathematics in a teachers' college. After several lessons in which they solved various mathematical problems, they underwent two sessions that focused on posing problems utilizing ChatGPT. During these lessons, the participants were asked to follow specific steps to compose and refine prompts for ChatGPT so that it would assist them in posing problems that would meet their educational needs.

Research tools

The study used a mixed method (combined quantitative and qualitative data collection and analysis) protocol (Creswell, 2014). During the two sessions, the researchers documented all stages of the problems and prompts that the teachers gave ChatGPT by integrating the links to the AI environment into a Google Form file that guided the teachers, step by step, through the process.

Following the two sessions, participants were asked to complete a two-part questionnaire that had been developed and validated by three mathematics education experts. Its purpose was to determine the pre-service teachers' experiences with GenAI and to explore its impact on their TPACK. The first section of the questionnaire included 10 Likert-scale statements, where participants rated their agreement from 1 (strongly disagree) to 5 (strongly agree) regarding their feelings about working with GenAI. The second section contained six open-ended questions designed to further elaborate on their responses from the first part and to provide deeper insights, particularly regarding the contribution of utilizing GenAI to their TPACK through PP.

Stages toward the problem-posing process using ChatGPT

During the two sessions, the teachers were required to employ ChatGPT for the process of writing a PP task. The process included the four main stages (based on Cai & Rott, 2024).

Stage 1: Orientation. The teacher poses a mathematics problem that is applicable for an advanced-level subject. The teacher lists the knowledge required to tackle the problem and the potential difficulties a student might confront while solving it.

Stage 2: Connection. The teacher defines their educational needs and formulates prompts for ChatGPT in order to receive recommendations for improving the problem.

Stage 3: Generation. The teacher considers the ideas received from ChatGPT and decides if and how they relate to their defined educational needs. The teacher decides which suggestions are suitable and reformulates the problem accordingly.

Stage 4: Reflection. The teacher identifies the benefits and challenges of using ChatGPT for the process of mathematics PP and decides whether to continue working with ChatGPT for another task.

Data Analysis

Quantitative and qualitative data were collected via the questionnaires, and additional qualitative data were obtained from the documentation. Quantitative data analysis (frequencies, means, and standard deviations) of the Likert-type statements allowed analyzing the contribution that ChatGPT made to the mathematics teachers' technological-pedagogical and mathematical knowledge, as perceived by them. To qualitatively analyze the data obtained from the teachers' responses to the open-ended questions, their responses were divided into "units of meaning" (from one word to a sentence or paragraph that focused on one idea), themes were identified and categorized using "constant comparative analysis" (Charmaz, 2014; Glaser & Strauss, 2017), and then the themes were divided into primary and secondary content areas. In the framework of this presentation, we offer part of the results based on the Questionnaire.

Results

First, we present an example of the four stages documented for one participant's process.

- Stage 1: Orientation. Problem posed: "Find a horizontal asymptote for the following function…"
- Stage 2: Connection. Educational need: "To improve the problem so that students better understand what a horizontal asymptote is."

- Stage 3: Generation. Participant's decision in accordance with ChatGPT's suggestion. “I am considering changing the formulation of the task to: Why does the function approach a certain value as *x* approaches positive or negative infinity?"
- Stage 4: Reflection. "ChatGPT helped me understand how changing the wording of the task can promote a deeper understanding of a mathematical concept."

Regarding the quantitative results, the mean and standard deviation of the participants' responses to the 10 statements in the questionnaire is presented in Figure 1 (Likert scale: 1, strongly disagree, to 5, strongly agree). The mean scores for all statements range from 3.20 to 3.93, that is moderate to high agreement, indicating that the teachers were satisfied using ChatGPT.

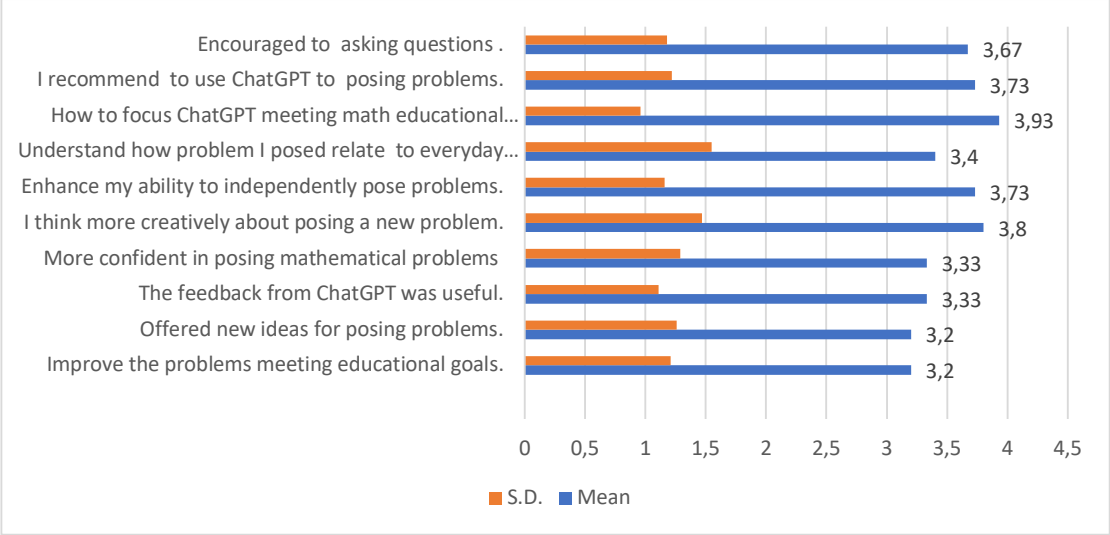

Figure 1. Chart showing mean (blue) and standard deviation (orange) of pre-service teachers' answers to the 10 closed statements on the questionnaire

The qualitative analysis of the open-ended questions revealed the five themes. The three with the highest frequency are presented below along with some sample statements. (The other two were challenges and limitations (n=6), and accessibility and efficiency (n=5))

(1) Exposure to new pedagogical ideas (n=10). “*ChatGPT gives new ideas such as how to connect mathematics to real life situations*”; “*ChatGPT helped me notice students' difficulties and formulate questions to help them, such as having them be more aware of the behavior of the function graph near its vertical asymptotes*” (TPK, TCK); “*ChatGPT offers ideas that promote deep understanding rather than procedures.*” (TCK)

(2) Develop critical thinking (n=8). “*ChatGPT suggests rich and varied opportunities to increase the challenge of a given task if appropriate for my students' abilities*” (TCK, TPK); “*ChatGPT gave me an incorrect answer related to function transformation, so I rejected that suggestion.*”

(3) Continued (future) implementation of ChatGPT (n=7). “*I will use ChatGPT to expand the repertoire of my pedagogical ideas*” (TPK); “*I intend to use ChatGPT to tailor existing textbook questions for students' daily situations because I believe it may increase their motivation.*” (TPK)

These qualitative findings, where teachers provided concrete examples of the benefits of ChatGPT, align with the quantitative data, as both indicate high satisfaction with ChatGPT. The teachers reported that the process gave them valuable pedagogical ideas and required critical thinking. They were encouraged to think about how to pose problems that were better related to their students and would be more interesting for them, whether by challenging them or by wording the questions to make the solution to the problems more accessible. All this provides strong evidence that ChatGPT enhanced pre-service teachers' TPACK.

Discussion

The results of this study indicate that the utilization of ChatGPT assisted the participants in posing mathematical problems according to their educational needs and provided a personalized and supportive environment where they could formulate prompts as much as needed. The pre-service teachers recognized the value of working with ChatGPT. These findings are consistent with the findings of Rane (2023) and Wardat et al. (2023), which showed that the personalized feedback the participants received from GenAI promoted their proficiency and capabilities in posing mathematical problems.

In addition, the results emphasized how the process of posing mathematical problems utilizing ChatGPT can serve as a lever to develop the pre-service teachers' TPACK as follows: they learned about an innovative technological environment that could aid in posing mathematics problems (TK); they were required to obtain in-depth familiarity with the problem they wished to pose for the chosen curriculum topic and to predict the difficulties that may arise in the process (PCK); their dialogue with ChatGPT helped them improve the clarity of the problem's wording (PK), deepen their mathematical understanding of the concepts by carefully examining the ChatGPT proposals and deciding if they were suitable for to their students and increase the relevance of mathematics by linking the problem to daily life (CK); they needed to formulate prompts that would generate problems that met their pedagogical needs (TPK); ChatGPT's answers led them to investigate whether all the mathematical data in a given task were required or if any mathematical data were missing (TCK); the process allowed them to expand their repertoire of mathematical tasks related to the curriculum and their mathematical needs (TCK).

In this paper, we explore differences in how KOM (Niss & Højgaard, 2019), computational thinking (Weintrop et al., 2016), and computational literacy (diSessa, 2018) frame teaching mathematics with computational technology. We find that a main difference lies in their perspectives on the disciplinary stability of mathematics when using computational technology, whether considered a tool, added disciplinary knowledge, or a re-mediating infrastructure. We conclude the paper with a discussion on the implications of these differences for teaching mathematics with technology in terms of the promotion of teaching activities pertinent to each framework.

Keywords: Computational literacy, computational thinking, mathematical competencies.

Introduction

Computational technology[1] has become increasingly ubiquitous in mathematics classrooms in Europe (Bocconi et al., 2022). While there is consensus of the benefits of using such technology in mathematics teaching, there are different perspectives on how and whether they bring changes to mathematics as we know it and what didactical work, they confront teachers of mathematics with. One view is that computational technology should be considered merely as a relevant tool to be mastered in subordination to mathematics it (e.g., Niss and Højgaard, 2019). Another view is that computational technology represents new knowledge from computer science that we should strive to incorporate as part of mathematics teaching in response to the increasingly digitalized world (e.g., Kallia et al., 2021; Weintrop et al., 2016). The work presented in this paper stems from ongoing research in a newly established National Centre for Digital Technology Comprehension in Denmark. Part of our research within this centre explores the interplay between computational technology and mathematics education from different theoretical positions. In this paper, we present a study on how the Danish KOM-framework[2] (Niss and Højgaard, 2019), computational thinking (CT) (Weintrop et al., 2016), and computational literacy (CL) (diSessa, 2018) frame the relation between computational

[1] In this paper, we rely on Weintrop et al.'s (2016) description of computational technology as referring to graphical programming environments, computational modelling environments and electronic prototyping kits.

[2] KOM is short for "kompetencer og matematiklæring", which translates into competencies and mathematics learning.

technology and mathematics teaching. While each of the frameworks has had a significant impact in discussions in mathematics education, most of the debate has concerned what is relevant for students to *learn* rather than new requirements of how to *teach* mathematics. Our paper contributes by providing such an overview, which we seek to develop by addressing the following research question: *What are the differences in how KOM, CT, and CL frame teaching mathematics with computational technology?*

In what follows, we provide a brief overview of research related to our work in answering this question.

Related work

The potential of computational technology in mathematics teaching can be traced back to Papert's (1980) influential book *Mindstorms*. Papert (1980) proposed that intuitive programming environments can make otherwise abstract mathematical ideas more accessible and tangible for students. As an alternative to interact with geometry through Euclidian notation, Papert and colleagues developed a "Turtle Geometry", where students could navigate a robot via a programming language similar to natural language to explore mathematical concepts. Although widely spread from 1980 and well into the 1990's, Papert's (1980) ideas never led to sustaining curriculum policy revisions and slowly received less and less attention. In the beginning of the millennium, Wing (2006) revitalized the term CT, and sparked an agenda that since has resulted in a momentum in research and curriculum revisions. In Europe, 25 countries have embedded CT in the compulsory school curriculum (Bocconi et al., 2022). Researchers in mathematics education have been highly active in embracing this term and explored potentials of programming environments (e.g., Scratch) to scaffold students' learning (Benton et al., 2018). Moreover, CT has led to fundamental discussions on the relation between computational technology and the discipline of mathematics. The increased interest in CT has led to myriad definitions in the context of mathematics teaching, each of which comes with different viewpoints of how to consider the relation between computational technology and mathematics education. It is these differences among CT, CL, and KOM and their implications for mathematics teaching, we study in this paper. Below, we briefly outline these three perspectives.

Three takes on the relation between technology and mathematics: Competencies, practices, and literacy

Mathematical competencies

The KOM framework was introduced in 2002 and developed "the concepts of mathematical competence and mathematical competencies with particular regard to their possible roles in the teaching and learning of mathematics" (Niss and Højgaard, 2019, p. 10). KOM primarily consists of the description of eight mathematical competencies. Niss and Højgaard (2019) describe the mathematical competencies as an alternative to a traditional focus on curriculum content and as a framework that can be applied both descriptively and normatively. While technology plays a role in e.g., the tools and aids competency, no explicit attention is devoted to computational technology. Moreover, as indicated by the name, the aids and tools competency primarily describes technology as *tools* that are part of a mathematical activity that students either carry out or in other ways relate

to. KOM however includes an outline of mathematical competencies for teaching (Niss and Højgaard, 2002), which consists of a characteristic, didactical and pedagogical comments and examples. With respect to teachers' competencies for the tools and aids competency, Niss and Højgaard (2002) stress that they must master a broad spectrum of available and relevant tools and aids to those that fit for a particular group of students. Moreover, they describe how teachers should be able to identify didactical potentials of new aids and use them to initiate or furthers students' learning. Since KOM is a widely used framework and has been used in studies on computational technology (e.g., Bråting et al. 2022), we regard it as a relevant perspective to include in our study.

Computational thinking

CT was introduced by Papert (1980) and revitalized by Wing (2006) in an influential paper in which she argued that "thinking like a computer scientist" is a strength in all knowledge domains (Wing, 2006, p. 34). In the past decade, research on CT in mathematics education contexts has grown rapidly and led to several definitions (e.g., Kallia et al., 2021; Weintrop et. al., 2016). For this paper, we rely on Weintrop et al.'s (2016) definition. This definition features four main practices—data practices, modelling and simulation practices, computational problem-handling practices, and systems thinking practices. Each practice includes five to seven taxonomic levels built from existing literature, educational activities, curriculum documents from the United States, and interviews with mathematicians and scientists. They argue that the taxonomy provides a set of actionable guidelines for teachers to follow when introducing CT to mathematics education as well as a shared language for teachers to better understand and systematically develop their teaching practices. As described, the taxonomy consists of *practices* (what students should *do*), which mirror the practices employed by researchers and scientists. The work by Weintrop et al. (2016) mainly characterize these practices as being distinct from, but relevant for, other practices or content taught within mathematics education. We chose this framework due to its wide adoption in mathematics education research.

Computational literacy

diSessa (2000) defines a literacy as "a social widespread patterned deployment of skills and capabilities in a context of material support (...) to achieve valued intellectual ends" (diSessa, 2000, p. 19). diSessa stresses that computational literacy "do[es] not mean a casual familiarity with a machine that computes" (diSessa, 2000, p. 5). Rather, computational technologies are thought to lead to a new literacy as we adopt "a particular infrastructural representational form for supporting intellectual activities" (diSessa, 2018, p. 4). Computational literacy involves four "R's":1) re-mediation, 2) reformulation, 3) reorganizing the intellectual terrain, and 4) revitalizing the ecology of learning activities (diSessa, 2018). *Re-mediation* concerns that the implementation of computational technologies in classrooms involves new representation forms. *Reformulation* is considered an important human intellectual resource due to "the possibility of substantial changes in what, when, and how we teach subject matter" (diSessa, 2018, p. 26). *Reorganization* concerns that teaching mathematics will change due to cultural changes in our society, requiring rethinking teaching and learning mathematics – not simply using/adding computers. *Revitalization* regards awareness of the activities within the classrooms to ensure that teaching and learning in mathematics remains relevant and authentic considering the newly implemented computational technology.

Theoretical approach and method

Our analysis of how the above frameworks above frame mathematics teaching follows ideas proposed by Popkewitz (1984). For Popkewitz (1984), theories in educational research are conceptual lenses that enable researchers to think about empirical phenomena that otherwise seem difficult to grasp. The choice of theory to study such phenomena implies that the line of inquiry is based on epistemological assumptions and values, leading to specific analytical outcomes (Popkewitz, 1984). *Epistemological assumptions* concern questions regarding the type of social phenomena that the conceptual lens orients the researcher towards, and what explanations of the phenomena it offers. *Values* regard questions of what rationale for change the lens proposes. *Nature of outcome of analysis* concerns how the conceptual lens suggests resolving emerging questions, and what the answers to these questions imply for professionals to do (Popkewitz, 1984). A central point for Popkewitz (1984) is that to grasp differences among conceptual lenses, we must scrutinize their differences along the three aspects mentioned above. To operationalize Popkewitz's (1984) ideas, we structure our analysis of KOM, CT and CL by the following three questions:

1. *Epistemological assumptions:* What ways of understanding and explaining mathematical learning and teaching do the lenses orient the researcher towards?
2. *Value of computational tools:* Which rationales do the conceptual lenses present for why mathematics teaching should include digital technology in relation to new computational tools, and what direction are given to accommodate this?
3. *Analytical outcome*: Which approaches do the conceptual lenses propose to resolve the questions brought by the emergence of computational technologies?

According to Popkewitz's (1984), co-existing traditions are vividly engaged in discussions about defining the adequate approaches to study a given phenomenon. Until this point, it is however our not our impression that sufficient attention has been devoted to discussing how to teach mathematics with computational technology. It is this discussion we wish to open with our paper. Our choice to focus on CL, KOM, and CT reflects that these lenses are internationally influential and yet offer highly different starting points for research on teaching mathematics with computational technology.

Results

Epistemological assumptions

KOM explicitly considers mathematical learning as a cognitive process (Niss and Højgaard, 2019), bound by a conception of what it means to master the eight mathematical competencies. KOM describes the eight competencies to be of a general and stable nature that, as such, not are affected by emerging tools. The eight competencies thus regard how we access and interact with mathematics, e.g., *through* tools, representations, reasoning, etc. KOM's *aids and tools competency* is particularly devoted to the role of the materials through which we engage with mathematics, here among digital technology. This competency concerns the ability to put aids and tools to "constructive use in mathematical work, as well as to critically relate to one's own and others' use of such aids and tools" (Niss and Højgaard, 2019, p. 18). Aids and tools are thus considered instruments for interacting with an otherwise stable discipline, which fundamentally remains unaffected by whatever tools we deploy.

Moreover, the competency of mastering this technology is largely described from a standpoint where mathematics is regarded as stable. The role of computational technology is considered like any other tool, e.g., a ruler or a calculator. Hence, computational technology is considered a tool to interact with mathematics. The few indications given on teachers' roles in students' development of competencies primarily stress the pedagogical potentials of tools and aids, and that teachers should master a broad spectrum of tools and aids to select those appropriate to further or initiate student learning of particular competencies or subject matter (Niss and Højgaard, 2002). This reflects the view described above, where the value of tools and aids mainly are ascribed to their potentials of supporting students' acquisition of stable mathematical competencies and subject matter areas.

Weintrop et al. (2016) discusses mathematical learning with a primary emphasis on what new practices students should learn. They argue that the role of computational technology in scientific contexts has led to an urgency to define CT "(...) and providing a theoretical grounding for what form it should take in school science and mathematics classrooms" (Weintrop et al., 2016, p. 127). Thus, their approach to CT regards what *could* be taught. They describe their taxonomy as an inspiration for possible content and not as a normative framework as such. Moreover, Weintrop et al. (2016) describe learning of computation and mathematics as reciprocal in that they each provide tools and contexts for learning the other. Here, their study thus foregrounds a content-perspective on *what* knowledge students should have rather than the cognitive process of acquiring mathematics. Moreover, Weintrop et al. (2016) subscribe to an ideal of congruence where what is taught should align with what is practiced in industry and research. Implicitly, the disciplinary nature of mathematics and the content it consists of are therefore considered constantly evolving, particularly as computational technology is widely used in the contexts surrounding schools.

Whereas KOM and CT ascribe importance to cognition and content respectively, CL is characterized by focusing on representation. diSessa (2018) argues that representations to be considered highly significant—and ultimately transformative—infrastructures, and that new infrastructures imply a change in the disciplinary core of mathematics. In diSessa's view (2018), disciplinary knowledge and (representational) infrastructure are thus inseparable, and the emergence of new tools implies both attention to mastering these tools and the transformative nature of the discipline in which they are used. Hence, literacies (including mathematical literacy) are to some extend in flux. As opposed to KOM (Niss and Højgaard, 2019) and CT (Weintrop et al., 2016), diSessa's (2018) perspective implies that mathematical learning in the context of computational technology should not be reduced to neither content nor tool, but should reflect their reciprocal and transformative relation.

Value of computational technology

In KOM, technologies are mainly seen as tools for mathematics' sake, and secondly as tools which usage can be orchestrated by teachers to support student learning. Students need to build competencies with the purpose of assessing limitations and affordances of specific tools and to reflectively make use of such tools within mathematical activities. Computational technologies are not assigned particular significance in KOM but are included in the aids and tools competency in juxtaposition to other tools. Mathematics represents a domain of knowledge that allows a particular approach to model the surrounding world. Computational technologies are thus considered new

contexts in which mathematical competencies may be exercised and not tools that influence the nature of mathematical mastery. However, new emerging tools may confront users with new knowledge of such tools and artefacts in their assessment of when, how, and for what purposes to use computational technology. In the parts of KOM (Niss and Højgaard, 2002) on the role on teachers in building students' competency, they argue that teachers need proficiency in the tools and aids they use in their teaching. Here, technology is predominantly described as pedagogical tools that can initiate and further students' learning – not as an occasion to reconsider the disciplinary core of mathematics.

In CT, computational technologies are thought of as a key to achieve economic and intellectual growth, why we need to address them in teaching. Weintrop et al. (2016) specify this as two interconnected values. First, computational tools represent "powerful tools for understanding phenomena across all spectra of human inquiry" (Weintrop et al., 2016, p. 131), particularly in STEM subjects. Thus, integrating computational technologies into mathematics teaching will give "learners a more realistic view of what these fields [science and mathematics] are, [which] better prepares students for pursuing careers in these disciplines" (p. 128). Second, Weintrop et al. (2016) argue that "the thoughtful use of computational technologies and skillsets can deepen learning of mathematics and science content" (p. 128), especially by providing authentic contexts. Thereby, the value of computational technologies in mathematics teaching adds to *what* students learn, and the value provides authentic *contexts* where mathematics has relevant applications. Primarily, these values are determined from considerations of how mathematics education can maintain, and perhaps increase, its relevant role in preparing students to contribute to an effective and competitive workforce.

In CL, computational technologies are thought of as interconnected in our interaction with science and mathematics. Computational technologies are not described as external to mathematics, but as infrastructure that redefines what mathematics and mathematical practices are. Computational technologies thus imply a demand to constantly pay attention to how they change our understanding of mathematics and what is appropriate to teach students. In diSessa's (2018) view, education and literacy are committed to developing mastery in relation to the most powerful intellectual infrastructures that humankind develops. When these infrastructures change, so does (or, at least, should) teaching. In this way, the CL perspective implies that computational technology is considered a bearer of values to potentially constructively develop societies. However, CL rather provides a framework for *relating to* and *analysing* the infrastructural transformations of technology, including the values added, rather than generically specifying the exact nature of these values.

Analytical outcome

KOM analyses typically focus on students' cognitive mastery of mathematics, either in terms of the extent to which they have activated certain competencies, or how to design teaching that will enable students' acquisition of a competency. Relating to computational technology from a KOM point of view will likely lead to an outcome of an analysis of what it means to master or how to enable the acquisition of one of the mathematical competencies. As the competencies are considered stable, the outcome of analyses will regard computational technology as *means* to, e.g., represent, communicate, or engage with mathematics without altering the core of the competencies. From a teaching perspective, the KOM-framework can be used for various purposes, including to diagnose students

learning of mathematics or to plan, orchestrate and evaluate teaching (Niss and Højgaard, 2019). The premise is however still that the mathematics to be learned remains unaffected by new tools.

With regards to analytical outcome, CT offers framework to make informed choices about which new computational thinking practices to add to mathematics teaching to align with needs from the industry. Contrary to KOM, CT practices originate from outside a purely mathematical discipline. This implies that an analytical outcome of such a perspective will concern interdisciplinary configurations between an existing mathematical discipline and an external computational discipline.

Where KOM and CT offer perspectives that aids specifying cognitive mastery of mathematical competencies and CT practices, diSessa's (2018) perspective implies a more radical view of the two disciplines as being in flux. Consequently, an analysis following diSessa's (2018) four R's will lead to a new understanding of how a specific computational technology re-mediates intellectual activity, reformulates subject matter, reorganizes intellectual terrain, and revitalizes the ecology of learning activities. The outcome of such analyses will thus be technology-dependent and apply to a specific infrastructure. When new technologies emerge, new analyses are needed to adequately understand the implications for our understanding of what mathematics what it means to master mathematics.

Discussion and conclusion

As evident from the analysis section above, there are notable differences among KOM, CT, and CL in their epistemological assumptions, the value ascribed to computational technologies, and the nature of the analytical outcome they afford. In KOM, the task of mathematics teachers lies in which computational technologies to consider relevant within their current understanding of mathematics as a discipline. While this becomes increasingly different as the complexity of computational technologies increases, teachers can rely on their mathematical proficiency and knowledge of the curricular content. CT brings a different task for mathematics teachers, as CT practices are described as extra-mathematical disciplinary knowledge, for which room should be made in mathematics education. Teachers are thus confronted with a task of selecting practices from the CT-taxonomy to incorporate and to consider how such new practices should relate to existing components of the mathematics curriculum. This is a challenge since most mathematics teachers do not have proficiency in computer science practices. By far, CL however represents the most radical viewpoint and its associated implications for mathematics teaching. This perspective implies that teachers not only are faced by having to relate to new technology but to analyse the reciprocal, infrastructurally transformative relation between discipline and tool. In KOM, the mathematical discipline is stable, and so are the mathematical competencies. What is in flux is the aids and tools used. In CT, mathematics is described as needing to expand its disciplinary demarcation lines, and Weintrop et al. (2016) contribute by specifying what is relevant to add. However, the perspective described in CL leaves open which tools to assign significant potential to transform mathematics and ultimately society, and to provide a framework to engage with these questions. Albeit it might be timely to welcome computational technology in mathematics education, decisions to do so require careful consideration of the implications for mathematics education and mathematics teaching. It is our hope that this paper has brought an initial foundation, which future studies can continue to elaborate.

Investigation of the use of AI as a scaffolding tool during mathematical discussion in geometry problem-solving

Serdem Yavuz and Ayşe Tekin Dede

Dokuz Eylül University, Faculty of Education, İzmir, Türkiye; serdemyavuz17@gmail.com

This study aims to investigate using ChatGPT as a scaffolding tool for pre-service mathematics teachers while solving a GeoGebra-based geometry problem. In this case study design, two volunteer pre-service mathematics teachers worked on a problem whose solution was not provided directly by ChatGPT. The data consisted of GeoGebra solution files, ChatGPT screen recordings, transcriptions of task-based and post-implementation interviews, and researchers' observation notes. As a result of the data analysis, the participants benefited from ChatGPT with the aim of guidance, questioning, feedback, and cognitive challenge in the context of scaffolding components. Although ChatGPT scaffolded the participants during problem-solving, the fact that they were too dependent on ChatGPT and wanted ready-made solutions prevented them from reflecting on their reasoning for the solution.

Keywords: ChatGPT, GeoGebra, geometry, scaffolding.

Introduction

Studies emphasize that digital tools are critical in deepening students' conceptual understanding and developing their problem-solving skills, increasing their risk-taking tendencies, and enabling them to try new strategies (Mohamed et al., 2022; van de Pol et al., 2018). Among these tools, artificial intelligence (AI) stands out for its ability to personalize learning experiences, provide instant feedback, and encourage students to explore new learning strategies. In recent years, the increasing role of AI in education has also brought along discussions that AI can completely replace teachers. While AI-based learning tools provide significant advantages to students by providing personalized guidance, feedback, and support for students to learn individually (Mohamed et al., 2022; Zawacki-Richter et al., 2019), the reduction of teacher-student interaction can create some challenges in terms of social and emotional learning. Within the scope of these discussions, the rationale for this study lies in exploring how ChatGPT, an AI tool, can influence students' learning processes while addressing how to establish scaffolding to balance between technological support and AI-student connection. This study aims to investigate using ChatGPT as a scaffolding tool while solving a GeoGebra-based geometry problem by pre-service middle school mathematics teachers.

Theoretical background

Vygotsky (1978) explains the Zone of Proximal Development (ZPD) as tasks that an individual cannot do independently but can accomplish with the help of a guide or a more competent individual. Wells (1999) defines scaffolding as "Vygotsky's concept of working in the ZPD as the basis for making learning effective" (p. 127) and emphasizes the importance of the scaffolding function of the tools used in this process. Providing these supports, especially in discussion processes during problem-solving in small groups, not only helps individuals to progress in ZPD but also contributes to a more effective and more profound learning experience in the small groups. The support provided

by teachers during small group work also comes to the fore, and various studies (e.g., van de Pol et al., 2018) show that teachers sometimes have difficulties supporting small groups during mathematical discussions. Calor et al. (2022) developed a tool for teachers to support small group mathematics discussions and thus focused on explaining mathematics teachers' scaffolding processes with five key dimensions: Guidance, Questioning, Feedback, Cognitive Challenge, and Fading Support.

While AI tools have shown promise in education, studies also highlight gaps, particularly in their application for problem-solving in mathematics (Zawacki-Richter et al., 2019). This underscores the need to explore how AI can effectively support mathematical discussions during problem-solving in small groups. This study aims to investigate the support provided by ChatGPT to students during small group mathematical discussions with the teacher in the background. In this direction, the aim is to examine the use of ChatGPT as a scaffolding tool for pre-service middle school mathematics teachers (PMTs) to solve a GeoGebra-based geometry problem. A literature review reveals that AI tools take center stage in most studies, primarily analyzing AI-generated responses (e.g., Gurl et al., 2024; McGalliard & Otten, 2024). However, no study has been conducted in which an AI tool is used as a supportive resource that participants can consult when needed, emphasising the nature of the support provided by the tool. Therefore, studies examining teacher support during mathematical discussions conducted in group settings were reviewed to conceptualize AI support. Among these studies, the dimensions of scaffolding in the framework of Calor et al. (2022) were adapted to examine the support provided by ChatGPT: Guidance refers to ChatGPT helping PMTs focus on the correct information and strategies. Questioning involves providing PMTs with strategies that encourage them to deepen their thoughts and ideas. Feedback refers to ChatGPT offering feedback and hints to help PMTs improve their work. Cognitive Challenge entails ChatGPT challenging PMTs in a way that fosters the development of more complex thinking skills. Fading Support is the gradual reduction of the support PMTs receive from ChatGPT over time. In this context, the following research question guided the study: How do PMTs use ChatGPT as a scaffolding tool to guide them in solving a GeoGebra-based geometry problem?

Methods

In this study, we adapted the case study design (Creswell, 2007). The participants were two PMTs (PMT1 and PMT2) studying in a state university's third year of the Department of Elementary Mathematics Teacher Education. The participants were selected based on criteria such as having a good level of proficiency in using GeoGebra, actively using ChatGPT, having a Cumulative Grade Point Average (CGPA) of at least 3.00, and volunteering in the study. The identities and information of the participants were kept confidential. To determine the PMTs' use of ChatGPT as a scaffolding tool, we conducted a task-based interview during the solution process of the Ship Problem (Yazıcı, 2022). The Ship Problem is as follows: "Suppose you are on the shore of an island. You see a ship anchored some distance from the shore. You want to swim towards the ship because you need food. You know from experience that you can swim at most 600 meters at sea. You want to swim towards the ship but can't estimate how far away you are. There is only one question running through your mind. Is the distance to the ship more or less than 600 meters?"

The reasons why we chose the Ship Problem were that ChatGPT did not give the problem solution directly and that the problem could be solved using GeoGebra. During the task-based interview, we asked questions such as “Can you explain what you did here?” and “Why did you think this way?” to encourage students to articulate their explanations and think aloud. After the task-based interview, we conducted a post-implementation evaluation interview to evaluate the PMTs’ experiences of using ChatGPT by asking questions such as “How did ChatGPT influence your thinking process?” and “Based on your experience in this implementation, what are your thoughts on the use of ChatGPT during teaching process?”. The video recordings of the task-based interview were transcribed and supported by the researcher’s observation notes. The transcripts and observation notes constituted the primary data source of the study. The transcript of the evaluation interview was used as a secondary data source to support the primary data. The collected data were analyzed by integrating ChatGPT screen recordings and GeoGebra files. The researchers analyzed all data to examine the PMTs’ use of ChatGPT as a scaffolding tool using the framework of Calor et al. (2022). Approximately one month after the data analysis, two researchers reviewed the coding and compared the codes. The data analysis process was completed by examining different situations in depth. In this way, the reliability of the data analysis was attempted to be ensured.

Findings

After reading the problem, the PMTs copied the problem text directly into the ChatGPT. The PMT1 explained the reason for this action: “I mean, for example, in the beginning, not every student knows what to start with and how to proceed...”. Since ChatGPT presented a solution method, including physics, the PMTs could not use it. “As I already said, when you type the problem directly, it transfers it to other paths. It takes the friction force... without these, the problem cannot be solved.” (PMT1, 280). Then, the PMTs reduced the problem text to simplify the solution path and avoid unnecessary complexity due to the other discipline. These actions in the Guidance dimension enabled the PMTs to eliminate unnecessary information in the problem. After that, the PMTs asked ChatGPT to model the situation and discussed the steps of the presented mathematical model, including inequalities. “We can use a simple geometric approach to model the ship’s distance. Let’s represent the distance to the ship as x. If the distance to the ship is less than 600 meters, x<600, and if it is more than 600 meters, x>600”. In fact, ChatGPT replied, “We can use triangle similarities to model this situation.” but they only focused on the numerical values in the answer. They constructed sliders and the line segments in Figure 1. However, since they could not connect these sliders to anything, they needed ChatGPT support again and constructed a right triangle in Figure 1 in line with the suggestions by typing the prompt “How can we show it on GeoGebra?”.

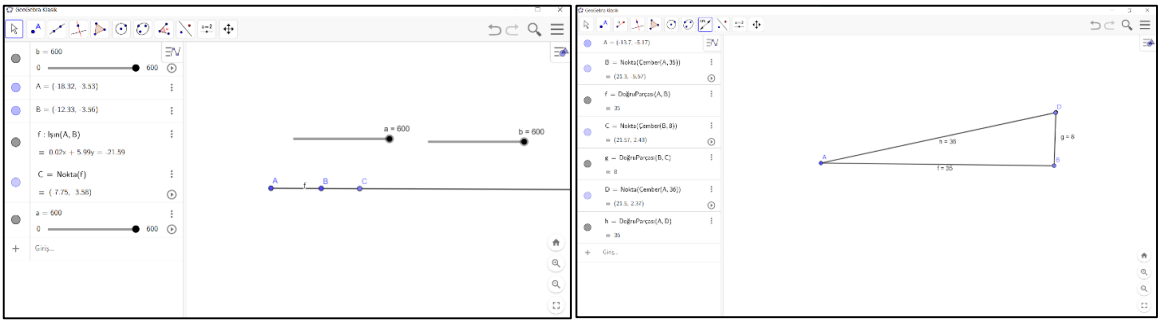

Figure 1: Initial attempts on GeoGebra

Although they followed the instructions, they did not know how to evaluate the triangle they drew, so they decided to proceed by asking ChatGPT, "If the distance from point A to point B is 600 maximum meters, is the distance from point B more or less than 600 meters?" and "How can we show it by using the slider". At this stage, the PMTs deepened their thinking within the Questioning dimension. They tried to interpret distances with the slider they constructed to assess whether the swimmer could reach the ship. Since they did not think that the swimmer had to turn back and they had to take the man's height into account as per ChatGPT instructions, they considered the man as a point (see Point A in Figure 1.b). So, their approach was unsolvable, and they fell into a Cognitive Challenge.

The PMTs realized they could not solve the problem by following ChatGPT instructions. As a result, they revisited the responses from the chat records and attempted to revise the problem text ("If 600 maximum meters can be traveled from point A to point B, is the distance to point B more or less than 600 meters?") using their reasoning in the context of the Questioning dimension. During their drawings, the researcher summarized what was done and provided scaffolding to the PMTs with the question, "So why did you take the man as a dot?" and the PMT2 explained their approach as "We did it from the direct viewpoint, and there should have been a height underneath. There is indeed a height there.". Therefore, they realized that the mathematical model they had constructed was invalid and decided to move to a different solution strategy, as follows:

PMT1: We will draw a line. We'll just draw a line to this point L and extend it to the line. I get it now.
PMT2: We'll set up a certain ratio based on the man's height.

Both ChatGPT chat records and the researcher's scaffolding enabled the PMTs to provide Feedback and an opportunity to evaluate the outcomes of their decisions and learn from these results.

The PMTs decided that they needed to construct a certain ratio based on the man's height and asked ChatGPT, "If we take into account the height of the man in the third answer you gave us, how can we construct a similarity relationship from there?" referring to the ChatGPT statement previously recommending the use of sliders. ChatGPT proposed a solution that included the use of the average height of a man: If we subtract the man's height (1.80 meters) from the distance from point A to point B (600 - 1.80 = 598.20 meters), we get the length of the hypotenuse of the second triangle. That is, if the distance to 600 meters is longer than 598.20 meters, it will have to exceed the swimming distance to reach the ship. To model this situation in GeoGebra, we can construct a triangle containing the distance from point A to point B and the man's height. Then, we can create a triangle containing the distance from point A to point B and 600 meters. We can find that these two triangles are similar and find the similarity ratio of the triangles. If the similarity ratio is less than 1, he must overcome the swimming distance to reach the ship.

They modelled the similarity relation by redrawing the mathematical model they constructed in GeoGebra (see Figure 2) following the steps provided by ChatGPT. They tested the model by moving the slider to change the man's height.

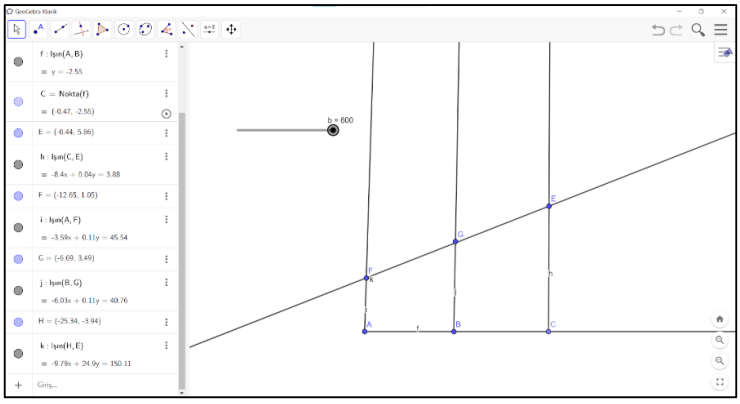

Figure 2: Final model regarding problem solution on GeoGebra

Having difficulty interpreting the meaning of the model, the PMTs again asked ChatGPT to find the similarity ratio to give a direct interpretation of the model they had constructed in GeoGebra. At this stage, it was observed that the PMTs wanted to reach a direct numerical value that was ready for problem-solving. In line with the response they received from ChatGPT, the PMTs said, "In case the similarity ratio is less than 1, it needs to reach the swimming distance to reach the ship. So, by looking at the |IF|/|HD| ratio, we get that if it is less than 1, it will reach, and if it is greater than 1, it will not reach.". Although the PMTs did not solve the problem, they thought they had concluded the solution process, and they presented their solution to the researchers for verification and tried to explain their reasoning. When asked why they could not solve the problem, the PMT2 said:

PMT2: I shut myself off from all my perspectives. Maybe if I had thought about it, I would have been able to find the height of the man and the ratio. I mean, although it [ChatGPT] is really very guiding in that regard, it always directed us toward a single perspective. So, it prevents me from seeing different things. When I looked at it, I ruled out my thoughts.

During the problem-solving process, the focus was on the dimensions of Guidance, Questioning, Cognitive Challenge, and Feedback in the context of the scaffolding purpose of the ChatGPT. Since the PMTs were so dependent on ChatGPT, they did not exhibit any approach in the context of the Fading Support dimension. The PMTs generally gave too much responsibility to ChatGPT and put their reasoning on the back. At the end of the problem-solving process, they were asked to interpret the influence of ChatGPT on their thinking process. The PMT1 explained their thoughts: "There were advantages and disadvantages. It was good for us to be available anytime and get short feedback. But not all answers were correct. There were stages where it led us to physics. For example, it takes the currents, wind, and wave conditions. I don't know what else happens in daily life... Since we try to solve the problem as if these realistic conditions do not exist, the steps it gives may confuse me. Someone may interpret the ChatGPT with the logic that the problem cannot be solved without them. But the prompts we enter in ChatGPT are also very important here. For example, if we had formulated appropriate prompts after interpreting the given instructions mathematically, we would have obtained more accurate answers." The PMT1 evaluated ChatGPT as a tool that provided accessible and quick feedback. However, she highlighted that the instructions given by ChatGPT were not always correct

and that the user needed to filter these answers. When the PMTs were asked about their views on the use of ChatGPT during instruction, the following responses were obtained:

PMT1: The teacher's responses in class are guiding and definitively correct. ChatGPT is also guiding, especially when we are limited by time, encounter a problem, or need immediate support. However, we must filter our thoughts through a certain reasoning process when writing prompts.

PMT2: I didn't think of a different point of view... Because I completely trusted what it said and did not think of such a possibility… While ChatGPT helped us progress to a certain extent in solving the problem, it was through your guidance that we became aware of the ideas we had neglected. This highlighted, for me, the significance of teacher support.

An analysis of these views reveals that the PMTs found ChatGPT helpful in terms of support but indicated that it would not be sufficient on its own, emphasizing the reliability of teacher guidance.

Discussion and conclusion

Calor et al.'s (2022) theoretical framework emphasizes the critical importance of scaffolding strategies in pre-service teachers' mathematical discussion. However, some studies advocating using AI tools and technological support in education offer an alternative perspective to these traditional guidance approaches. For example, Luckin et al. (2016) argue that AI-supported educational tools offer personalized support based on students' individual learning needs and thus can be more effective than teacher guidance. However, our study demonstrated that ChatGPT cannot surpass or substitute teacher support. We can conclude that ChatGPT has the potential to enhance education and student learning; however, it is essential to use it as a complementary tool in support of human teachers (Wardat et al., 2023).

This study has contributed to the current literature by examining the scaffolding dimensions in the problem-solving process with an AI tool. Within the framework of the Guidance dimension, the PMTs consistently aimed to reduce and simplify the problem text during the process. Although they obtained progressively more reasonable responses from ChatGPT, they could not effectively utilize them, as they did not engage in critical reflection or interpret them through their reasoning processes. In other words, the PMTs' resorting to copy-paste strategies without adequate interpretation caused them to fail in problem-solving. The Questioning dimension played a crucial role by encouraging the PMTs to think critically, reflect on their prior knowledge, and explore new avenues for solutions, as outlined in Calor et al. (2022). But they still concentrated on ready-made answers or solutions. The Cognitive Challenge dimension became evident when the PMTs recognized that the solutions they applied based on ChatGPT's instructions were invalid. This was a result of their direct reliance on ChatGPT. Similarly, Opesemowo and Ndlovu (2024) highlight that overreliance on AI technologies prevents students' problem-solving skills. Consequently, the PMTs required researcher support. The Feedback dimension (Calor et al., 2022) was focused on the hints provided by ChatGPT. Although the PMTs received appropriate feedback from ChatGPT when they engaged in their thinking to create correct prompts, they could not adequately assess this feedback due to insufficient interpretation in other dimensions. The Fading Support dimension was not applied as suggested by van de Pol et al. (2018). This situation reveals the importance of gradually reducing guidance. AI cannot provide the dynamic support the teacher molds to the student's learning needs; therefore, it cannot be an efficient

learning guide. Therefore, although AI tools complement guidance, human guidance is critical, especially in mathematical discussions (Neogrády-Kiss et al., 2023).

In conclusion, technological tools and teacher guidance should be used strategically to help students develop independent thinking skills. Future studies can be conducted with the recognition that ChatGPT alone will not be sufficient to support the instructional process. In these studies, it is recommended that a limitation be imposed beforehand to examine ChatGPT's support in the problem-solving process and that these limitations continue to be applied once they are input as prompts. This approach would allow for in-depth analyses, enabling the evaluation of participants' utilization of ChatGPT from different perspectives.

A pre-service mathematics teacher's digital resource design capacity

Melike Yiğit Koyunkaya [1] and Gülay Bozkurt [2]

[1] Dokuz Eylül University, Faculty of Education, İzmir, Türkiye; melike.koyunkaya@deu.edu.tr

[2] İzmir Demokrasi University, Faculty of Education, İzmir, Türkiye

This study examines a pre-service mathematics teacher's (PMT) design capacity based on designing and implementing a technology-based task focusing on the objective of subtraction in fractions with unlike denominators through a ratio word problem. The recently developed Digital Resource Design Capacity framework provided the conceptual foundation of the study. This case study was conducted in the context of a practicum course in a mathematics teacher education programme in Türkiye. The data included the PMT's planning of a technology-based task and audio recordings of pre- and post-lesson interviews and classroom teaching. The results showed that the PMT planned detailed and sequential questions/prompts to teach the topic and utilised the affordances of GeoGebra, particularly the role of different sliders, which enabled her to support students' inputs and explorations in the classroom.

Keywords: Teacher design capacity, digital resource, pre-service mathematics teacher.

Introduction

In the evolving landscape of mathematics education, integrating technology into teacher education programs has become increasingly crucial. Pre-service mathematics teachers (PMTs) must develop both a deep understanding of mathematical content and the ability to effectively incorporate technological tools into their teaching practice (McCulloch et al., 2021). Effective integration involves not only familiarising PMTs with a range of technological tools but also fostering their ability to critically evaluate and select appropriate tools based on pedagogical goals (Clark-Wilson et al., 2023). Practicum courses, serving as a critical bridge between theoretical knowledge and practical application, offer opportunities for PMTs to evaluate the affordances of digital resources based on curriculum needs and to make decisions about how to use them efficiently (McCulloch et al., 2021). As teacher educators and mathematics education researchers, our long-term aim has been to develop PMTs' professional knowledge and experience regarding the successful integration of digital technologies (Bozkurt & Yiğit Koyunkaya, 2022). Our professional development (PD) ideas focused on orienting and conceptualising the PMTs' lesson planning and classroom practices allowing them to critically interact with digital resources throughout the practicum course and enabling them to make connections between planning and implementation (Bozkurt & Yiğit Koyunkaya, 2022). Effective use of technology requires more than just familiarity with tools; it involves the ability to design and adapt digital resources and activities that support curricular goals (Clark-Wilson et al., 2023; Trgalová & Tabach, 2024). PD and collaborative planning are essential for teachers to build and sustain their design capacity, allowing them to continuously innovate and refine their use of technology in the classroom (Pepin et al., 2017). Hence, we focus on PMTs' design capacity, particularly with the use of digital technology,

in the context of a practicum course. This study potentially contributes to mathematics teacher education by shedding light on how one PMT navigates design decisions when planning and implementing a technology-based task during a practicum course.

Theoretical framework

According to Pepin, Gueudet, and Trouche (2017), the process by which mathematics teachers engage with digital resources significantly influences their ability to design and implement effective instructional materials. The authors highlighted that teachers' interactions with these resources—encompassing their selection, adaptation, and integration—play a critical role in enhancing their design capacity. Recently, Trgalová and Tabach (2024) developed the Digital Resource Design Capacity (DRDC) framework by considering mainly Pepin et al.'s (2017) teacher design capacity conceptualisation and combined it with the notion of instrumental orchestration (Drijvers et al., 2010) that includes three main concepts: *didactical configuration* referring to the arrangement of the teaching with the use of technology; *exploitation mode* referring to teachers' planning decisions to reach their objectives; and *didactical performance* is about teachers' on-the-spot decisions based on the selected teaching setup and strategies. In this sense, the DRDC framework focuses on teachers' designing and teaching processes with the use of technology, and thus would serve a better theoretical tool for our study.

The DRDC framework includes three main components: designing for teaching (DefT), design-in-use (DeiU), and re-design (ReDe). The first component, DefT, is essentially related to teachers' skills in the planning stage of the digital resources. The second one emphasises teachers' actions on the spot by focusing on their didactic performance of the instrumental orchestration and their reflections and interventions during the actions. The third component, ReDe, is concerned with teachers' ability to assess the task design, considering the affordances and difficulties in the teaching and revising the design. Table 1 provides the descriptions of each component in the DRDC framework.

Table 1: The DRDC framework (Trgalová & Tabach, 2024, p. 662)

Design for teaching (DefT) (before enactment)	**(DefT0) To set up a mathematical learning goal** (a) Choose a mathematical content that the task will be aiming at. (b) Analyse how the mathematical goal is aligned with the curriculum.
	(DefT1) To choose relevant digital technology (DT) (a) Identify affordances of DT allowing to achieve the learning goal. (b) Identify affordances of DT allowing to address students' difficulties or misconceptions.
	(DefT2) To design tasks mobilising the chosen DT and justify the design choices (a) Analyse in what way the tasks contribute to the achievement of the learning goal. (b) Identify previously acquired (math. and inst.) knowledge necessary to engage in the tasks. (c) Highlight affordances of the DT that allow for a different approach to achieving the targeted learning (added value of DT).
	(DefT3) To plan classroom enactment of the tasks: (a) Organise phases of the task enactment (introduction, individual /group work, whole class discussion...).

	(b) Plan didactic configuration and exploitation mode. (c) Plan teacher's interventions in response to anticipated students' strategies and difficulties (planned didactic performance). (d) Plan the institutionalisation articulating math and instrumental knowledge. (e) Provide material to support the teacher's interventions (presentations, student worksheets..).
Design-in-use (DeiU) (during enactment)	**(DeiU) On-the-spot teacher's actions and decisions (improvised didactic performance) about:** what question to pose now, how to do justice to (or to set aside) any particular student input, how to deal with an unexpected aspect of the mathematical task or the technological tool, or other emerging goals
ReDesign (ReDe) (after enactment)	**To assess the task design based on an a posteriori analysis:** (a) Identify what went well and what did not. (b) Identify what can be improved and suggest modifications of the tasks.

We chose to employ this framework since our PD context included first PMT's task design, then teaching the task in the classroom, and finally re-designing the task based on the implementation.

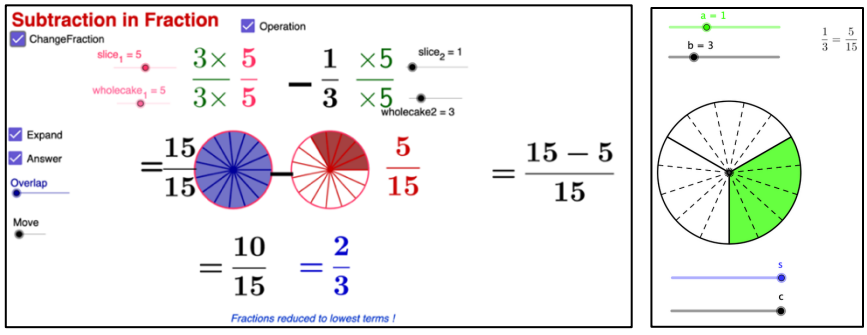
Methods

This case study illuminated a PMT's DRDC in the context of a practicum course. By following Stake's (2005) suggestion "a case study is both a process of inquiry about the case and the product of inquiry" (p. 444), we explored and illustrated one PMT's DRDC by examining her thoughts and experiences related to designing and implementing a technology-based task.

Context, participants and procedure

The study took place during a compulsory final-year practicum course in a four-year mathematics education programme at a Turkish university. Twelve PMTs enrolled in the course were purposively selected based on their interest and ability in using dynamic technology for mathematics teaching and task design, as well as their willingness to participate.

The practicum requires PMTs to observe/teach six hours per week under the supervision of a mentor teacher in a school placement and attend a two-hour university seminar. Although technology use was not mandatory, the course content was designed to enhance PMTs' skills in using digital resources, focusing on task design (DefT), didactic performance during teaching (DeiU), and task redesign based on experience (ReDe). In the first weeks, we offered seminars on designing and implementing technology-based tasks. During the first 3–4 weeks, PMTs observed their mentor teachers and then planned a technology-based lesson aligned with the mentor's schedule. After reviewing their plans, we conducted individual pre-lesson interviews to explore their design decisions (DefT). PMTs then taught their lessons (DeiU) and participated in post-lesson interviews to reflect on their teaching, including challenges and adaptations (ReDe).



This study reports on one PMT's (pseudonym Nil) planning and implementation of a technology-based task involving a ratio word problem focused on subtracting fractions with unlike denominators. We chose to present her task because her planning reflected thoughtful consideration of multiple factors, including the different roles of sliders in the digital environment to support

students' thinking in reaching a generalisation, as well as her attention to students' prior knowledge and potential misconceptions.

Data collection and analysis

Nil's planning of a technology-based task and audio recordings of pre- and post-lesson interviews and her classroom teaching constituted the data of the study. We prepared interview questions by considering and revising Pepin et al.'s (2017) ten teacher design questions by focusing on using digital resources. Example pre-lesson interview questions (completed in 20 mins) included: "How will technology help you to achieve your goal?", and "What resources or tools did you use to plan the task?". Then, she implemented her plan and we audio-recorded her teaching (completed in 35 mins). Example post-lesson interview questions (completed in 25 mins) included: "Did you have any difficulties during the teaching?" and "What do you think about your response to the students' questions in the classroom?".

In her task, she initially planned to propose the following problem "*At the end of a busy working day, a pastry chef wants to calculate the amount of the cake sold during the day. 1/3 of the cake served for 5 people was sold during the day. What is the ratio of cake slices remaining for sale the following day compared to the whole cake? Why?*" and aimed to solve it with the use of technology. In her planning, she used two separate GeoGebra (GGB) files, and the sliders were the main technological tool in both files for reaching her aim. She selected ready-made files and re-designed them (i.e., changed the colours and language). The first GGB file was the main file (Figure 1.(1), https://www.geogebra.org/classic/apve8uwj) in her task, and she aimed to use the second file to remind of the equivalent fractions (Figure 1.(2), https://www.geogebra.org/classic/hazfkdw4), which are prerequisite knowledge for learning subtraction in fractions with unlike denominators.

(1) (2)

Figure 1: Nil's GGB files in her task

In her main GGB file (Figure 1.(1)), there were six sliders representing two numerators and two denominators in different fractions, overlapping the fraction models, and moving the final model of the subtraction. She used different colours to represent different fractions and four checkboxes for changing the operation (addition or subtraction), showing the fractions, expanding the fraction, and presenting the result. She planned to use the sliders to direct students in finding the subtraction and to use the checkbox for guiding the discussion or presenting the numerical values of fractions. Additionally, she planned to use the dynamic texts to support her teaching and verifying responses.

We analysed the data, considering all the components of the DRDC framework. While analysing Nil's planning and pre-lesson interview accounts, we focused on her design choices for teaching (DefT), including her emphasis on the objective in the curriculum, the rationale behind selecting relevant digital technology, her consideration of students' existing mathematical and instrumental knowledge, and her analysis regarding the affordances of the task and chosen technology. We also examined how she organised the phases of the task and planned her didactical configuration and exploitation mode. In analysing Nil's teaching (DeiU), we examined how she implemented her lesson plan, considering the components of the instrumental orchestration framework. Specifically, we identified key moments related to her ability in guiding students and her questions/prompts to facilitate the whole-class discussion. This analysis helped reveal how she implemented her plan and to identify the critical points related to her DRDC. In the analysis of the post-lesson interview, we focused on how Nil criticised her own teaching and how she planned to revise her task (ReDe). Throughout the analysis, triangulating her planning and the audio recordings of her interviews and teaching enabled us to validate and verify the data.

Results

Here, we report Nil's DRDC by presenting her planning and implementation of a technology-based task, as well as her reflections on planning and teaching the task in the classroom. While setting a mathematical learning goal (DefT0), Nil decided on the topic with the mentor teacher. In the pre-lesson interview, she explained that although she had other options, she intentionally chose to teach fractions due to her personal interest in the concept. She also emphasised that GGB is a valuable tool for enhancing both the teaching and learning of fractions. In her own words, she stated:

> Nil: It was not only that fractions were the next objective to teach in the school placement, but also, I am personally interested in teaching fractions with technology. I believe that using GGB is very relevant while teaching this topic as we can easily show equivalent parts in a fraction model. To be honest, I realised why we really equalise the denominators while working on the concept in GGB.

While preparing her plan, she examined the curriculum, digital resources, and existing literature, which helped her identify the existing knowledge and misconceptions of 6th grade students. Nil preferred to use GGB for designing the task (DefT1) indicating that the tools and features of GGB support drawing, dividing, or changing the fractions easily and enable students to visualise and concretise any model of any fraction. She also noted that the models in GGB could help overcome students' misconceptions, such as failing to divide fractions into equal parts and incorrectly expanding the denominator without adjusting the numerator when expanding fractions.

In terms of mobilising the tools in GGB and justifying her design choices (DefT2), she provided evidence by effectively planning her technological actions, particularly using the sliders for different purposes. For instance, with the help of sliders, she planned to initially present the cakes (Figure 2.(1)) and ask students to find the remaining part of the cake. Then, by using another slider,

she aimed to overlap the models (Figure 2.(2)) and guide students to consider whether it is possible to find the remaining part of the cake. At this point, she planned to open another GGB file (Figure 1.(2)) to help them think about dividing the cakes into the same number of slices by dragging the sliders. According to her, one of the biggest affordances of GGB was drawing, dividing, and expanding the fraction to find equal denominators and moving the models on top of each other to see the remaining part, which would have been impossible to do on a traditional board.

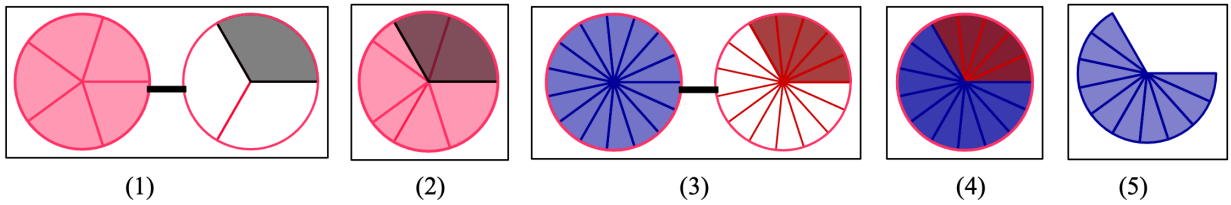


Figure 2: The fraction models obtained by dragging the sliders in the task

For the planning classroom enactment of the task (DefT3), Nil prepared a detailed, step-by-step plan for launching the task and facilitating classroom discussions. In her plan, she prepared detailed and sequential questions considering students' responses and misconceptions. Initially, she planned to present the problem and ask students to draw ⅓ of a cake, which was difficult for them. Afterwards, she planned to present and discuss how the cakes could be divided (Figure 2.(1)). Then, she aimed to overlap the models (Figure 2.(2)) and propose the question, "From the figure, could you infer how many slices of the cake was sold?". Nil anticipated that students might struggle to find the answer, and if they were unable to equally divide the models, she planned to guide them in equalising the denominators. In this process, she planned to help students remember the role of the least common multiple in equalising the denominators. She then planned to divide both cakes into 15 slices (Figure 2.(3)) and help students observe any changes in the slices that were sold. If students noted a change, Nil intended to open a second GGB file to remind the students of the equivalent fractions. In this part, Nil aimed to drag the sliders to help students focus on what changes and remains the same in the model, aiming to show how ⅓ equals 5/15. She then planned to return to the main file and discuss the reasoning of equalising the denominators. Afterwards, she intended to overlap the models and guide students to calculate the slices sold by focusing on the red and blue parts (Figure 2.(4)). Finally, she planned to use another slider to move the remaining part of the cake to a different place on the screen to present the answer (Figure 2.(5)). Throughout her teaching, she also planned to use the dynamic texts step by step to verify students' inputs. From the perspective of DefT component, it became apparent that Nil's task design was informed by both her pedagogical goals and the particular affordances of GGB. Her design process exemplifies how a deliberate integration of technology could enhance the teaching and learning of fractions.

Nil implemented her plan with a class of 6th grade students in a school placement. In terms of criticising her actions and decisions on-the-spot (DeiU), Nil stated that her didactic performance was good, and she was able to reflect on each step of her planning. Initially, Nil wanted students to draw ⅓ slices of the cake on paper with a pencil, but the students had difficulties dividing it into equal slices. Then, Nil introduced the fraction models on the screen by dragging the sliders and continued to discuss how to find the remaining part of the cake as follows verbatim:

Nil (N): The left model represents the whole cake, and the right model represents the cake that was sold, right? Could you observe what changes occurred on the screen when I drag the slider [she dragged the slider for overlapping the models]?
Student (S) 1: The pieces, slices. S2: But this does not work because the cakes are not equal.
N: They are not equal. Can I now find how much of the cake has been sold?
S3: No, the given slices are not equal. S4: About one and a half slices were sold.
S5: The slices are not equal; thus, they do not match up.
N: Well, I can't say exactly how much was sold. Maybe it is one and a half; it could be more than one and a half or less. What did your friend say before? He said the slices of the cakes did not match. What should I do to make them match?
S6: We need to expand. S7: We must equalise the denominators.
N: How do I equalise them?

Nil guided students step by step, adjusting her questions based on their responses to facilitate their progression through the task. She emphasised the reasoning behind equalising denominators when operating on fractions and used the other GGB file to demonstrate how ⅓ equals 5/15 by dragging the sliders. Then, she went back to the main GGB file and discussed the rationale for equalising the denominator with the help of the sliders. She also discussed the meaning of the blue and red parts to identify the remaining part of the cake. Finally, Nil used the sliders to overlap the models and moved the remaining part to a separate section to verify the solution. During her teaching, she supported her explanations and responses using dynamic texts on the screen. From the perspective of DeiU component, these actions highlight Nil's capacity to use affordances of GGB in ways that encourage students to engage actively with the learning process. In the interview, Nil stated that she was able to gain students' attention through the tools and features of GGB. Utilising the sliders with different aims was a key technological action for her to develop students' reasoning on the rule for subtraction in fractions. In the evaluation of her teaching (ReDe), Nil reported that she successfully implemented her plan without encountering unexpected issues or emerging goals and thus saw no need for revisions. However, this could point to a lack of experience in recognising challenges, identifying emerging goals, and critically reflecting on her teaching practice.

Conclusion

This study examines one PMT's design capacity by analysing her design choices and knowledge related to the selection and use of digital resources in both planning and teaching a technology-based task. The results indicate that the PMT's design decisions concerning the DefT component appear to be the key to an effective use of technology in the classroom. Nil carefully prepared and adjusted detailed sequential questions and coordinated them with the tools and features of GGB. According to Nil, her careful planning during the DefT stage contributed to a successful DeiU stage, where she effectively utilised different sliders for different aims, enabling students to reach generalisations on the topic. Nil emphasised that designing a comprehensive lesson plan—carefully considering all details—helped her anticipate potential challenges during instruction, allowing the lesson to proceed smoothly without unexpected situations. As a result, she did not perceive a need to revise her lesson plan following its implementation (ReDe stage). While thorough planning can indeed facilitate effective teaching, this result should be interpreted with caution. As Clivaz and Miyakawa (2020) highlight, cultural and institutional contexts play a critical role in shaping how

mathematics is taught and how teachers reflect on and enact designed lessons. Moreover, existing research (e.g. Cavanagh & Prescott, 2010) suggests that beginning teachers often struggle to engage in reflective practice, as their attention is typically directed toward technical skills and practical concerns, such as classroom management, rather than focusing on students' perspectives and learning processes. Overall, this study highlights the potential of practice-based practicum courses as important places for teacher educators to assess and foster PMTs' design capacities, particularly in terms of technology integration. The findings also suggest that the DRDC framework is a valuable tool for teacher educators—not only for course design but also for evaluating PMTs' planning and instructional decisions within such courses (McCulloch et al., 2021).

Maths AIde: Can GenAI support mathematics teachers to plan engaging, student centred lessons?

Eleanor Byrne, Aibhín Bray and Brendan Tangney

Trinity College Dublin, the University of Dublin, School of Education, Dublin, Ireland; e.byrne@tcd.ie

Keywords: Generative artificial intelligence (GenAI), second level mathematics education, professional development, in-service teacher education.

Introduction

Mathematics is a subject which students find difficult, it is perceived as hard, tends to be taught as abstract, unconnected topics (Boaler, 2022). A historical over-reliance on rote-learning and procedural fluency has led to a lack of conceptual understanding and increased disengagement throughout adolescence (Berry et al., 2021). Reforms in maths education have attempted to address these issues by focusing on student-centred, problem-solving activities (NCCA, 2017). However, change is hard and years after curricular reform teachers still require further professional development (PD) (Berry et al., 2021). For PD to be successful it needs to be experiential, situated in the teacher's own classroom, beneficial for their students and sustained (Byrne & Prendergast, 2020). There are many concerns around the emergence of GenAI in terms of education, such as its usefulness when cheating, it's propensity to lie and inbuilt biases (Luo, 2024). Notwithstanding GenAI is an emerging technology which could potentially support teachers to lesson plan, create resources and support critical thinking (Hu et al., 2024).

The intervention

Maths AIde is a PD offering which supports a collaborative dialogue between a teacher, their colleagues and the GenAI. The teachers initially survey their students to determine their interests outside of school. They engage in a collaborative workshop with both the GenAI and their colleagues where they complete a series of tasks using the GenAI. The outputs are reflected upon with their colleagues, refined and implemented in their classes.

Methods

The aims of the research are twofold to improve maths planning and teaching while also supporting teachers to gain confidence engaging with GenAI. This research is following a design-based/ action research methodology and will consist of at least four cycles of planning – acting – developing – reflecting (Mertler, 2017). As there are less than 30 participants involved in the research it will utilise a case study approach. Both quantitative and qualitative data will be collected to strengthen the understanding of the case (Creswell & Garrett, 2008). Quantitative data in the form of surveys and qualitative data such as interviews, GenAI transcripts and artefact analysis will be used.

Data collection and analysis

A baseline survey was administered (N=27) before the introduction of the intervention. Following one cycle of the intervention interviews were conducted using voluntary sampling

(N=6). Teachers from Ireland, Austria & Sweden took part in interviews conducted over Teams. Interviews were 8-10 minutes in length. Transcripts were downloaded to Word, and adapted to ensure conversations were accurately recorded. Transcripts were then uploaded to the coding software NVivo for initial coding. Following multiple refinements three areas emerged: GenAI uses, professional development and technology adoption.

Preliminary results

80% of respondents had never used or only used GenAI once to plan or create resources prior to the intervention. During the interviews teachers spoke about how they were using GenAI to structure lessons, create resources, tailor activities to groups of students and adapt previous assignments. Most of the teachers felt they needed to upskill in GenAI to ensure they were not outpaced by students. The teachers liked the supportive structure of the workshops. It was noted that older more experienced teachers in that school were most resistant to upskilling in GenAI while those newer to the profession were embracing it's potential.

Chatbots performance in problem posing: An exploratory study

Sara Embid and Josefa Perdomo-Díaz

University of La Laguna, Spain; sembidso@ull.edu.es

Keywords: Artificial intelligence, problem posing, chatbots, mathematics education.

Introduction

Conversational agents, or chatbots, are gaining prominence in mathematics education for their potential to support teachers in various tasks by acting as "teacher-agents." These AI-driven tools are designed to generate coherent, human-like text (Kuhail et al., 2023). Their outputs, shaped by large language models (LLMs) and user inputs, often exhibit significant variability. While chatbots are well-documented in problem-solving contexts (Schorcht et al., 2024), their application to other mathematical practices, such as problem posing, remains largely unexplored. This study aims to address this gap by examining the quality of outputs generated by four widely used chatbots in the context of a problem-posing task including fractions.

Theoretical background

Problem posing involves creating new problems or reformulating existing ones according to specific instructions (Silver, 1994). Central to this practice is the quality of the problems posed. Desirable features for mathematics problems include motivating contexts, clarity, and diverse solution strategies (Leavy and Hourigan, 2022). A key characteristic is plausibility, meaning the problem must be free from mathematical contradictions and include all necessary information for complete understanding and solvability (Grundmeier, 2015).

This research focuses on the following question: To what extent do chatbots generate plausible math problems with all necessary information for solvability?

Methods

This qualitative exploratory study evaluated outputs from four chatbots: GPT-4, Claude 3.5 Sonnet, Copilot (precise mode), and Gemini. These chatbots were chosen for their relevance in educational AI applications and their diverse underlying LLM architectures. The study employed zero-shot prompting, a technique that elicits responses without additional contextual information, (Schorcht et al., 2024) to assess the chatbots' baseline performance in problem posing. Each chatbot was given the following prompt five times: "Formulate three problems of varying difficulty that include the numbers 1/4 and 3/8, which can be used as either data or solutions. You may incorporate any type of information (numerical, contextual, etc.)." Outputs were analysed using Grundmeier's (2015) coding scheme: problems with mathematical contradictions (non-plausible), plausible problems with omitted yet understandable information (P1), plausible problems requiring a single task to solve (P2), and plausible problems requiring multiple tasks (P3).

Results and discussion

Copilot frequently failed to include the required fractions, resulting in unacceptable problems. Claude produced the most plausible problems overall (13 out of 15, with 7 categorized as P3). ChatGPT

followed with 10 plausible problems, while Copilot and Gemini produced 7 plausible problems each. A detailed breakdown of the results is shown in Table 1.

Table 1: Chatbot performance and plausibility of problems generated

	Unacceptable	Non-plausible	P1	P2	P3
ChatGPT	0	1	4	8	2
Claude	1	1	0	6	7
Copilot	5	0	3	5	2
Gemini	0	3	5	7	0

These findings suggest that some chatbots can act as teacher-agents by generating plausible and complete problems, while others demonstrate significant deficiencies. The variability in AI-generated content underscores the need for robust validation mechanisms and improved training of chatbots for educational contexts (Schorcht et al., 2024). Further research should explore larger datasets, diverse prompts, and teachers' experiences using chatbots in professional contexts. Such studies will deepen our understanding of how emerging technologies can support mathematics educators in designing effective and engaging instructional materials.

Computational literacy in mathematical problem solving

Jack Jalal Kallo

University of Copenhagen, Faculty of Science, Copenhagen, Denmark; jkallo@ind.ku.dk

Keywords: Computational literacy, mathematical problem-solving, computational thinking.

Introduction

As the integration of digital technology into everyday life accelerates, the urgent need to leverage its potential in education has been recognized (Kaup, 2022). This transformation underscores the necessity to equip future generations with essential technological skills, highlighting the importance of Computational Literacy (CL) in fostering a deeper understanding and innovative application of technology, particularly in mathematics education (diSessa, 2018).

The introduction of Computational Thinking (CT) in educational systems aim to meet this need. Wing (2006) defines CT as a focus on problem-solving (PS) and system design through computational principles, offering a framework for a deeper understanding of technology. Despite CT's potential contributions to mathematics education (Tamborg et al., 2022), its practical implementation has been difficult. CT is often reduced to an extension of traditional mathematical thinking, including algebraic thinking (Bråting & Kilhamn, 2021), rather than being applied to PS as Wing (2006) originally envisioned. diSessa (2018) criticises how current dissemination of CT often mirrors Pólya's (1945) older mathematical PS techniques. This limits its potential in education.

The PhD project from which this poster reports hypothesizes that introducing CT through PS in mathematics, rather than an extension of 'mathematical thinking' can better harness its potential to develop students' abilities to engage with complex problems in a digital context. CL offers a more expansive framework, focusing not just on learning programming or algorithms, but on empowering students to think critically, creatively and holistically about the application of digital technologies. By embedding CT within a CL framework, the project posits that students will develop not only technical skills but also the critical and adaptive mindsets necessary for effective PS in a world increasingly shaped by digital technology. The research is guided by the following research questions:

RQ1: In what ways can the integration of Computational Thinking in mathematics education support students' ability to solve (complex) mathematical problems?

RQ2: How can mathematical competence in problem-solving be rethought through a Computational Literacy perspective?

A response to RQ1 will serve as input for addressing and discussing RQ2.

Methods

This project uses Design-Based Research (DBR), which integrates design and research to improve educational practices and generate theoretical knowledge. This makes DBR suitable when examining the integration of CT in mathematics education and how this evolves into a broader CL framework. The project is structured around three iterative cycles, with the following phases:

1. **Activity Design**: Develop teaching activities that integrate CT and mathematics concepts. Adjustments will be made based on teacher input, with a focus on how CT supports PS (RQ1).
2. **Reflective Adjustment:** Students' work will be analyzed to assess the effectiveness of activities, particularly CT's impact on PS abilities. Discrepancies between planned and realized outcomes will be evaluated to refine activities in subsequent cycles.
3. **Theory Development**: Insights from the iterative cycles will contribute to theoretical advancements, specifically addressing how CL can further enhance PS competence (RQ2).

This project aims to deepen the understanding of how CT through CL can transform PS into mathematics. Initial challenges in integrating CT into mathematics education will be addressed, providing insights into how CT supports PS. These insights will then serve as the foundation for a broader exploration of CL, ultimately proposing a redefined framework for PS that moves beyond traditional mathematical thinking approaches.

Engaging and explorative digital tasks designed by pre-service teachers: A teacher training course design

Edith Lindenbauer[1] and Eva-Maria Infanger[2]

[1]University College of Education Upper Austria, Linz, Austria; edith.lindenbauer@ph-ooe.at

[2]Johannes Kepler University Linz, Austria

Keywords: Professional development, digital materials, task design, cognitive activation.

Introduction and theoretical frameworks

As teachers and teacher educators, we aim to enhance learners' conceptual mathematical understanding to foster engagement, motivation, and sustainable learning. This can be achieved via effective integration of digital tools and resources into mathematics education (Hoyles et al., 2013). A central aspect of this purpose is the design of tasks, lesson planning, and student activities (Drijvers, 2018). However, a major challenge is the abundance of digital resources with varying quality. Successful implementation of digital media strongly correlates with the role of the mathematics teacher (Clark-Wilson et al., 2020), highlighting the need for pre-service teachers (PSTs) to develop the skills to competently evaluate the potential of digital materials (dMs) and integrate them to support conceptual understanding. In this study, dMs refer to pre-designed GeoGebra-based configurations embedded in online worksheets with accompanying tasks for learners. Assessing and designing such dMs is a complex process that requires focusing on various aspects such as content-specific pedagogical considerations, visualization, presentation, or task wording, which represent quality issues for technology integration (e.g., Trgalova & Jahn, 2013). Drijvers (2018) outlines three didactic functions of digital technology: doing mathematics, practicing skills, and *developing concepts*. The latter is particularly challenging to implement technologically but entails the potential to discover and explore mathematical objects by utilizing dMs (Drijvers, 2018). The emphasis on enhancing learners' conceptual understanding leads to a specific focus on dMs, which encourage the exploration of mathematical content and provide technology-added value compared to paper-and-pencil tasks.

The presented project investigates how to design aspects of a teacher training (TT) course that focuses on dM and task design to enhance PSTs' skills in creating (i) dMs for exploring mathematical content and (ii) accompanying tasks that engage students in high levels of cognitive thinking. The specific skills are informed assessment, design, and implementation of dMs. As theoretical foundation, we adopt, among others, the TPACK framework that encompasses teachers' knowledge and skills required for teaching with digital media (Koehler & Mishra, 2009).

Methods and context of the study

For approaching the research question, we analyse data from a pilot study and an exploratory qualitative study of a TT course at an Austrian university for secondary mathematics teacher education. This course focused on the design of two dMs with accompanying tasks. The PSTs worked in pairs, selected a lower secondary education topic, conducted an intensive review of relevant mathematics education literature, and engaged in a design and redesign process with integrating feedback from peers, teacher experts, and the mathematics teacher educator, finally presenting their

work. Qualitative data was collected in the form of PSTs' learning diaries, working notes, digital designs, and interviews, and analysed using thematic analysis procedures (Braun & Clarke, 2006).

Exemplary results and outlook

Thematic analysis enriched by theoretical literature review leads to the following successfully supporting design principles: (i) provide foundational mathematical knowledge for teaching and dM design, (ii) request intensive literature review of mathematical knowledge for teaching on the topic addressed by the dM, (iii) enable and foster peer exchange, (iv) implement reviews with experienced teachers and/or teacher educators. Further data analysis reveals two main challenges for the designing skill: First, PSTs repeatedly struggle to distinguish between materials for exploring versus practicing mathematical concepts, making it difficult for them to design tasks that encourage learners to explore mathematical content. Second, PSTs face difficulties in formulating engaging, cognitively activating tasks for the presented mathematical content. A theoretical model could support PSTs in this regard.

In a next course, we will thus use an adapted version of the DGTA framework (Trocki & Hollebrands, 2018; Lindenbauer et al., 2023) for non-geometric topics, refining it in the future with newly collected data. In addition, integrating this adapted task design model into the already complex TT course requires careful considerations. It will be essential to examine what makes tasks cognitively activating for learners, effectively supporting them in exploring and understanding mathematical concepts.

Developing lower secondary mathematics teachers' ICT competencies: The case of China

Bohan Liu, Eirini Geraniou, Cosette Crisan and Jeremy Hodgen

University College London, United Kingdom; bohan.liu.20@ucl.ac.uk

Keywords: Mathematics teachers, information and communication technology (ICT) competencies, secondary school, China, geometry.

Background and rationale

Integrating ICT into mathematics teaching has been widely promoted globally (Foster, 2023), including in China (Ministry of Education, China, 2022). However, Chinese mathematics teachers' ICT use remains superficial, and their ICT competencies are still limited (Sun et al., 2019). Inspired by Niss and Højgaard (2019), this study defines ICT competencies as teachers' ability to use ICT, act appropriately, and adapt their teaching in response to specific challenges in various mathematics topics for students with diverse learning needs to enhance their understanding.

Teachers' professional knowledge is shaped by teaching practice and developed through adaptation in response to experience (Ruthven, 2009). This highlights the importance of relevant and well-designed teaching tasks and training for developing teachers' ICT competencies. Such sign should be informed by an understanding of mathematics teachers' daily practices and experiences.

This poster presents preliminary findings from an exploratory study on Chinese lower secondary (12-15 years old) mathematics teachers' use of ICT, as well as their views of the opportunities and challenges ICT presents to their teaching practice and their students' learning of mathematics.

Methods

Data was collected via questionnaires and individual interviews with lower-secondary mathematics teachers in China. GeoGebra (GGB) was first chosen as the ICT and task design platform due to its popularity and potential in mathematics teaching. 11 teachers engaged with a GeoGebra-based activity, *Euclid: The Game* [https://www.geogebra.org/m/gzfn4pe3], followed by a questionnaire on their experiences and perceptions of the activity. This activity, featuring progressively challenging geometry tasks, aimed to assess teachers' familiarity and proficiency with GGB, particularly in constructing geometric shapes and solving problems using a limited set of tools.

The questionnaires revealed these teachers' low usage, unfamiliarity, and negative perspectives on GGB, which suggests the need for more in-depth interviews to explore their commonly used ICT and their experiences, challenges, and needs. Therefore, the focus was shifted to collect information about Chinese teachers' widely-used ICT, through individual interviews with another group of 15 teachers from 4 schools in 3 cities. The interviews also served to verify and further test the preliminary findings from the questionnaire responses, and the inclusion of this second group aimed to gather a broader range of the use and perspectives on ICT integration in classroom practices.

Findings and analysis

From the questionnaires, teachers expressed mixed views on GGB, with more disadvantages than advantages noted. Compared to traditional methods, the advantages include accurate and easy

drawing, integrating new tools that align with students' cognitive development, an intuitive interface, and supporting cross-platform compatibility. Disadvantages include insufficient instructions, high demands for plane geometry knowledge, no "undo" button resulting in messy drawings, and a lack of immediate feedback. More importantly, teachers' low use and negative attitudes to GGB make it impractical to continue to design ICT tasks exclusively on GGB, as it may increase teachers' workload and cause resistance. However, teachers' initial exposure to GGB still holds value in promoting the use of this powerful mathematics-specific ICT in China.

Following the shift in focus, the interviews showed that ICT hardware, such as laptops, projectors, and interactive whiteboards, is extensively used. Regarding software, PowerPoint is universally adopted, and Seewo [https://www.seewo.com/en/] and Geometer's Sketchpad (GSP) [https://sketchpad.keycurriculum.com] are the most frequently mentioned ICT. Hence, future task design could prioritise more familiar tools, such as Seewo and GSP, to better align with teachers' existing practices and reduce potential barriers to ICT integration. Teachers also reported challenges in using ICT, including a lack of dynamic presentation tools, insufficient interactivity, outdated activities, and inadequate training. Additionally, they faced difficulties in visualising geometric transformations and integrating traditional with digital methods. Expectations for future tools include better shape generation, dynamic visualisation, and generalisable activity templates.

Future plans

The next steps involve developing a quantitative tool to evaluate secondary mathematics teachers' ICT competencies. Using a design-based research approach, ICT-integrated geometry tasks will be created with different teacher groups in China, prioritising widely used ICT such as Seewo or GSP. The task design will address the challenges and needs identified in the teacher interviews and aim to enhance their ICT competencies through targeted, iterative implementation. Moreover, mathematics teachers' communication and collaboration around ICT use within professional learning communities will be observed and analysed to support continuing professional development.

Group Instrumental Genesis

Liv Nøhr[1], Cecilie Carlsen Bach[1], Andreas Lindenskov Tamborg[1], and Morten Misfeldt[1]

[1]Centre for Digital Education, University of Copenhagen, Denmark; lsnl@ind.ku.dk; ceba@di.ku.dk; andreas_tamborg@ind.ku.dk; misfeldt@ind.ku.dk

Keywords: Instrumental genesis, Group cognition, Group Work

Introduction

Working in groups in mathematics today will oftentimes involve sharing tools (e.g., GeoGebra or similar) on a computer. To work *collaboratively* with these tools, students need to create a shared interpretation of what the tools are and what they should be used for. This poster has a theoretical contribution through presenting a bricolage between theories to describe how groups can engage in such an endeavor.

Since the mainstream adoption of digital tools in mathematics teaching around the millennium, a detailed conceptual language of distributed cognition has helped mathematics education researchers and teachers understand instrumented learning processes (Guin et al., 2005). This is most prominently articulated in the instrumental approach, which focuses on how artefacts are shaped into personal instruments by individuals over time. Collaboration and cognition in groups have garnered similar interests, with instrumental genesis being highlighted as a relevant framework to understand the relationship between group work and tools (Overdijk et al., 2012). However, the inherent focus on individual instrument processes in instrumental genesis limits its ability to conceptualize groups' tool use and view of tasks. Therefore, we pose the following research question: How can we conceptualize the influence of artefacts on group work in continuity with Instrumental Genesis?

Role of Others in Instrumental Genesis

The Instrumental Approach concerns the relationship between tools and users, often with a cognitive focus on how the tools influence cognitive schemes (Guin et al., 2005). Two central concepts describe the processes of continuation and dialectics between design and use: *instrumentation*, where the use of a tool shapes a user's goal-directed activity, and *instrumentalization*, where the pupil's goal-directed activity reshapes the tool (Rabardel & Bourmaud, 2003, p. 673).

'Others' are embedded in instrumental genesis, as the *artefact* is understood as a social construct mediating human activity. The concept of *instrumental orchestration* furthermore highlights an embedded social dimension, as it denotes the class-level introduction to artefacts leading to a more coherent instrumentalization process (Guin et al., 2005). A group-level introduction to the artefact can thereby change the foundation of the processes of *instrumentation* and *instrumentalization.*

The Instrumental Approach describes a social dimension, through the artefact and (potential) instrumental orchestration, as an institutional element which conditions how students use tools. While it adds to our understanding of the basis for the group work, it does not address the social dimensions of the dialectic processes between individuals, tools, and goals. In other words, we still

lack a conceptual framework for (1) how the artefact shapes the group constellation and (2) the role of the group in the instrumentation and the instrumentalization processes.

Group Cognition and Instrumental Genesis

Group cognition can be a relevant theoretical framework for understanding the social dimension of instrumental genesis (Stahl, 2011). Informed by activity theory, group cognition conceptualizes the process by which object-oriented group work establishes group knowledge. It describes group cognition through three dimensions; (1) a temporal dimension of ordered events, (2) a problem space of shared knowledge artefacts, and (3) an interaction space of positioned actors. Here, the second and third dimensions are particularly relevant, as they touch upon the role of artefacts for groups. Stahl (2011) describes that a (math) object is constructed through visual, narrative, and symbolic reasoning. The object exists as a shared knowledge artefact, with meaning embedded by and visible in the group interactions. Beyond conceptualizing the negotiation of the social meaning of the artefact, it allows for the creation of a *group instrument*, where the instrumentalization and instrumentation of the artefact occur at a group level. The temporal dimension and the interaction space between actors provide a conceptual framework to discuss the potential process of *group instrumental genesis* over time. Our pre-liminary definition of group instrumental genesis is the following: *the temporal order of events in which interaction between problem space, discourse, individual subjects' roles and position in a group of subjects lead to the emergence of a group-level instrument with a cognitive function distributed across the participating members of the group* .

The group instrumental genesis allows us to discern between groups by whether they engage in a process of group instrumental genesis. This allows us to understand both the artefacts' shaping of group constellations and the role of the group in the instrumentation and instrumentalization process. For future work, a pressing issue is how this process unfolds, particularly how group cognition includes body communication when applied outside the virtual space from which the group cognition theory originates.

TWG 16: Learning Mathematics with Technology and Other Resources

Learning mathematics with technology and other resources: A short report from TWG16

Abstract: This brief report summarizes the results of TWG16 based on the five themes identified from the contributions received. Overall, we observe that the contributions were distributed fairly equally across these themes. This distribution indicates that our field is interested in emerging digital tools while still valuing traditional digital tools among researchers. Based on the diverse contributions and our discussions during TWG16, we will outline potential areas for future research.

Keywords: Programming, 3D design, feedback, problem-solving, mathematical reasoning, AI, Eye tracking.

Overview of themes and contributions

The scope of the thematic working group TWG16 is to address the potential and limitations of incorporating digital technology and other resources to enhance students' learning of mathematics. As a targeted outcome, we aimed to establish an understanding of the current state of the art of technology in mathematics education. Therefore, we are looking to establish an overview, focusing on themes such as programming and 3D design, feedback and interaction, artificial intelligence (AI) and eye tracking, technology and mathematical problem-solving, and tools to promote mathematical reasoning. In addition, we aimed to suggest future directions for technology-rich mathematics education, including a research agenda.

Table 1: TWG16 themes and contributions

Theme	# accepted papers	# accepted posters
1. Programming and 3D design	4	2
2. Feedback and interaction.	4	1
3. AI and Eye Tracking	4	1
4. Technology and mathematical problem-solving.	4	1
5. Tools to promote mathematical reasoning	4	2

The contributions presented to TWG16 highlighted five primary themes to be addressed. Table 1 offers a summary of these themes along with the number of contributions for each. In total, we accepted 20 papers and 7 posters. Approximately 35 participants from various countries, both within Europe and beyond, participated in the sessions, which were characterized by a positive and productive atmosphere.

Main results per theme

Programming, 3D design, and 3D printing: Four papers and two posters addressed this TWG16 theme. The central focus across these contributions was the relationship between computational thinking and programming on the one hand, and mathematics learning on the other. The presented studies, conducted at various educational levels, from primary school to university, highlight the rich potential for cross-fertilization between computer science and mathematics through computational thinking. This intersection creates valuable opportunities for mutual enrichment. However, to fully realize this potential, a crucial element is the inclusion of a reflection phase following programming tasks. Such reflection helps students make explicit connections between computational and mathematical thinking, thereby drawing out the targeted mathematical knowledge. Several contributions emphasized the educational value of using robots in mathematics classrooms. Interacting with robots can create a safe and engaging learning environment that reduces the effects of the didactic contract. Nevertheless, achieving meaningful mathematical learning requires careful orchestration by the teacher, with clear and explicit learning goals to avoid distraction or off-task engagement. Programming robots, along with 3D design and 3D printing, offers students hands-on, concrete experiences that support mathematics learning in multiple ways. These activities serve as springboards to more abstract mathematical thinking; they encourage argumentation and explanation; they foster creativity, freedom, and flexibility; and they open up possibilities for interdisciplinary STEAM approaches that connect subject matter, real-world objects, and aesthetic dimensions.

Feedback and interaction: Five papers and one poster addressed this theme. The central focus across these contributions was the role of feedback and interactive formats in enhancing mathematical learning within digital environments. The presented studies highlight the complex interplay between feedback type, cognitive demands, learner autonomy, and emotional engagement. This intersection creates opportunities to design feedback mechanisms that support metacognition and meaningful task engagement. However, to fully realize this potential, feedback must be carefully aligned with students' prior knowledge, cognitive readiness, and motivational needs. Such alignment may help reduce overload, sustain attention, and foster independent reasoning. Across the contributions, different feedback types, such as correctness, attention, and explanation, were explored, showing that while correctness feedback can increase engagement, explanation feedback is often skipped, and attention cues may offer a balanced alternative. Research on interactive video formats revealed that embedded feedback is frequently ignored and that solutions are often reached through trial-and-error, suggesting that interactivity alone does not ensure effective learning. Mixed Reality environments offered less formalized feedback but supported spatial reasoning through embodied interaction. Collectively, these studies emphasize that effective feedback and interaction require intentional design and orchestration to support both cognitive and emotional aspects of learning. They also

suggest the value of expanding feedback beyond textual forms to include multimodal and embodied dimensions within classroom contexts.

AI and Eye Tracking: Four papers and one poster addressed this theme. The central focus across these contributions was the potential of AI and eye-tracking technologies to support mathematical learning and inquiry. The presented studies highlight how Gen-AI tools can promote productive engagement with mathematical tasks by shifting student behavior away from seeking quick answers and toward deeper reasoning and problem-solving. This intersection creates new possibilities for developing core mathematical skills and encouraging the use of multiple representations. However, to fully realize this potential, educational guidance is essential, as students often default to using Gen-AI as a basic search tool. Such guidance may help students use AI critically and reflectively, rather than passively consuming responses. In parallel, the contributions addressed how AI-based analysis of eye-tracking data can provide insight into students' attention patterns and conceptual difficulties. While promising, this approach requires triangulation with qualitative or physiological data, as current AI interpretations of gaze data are still limited in scope. Results derived from such analyses should inform instructional practice, for example, by helping redirect students' attention to key mathematical structures. Collectively, these studies underscore the need for further research on how to integrate AI and eye-tracking meaningfully, and how to design supportive environments that cultivate critical thinking and mathematical understanding through these emerging technologies.

Technology and mathematical problem-solving: Four papers and one poster addressed this theme. The central focus across these contributions was the design and impact of digital tools on students' mathematical thinking and problem-solving. The presented studies highlight how thoughtfully structured digital environments can support metacognition, engagement, and flexible problem-solving strategies. This intersection creates opportunities to enhance learning through intuitive interfaces, contextualized tasks, and interactive representations, while reinforcing the ongoing importance of teacher support. However, to fully realize this potential, digital tools must be designed to balance student autonomy with instructional guidance. Such balance may help students engage meaningfully with mathematical challenges while developing strategic approaches to learning. Across the contributions, a variety of tools and environments were examined. Augmented reality applications supported embodied exploration in geometry, enabling students to detect and correct conceptual errors. Eye-tracking studies revealed that non-routine problems encouraged deeper, exploratory strategies, particularly among higher-achieving students, while routine tasks led to more superficial engagement. Structured hint systems, such as heuristic trees, were found to promote ownership and desirable help-seeking behaviors. Short interventions using tools like spreadsheets, GeoGebra, and Scratch improved students' problem-solving abilities, though their capacity to articulate justifications remained limited. Collectively, these findings suggest that digital tools, when carefully designed and integrated, can play a powerful role in fostering problem-solving and reasoning, particularly when combined with explicit attention to students' explanatory practices.

Tools to promote mathematical reasoning: Four papers and two posters addressed this theme. The central focus across these contributions was the use of digital and non-digital tools to promote various forms of mathematical reasoning. The presented studies highlight how interactive resources, ranging from digital textbooks and dynamic geometry environments to physical models and collaborative

platforms, can support students in constructing arguments, identifying patterns, and developing conceptual understanding. The intersection of the contributions in this theme creates opportunities for integrating multiple representations into learning environments, allowing learners to transition between visual, symbolic, and verbal modes of reasoning. However, to fully realize this potential, tool design must attend to both the mathematical goals and the orchestration required to guide students through increasingly abstract forms of reasoning. Such orchestration may help learners connect concrete experiences with formal mathematical structures. Contributions involving interactive textbooks demonstrated how multimodal elements (e.g., handwriting, audio, and applets) can support generalization and proof construction. Other studies explored dynamic geometry tools that help students navigate between Euclidean and alternative geometries through covariational reasoning. Collaborative settings were shown to foster participation and reflection, with teacher guidance playing a critical role. Collectively, these studies underscore the importance of designing tool-rich environments that promote reasoning, while highlighting the complementary roles of technology, collaboration, and teacher mediation in shaping mathematical understanding.

Conclusion and outlook

The discussion in the TWG 16 aimed, first, to establish an overview of the current state of the art in technology-rich mathematics education. Several cross-cutting insights emerged from the thematic contributions. First, technology-mediated learning environments are increasingly being seen not just as transformative platforms but as catalysts for developing essential mathematical competencies such as abstraction, argumentation, and problem-solving. Interdisciplinary approaches that integrate programming, robotics, or 3D modeling with mathematical inquiry demonstrate the potential for meaningful learning when tasks are accompanied by reflection and pedagogical guidance. Additionally, the nuanced roles of feedback and interaction, especially in terms of aligning with learners' cognitive and emotional needs, underscore the importance of careful instructional design. While AI technologies hold promise for fostering critical thinking and engaging students through multiple representations, their integration must be structured and supported with effective scaffolding to avoid superficial usage.

The second aim of the discussion was to outline future directions and research agendas for technology-rich mathematics education. Looking ahead, several key areas emerge. These include designing learning environments that explicitly connect computational and mathematical thinking; developing adaptive feedback systems that respond to learners' individual profiles; integrating AI technologies in pedagogically meaningful ways; and supporting tasks that promote conceptual understanding through both digital and physical tools. A critical area for further research is examining how digital and non-digital tools work together in real classroom settings, where learning occurs through dynamic interactions between students, teachers, and resources. Future TWG 16 may focus on promising themes such as hybrid learning environments, students learning in multi-tool environments, and the role of embodied experiences in supporting abstraction. These directions encourage further theoretical development and empirical investigation into how technologies, along with their integration into broader pedagogical practices, can effectively support mathematics learning.

The icosahedron in the room: Revisiting pedagogical dilemmas of individual learning in collaborative activities

Dor Abrahamson[1,2], Catalina Lomos[3] and Alik Palatnik[4]

[1]University of California Berkeley, USA, [2]Korea University, Korea, dor@berkeley.edu

[3]Luxembourg Institute of Socio-Economic Research, Luxembourg

[4]The Hebrew University of Jerusalem, Israel

Four adult study participants successfully built together a body-scale polyhedron with minimal instructions. Preliminary observation of their rapid construction process would suggest that they were generally "on the same page" and, therefore, perhaps all entertained the same geometrical ideas. However, deeper analysis of their multimodal behaviours and utterances, both during the activity and in post-intervention stimulated-recall individual interviews, suggests acute divergence in perceptual Gestalts, even when two or more participants referred in speech and gesture ostensibly to the precise same material element, voicing operational consensus. As such, our findings query cognitive–anthropological theory of organised social activity, e.g., Goodwin's Co-Operative Action, by producing empirical evidence of productive joint action on indexically referenced co-attended features of the environment yet in the absence of conceptual cohesion.

Keywords: Collaboration, co-operative action, geometry, groupworthy tasks, joint action.

> Let us imagine a language ...The language is meant to serve for communication between a builder A and an assistant B. A is building with building-stones; there are blocks, pillars, slabs and beams. B has to pass the stones, and that in the order in which A needs them. For this purpose they use a language consisting of the words 'block', 'pillar', 'slab', 'beam'. A calls them out; — B brings the stone which he has learnt to bring at such-and-such a call. — Conceive this as a complete primitive language. (Wittgenstein, 1953, §2)

Design problem: learning despite collaboration

It is not simple to facilitate equitable collaborative learning. When a group of students works on a challenging task, they may not enjoy equal opportunities to engage with the task's core cognitive challenges, as evidenced in process analyses and individual assessments. Instead, group members may spontaneously distribute the labour so as to maximise the group's productivity and ultimate success. Consequently, members best pre-equipped to tackle conceptual problems lead others down the production line, who design, manufacture, and assemble artifacts, thus engendering what Abrahamson and Wilensky (2005a) diagnose as a *stratified learning zone*. As such, group activities may not always hoist the lower-achieving students as hoped. Worse, teachers are liable to both congratulate students on their successful achievement as a group and critique struggling group

members for their unequal achievement on individual assessments. Something is not working in group work.

Well aware of this pedagogical tension between the quality of collaboration versus individual learning, Cohen (1986) developed the *complex design* framework, which included: (1) a set of heuristics for creating *groupworthy* tasks—tasks that authentically require a number of contributing participants, each with a distinct role, who must consistently coordinate their actions; along with (2) facilitation guidelines, such as rotation schedules, to ensure that each participant fills each of the roles. Approaching the same design tension from a constructionist perspective, Abrahamson and Wilensky (2005b) explored digitally enabled groupworthy tasks that create equitable participation, without prescribing rotation regimens, by ensuring that all students were operating similarly on the same types of objects (see also White & Pea, 2011).

Still, when students engaged in a shared task are handling the same objects together, are they necessarily perceiving and understanding these objects in one and the same way, such that, by and large, they are learning the same notions?

Sharing perception through the social enactment of cultural practice

According to the Theory of Co-Operative Action (Goodwin, 2013), human activity is intensely co-operative, emerging from interpersonally elaborative actions. New forms of co-operative action by a social group of common interest rely on their developing a *substrate*—a cumulative amalgam of iteratively laminated heterogeneous semiotic contributions respecting a shared domain of scrutiny. The substrate is the group's ever-growing resource of endorsed notions, routines, and perspectives for fluently managing their practice. Drawing on the substrate, co-operative action is coordinated through: (1) participants physically orientating their bodies towards each other and their shared domain of scrutiny and manipulation, creating a focus of perceptual attention and a sense of collective endeavor; (2) a spatial arena that includes phenomena of shared interest; (3) production and regulation of consensual linguistic tokens organising mutual interactions; and (4) gestures—deictic, iconic, and emblematic—for indexing features of the shared environment and imbuing them with contextual meanings.

Moreover, theories of joint action often underscore the vital function of joint intentionality, attention, and frames of reference, as well as semiotic interaction, in facilitating participants' coordination of effective simultaneous actions (Marschner et al., 2024). These theories of co-operative and joint action could be read as suggesting that when several students engaged in a groupworthy task appear to be doing literally the same manual actions, looking at the same objects, and even discussing these same objects, we could quite safely assume that they are developing similar conceptual understandings. But is that necessarily true? Our motto quotation from Wittgenstein's Philosophical Investigations suggests the possibility of joint action absent of shared meanings. We now look at resonant voices from systemic paradigms.

Critiques of joint-action and joint-attention theory

Alternative theorisations of coordinated action are rooted in scientific paradigms such as cybernetics, as well as phenomenological philosophy that promote a different fundamental sensibility of order, one that can embrace the complexity of dynamical systems in flux (Kelso, 2021). Embodiment, a rising exemplar of such post-Cartesian perspectives, has been evaluated as bearing dramatic implications for the learning sciences (Hutto et al., 2015; Macrine & Fugate, 2022; Nathan, 2021; Shapiro & Stolz, 2019). We now overview some recent cognitive science work in this vein that queries traditional models of joint action.

Rejecting reductive theories of collective intentionality, philosopher Seemann (2024) develops an *enacted theory of joint attention*, where, "The openness of joint agents' intentions and meshing subplans is explained by appeal to their practical knowledge of how to maintain the process by way of which they pursue the collective intention" (p. 259). The would-be golden link between joint attention and joint action is further interrogated by questioning the inter-cultural universality of previous assertions that were based on empirical work within WEIRD societies (i.e., Western, educated, industrialised, rich, and democratic; see Henrich et al., 2010). Investigating parent–child naturalistic interactions in non-industrialized societies, Taverna et al. (2024) demonstrated joint action in the absence of joint attention, thus posing questions for ontogenetic theories that foreground joint attention as a critical developmental marker (Tomasello, 2019). In a resonant view from the philosophy of sports, Birse (2024) rejects representationalist assumptions that what is shared in joint attention is mental content. Instead, he sides with relationalist interpretations that look to include individuals' aspectual perceptual perspectives as well as the actions that perception inherently enables (see also Story, 2021, on the emergence or joint action without a theory of mind). Finally, Loehr (2022) problematizes what she views as facile models of individuals' sense of agency as mediating joint action.

What might all this mean for pedagogical frameworks and, more generally, anthropological theories of sociogenesis and semiosis? We wish to leverage these alternative theorisations of joint action in the study of individual learning in groupworthy tasks. As such, we ask:

1. Can individuals engaged in the successful collective enactment of a group task entertain different perceptions of the objects they are jointly handling?
2. How would productive collective enactment be possible when individuals perceive differently the key objects they are jointly handling?
3. What causes such hetero-perception? What are its educational implications?

Methods

Our empirical context is a groupworthy task, in which 4 adults, several of whom had worked as math teachers, are tasked to construct and analyse a body-scale polyhedron. Whereas we had used this activity extensively in researching geometry education (Benally et al., 2022; Palatnik & Abrahamson, 2022, 2025; Rosenbaum et al., 2024), we had yet to closely examine individual

experiences. An auspicious opportunity emerged during our workshop on learning analytics (EDaMMLA 2024), where a team built a large icosahedron (see illustration in Figure 1, left) from long wood dowels and silicon-pipe joiners, with no instructions for construction.

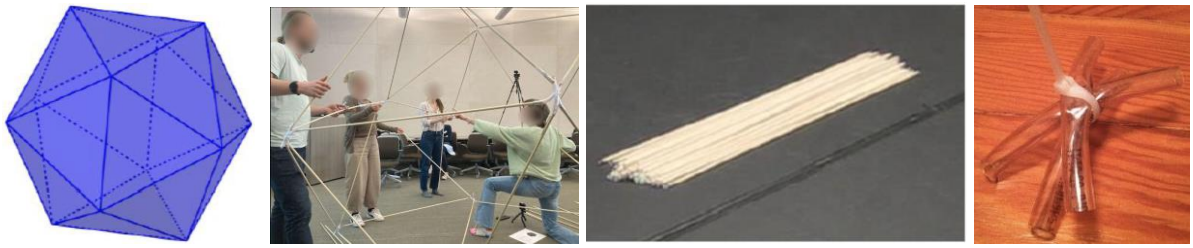

Figure 1: Building a body-scale icosahedron from wood dowels and joiner links

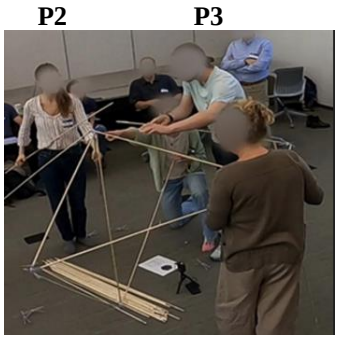
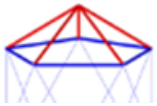
The session was audio–video recorded. Our data further comprise post-intervention individual stimulated-recall interviews, where participants (hence, e.g., P3) discussed their experience of collaboratively constructing the form. We analysed mutual physicality, language, gestures, and the surrounding phenomena. The video was coded by marking key moments in the construction process to capture elements of co-operative action. Utterances were transcribed and coded, marking aspects of perception and action. We later juxtaposed key video moments in the construction process with relevant testimonials from stimulated-recall interviews (hence, SRI).





Results

To address our research questions, we examine 3 vignettes (see Table 1) that triangulate the activity's transcribed videography with the post-intervention individual SRIs.

- Vignette 1 shows four participants engaged in a groupworthy task, performing the same manual actions, looking at and discussing the same objects, while the SRIs of P1 and P2 indicate that they are not developing similar conceptual understandings, implying the possibility of *joint action in the absence of shared meanings*.
- Vignette 2 suggests that what is shared in joint attention is not mental content, as P1 and P2 evidence hetero-perceptual perspectives and actions that nevertheless support *joint action without a shared theory of mind*.
- Vignette 3 illustrates that individuals can engage in successful collective enactment of a group task while entertaining different perceptions of the objects they are jointly handling, such that they manifest and *learn different notions*.

In building the icosahedron, P1 and P2 followed different conceptual perceptions: P1 counted the five edges in each vertex, while P2 tried to build "the roof." Meanwhile, P3 deliberated over these two strategies—he would later admit that the activity's hardest aspect was "knowing who[m] to listen to in such moments of confusion." P4 followed on, attentive to the various framings.

Table 1. Collective enactment through hetero-perceptions in joint action

The vignettes (60 seconds)	The transcript (selected utterances)	P1: SRI	P2: SRI
Vignette 1 (98 s to 111 s)  **P2** **P3** **P1** **P4**	**P3 [leaning in, centre right]:** Ok, I'm making… [attempts to connect a sixth edge to a vertex] **P1 [kneeling, centre]:** But there is only…, is it…, should be… **P2:** But there's, yeah… **P1:** I think we're… is there five [points to a vertex]? I think there should be five vertices or five edges meeting. **P2 [on left]:** But then this one is extra, yeah. **P1:** Yeah…. **P2:** …we need to take this off [holds the edge going down in the middle of P1's vertex]	I don't know… I think it's just like "I was just doing the 5s patrol." I was just like "I have to say something now because this is a thing that…". Maybe I should have vocalized it earlier: "Oh, there's five," but I think in my head I was like, "Oh, there's five!" 	Now I can see that this is not how I imagined "the roof"—the roof is not working well. (...) Everyone is working on a different side, so I can see that it is not symmetrical. 
Vignette 2 (112 s to 121 s)  **P2** **P1** **P3**	**P2 [on left]:** [to herself] This extra one in the middle… [Instructor intervenes] (...) **P2:** Yeah… **P1 [leaning in, centre]:** [to herself] Oh, there should be... [looks carefully at what P2, on left, is doing]	(...) That was the first time that I thought, "We don't need to add any more of these, because there are five." (....) It seems like that was the first time that I actually felt like I had to say what I was thinking for the past two minutes.	(...) It came from "the roof" idea, because there was something in the middle, [an edge], that's why I thought that, "Okay, it's not the roof yet."
Vignette 3 (122 s to 160 s)  **P2** **P1** **P3** **P4**	**P2 [on left]:** (…) [removes an edge from one side of the "top" vertex," joins it into opposite side, rendering the top vertex visible] Yeah, this is the now "top" [raising the vertex]. **P1**: Oh, cool. **P2:** Yeah, we can think like this and then… **P1:** Yeah. **P3 [right]**: Yeah. **P2**: …we go from here. **P3**: Alright **P1**: Ok **P4**: [silent, looks at "top"]	I don't think I noticed this ["the roof"] in the activity itself, but watching it now, I see this shape of the five triangles at the very top. It is interesting that we didn't even finish that shape first—we started going into the next... 	Now, the idea of "the roof" is becoming more and more urgent for me, so now I'm…yeah…ye ah…" 

Our four "Rashomon" participants experienced different learning opportunities, pursuing self-assigned purviews ("5s patrol" versus "the roof") or following the group's actions. P1, who "just kept an eye on the five," maintained her role as "5 patrol"; she did not perceive the whole polyhedron "until the very end, when it all came together." P2, per the SRI, drew on prior knowledge that the shape comprises congruent triangles to form her "roof." P3 grasped the form as a whole only towards the end of the activity, "when the shape was already correct and there was very little missing." Even though P4 did not always understand the task at hand and was comfortable following the group, per her report, the "5s rule" prompted her sense-making. She stated, "OK, if I have to repeat it, I know how to do it." In sum, the vignettes described task participants who, while engaged in task-effective co-operative action, nevertheless: bear different *perceptual orientations* on the situation; highlight *different properties* of the environment as action affordances; entertain different *construction objectives*; and consider different *task constraints* which they announce, monitor, and enforce. We thus witness a set of individuals who, though inhabiting different environments (Shvarts & Abrahamson, 2023), nevertheless successfully perform an apparently well-coordinated collective task.

Discussion

Regarding RQ1, we have told the tale of four persons who, though successful in building together a complex geometric structure, each perceived it differently (Borovska et al., 2024) and, later, retained different conceptual notions about its geometry (Zamecnik et al., 2024). This tale demonstrates that participants in collaborative activities may not enjoy equal opportunities to engage with the task's core cognitive challenge, highlighting the pedagogical tension between the quality of collaboration and individual learning (Abrahamson & Wilensky, 2005a).

Regarding RQ2—the issue of how productive collective enactment is possible given a group's hetero-perceptions—our findings pose new questions to cognitive–anthropological theory of organised social activity, such as Goodwin's Co-Operative Action. Namely, we have produced empirical evidence of productive joint action on indexically referenced, co-attended features of the environment yet despite the absence of conceptual cohesion: When task members make heterogeneous semiotic contributions that are apparently endorsed by others, what may actually be endorsed are practical operations on designated *local* features, while colleagues' idiosyncratic *global* perceptual constructions of these features are filtered out in communication. Co-operation does not imply, and may not require, co-perception. When teachers conduct group activities in their classrooms, they should remain vigilant that effective coordination may nevertheless conceal hetero-perception and divergent understandings (Abdu & Schwarz, 2020). These divergent perspectives could be gainfully leveraged through facilitated post-activity reflection.

Regarding RQ3, we thus rekindle long-standing research concerns over the pedagogical optimisation of groupworthy assignments. Efficacious joint action may result not from explicitly negotiated engineering, distribution, and monitoring of individual roles, which would occasion pedagogical opportunities for engaging in disciplinary discourse around a lesson's target content. Instead, it may result from the emergence and stabilisation of multiple, loosely recurring, ad hoc

local transactions among spatially proximate participants, each with their self-assigned purviews, who temporarily and unwittingly become functionally co-dependent, thus requiring only brief, cursory coordination.

Developing interpersonally heterogeneous perceptions of shared objects may be an adaptive evolutionary social heuristic for collaborative problem solving in novel contexts under conditions of uncertainty, namely, disaggregating exploration so as to maximise discovery opportunities (Richardson et al., 2008). Educational designers, however, ultimately are charged with converging students towards more-or-less homogeneous understanding of the subject content. We believe that educators should keep deliberating how to utilize humans' atavistic genetic inclinations for hetero-perception—leveraging it, rather than inhibiting it—nevertheless while also ensuring equitable instruction. As such, we propose, if indeed we are to foster the skill of collaboration, we should appreciate, understand, embrace, and support humans' soft-assembly routines, including tinkering, divergence, emergence, and loose coordination, rather than impose regimens for the arbitrary distribution of labour that are liable to suppress students' powerful evolutionary proclivities. At the same time, we should surface the phenomenon of hetero-perception for the students themselves, so that they can learn through coordinating their divergent visualisations. Further investigations of equitable learning in collaborative activities are called for, because our speculations are inferred from a single group of adult participants working in a unique social context (an international workshop) on a rather irregular task, using unusual media.

Students' use of feedback when working on fractions with a digital learning platform and its effects on mathematical performance

Larissa Altenburger[1] and Michael Besser[2]

[2]Leuphana University Lueneburg, Institute for Mathematics and its Didactics, Lueneburg, Germany

The present study analyses the use of feedback – a factor that does not necessarily go along with higher performance – when working with fractions via a digital learning platform, and its impact on students' performance. In this context, in 2021/2022 a laboratory study was conducted with 137 seventh graders from German schools. The students were randomly assigned to one out of two experimental groups. Within the groups, all students worked on fraction tasks by using a digital learning platform. The groups differed in the complexity of the feedback (right/wrong feedback vs. elaborated feedback) presented by the learning platform. Results highlight a low utilisation of right/wrong feedback and a very heterogeneous use of elaborated feedback, with increased use being associated with lower fractions performance. This can be partly explained by the students' prior knowledge. Educational stakeholders should therefore consider how feedback should be designed and implemented in the classroom so that it is (1) used by learners and (2) supports their learning.

Keywords: Feedback, Intelligent Tutoring Systems, Fractions

Introduction

With the introduction of fractions, mathematics becomes a major challenge for many learners (Obersteiner & Tumpek, 2015). Feedback plays a crucial role in helping learners meet this challenge, as feedback has been highlighted being one of the most important factors in successful learning (Wisniewski et al., 2020). Studies have shown that elaborated feedback is superior to right/wrong feedback, even though a lack of elaborated feedback in teaching-learning processes has been identified (e.g. Harks et al., 2013). To address this issue, digital learning platforms offer potential for individual learner support through automated feedback. However, the results of studies conducted on the effectiveness of learning platforms have been inconsistent (Hillmayr et al., 2020). Given this heterogeneity in research findings, it is important to identify the factors that influence the effectiveness of digital learning platforms in general and feedback on digital learning platforms in particular. Current research results, for example, raise the question of whether and when increased use of feedback actually leads to higher performance or whether the effect of feedback use depends, for example, on the prior knowledge of the learners (e.g. Reinhold et al., 2021). Due to the research gap on when feedback is actually conducive to learning, this study will address the questions of whether and to what extent learners use two different types of feedback and to what extent the use of feedback has an influence on mathematical performance.

Theoretical Background

The topic of fractions is considered being a widely researched field (Siegler et al., 2013). In practical teaching, however, the topic is identified as a challenge for both teachers and learners (Obersteiner

& Tumpek, 2015). At the same time, fractions appear to be of particular relevance for other mathematical topics as well as for future live (Lortie-Forgues et al., 2015). One effective approach to addressing challenges in complex mathematical domains, such as fractions, is to provide students with feedback. The primary objective of feedback is to modify the recipient's thinking and/or behaviour, typically with the aim of enhancing performance by closing the gap between the current state of learning and the learning goal (Narciss, 2004; Shute, 2008). Feedback is considered being one of the most important factors influencing learning success. Various meta-analyses have demonstrated the superiority of feedback over no feedback. However, the study results vary widely (e.g. Hattie & Timperley, 2007; Mertens et al., 2022). Consequently, empirical research does not seek to determine whether feedback *can* be effective, but rather *how* feedback should be designed to support students in their learning. One factor that contributes to the variability in the effectiveness of feedback is the variety of ways in which feedback can be designed (Mertens et al., 2022). In essence, two types of feedback can be distinguished: simple feedback, such as information about whether an answer is correct or incorrect (= right/wrong feedback), and elaborated feedback. Elaborated feedback typically consists of an explanation indicating whether the response is correct or incorrect, accompanied by supplementary information. The information provided can be diverse (van der Kleij et al., 2015), with the degree of complexity of elaborated feedback varying considerably across studies. For instance, elaborated feedback may comprise illustrative examples of solutions or concrete help. Elaborate feedback seems to be superior to right/wrong feedback, although too much information can be overwhelming for learners (keyword: cognitive load) (Sweller et al., 2011; Shute, 2008).

Given the multifaceted nature of teaching roles, it can be postulated that the provision of elaborated written feedback and tailored support for students' learning is not a common practice. Digital learning platforms offer considerable potential in addressing the dearth of written feedback that is currently observed. As Petko (2020) notes, digital learning platforms are capable of generating reactions to learner input. Consequently, digital learning platforms are designed to store, process and record information in a manner that enables learners to interact with them both within and beyond the confines of the classroom. Digital learning platforms provide users with feedback on their input (Daniela & Rudolfa, 2019), thereby facilitating interactivity between the learner and the learning platform (Petko, 2020). The feedback from digital learning platforms can be characterised by a considerable degree of complexity. This can be attributed to the fact that, despite the prevailing view that learning platforms are conducive to learning, empirical studies have yielded disparate results with regard to their effectiveness (e.g. Mertens et al., 2022). However, the complexity of the feedback is not the only decisive factor for its effectiveness. Another factor is how learners deal with the feedback. This is because the desired target state can only be achieved when learners actively use feedback (van der Kleij & Lipnevich, 2020). Empirical evidence suggests a correlation between the use of feedback and (mathematical) performance. However, increased feedback use does not necessarily lead to higher performance (e.g. Reinhold et al., 2021). Operationalising the use of feedback is not easy. A variety of approaches have been identified in the literature for capturing the use of feedback. For instance, van der Kleij et al. (2011) refer to the duration of a window containing feedback in order to differentiate the use of feedback by learners. In contrast, Beal et al. (2010)

operationalise the use of feedback via the number of aids that learners look at. In a similar vein, Reinhold et al. (2021) employ process data to record the number of hints displayed and the feedback time. To gain further insight into (1) learners' use of feedback and (2) the effect of feedback use on performance, the study addresses the following research questions: (1) (To what extent) Do learners use two different feedback types (right/wrong vs. elaborated feedback) from digital learning platforms? (2) (To what extent) Does the use of two different feedback types (right/wrong vs. elaborated feedback) impact upon learners' fraction performance?

Methods

In 2021/2022, an experimental laboratory study was conducted with $N = 137$ seventh graders from different German middle-class schools. Before starting the intervention, at a first measurement point general background variables and students' prior knowledge of fractions (using a standardised test by Lenz et al. (2019); 37 items; dichotomously coded) had been assessed. The students were then randomly assigned to one out of two experimental groups. During the intervention, both experimental groups worked on fractions for around 30 minutes using a digital learning platform. While experimental group 1 (EG 1; n = 67) received feedback on correct and incorrect answers at the end of all tasks, experimental group 2 (EG 2; n = 70) received elaborated feedback continuously while working on the tasks. The elaborated feedback included feedback on the correctness of the answer as well as concrete help: show tip (e.g. "Expand to the main denominator."), look up ("usually consisting of a similar type of task including a sample solution"), show solution, definition of mathematical terms) for processing the task (see Figure 1). Following the intervention, at a second measurement point the students were required to complete the same test that was used to assess prior knowledge at the first measurement point in order to assess their performance in relation to fractions after the intervention.

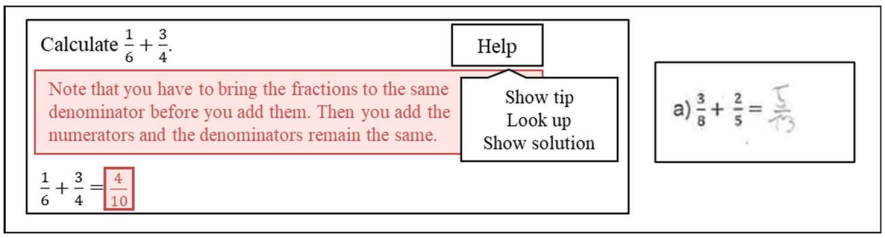

Figure 1: Exemplary fraction calculation task from the intervention including elaborated feedback (left) (own illustration based on bettermarks (2023)) comprising an exemplary task from the fraction calculation test including student solution (right)

The operationalisation of feedback use for EG 1 was based on the decision to categorise them as either having worked on the incorrectly solved tasks a second time after receiving feedback on correctly and incorrectly solved tasks (coded as 1), or as having not done so (coded as 0). The use of feedback for EG 2 was documented throughout the intervention using screen recordings. Subsequently, the use of feedback was operationalised based on the duration (time on feedback) and the number of times help has been viewed (frequency of feedback usage). The feedback usage behaviour is initially described descriptively. Unpaired t-tests examine whether different feedback types have an influence on fraction performance. Subsequently, regression models with moderation

analyses were carried out to investigate the relationship between the use of feedback, prior knowledge of fractions and fraction performance at the end of the intervention. The assumptions for carrying out the tests have been checked and are considered to be met. The analyses were carried out using IBM SPSS Statistics Version 28.0 (IBM, 2022).

Results

Research question 1: Of the 70 learners in EG 1, only 19 (27.1%) attempted the incorrectly completed tasks a second time. 50 learners (71.4%) did not use a second attempt and therefore did not use the feedback provided. In the case of one student, it was not possible to determine whether a second attempt was made. For EG 2 the high standard deviations indicate a considerable degree of variability in the use of feedback. Considering the variance observed, it is notable that the empirical minimum for all usage indicators is zero (see Table 1). A more detailed examination of the data indicates that six students did not utilize the feedback provided. One student used the feedback 60 times.

Table 1: Descriptive results of feedback usage of EG 2

	Min	Max	M	SD
Time on feedback (in sec)	0	344	73.90	90.29
Frequency of feedback usage	0	60	12.91	13.81

Research question 2: A comparison of the two experimental groups reveals that EG 2 exhibits superior performance. However, as Table 2 illustrates, this effect is not statistically significant.

Table 2: Descriptive results of fraction performance and mean differences by experimental group

	n	Min	Max	MW	SD	
Fraction performance	137	0	36	13.42	8.96	
EG 1	70	1	33	13.34	9.11	t(135) = -0.10, p = .46, d = - 0.02
EG 2	67	0	36	13.49	8.87	
Maximum score = 37; d was calculated with: Hemmerich (2015) (two-sided test)						

Table 3 shows models for the influence of feedback use on fraction knowledge (M1 & M1.1) and this influence when controlled by prior knowledge of fractions (M2 & M2.1). Models 3 and 3.1 examine whether prior knowledge has a moderating effect. The results regarding the influence of feedback use on fraction performance in the context of EG 2 show that the decisive factor is the frequency of feedback, rather than the time on feedback. The results demonstrate that 4% of the variance in fraction performance can be attributed to the frequency of feedback usage. It is notable that the significant

regression coefficients are negative, indicating that learners tend to perform less well on the fractions test as the frequency of feedback usage increases. However, the significant effects of feedback on fraction performance are no longer apparent when prior knowledge of fractions is taken into account.

Table 3: Results of the regression models with interaction effects for the prediction of the fraction knowledge

	Fraction knowledge					
	M1	M1.1	M2	M2.2	M3	M3.1
Time on feedback	-.90		-.31		.47	
Frequency of feedback usage		-2.22*		-1.50		.01
Prior knowledge			2.43	1.99	3.33**	3.48*
Prior knowledge*Time on feedback					2.76	
Prior knowledge* Frequency of feedback usage						3.43**
Significance	.43	< .05	.07	< .05	< .05	< .01
R^2 corr	-.01	.04	.05	.07	.09	.12
Shown are the unstandardized (B) regression coefficients; R^2 corr = corrected explained variance; * p < .05, ** < .01, the analyses were carried out with z-standardized values						

The Johnson-Neymann diagram demonstrates that learners with limited prior knowledge of fractions demonstrate a decline in fraction performance with increasing feedback usage (see Figure 2). However, as prior knowledge increases, the significant effect disappears and prior knowledge of fractions has no moderating effect. This indicates that, in instances of elevated prior knowledge, the use of feedback is less likely to exert an influence on subsequent fraction performance following the implementation of an intervention.

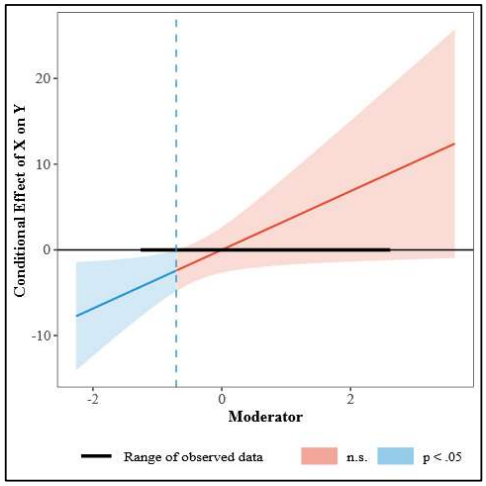

Figure 2: Moderating effect of prior knowledge (= moderator) on the relationship between frequency of feedback usage (= X) and fraction performance (= Y), Note: If the moderator is outside the interval [-0.71, 8.19], the conditional effect of X on Y is significant, p < .05, Hemmerich (2020)

Discussion

The results of the present study highlight that right/wrong feedback (EG 1) provided by a digital learning platform is rarely used by learners as an opportunity to revise incorrectly solved tasks. The low use of feedback may be explained by the delayed presentation of feedback (Winstone et al., 2017). However, a lack of information, e.g. on how to proceed, may also be the reason for the low use of feedback (Fong & Schallert, 2023). The use of elaborated feedback seems to be quite heterogeneous (EG 2). It can be assumed that too much information is offered, which not all learners (want to and/or can) use, as the large amount can be overwhelming (van der Kleij & Lipnevich, 2020). The analyses to answer the question of whether the use of feedback affects fraction performance showed no effect of right/wrong feedback. For EG 2, the more feedback is used, the lower the fraction performance. In relation to this result, it was assumed that the negative influence of the use of feedback on fraction performance is mainly explained by the prior knowledge. Graphical analyses confirm that learners with little prior knowledge of fractions have poorer fraction performance with increasing duration of use. The fact that learners with less prior knowledge do worse as feedback use increases seems to contradict previous research discourse at first (Fyfe & Rittle-Johnson, 2016). However, 'cognitive load' is a recurring theme in the context of feedback (e.g. Sweller et al., 2011). Learners with less prior knowledge may feel overwhelmed by elaborate feedback, and more frequent use may require more cognitive resources to process feedback, making it more difficult to focus on the task at hand. Therefore, teachers should be aware that learners with less prior knowledge in particular need additional support that goes beyond the functions of a digital learning platform. The task of feedback designers is to consider the different levels of prior knowledge of the users. Although the topic of 'feedback' has been extensively researched, the authors of this article agree with the call for further research into when feedback is conducive to learning. The focus should be on students and their individual needs. For example, qualitative (interview) studies could contribute to a better understanding of the use of feedback in general and of problems in implementing feedback information in particular.

This design research study investigates students' processes in an interactive and conceptually oriented video on understanding variables. Data has been collected in design experiments with eight pairs of adolescents. In the drag-and-drop question in focus of this paper, they receive feedback and can answer multiple times until correct. The qualitative analysis investigates their different attempts regarding cognitive engagement and use of feedback. It reveals that video interactions can support cognitive engagement but also bears a risk of eliciting superficial processes. While feedback on the result seems to trigger several attempts, sometimes by trial and error, elaborated feedback was hardly read in our sample. This shows the importance of a research-based design of interactive videos in general and automated feedback in particular.

Keywords: Interactive video, cognitive engagement, student processes.

Introduction

Providing learning opportunities with instructional videos opens up potentials for learning at one's own pace and for illustrating dynamic processes, which has proven effective for the acquisition of different types of knowledge, including conceptual knowledge (Kulgemeyer, 2020). A key condition of success, however, is the depth of students' cognitive engagement (Chi & Wylie, 2014). In general, interactive elements (such as drag-and-drop questions with automated feedback) have been shown to support students' cognitive engagement (Moreno & Mayer, 2007). In our overarching project MuM-Video, we explore to what extent we can transfer these interactive supports to videos offering learning opportunities for deep conceptual understanding. In the current paper, we report from a qualitative analysis of process data from Cycle 2 of a design research study with a focus on potentials and limitations of drag-and-drop tasks and automated feedback for the particularly challenging case of adolescents who receive a second chance for learning algebra, with the following research questions:

(RQ1) How do students cognitively engage in their work on a drag-and-drop task?
(RQ2) How is the engagement supported by their use of the feedback provided by the video?

Theoretical background: Cognitive engagement and feedback

Cognitive demands that engage students in deep thinking processes are considered to be a key condition for successful mathematics learning. That is why cognitively demanding tasks and teachers' moves have intensively been researched in mathematics education (Henningsen & Stein, 1997). For our target group – adolescents in need of a second chance of learning an especially challenging content (understanding variables) – effective strategies to foster engagement are of particular relevance for two reasons: First, the association between cognitive activation and achievement is

stronger in classes with low average socio-economic status (Li et al., 2021) and second, transition points in school come along with the risk of a decline of engagement (Skilling et al., 2021). Yet, one cannot draw conclusions from the cognitive demand of a task to each student's cognitive engagement, so new instructional designs (such as for videos) must be investigated with respect to the cognitive engagement they actually initiate and support (Chi & Wylie, 2014).

The depth of students' cognitive engagement can be operationalized within the ICAP framework using students' overt behavior as an indicator for cognitive processes (Chi & Wylie, 2014). ICAP distinguishes four modes of engagement, from *interactive* (generating information and connecting ideas through dialogue) over *constructive* (generating information and connecting ideas) and *active* (manipulating information or materials) to *passive* (receiving information), or even less than passive, *disengaged* (if students are either off-topic or if they try to somehow get to the solution without actually solving the problem). Empirical studies have shown that higher modes of visible engagement correlate with deeper cognitive processes and higher learning outcomes (Chi et al., 2018), this allows the ICAP framework to connect elaborated knowledge construction with the constructive mode of engagement (Chi & Wylie, 2014). Hence, support for cognitive engagement is to be carefully designed in learning environments.

In fact, learning from video often goes hand in hand with the passive mode of engagement, not least within mathematics education: Students just receive information from the video and are not necessarily encouraged to give reasons or to come up with own considerations (Bersch et al., 2020). Integrating interactive elements, such as drag-and-drop or multiple-choice questions, into videos can initiate deeper engagement by providing time to elaborate, demanding physical action, or delivering automated feedback (Delen et al., 2014). Also, the activity setting of working in pairs can contribute to eliciting constructive and interactive student processes (Chi et al., 2018).

One important advantage of interactive video is its potential to give automated feedback. Feedback is defined "as information provided by an agent … regarding aspects of one's performance or understanding" (Hattie & Timperley, 2007, p. 81) and has been shown to enhance students' learning gains. Kulhavy and Stock (1989) classify feedback with respect to two main aspects: *verification* (students are only informed whether their result is correct) and *elaboration* (students receive information beyond that, either on the task or on metacognition). By pointing to specific aspects of the content in view, elaborated feedback has the potential to support focused cognitive engagement. In a meta-analysis on feedback across subjects and media, elaborated feedback was found to be associated with high effect sizes (Wisniewski et al., 2019). While the meta-analysis revealed differences between learning contents, no differences occurred between target groups. However, we assume that our target group might have more difficulties in exploiting the offered support.

Methods

Research context: Design of the learning environment and interactive video

The conceptually focused video investigated in the overarching design research study (Korntreff & Prediger, 2024; Korntreff et al., 2023) explains the meaning of variables as generalizers in a realistic context of costs for e-scooter rides that vary with the riding time. In the learning environment, students first work on a worksheet to complete a table, make sense of its columns and re-invent

variables for describing the costs for any riding time (Figure 1). The video itself serves to systematize the learning content after students' free inquiries and has a duration of 5:52 min. In order to foster cognitive engagement, we integrated interactive elements (implemented with the open-source software H5P), such as reflective questions, summaries, or cognitive prompts. For the analysis in this paper, we chose one drag-and-drop interaction on the interpretation of arithmetic expressions in the given table. When working on the worksheet, students tended to skip this task, because it is not obviously mathematical. In fact, it is an important intermediate step towards the symbolic generalization of the arithmetic expressions using variables.

Students receive feedback on their answers to the drag-and-drop question (cf. Figure 1) and are invited to answer multiple times until correct. The feedback refers to both: *verification* of correctness using colors and symbols (red and cross marks for incorrect matches, green and check marks for correct matches). Furthermore, *elaborated feedback* is provided through sentences or questions for incorrect answers (when no description is correctly dropped into a column of the table), partially correct answers (when one or two descriptions match correctly), and correct answers (all three match correctly). In the frequent case of partially correct answers, the elaborated feedback reveals two prompts: a *cognitive prompt (*"Did you make sure to not only describe what is new?") and a *metacognitive prompt* ("Explain to each other what the calculations in the columns mean"). Elaborated feedback was added as superficial active behaviors were found in earlier cycles (documented in Korntreff & Prediger, 2024). The cognitive prompt addresses a typical student error focusing recursive building rules instead of the whole expression. Due to the capabilities of the software, the feedback had some technical limitations, such as just one feedback for all patterns of partially correct answers or the spatial distance between the actual answer and the feedback. These limitations have been solved in the subsequent design experiment cycle (cf. Korntreff et al., 2023).

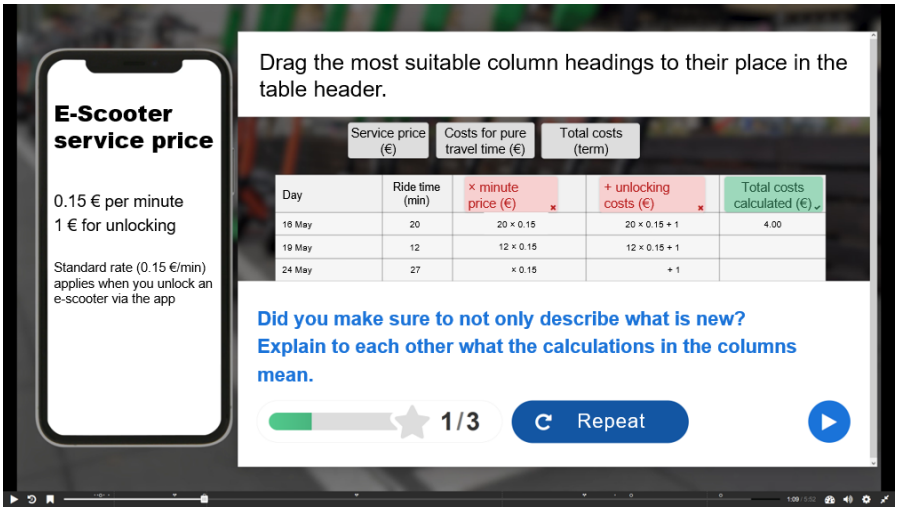

Figure 1: Drag-and-drop question with feedback, translated from German (Korntreff et al., 2023)

Data collection

For the second cycle from which the empirical part of this paper reports, data was collected in design experiments at vocational schools, with adolescents in need of a second chance to understand algebra.

Eight pairs of learners (5 females and 11 males between 15 and 33 years old, $M = 19.6$ years) collaboratively worked with the interactive video in a laboratory setting. After an individual inquiry and activation of prior knowledge with a paper-and-pencil worksheet, the learners worked with the video in pairs sharing one device (mostly smart board, some with tablet). The work was screen- and video-recorded and transcribed. The eight drag-and-drop sequences analysed here lasted between 1:00 min and 4:25 min ($M = 2:24$ min) from the first presentation of the task until the mouse click on continue.

Data analysis

The video data and transcripts of the drag- and drop sequences of eight pairs were qualitatively coded in a deductive coding procedure (Mayring, 2015). In *Step 1*, the sequences were segmented into *coding units* that comprise one solution step – typically one attempt or, if no further attempt follows, one engagement with a feedback offer. For each attempt, the correctness of the students' answer was tracked (correct vs. partially correct or incorrect). Three coding units were later split to capture engagement changes. In *Step 2*, students' cognitive engagement was deductively coded with codes derived from the ICAP framework (cf. Figure 2): *No engagement* corresponds to disengagement, *moderate engagement* to the active mode and *strong engagement* to the constructive or interactive mode (which are not distinguished because interactivity usually scratches over several coding units). The passive mode of engagement cannot occur as every coding unit ends with a click on either "check" or "continue" which is "overt motoric action or physical manipulation" (Chi & Wylie, 2014, p. 221) and coded in active mode. In *Step 3*, we deductively coded the use of elaborated feedback with parallel codes (cf. Figure 2), with the important difference that the passive mode of engagement *can* occur for feedback. Additionally, we analysed how the provided feedback aligned with students' thinking in the particular moment. This relates to the question how helpful the feedback could have been in the specific problem-solving situation.

Codes for cognitive engagement		Description
C3	Strong engagement	Constructive or interactive engagement with the task: Explaining, justifiying, making connections.
C2	Moderate engagement	Active engagement with the task: Reading out loud, repeating, asking questions, describing using similar words.
C1	No engagement	Disengagement with the task in terms of content: Superficial strategies (e.g., trial and error) or no focus on the task at all.
Codes for use of feedback		**Description**
F3	Strong use of feedback	Elaborated feedback is read and applied to the problem.
F2	Limited use of feedback	Elaborated feedback is passively read but not applied to the problem.
F1	No use of feedback	Elaborated feedback is not read.

Figure 2: Deductive codes for cognitive engagement and use of elaborated feedback

Results on students' engagement and use of feedback

Number and correctness of attempts

In Figure 3, we provide an overview of the analyses and findings which are presented in this section. With respect to the number and correctness of attempts, the boxes in the visual summary reveal that no pair succeeded to correctly drag all matching descriptions in their first attempt, one in the second,

two in the third, and one in the fifth attempt. Four pairs continued the video without an own correct solution (as visualised by the missing check marks in the visual summary).

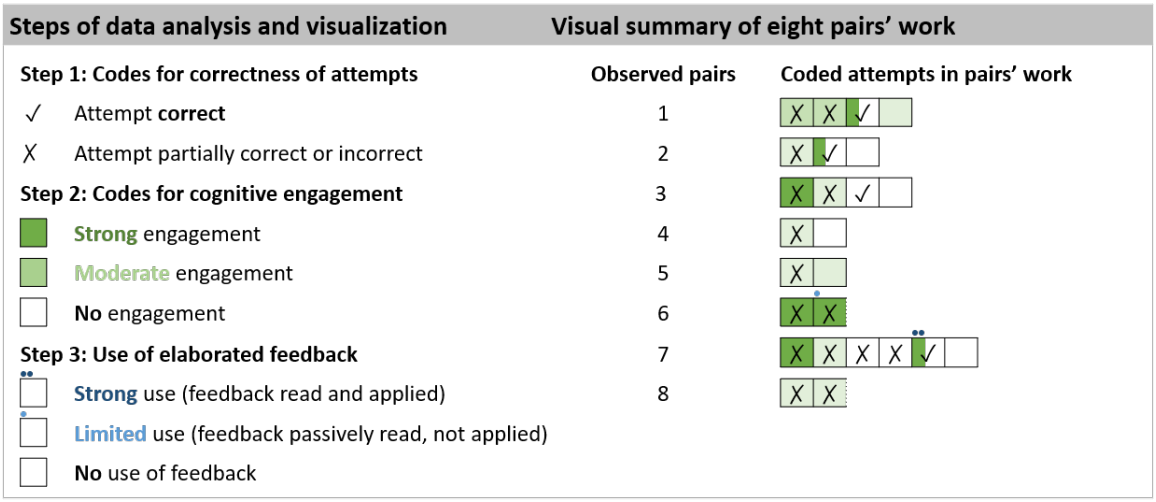

Figure 3: Visual summary of the analysis of eight pairs' processes

Students' cognitive engagement

RQ1 asks how the students cognitively engage in their work on the drag-and-drop task. As intended, the video interaction seems to have supported students' cognitive engagement: All eight pairs interrupted the passive mode of watching the video and engaged at least *moderately* (as visualised by the light green boxes in Figure 3) with the drag- and-drop question. Five pairs *strongly engaged* by performing deeper processes such as justifying or making connections. One example is given by Student 2B from Pair 2 in their second attempt:

Student 2B: The unlocking costs are actually coming next, because there is always the one euro added with the unlocking costs [*drags "+ unlocking costs (€)" into the 4th column*].

Nevertheless, although all pairs started with at least moderate engagement and thought about the task in terms of content, several switched to superficial strategies such as trial-and-error or answering by exclusion (coded as no engagement and visualised by white boxes in Figure 3) towards the end of the solution process. Especially, no pair finally found the correct answer by strong engagement, not even Pair 7. Also, none of the four pairs who answered the question until correct (check marks in Figure 3) engaged with the correct answer on a deeper level, as the example of Pair 7 illustrates:

Student 7B: We have had this one [*points to "service price (€)"*], that one [*points to "× minute price (€)"*] and that one [*points to "+ unlocking costs (€)"*]. So, it has to be this one [*drags "Total costs (term) (€)" in the 4th column, clicks on "check"*].
Video: [*Shows feedback for correct answer*]
Student 7B: Yes, yes, it's this one [*smiles*], we were so bad. [*Clicks on "continue"*]

Pair 1 was the only pair that at least copied the correct answer to their worksheet (moderate engagement in their last step after the correct attempt), the other three were satisfied with the green check marks on the screen and just continued, even though the correct answer had not been understood and only been found by exclusion or trial-and-error. In total, we see moderate and strong cognitive engagement, but also superficial ways of coming to and engaging with the correct answer.

Students' use of feedback

As each attempt receives an automated response by the interactive video, in Figure 3, each closed box with a check or cross mark stands for a feedback at the beginning of the subsequent step (Pair 8, for example, interrupts without asking for feedback again). In total, 17 feedback offers were analysed, four for correct and 13 for partially correct or incorrect answers. The mathematical adaptivity of the elaborated feedback to students' thinking in the moment could have been mostly high: Out of the 13 feedback offers for partially correct or incorrect answers, seven had a high fit, indicating that the feedback prompt precisely focused the difficulty in understanding, another three had a medium fit (the prompt matched one of the answers) and only three a low fit. This stands in noticeable contrast to students' actual use of the feedback prompts: Elaborated feedback was only *read* in two cases out of the 17 feedback offers analysed and only one pair went beyond reading and tried to apply the prompt to the actual problem. In the other 15 situations, the elaborated feedback was not even read, like for Pair 1 in Attempt 3:

Video:	[*Verification feedback: "× minute price (€)", incorrect | "+ unlocking costs (€)", incorrect | "total costs calculated (€)", correct.* *Elaborated feedback (unread): "Did you make sure to not only describe what is new? Explain to each other what the calculations in the columns mean."*]
Student 1B:	Huh? But it has to be this one. Because ride time times minute price really is "ride time times minute price". [*Drags "× minute price (€)" into Column 3*]
Student 1A:	But this is just "times minute price".
Student 1B:	Yes, but maybe … [*continues the discussion without getting back to 1A's point*]

Regarding verification feedback, after a partially correct or incorrect first attempt, six pairs took at least a second attempt and the feedback that the first solution was not fully correct seems to represent an important trigger here:

Video:	[*Verification feedback: "service price (€)", incorrect | "total costs, term (€)", correct | "total costs calculated (€)", correct.* *Elaborated feedback (unread): "Did you make sure to not only describe what is new? Explain to each other what the calculations in the columns mean."]*
Student 3B:	Crap! Can we find the correct answer anywhere or should we repeat the question?
Moderator A:	This is up to you.
Student 3B:	Then, we'll do it again …

Four pairs worked on the task until finding a correct solution while two continued the video on purpose, before they got to the correct answer. Another two pairs continued the video accidentally by clicking on "continue" instead of "check". On average, the students took 2.4 attempts on the question. We concede that our target group of students in need of second chances made only limited use of the provided elaborated feedback.

Summary and discussion

The small excerpts from eight students' working processes shows that integrating interactive elements into instructional video has the potential to foster cognitive engagement: All eight pairs at least moderately engaged with the task in one solution step. Thus, making instructional video interactive seems to be a potential support for cognitive engagement (Delen et al., 2014), also in our case of algebraic understanding for students with limited school success in need of second chances. As in earlier studies (summarized by Chi et al., 2018), the collaborative setting also appears to have

contributed. However, in particular for the target group in view, there is a risk of initiating only superficial processes just to get to the correct solution due to an actual or perceived lack of content-specific support. This pattern is mirrored in the engagement with the correct answer: There was no case of strong engagement with the actual solution to the problem. Quite the contrary, most of the time it was either simply accepted or even ignored even though it had not been understood.

In the meta-analysis summarizing studies with other target groups, providing specific feedback proved effective for students learning and was considered as a promising way to tackle these problems also in our design. However, while the simple verification feedback turned out to be an important stimulus for students to take more than just one attempt, the elaborated feedback was hardly used by the target group of adolescents in need of second chances after their regular high school pathway. Only one pair used the elaborated feedback by applying it to the actual problem (strong use), while it was mostly not even read. This stands in a strong contrast to the high mathematical adaptivity the feedback prompts could have provided, as most prompts precisely focused the students' problems in the particular moment. Yet, these target group's self-regulation strategies were not strong enough to make use of this opportunity. In the next design experiment cycle, we learned from these experiences and modified where and how the feedback was given. Embedding the interactive video in a learning environment with succeeding whole class discussions and follow-up tasks was a second consequence taken (Korntreff et al., 2023).

In more general terms, the observed need for focused cognitive and metacognitive support in order to prevent superficial processing, on the one hand, and the danger that the provision of elaborated feedback is not automatically used due to existing self-regulation obstacles, on the other hand, presents a recurrent challenge to teachers and instructional designers (Chi & Wylie, 2014). The interactive task itself as well as the feedback it provides have to be designed in ways that students can both, perceive it and apply it to the actual situation. When interactive videos are used in classrooms, teachers can make sure that superficial processing is deepened in a classroom conversation (Henningsen & Stein, 1997). In a more longitudinal perspective, students' self-regulation competences should be fostered as well.

Acknowledgement

The planning, media design, and data collection of this study was conducted within the project MuM-Video (financially supported by BMBF-grant 01JD2001A to S. Prediger and M. Altieri by the German Ministry of Education and Research, 2020–24).

Covariational reasoning is a complex form of mathematical reasoning. Recently, eye-tracking data have been used to identify strategies in the field of research on covariational reasoning. However, in adopting such an approach, the richness and interlacing of multimodal resources involved in cognitive processes might be lost. Hence, in this methodological contribution we analyze an episode of a student reasoning covariationally by including all the multimodal resources involved in his learning process: speech, gestures, gazes, and representations. Our findings suggest an added value of such a multimodal approach for the identification of strategies for covariational reasoning. Benefits and limitations of this approach are finally discussed.

Keywords: Covariational reasoning, multimodality, eye tracking.

Introduction

Covariational reasoning is recognized as both an important and challenging type of mathematical reasoning (Thompson & Carlson, 2017). Supporting it in school practice is a relevant educational goal, but such a supportive approach also requires a better understanding of how students reason when engaging with varying quantities or relations between them. The extensive research done in this area identified *cognitive levels* (e.g., Thompson & Carlson, 2017) and *characterizations* of covariational reasoning (e.g., Bagossi, 2024). In recent studies, researchers have been looking into covariational reasoning from a socio-cultural perspective considering a multimodal approach to learning. Some studies have looked at students' gestures and language (e.g., Bagossi et al., 2022), while others have focused on students' interactions with representations while reasoning covariationally (e.g., Johnson et al., 2017).

The use of eye tracking (ET) has also been recently explored for the elaboration of strategies that can be detected from gaze patterns when students interpret contextual graphs (Thomaneck et al., 2022a). The value of ET in unraveling strategies has been widely acknowledged in different mathematical areas (e.g., Sthromaier et al., 2020; Van Dooren & Ufer, 2023), stressing the importance of triangulation of data - such as with stimulated recall interviews (e.g., Thomaneck et al., 2025; Van Dooren & Ufer, 2023) and the need for domain-specific interpretation (e.g., Schindler, & Lilienthal, 2019). Indeed, considering just eye movements in the elaboration of such strategies might result in an oversimplification in which the richness and interlacing of multimodal resources involved in cognitive processes are lost. Hence, in this contribution, we argue that the identification of strategies for covariational reasoning requires a triangulation of all the multimodal resources involved in the learning process: speech, gestures, gazes, and representations. Such a complex approach requires first a *methodological* reflection. Hence, this contribution argues for the necessity of such a multimodal

approach and does so by introducing an episode analyzed in this way. Benefits and limitations of this approach are finally discussed.

Covariational reasoning and its investigation

Interpreting functional relations as dynamic concepts, rather than static objects, requires disentangling the quantities involved and conceptualising how such quantities vary simultaneously. We call this form of functional thinking *first-order covariation*, and it turns out to be essential both when moving from a real-world context to its mathematical model and when interpreting a graph representing a real phenomenon (Thomaneck et al., 2025; Thompson & Carlson, 2017). In addition, the conceptualization of a mathematical relation within a variety of connected situations or scenarios requires a form of covariational reasoning, called *second-order covariation* (Bagossi, 2024). Reasoning at this second-order concerns the conceptualisation how a relation between co-varying variable-quantities varies simultaneously with a parameter-quantity. Even though a covariational approach has been shown to be important for developing a deep and meaningful understanding of functions, students struggle to develop and apply covariational reasoning (Thompson & Carlson, 2017). Hence, it is essential to investigate which forms of functional thinking students enact in contextual situations and which task design and digital tools may support them. Throughout the longstanding research in mathematics education aimed at investigating students' ways of covariational reasoning, several theoretical perspectives and methodological approaches have been adopted.

The foundational work by Thompson and Carlson (2017), which builds on decades of research contributions, stems from a *constructivist perspective* according to which knowledge is actively built by the subject by developing schemes of reasoning. Such work has led to elaborating a taxonomy of six cognitive levels describing how one can reason covariationally: no covariation, pre-coordination of values, gross coordination of values, coordination of values, chunky continuous covariation, and smooth continuous covariation. These levels have been investigated taking the teaching experiment as methodology (Steffe & Thompson, 2000) in which a teacher-researcher interacts directly with the investigated subject to better understand the students' hypothesis and ideas. Other works adopted a *socio-cultural perspective* in which knowledge is built with and through interaction with others (both peers and the teacher) as well as with digital and non-digital artefacts. In this approach, human activity is understood as being multimodal so all modalities should be analysed to understand cognitive processes (Gallese & Lakoff, 2005). Thus, to investigate short classroom excerpts adopting such a multimodal perspective on learning (Arzarello & Robutti, 2010), for example, Bagossi et al. (2022) considered all the relevant interactions between the subjects and artefacts together with all the semiotic resources involved (students' perceptuo-motor experiences, languages, signs, representations, and tools) by means of the Timeline as analytical tool. In addition to all the semiotic resources previously mentioned, also relevant gazes are considered meaningful to disentangle students' reasoning. This approach has contributed to a preliminary characterization of second-order covariation (Bagossi, 2024). Even though the analysis of gazes may sound peculiar within the multimodal perspective, ET has become a more and more appreciated methodological tool to investigate processes that we as researchers, cannot directly access by interpreting eye movements. The eye-mind hypothesis (Just & Carpenter, 1976) broadly states that the eyes fixate on what is

currently being processed as long as it is processed. With respect to the investigation of covariational reasoning, Thomaneck et al. (2022a, 2022b, 2025) have interpreted students' gazes when reading contextual graphs. They were able to detect gaze patterns and revealed emerging forms of covariational reasoning.

In light of all these previous considerations, in this study, we aim to investigate how a multimodal analysis, when integrating also ET data, could shed new insights into the investigation of covariational reasoning. Hence, through a feasibility case study, we will reflect on the following research question: *How is it possible to identify covariational reasoning from data integrating multimodal resources, including ET data?*

Method

Feasibility study and task design

This feasibility study was conducted with an Israeli 10th-grade public school student (16 years old), which we call here Yuval. The student indicated that he was male and that he studied according to the high level of the mathematics curriculum. The study presented here is part of a larger study in which participants worked with two animated task units containing both a dynamic applet and a function graph, and three purely inner mathematical task units showing a graph of a second or third-degree function. In this feasibility study, we focused only on the first animated task dealing with a ball rolling down an inclined plane focusing on the dependence of the distance traversed on time (Galileo unit). The animated tasks consisted of three parts, which we are going to refer to as (a) stimulus, (b) descriptive task, and (c) drawing task. At first, the participants could watch the video of the applet three times, i.e., a ball rolling down a plane[1]. This video acted as a *stimulus* to introduce the contextual situation. Then, in the *descriptive task*, the participants were asked to describe the dependence of the quantities involved, i.e. time and distance (Figure 1, left), with reference to the graph. In the *drawing task*, they were asked to sketch at least two more distance-time graphs when the length of the plane is kept fixed whereas its slope is changed (Figure 1, right) and to explain the shapes of the graphs.

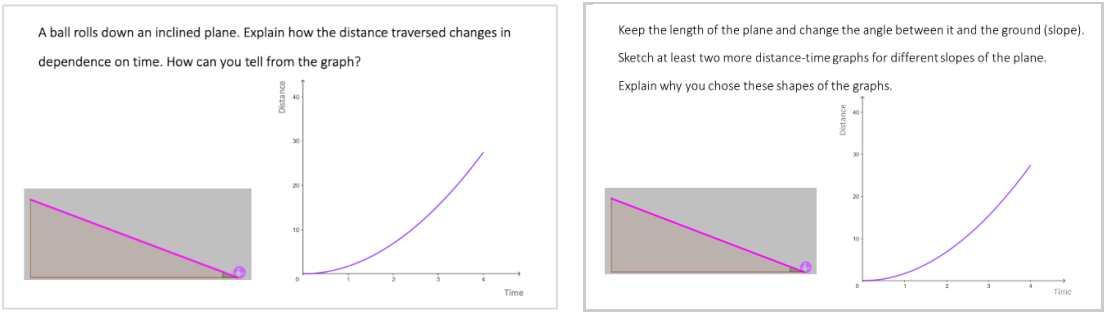

Figure 1: Galileo-unit (translated from Hebrew into English): descriptive task (left) and drawing task (right)

[1] The dynamic applet for the Galileo unit: https://www.youtube.com/watch?v=U2XfNJCJdkw

Setting and data collection

The study took place in a quiet room with the participant and the fourth author administering the tasks. There was no time restriction for working on the tasks. The participants sat on a firm chair in front of a table where a monitor was located. The tasks were presented on a 23" screen. The viewing distance was approx. 60 cm. Data was collected with a screen-based eye tracker: Tobii Pro Fusion (250 Hz, binocular). First, a 9-point calibration procedure was performed. Under optimal conditions, gaze accuracy is 0.3° (Tobii Pro Fusion, 2024). Inaccuracy was taken into account in the task design by placing the relevant objects far enough apart and data interpretation. In our study, the accuracy was 0.88° on average. In addition to the eye movements, we also recorded videos of the student: one facial video recorded by the webcam integrated into the monitor, and one video generated by a camera positioned behind the students' back recording both the student and the screen. After solving all five units, a *stimulated recall interview* (SRI) (Nguyen et al., 2013) was conducted, in which the student was shown the gaze-overlaid videos generated by the software Tobii Pro Lab (Tobii AB, 2022) as stimulus. Such a technique, also used in previous studies on covariational reasoning (Thomaneck et al., 2022a), allows participants to view a recording of the screen together with their gazes, animated as wandering red dots, jointly with the dialogues taking place while working on the tasks. The SRI took place immediately after Yuval was working on the tasks, so that his memory of what he was doing was still fresh. Both the interviewer and Yuval could stop the video: the interviewer to ask the participant to express his thoughts, and Yuval to explain what he was thinking.

Data analysis

The Galileo unit lasted in total 02:13 minutes and it was split into 20 segments. The analysis of each segment was conducted by means of an analytic table (see Table 1) in which columns 1-5 were devoted to collecting information on a specific semiotic resource each: 1. transcription of verbal *utterances* made while working on the tasks, 2. description of the *gazes*, as displayed in gaze-overlaid videos, transcribed by the researchers, 3. *gaze plot* created by Tobii Pro Lab for the corresponding time duration of the segment considered in that specific row, 4. *gestures* of the student, 5. the student's *representations* created while solving the drawing task. In a first step, the description of the gazes was related to the other semiotic resources so that hypotheses were developed on why Yuval fixated on the different locations of the stimulus. Where appropriate, these hypotheses were then elaborated into a *preliminary domain-specific interpretation* of the detected forms of covariational reasoning (column 6). In a second step, this interpretation was related to the respective utterances from the *SRI* (column 7) in order to elaborate on a *final interpretation* of covariational reasoning for the respective sequence (column 8). We finally considered all those segments where the final interpretation revealed some forms of covariation for this feasibility study. The analysis of the Galileo unit was conducted by the third and fifth author and then discussed with and validated by the first and second author. Rows that were presenting a discordant final interpretation were discussed and revised until reaching a shared interpretation.

Results

In this section, we will comment on one episode, corresponding to segment 6 in the overall analytic table, in order to elaborate on the methodological approach adopted in this study and elaborate directly on the final interpretation by addressing all the semiotic resources involved: utterances, gaze plots, gestures and representation. Table 1 (presented in a more compact way than used for data analysis) contains all the elements considered for the final interpretation.

In this episode, Yuval engages in answering the descriptive task (b) of the Galileo unit asking to elaborate on an explanation of how distance traversed by the ball changes in time elaborating on the provided graphical representation. The specific request leads Yuval to connect the quantities involved (distance and time) with the specific representation in the Cartesian system and so at first he directs his gazes to the two axes and specifically the points of coordinates (0,40) and (2,0) (Table 1, lines 2 and 5 in gaze description corresponding to gazes 12 and 13 in the gaze plot). In this short segment, Yuval claims that "As time passes, the distance increases". Yuval acknowledges covariation between time and distance and the direction of change of the two quantities expressed qualitatively ("passes", "increases") here. We interpreted this sentence as a form of gross coordination, i.e. first-order covariation (Table 1, column 6). Progressing with his explanation, Yuval moves his gaze to the graph itself starting from the point (1,2) and fixes it for a while (Table 1, gaze 14 in gaze plot). While following the graph with his gazes (Table 1, line 10 in gaze description) he adds that "because the ball is accelerating then we can see that the graph increases in this way". He simultaneously accompanies these words with an iconic gesture performed with his right hand tracing the course of the graph. Finally, his gazes jump back to the center of the graph (2.7, 12) (Table 1, gaze 20 in the gaze plot). This further multimodal explanation suggests a deeper understanding with respect to the first half of the sentence (Table 1, column 6), expressed by means of a combination of verbal and non-verbal resources. The hand gesture enables Yuval to refer to the increasing trend of the graph considering it as a dynamic mathematical object. The way in which Yuval addresses acceleration in his words is not clear from the data interpreted so far. Yet, the triangulation of these data with the SRI suggests a clearer interpretation. Yuval disentangles the variations of velocity and acceleration in this context (Table 1, column 7): "velocity is increasing" while "acceleration is constant" and this justifies the shape of the graph ("like this"). Hence, we can conclude that in this segment emerges a form of smooth continuous covariation (Table 1, column 8) in which the variation of distance in time (velocity) is increasing in a constant way and if the ball had continued travelling, in a possible interpretation of Yuval's words (SRI), "the slope would have been further and further increasing".

Concluding discussion

This contribution brings to the discussion the need for a deeper understanding of cognitive phenomena by means of a methodological approach that goes beyond the triangulation of ET data and SRIs: such an approach takes into account all the semiotic resources involved in the learning process and considers them globally. The *multimodal analysis* of the short segment of an experiment involving Yuval in the interpretation of a contextual task shows how the learner's conceptualization reveals a full understanding of the phenomenon which may not be grasped without such a multifaceted analysis. What is not fully expressed by words (Yuval cannot come up with a

mathematical term describing the trend of the graph, e.g., increasing) is supported by a gestural conceptualization reflecting the shape of the graph - performed while following the whole graph with his gazes. The lack of proper mathematical terminology is offset by a detailed embodied explanation using both arm and eyes. Yuval also elaborates on the variations of velocity and acceleration which correctly justifies the graphical relation between distance and time. Therefore, he reasons covariationally in a smooth and continuous way and properly argues for the motivations of such covariational relation. The gaze plot suggests that Yuval focused his gazes mainly on the y-axis and the beginning of the graph. He almost ignored the inclined plane despite mentioning the elements that refer to the contextual situation (ball, velocity, time, distance, etc.). The added value of such an approach does not end with a deeper understanding of the phenomenon investigated, in our case covariational reasoning. It aims to prepare the ground, theoretically and methodologically, for an unraveling of students' possible strategies in various contexts. Such an approach does not reduce to an oversimplification of the identified strategies but considers the interlacing of multimodal resources involved in cognitive processes by valuing an embodied perspective on cognition. However, we acknowledge the time-consuming nature of such an approach, which may be worthy of future discussion to distinguish those contexts in which such a rich analysis is needed or to better ponder how to use eye-tracking data. Even though the identification of covariation strategies goes beyond the purpose of this contribution - it is the final goal of the research project - the exemplificative analysis proposed here still provides an argument for the simplification of the context-related interpretation we would have run into without considering all the semiotic elements involved.

Ethics statement

The Human Subjects Research Committee of Ben-Gurion University has approved this study.

Identifying design criteria of digital learning environments for geometry learning: A student-centred approach

Selina Baldinger and Robert Weinhandl

University of Linz, Center for Open Digital Education, Austria; selina.baldinger@jku.at

In response to the Austrian Federal Ministry of Education's initiative to distribute digital devices to all students of lower secondary level, the demand for high-quality digital learning resources has increased. Despite this growing need, there is limited research on the optimal design of these materials. This study therefore investigates the design of digital learning environments (DLEs) for geometry learning at lower secondary level from students' perspectives. Employing a qualitative methodology through the Think-Aloud technique, this study engaged 17 fifth-grade students with digital geometry learning materials from the FLINK in Maths project. The research identified three critical design aspects: a) navigation, b) contextual framing of tasks, and c) fostering self-effective experiences. These findings emphasise the need for interactive exercises and the crucial role of teacher guidance in effective DLE design.

Keywords: Digital learning environment, design aspects, discovery learning, geometry learning.

Introduction

As digital technologies increasingly influence modern life, their integration into educational settings, particularly mathematics classrooms, has gained significant attention (Drijvers, 2022). Austria has actively embraced this trend with a thorough digitalization strategy that seeks to equip students from the fifth grade onwards with digital devices to foster active learning (BMBWF, 2024).

However, the increase of digital devices in classrooms necessitates the creation of high-quality digital learning materials customised to suit students' requirements. Therefore, more empirical research on the design aspects critical for digital mathematics learning experiences needs to be done, particularly for geometry learning. This study addresses this research gap by exploring key design aspects of digital learning environments (DLEs) for geometry learning in lower secondary education, focusing on students' perspectives. The research question guiding this exploration is:

What design aspects of digital learning environments for geometry learning hold relevance for students at the beginning of lower secondary level?

This research utilised a qualitative research approach employing Design-Based Research. The Think-Aloud method was used to observe fifth-grade students (ages 11 to 12) interacting with digital geometry materials from the FLINK in Maths[1] project. FLINK, an educational platform developed by the Center for Open Digital Education at Johannes Kepler University, provides a DLE that focuses on enhancing mathematical concept development and skills acquisition. This research aims to enhance the design of DLEs in digital geometry learning, bridging theoretical insights with practical applications.

[1] https://www.jku.at/flink-in-mathe/

Theoretical framework

This research adopts the frameworks of Constructivist Learning Theory and Artifact-Centric Activity Theory to investigate the design of DLEs for geometry learning at lower secondary level. These theoretical frameworks will help to provide a foundation for understanding how students interact with digital tools and how these interactions facilitate meaningful learning experiences.

Constructivist Learning Theory as described by Boyle (1997) is a framework that postulates that learners actively construct their knowledge through experiences and interactions with the world around them. This theory emphasizes the importance of students' active engagement in the learning process through exploration, experimentation, and the connection of new information to their existing knowledge (Boyle, 1997). In the context of geometry learning, digital tools such as graphing calculators and Dynamic Geometry Software (DGS) play a key role in fostering this active engagement. These digital tools allow students to manipulate and visualize geometric figures, thereby promoting independent exploration (Barzel et al., 2005). The underlying research draws on this theory to analyse the design of DLEs that encourage students to take an active role in their learning.

Artifact-Centric Activity Theory (ACAT) provides a complementary perspective by integrating principles from both Activity Theory (Vygotsky & Cole, 1978) and Instrumental Genesis (Verillon & Rabardel, 1995). ACAT focuses on the interactions among subjects (students), objects (mathematical tasks), and artifacts (digital tools) and how they mutually influence each other and the learning process (Ladel & Kortenkamp, 2016). By incorporating the social aspects of Activity Theory and the meaningful use of artifacts as described by Instrumental Genesis, ACAT allows for an examination of how digital manipulatives can facilitate both the internalization and externalization of knowledge. This theoretical framework provides a comprehensive approach to evaluating DLEs by ensuring that they serve as tools for learning and contribute to a meaningful learning experience that aligns with students' requirements (Ladel & Kortenkamp, 2016).

Literature review

This concise review of literature highlights key aspects of DLEs identified by scholars, relevant to our research question on design aspects for geometry learning at the lower secondary level.

The integration of digital technologies in classrooms has revolutionised the teaching and learning landscape, especially in the domain of mathematics (Drijvers, 2022). Geometry learning has particularly benefited from technological advancements (Henn & Filler, 2015), with DLEs becoming central to modern pedagogical strategies that emphasise discovery learning and student-centred approaches (Barzel et al., 2005). Digital tools enable dynamic visualisations and manipulations of geometric objects (Henn & Filler, 2015), allowing students to explore and experiment with mathematical relationships in ways that pencil-and-paper based methods cannot achieve (Haug, 2012). Additionally, automated feedback from digital tools enhances personalised learning by providing instant responses, similar to one-on-one tutoring (Barana & Marchisio, 2019).

According to Reiss and Hammer (2021), digital technologies are also fitting to promote discovery learning. Discovery learning, rooted in Constructivist Learning Theory, allows students to independently explore mathematical concepts to foster a deeper understanding of the materials (Reiss

& Hammer, 2021). However, balancing independent exploration with necessary guidance is crucial to prevent students from becoming overwhelmed (Kollosche, 2017).

Research on task design for digital learning in mathematics highlights the need for a strong conceptual foundation in developing digital tools. Bennison et al. (2020), as well as Yerushalmy and Olsher (2020), emphasize that tool design should be guided by clear educational goals to support students' learning outcomes. Additionally, Boyle (1997) outlines requirements for learning environments, that not only apply to DLEs itself but also to its implementation within a constructivist-oriented teaching framework. These requirements for DLEs include enabling individual experiences, embedding knowledge in real-world contexts, reinforcing learning through social interactions, incorporating diverse forms of knowledge representation, and fostering self-efficacy in independent knowledge construction (Boyle, 1997). Our study builds upon these insights by exploring how DLEs can be designed to enhance geometry learning, focusing on the integration of digital tools that promote self-efficacy, and independent exploration. We aim to connect theoretical insights with practical findings to better understand how DLEs can be optimized for lower secondary education in geometry.

Methods

This study focuses on the FLINK in Maths project, which aims to create high-quality digital learning resources for mathematics. FLINK resources are structured as interactive, thematic books that align with the Austrian mathematics curriculum and, in line with the principles of ACAT, serve as digital artifacts that mediate learning experiences. Each book includes sections for both discovery and practice and uses automated feedback and dynamic visualizations (Johannes Kepler University, n.d.). By analysing the discovery learning processes, this study draws on Constructivist Learning Theory to examine how FLINK resources aid students in building their understanding of geometry. The development of the FLINK resources follows an iterative Design-Based Research approach, including design, evaluation, and refinement (Bakker & van Eerde, 2015). This study specifically engages with the evaluation phase by analysing the resources in classroom settings using the Think-Aloud method. Through this approach, the research identifies areas for improvement and thereby directly contributes to the iterative refinement of the DLE.

Table 1 summarizes the observations conducted across five schools – both middle schools (MS) and lower secondary schools (AHS) located in urban and rural areas – where researchers had established contacts with teachers. Following the approval from the Education Directorate of Upper Austria, schools were chosen based on their consistent use of digital devices in mathematics and familiarity with FLINK resources. The study involved fifth-grade students (ages 11 to 12), and out of 63 observations conducted by three researchers between May and June 2023, 17 were selected for detailed analysis based on their relevance to the study's objectives in investigating geometric learning experiences. This selection aimed to capture a diverse representation across gender, school type, and geometrical topics such as cuboids and cube nets, geometric solids, and the introduction to circles.

Table 1: Overview of the conducted observations

School, Region	Mathematical content	Quantity male	Quantity female	Total number

MS, countryside	Cuboid and cube nets[2] Geometric solids[3]	1	2	3
AHS, city	Cuboid and cube nets	2	2	4
AHS, city	Circle introduction[4]	2	1	3
MS, countryside	Cuboid and cube nets Geometric solids	5	2	7

Data collection involved using the Think-Aloud method (Ericsson & Simon, 1984), which was chosen for its ability to capture students' immediate reactions as they engaged with FLINK materials. In line with Constructivist Learning Theory, this approach helps to comprehend how students actively build understanding by allowing them to verbalize their thoughts in real time to provide insights into their strategies and challenges when interacting with DLEs (Cotton & Gresty, 2006). Given the students' unfamiliarity with the Think-Aloud process, the observers sometimes posed targeted questions to direct the discourse toward the research question. Additionally, valuable insights emerged from observing students as they worked with the materials. By observing and analysing students' interactions with the DLE, this study aligns with ACAT's emphasis on considering also social and contextual dimensions of learning. The interactions were recorded in audio-visual format, transcribed, translated to English, and analysed by three coders using Qualitative Content Analysis. The analysis, guided by Mayring's (2022) summarising approach and Kuckartz's (2019) content-structuring approach, identified three key categories and eight subcategories of students' learning preferences. In developing the codes and categories, the analysis relied on Constructivist Learning Theory and ACAT to structure insights into students' learning experiences with DLEs. Constructivist Learning Theory informed codes related to active knowledge-building and captured how students used the digital tools to construct understanding independently. ACAT provided a framework for categorizing interactions and dynamics between students, tasks, and digital artifacts. Figure 1 outlines the resulting code and category system.

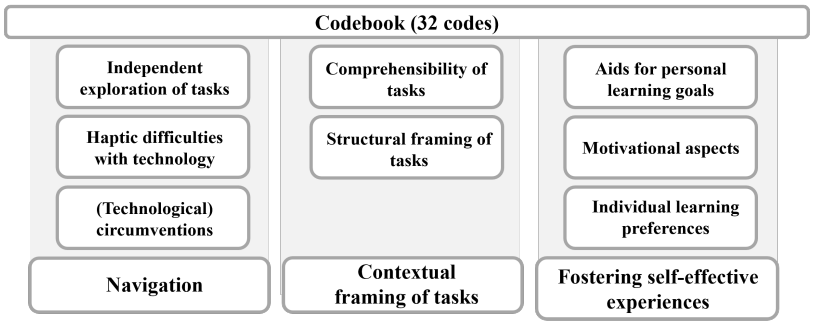

Figure 1: Code and category system

[3] https://www.geogebra.org/m/daekxjzz

[4] https://www.geogebra.org/m/a4pppe7a

To ensure objectivity in assigning codes to subcategories and main categories, intercoder reliability was assessed. The resulting Cohen's kappa coefficient of .78 indicates substantial reliability of the research findings according to Landis and Koch (1977).

Results

The research question of this paper aims to pinpoint design aspects of DLEs for geometry learning, focusing on lower secondary level students' perspectives. The analysis identified three main findings: a) navigation, b) contextual framing of tasks, and c) fostering self-effective experiences.

Navigation

The analysis underscores the importance of navigation within DLEs for geometry, identifying three key aspects: independent task exploration, haptic difficulties, and technological circumventions. Students enjoy interacting independently with DLEs and find their interactive nature more engaging than traditional pencil-and-paper methods. They appreciate the opportunity to manipulate shapes, adjust parameters, and rotate objects to deepen their geometrical understanding.

> Student (AHS|m): This is an interactive exercise; it has more momentum. Without the interactive elements, learning is simply boring.

However, haptic challenges can detract from this experience, especially on touch devices without an external mouse, making certain interactions like drag-and-drop and scrolling frustrating at times.

> Student (MS|f): It's a bit of a pain when you have to drag [the slider] like that all the time.

Furthermore, the ease of accessing correct answers can prompt some students to take shortcuts instead of fully engaging with the material, which potentially hinders the learning experience within the DLE.

> Student (MS|f): I write something briefly, then I click on "check answer" and then I can simply copy the text.

Contextual framing of tasks

In addition to navigation, the study reveals that contextual framing of tasks is crucial for DLEs in geometry, as perceived by students. Two primary aspects emerged: comprehensibility and structural framing of tasks. According to the observations, clear and precise instructions, along with logical colour coding, significantly enhance task comprehensibility within DLEs.

> Student (AHS|m): I think it's good that […] they also instruct you step-by-step on how to do it.

For structural framing of tasks, students find that visual aids and 3D models within DLEs make abstract geometric concepts, like nets of cuboids and cubes, more accessible and engaging.

> Student (AHS|f): This 3D view, in general, helps me to visualise the concept.

Fostering self-effective experiences

Finally, the data shows that fostering self-efficacy is essential for DLEs for geometry learning, with key factors including providing aids for personal learning goals, motivational aspects, and catering to individual learning preferences. Observations reveal that students appreciate DLEs that promote autonomy, for instance through automated feedback.

> Student (AHS|f): I don't always have to ask the teacher whether it's right or not. That's why I find it very practical and good.

Additionally, the data indicates that using digital devices increases motivation, as many students prefer digital resources over traditional methods. Students find that digital interactions help them grasp mathematical concepts better and enjoy features like hints, which contribute to their independent learning experiences within DLEs.

> Student (MS|m): I actually find the materials very exciting because […] I understand it [the mathematical content] much better straight away.

The observations indicate that students generally navigate DLEs successfully and appreciate their autonomy when working with digital devices. However, it is essential to address any technological challenges that may arise during this process. Furthermore, by improving the contextual framing of tasks and fostering experiences that enhance self-efficacy, DLEs can enrich geometry learning experiences from students' perspectives.

Discussion, conclusion, and further research

Drawing from the insights gathered in our investigation into DLEs for geometry learning, our findings highlight several critical aspects of DLEs that impact students' learning experiences. Firstly, navigation proves essential, as students value the independence to explore tasks on their own and manipulate objects, reflecting principles from Constructivist Learning Theory (Boyle, 1997) that emphasize active self-directed exploration. Students' enthusiasm for tasks that allow them to manipulate and explore shapes aligns with previous studies on dynamic geometry environments (Henn & Filler, 2015), which highlight how these tools encourage experimentation and enhance engagement through interactive visualizations. However, this independence also reveals practical limitations, as students occasionally resort to technological circumventions, such as copying answers, which can reduce engagement. This finding underlines the need for integrating gradual task scaffolding to support discovery while reducing tendencies to circumvent the learning process.

Secondly, the study's findings emphasize the importance of contextual framing in task design within DLEs, which was highly valued by students for promoting comprehensibility. Clear instructions, visual cues, and 3D models help students to grasp abstract geometric concepts. In line with ACAT, the structured use of digital artifacts supports the internalization and externalization processes that are critical for meaningful learning experiences. These insights align with prior research (Henn & Filler, 2015; Haug, 2012) that emphasizes the value of visual aids and consistent task framing for facilitating comprehension. However, observed haptic difficulties, particularly with touchscreen interfaces, highlight the need to consider device compatibility to prevent frustration and maintain engagement. Addressing such challenges by designing interfaces that are more touch-friendly could significantly improve the overall learning experience.

Finally, fostering self-effective experiences emerged as essential for supporting students' motivation and confidence, as seen in students' appreciation of features that allow for immediate feedback and self-correction. These features align with the research findings on automated feedback (Barana & Marchisio, 2019), which enables students to assess and correct their understanding independently. Creating self-efficacy experiences within DLEs also resonates with Boyle's (1997) emphasis on increasing students' confidence in line with constructivist learning principles. To strengthen self-efficacy, DLEs could integrate reflective prompts that encourage students to assess their learning

strategies and progress. This feature would empower students to take ownership of their learning process and enhance their sense of control which boosts their self-efficacy as they work through geometric tasks within DLEs.

Thus, our study highlights the vital role of well-designed DLEs in enhancing students' learning experiences in geometry. By addressing key aspects such as enhanced navigation, effective contextual framing of tasks, and fostering self-efficacy, educators can create digital tools that support students' autonomous learning. As digital technologies become more integrated into education, these tools must be thoughtfully designed to meet the diverse needs of learners. While our study provides valuable insights, several limitations demand consideration. The sample size and specific demographic may limit generalisability. Moreover, the study primarily focused on student perceptions rather than objective learning outcomes, suggesting a need for further research integrating qualitative and quantitative approaches.

Programming and mathematics – Experiences using programmable robots in a 6th grade mathematics class

Ingeborg Lid Berget and Beate Krøvel Humberset

Volda University College, Norway; bergeti@hivolda.no

This paper reports on the first intervention of an action research study involving a series of four tasks designed to provide experiences for learning mathematics through programmable robots. We examined opportunities observed in a Norwegian 6th-grade class working on these tasks and propose recommendations for classroom implementation. We found that the programmable robots provided opportunities for open tasks where students can discern which mathematical content areas or algorithms are beneficial in a practical hands-on context and where the environment gives feedback on the mathematical solutions. We also found indications that perceptible experiences from programmed sounds and robot movements can help students focus on the mathematics. Nevertheless, technological distractions and task openness require a teacher's guidance towards the mathematical aspects.

Keywords: Programming, mathematics education, 6th grade students, programmable robots

Background

A school requested assistance from our university college to make use of their programmable robots, LEGO Education SPIKE, in their mathematics teaching. This was the start of an action research study (Cohen et al., 2018), and the current paper is based on the first intervention of this study. In Norway, programming has been a part of the curriculum since 2020, and is included in the mathematics education (The Norwegian Directorate for Education and Training, 2019). The role of programming in mathematics education is multifaceted, and programming can e.g. be seen, as a pedagogical tool, to increase engagement, as a new way of thinking (computational thinking), or as a way of learning mathematics (Kilhamn et al., 2021). Boaler (2001) pointed out that to learn how to use mathematics in different situations, students need to not only learn mathematical procedures, but also to work on open-ended tasks. In this study, we aim to investigate the mathematics learning opportunities provided by programmable robots and open-ended tasks that invite various solving strategies.

In a literature review, Zhong and Xia (2020) studied the use of robotics in mathematics education and pointed out the opportunity for hands-on learning experiences. As within mathematical modelling, there is not a given correct answer, but the aim is to find a sufficient way of solving a problem. This includes validating the answer and refining your solution. To validate their answers has previously been seen as a part of the teacher's role, and students might stop working on a task once they have an answer (Blum, 2015). When developing problems including robots, we focused on designing a task where the robots could give the students feedback on their solution and exploit the potential for hands-on learning experiences. Zhong and Xia (2020) also pointed out that the introduction of robotics in mathematics education can elevate students' cognitive load and divert their attention from mathematical problem-solving due to the novelty of robotics. In a research project where one of their aims was to find out if the students would perform better in mathematics after working with programmable LEGO teaching materials during a school year, Lindh and Holgersson (2007) found

that the teacher's role is important, and that the use of robots does not necessarily have a positive effect on cognitive development. It is important to further investigate how to teach programming in primary school mathematics, especially performing intervention studies and empirical classroom studies in collaboration with teachers (Holo et al., 2022).

In this paper, we present an activity in four parts that was developed for an intervention in a 6th grade at the school which invited us. We examine scenarios from their classroom, and our research question is formulated: *What opportunities for learning mathematics can be identified when using programmable robots in a 6th-grade classroom, and how can the execution of the tasks be improved based on these classroom experiences?*

Development of tasks

In collaboration with a teacher and three fellow researchers in mathematics education, we developed a four-step activity for learning mathematics. The class teacher, citing his limited experience with programming, requested that we propose activities and actively participated in discussions about them. The students had limited experience with programming and the LEGO Education SPIKE environment, which utilises a robot, a tablet device and block programming, as shown in Figures 1 and 2. Therefore, the task was designed to provide students with programming experience while using programming and robots as tools for gaining mathematical insights. Following Boaler (2001)'s recommendation, we aimed to present students with open-ended tasks to encourage the use of diverse solving strategies. We decided to create a task centred around measurement, with the objective of providing students opportunities to refine strategies and engage in mathematical generalisation.

Each pair of students received a robot equipped with motorised wheels and a light sensor, which they connected to their tablet device. We decided not to let the students build the robots, because we did not want them to focus on aesthetic purposes or building techniques, but rather on solving strategies. On the classroom floor, we marked a starting point and placed a finish line made of a red paper strip. The tasks were given orally, one by one. The first was formulated:

a) Ensure the robot halts as close as possible to the finish line, which is situated 100 cm away from the starting point.

We wanted the students to explore different strategies, e.g., to find the length of one rotation by testing, or by measuring the radius of the robot's tyre and adding numbers of rotations to run. They could also find out how many seconds the robot used on the distance and add numbers of seconds to run. In task a) the students could explore by trial and error and had the opportunity to change strategy several times. In the next task, the opportunities for trial and error were narrowed down, and we wanted them to generalise a strategy and program the robot to run any given length:

b) Program the robot to halt as close as possible to an unknown/secret distance from the starting point. The distance will be revealed 1 minute before the race. Leave your robots while figuring out a strategy.

The students are asked to leave their robots while figuring out a strategy following the teacher action "disable the run-command" presented by Berge et al. (2024). This aims to foster discussions and

reflection to generalise the findings from task a). We anticipated that the students would generalise by making use of the number of rotations/seconds found in task a). They could then either make a table with possible lengths and corresponding numbers of seconds/rotations or they could find the function expressing the number of seconds/rotations per distance. They can implement their general function expression by programming the input to be the number of meters to run. An alternative, simpler method for solving the task is to calculate (or read their table to find) numbers of rotations/seconds for the given length. The coding will then be to enter the number of seconds/rotations into a single command block, as shown in Figure 1.

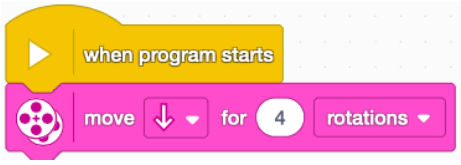

Figure 1: Example of solution task a). The number 4 can be changed before the race in task b)

In the next two tasks, we aimed to provide students with hands-on experience with the use of a loop, condition, and a variable as included in the curriculum (The Norwegian Directorate for Education and Training, 2019) and opportunities to refine their solutions. Through task c) the students will be challenged to predict, run and investigate, and in task d) modify, which is four of five components of PRIMM suggested as a way of learning programming (Sentance et al., 2019).

c) What does this programme do?

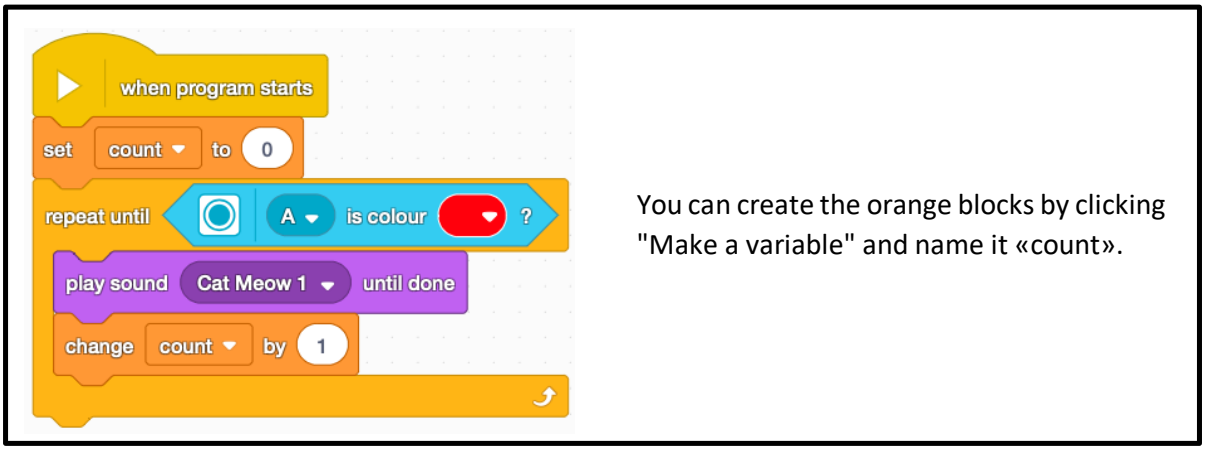

Figure 2: Handout task c), printed on paper

The programme makes the robot repeat a sound and counts how many times the sound is repeated until a red colour is identified through the light sensor. The students can make the programme on their tablets. This task provides a tangible experience with a variable, as the students can see the counter changing its value in correspondence with hearing the sound.

d) Utilise your experiences from tasks a)–c) to modify the programme in order to measure any distance from the starting point to the red finish line.

One solution to task d) is to remove the purple block for making the sound and insert a pink move-block as shown in Figure 1. We expected that most of the students would make the robot move one rotation per count and calculate the distance by multiplying the circumference of the wheel with the number of counts. If they used seconds in task a) and b), they could do the same in d). The students could either use the output to calculate the distance or, for a more generalised solution, make a programme that gives the length of any measured distance as output. The execution of the programme decides the value of the count variable, which later in the programme can be used in a length function dependent on the count. This type of generalisation might be within reach for sixth graders if the task specifies that the output should be given in metres. The task could potentially be extended to a relay race measuring different lengths for each round, where time matters, and they thus find it useful that the programme calculates the length for them. It has been found that programming languages might constrain students' development of algebraic thinking due to confusion of concepts, for example, the count variable changing its value during the execution of the programme, which is different from the variable concept in algebra (Bråting & Kilhamn, 2021). It is, however, found that for the block-based programming language used in this task, the concept of functions behaves as its counterpart in mathematics (Bråting & Kilhamn, 2021). This task might thus be suitable for working on the intersection between programming and algebra.

We made the finish line 10.5 cm thick, less than the circumferences of the wheels used. After running the loop, the programme instructs the light sensor to check if the condition for repeating the loop is true. If the students opted for a complete rotation, they might observe that the robot does not halt at the line if it is crossed during a rotation. Consequently, the robot would not come to a stop but continue onward. If they first, based on what they found in task a), instruct the robot to run for 1 m in each loop, they will discover that they need to reduce the length per loop to improve the accuracy. Thus, to generalise by expanding from natural numbers to rational numbers can be encouraged by asking the students to develop more accurate and refined solution methods.

Experiences gained and possible further directions

The classroom activities were carried out in a 6th grade where the teachers and students had limited experience with programming and LEGO Education SPIKE. The activities were conducted by their teacher. Five pairs of students were filmed by researchers, and their tablet screens were recorded. The teacher tried to solve the tasks himself before giving them to the students but had only time to work on the first two tasks. Concerning what is pointed out by Lindh and Holgersson (2007), that "[t]he role of the teacher, as a mediator of knowledge and skills, [is] crucial for coping with problems related to this kind of technology" (p.1097), this was not optimal. The teacher also expressed uncertainty about his role and found the tasks more open than he often presented to his students. They usually worked with one mathematical topic at a time. A strength of the data is authenticity. Many teachers have no experience regarding programming themselves, and do not know how to implement it in their mathematics teaching.

We have selected three scenarios in which we identify opportunities for learning mathematics. Now, we will discuss them and connect our findings to the literature used in the design process. These

scenarios are merely examples of potential opportunities and should not be considered exhaustive. The participating teacher has reviewed this paper and discussed the interpretations presented.

Opportunities for choosing appropriate strategies in the application of mathematics

In task a), one of the student groups ran one rotation and measured the distance from the starting point to where the robot stopped. They found it was approximately 17.5 cm, and Student 1 wrote 17.5 on their board (the groups had one board each) and said: “We just need to figure out how many times we need 17.5 to get to a hundred.” Student 2 replied: “Oh no, not multiplication.” Student 1 tried to mentally multiply and add up before he looked at the board of Student 3 and Student 4. They had a different size of wheels, with a circumference of 26 cm, and had written $26 + 26 + 26 + 26 = 104$ and were satisfied with their 4 cm too long solution. Student 1 said: “It's probably better to rather use seconds.” To add up was easier for the other group which added up 26 cm. Rather than using division, a more accurate way of finding out how many 17.5’s they needed to get 100, they switched strategy. According to the teacher, the students had primarily dealt with divisions involving whole numbers. The length 17.5 could have deterred them, especially since the teacher did not expressly permit the use of calculators. Or it may be due to their difficulty in associating the operation of division with the practical context. In task a), students applied arithmetic in a practical situation without predefined operations. The teacher noted that they typically focused on one mathematical concept at a time, but this task allowed for more open solution strategies. Boaler (2001) emphasises the importance of open tasks and diverse situations to help students use their mathematical knowledge beyond procedural repetition. It was positive that groups explored various strategies, though it was surprising that most used addition rather than more precise calculations in task b). One group used division to calculate "five point something" rotations per meter, while another group added rotations to reach a whole number. Task a) provided an opportunity for the teacher to discuss and compare these strategies with the class. Encouraging multiple strategies helps students evaluate their choices and understand the accuracy needed for the task. Moreover, this task provided them with feedback on the level of accuracy required when executing the race.

Waiting or refining the strategy?

In task b), the students needed to use their result from task a) and generalise their strategy to any distance. The students got 14 minutes to work on a strategy and were only given one minute after the distance was announced to prepare their programme and robot to run. One pair of students found that their robot did not reach the finish line in a). For task b), they therefore adjusted their estimate from 4.27 to 5 seconds per meter. Student 1 reasoned out loud: “Now we have how many seconds it took for one metre. So, if it's 2 metres, it takes about 10 seconds, because it takes 5 seconds on one metre,” while student 2 wrote “10 seconds on 2 metres” on the board. After careful consideration, Student 1 suggested that “if [the teacher] says like 10 cm, we need to start dividing right after he announces it. Because we have the basis of 1 metre.” From this, it seems like their general strategy is to multiply or divide 5 seconds depending on whether the distance is longer or shorter than 1 meter. The group now sat quietly and said nothing for around 9 minutes until the length was announced. It seems like the students were satisfied when they came up with one strategy, and did not discuss others. There is, however, potential for further generalisation and accuracy of their strategy.

Other groups also used approximated values expressed as whole numbers and struggled to find a general strategy. One of the groups used doubling as a strategy to find the number of rotations for two more distances. They added up from 104 cm (four rotations) and got 208 cm (eight rotations) that they rounded off to 200 cm. They seemed frustrated and in need of a better way to work with the problem. When they got the distance of 4.5 metres, they continued by doubling their previous calculation on the board to 416 cm (sixteen rotations) before adding 26 cm (one more rotation). They did not openly reflect on the fact that the robot would stop at 442 cm (8 cm before the finish line, according to their calculations). If the students are used to solving procedural tasks, they might have the understanding that "[c]hecking the correctness and suitability of a solution is exclusively the teacher' responsibility" (Blum, 2015, p. 79). As pointed out by Blum (2015), students need to be challenged to justify and improve their answers.

Both groups could have benefited from reflective questions posed by the teacher. He could have encouraged them to create a table or articulate their strategy before the secret distance was revealed. While they were formulating a strategy, the teacher could have presented hypothetical scenarios such as: What if the distance is 50 metres? Or 100? Or 33.7? Such queries could have aided them in recognising that they could multiply the secret distance d by 5 for any given d metres or that addition might not be the optimal strategy for all distances. Given their knowledge that the robot took between 4.27 and 5 seconds to cover 1 metre, they could have investigated methods to determine a more precise value. The teacher could have asked the students how the margin of error would change for longer or shorter distances and discussed if it is sufficient with an inaccurate value.

Students' hands-on experiences and troubleshooting

Just a few seconds after task d) was announced, and while the teacher was still speaking, a student modified the programme provided in task c) by replacing the "cat meow" block with the "move 1 rotation" block. We interpreted this as an intuitive idea from the student. The sound of the meow and the sound of the robot's wheel running for one rotation were easy to count individually. Therefore, even if they were not conscious of the variable and the counting within the programme, they still utilised their experiences.

However, this group, along with others that tested their programme, quickly realised that the robot did not always halt at the red finish line. The students grappled with understanding the concept of stepwise instruction in relation to a loop and made assumptions that we had not foreseen. Instead of evaluating the meaning of the programme to find that the light sensor registered colour only after a whole rotation, they suggested that the robot "drives too quickly over it" (Student 3). And "maybe it [the finish line] is not sufficiently red" (Student 5). They were both questioning the capabilities of the light sensor (too slow/wrong colour) and thus worked on troubleshooting technical issues. In this situation, the teacher alternates between the groups with the aim of guiding towards counting numbers of rotations/seconds and might not be aware that several groups are grappling with this issue. This could be a crucial moment to halt the exploration, reassure the groups about the functionality of the light sensor, and emphasise that the key to comprehending the problem lies in going back and understanding the programme. This could involve a discussion about the programming concepts of condition and stepwise instructions in relation to a loop. However, we should utilise the potential that

lies in hands-on experiences with the robot (Zhong & Xia, 2020), like the sound effect in task c). A more tangible experience with stepwise instructions within a loop could involve prompting the students to determine what the robot does when the counter alters its value (it halts to do a colour measurement). Another possibility is to conduct a plenary session to test where the robot halts when the finish line is made thicker and what happens if the starting position of the robot is shifted by 10 cm. The latter activity will also have the groups reflect on the concept of conditions. It was already tried out by one of the groups, but not in a systematic manner. It is also possible to make the concept of conditions even more tangible by adding sound blocks to the programme in task c, that read the result of the colour measurement. These realisations are pivotal to initiate work on refining solution strategies.

The students' interactions with the robot stimulated suggestions to surmount obstacles. Some of these suggestions were deviations from the given problems. The students could be directed to systematically investigate the situation to discern which suggestions are relevant and which are not.

Summarising

Through the given task in four steps, the students experienced mathematics to be useful for solving problems, and the hands-on experience with the robot aided their mathematical work. Working with the task provided opportunities for the students to engage in several mathematical content areas, in contrast to how they normally worked, one topic at a time. The nature of the tasks allowed for the precision of their solutions to be revealed, and the students could be given the opportunity to refine their strategies. The repeating sound in task c) gave an intuitive experience of what a loop is, and the stops by the robot between loops helped the students count the repetitions to predict and check their programmed measuring results.

When considering the improvement of task execution, we found that the teacher's role is crucial due to the open-ended nature of the task and the technical environment of programmable robots. While the teacher could have divided and restricted the problems, doing so would have compromised their openness. To enhance the learning experience in task c), the teacher could provide step-by-step instructions within a loop, prompting students to observe the robot's actions when the counter changes its value. Additionally, a plenary session could be conducted in task d) to test the robot's behaviour when the finish line is made thicker, or the starting position is shifted. There are opportunities for generalising the solutions in task b) by changing the input variable by including a general formula in their coding, but this was not observed during the intervention. We did not identify generalised solutions in task d) either, possibly due to time constraints. They could for example have programmed the output to display the race distance in centimetres instead of the number of rotations. In further interventions, we will therefore suggest placing greater emphasis on this part of the solution process to investigate the intersection of algebra and programming as part of generalisation in mathematics.

In the beginning of the 2020s, a number of Generative Artificial Intelligence (GenAI) systems emerged and started to be used by the students for their ability to process natural language input and give immediate feedback. Although schools are mainly struggling to reduce the possibilities of cheating, researchers in education are interested to understand if and how generative AI technologies might open up new possibilities and approaches to improving student learning. In this regard, we seek to explore the potential of GenAI to support students mathematical learning. This work presents an a priori analysis in which researchers simulated the use of a GenAI system, by undergraduate students, to explore if and to what extent GenAI can be used as a scaffolding tool for learning the concept of function continuity. Results reveal the high potential of the tool but underline the need to further investigate the nature of the changes that GenAI brings to mathematics teaching and learning.

Keywords: GenAI, scaffolding, function continuity.

Introduction and rationale

In recent years, the integration of artificial intelligence (AI) into education has expanded considerably, giving new impetus to Artificial Intelligence in Education (AIEd). AI can enhance teaching, learning, and decision-making processes by automating tasks such as student assessment, providing feedback, and identifying learners at risk. Moreover, AI can personalize learning experiences through tutoring, adaptive content, and support for self-regulated learning (Hwang et al., 2020). In mathematics education, AI can play a crucial role in addressing challenges such as generating problems, tracking student progress, and evaluating performance. As recently highlighted, these innovations particularly boost student engagement and empower educators within STEM education. In this context, three major paradigm shifts can be identified to define AI's evolving role in STEM education (Ouyang et al., 2021): a) *AI-Directed Education* – Based on behaviorism, this model sees AI as the main instructor, leading students through predefined learning paths. AI is seen as a "black box" teaching machine that can present the knowledge subject and guide the learning process through enquiry and by providing the learner with knowledge of correctness (Burton et al., 2004). b) *AI-Supported Education* – Grounded in cognitive and social constructivism, this model points on the collaboration between AI systems and the learner to focus on his/her learning process. AI can provide personalized feedback and real-time assessments to guide student learning, through the information collected from learner's input. The mutual interaction between AI and the learner moves toward a more learner-centered learning (du Boulay, 2019). A main issue is the complexity of the interaction due to the complexity of both the learner and the system. c) *AI-Empowered Education* – Based on the notion of learner agency (Bandura, 2006), this model sees AI as a tool to augment

human intelligence and foster collaboration. AI can assist in decision-making, offering personalized support and feedback, while learners take a leading role in their education. Central in this model is the promotion of a significant interaction between the learner and the AI system that can give as a result adaptive personalized learning (Hwang et al., 2020). Assuming these three paradigm shifts can be considered for mathematics education as well, we claim that the role of GenAI as a supporting learning tool still needs to be investigated.

In our work, with the aim to explore if and how the second paradigm—AI-Supported Education—can be realized, we consider the notion of scaffolding. As in the field of educational psychology, we refer to scaffolding as the process of providing structured support to learners in order to help them achieve tasks just beyond their current capabilities (Wood et al., 1976). As students gain proficiency, this support is gradually reduced, allowing them to become independent learners. In our view forms of scaffolding can be applied by using AI systems that not only provide personalized feedback and real-time assessments but also adjust the level of guidance based on the learner's evolving needs. We are interested in exploring if, by dynamically responding to student progress, AI can offer more targeted interventions, enabling students to engage with complex tasks while maintaining an appropriate level of challenge.

To understand whether and how GenAI could be used as a scaffolding tool to support learners in developing mathematical concepts, we conducted an a priori analysis of the tool's potential. It is important to note that we did not work directly with students: the first two authors rather tested a GenAI system through a simulated interaction. This decision was driven by the need to first evaluate the tool's effectiveness in addressing learning challenges before moving on to testing it in real context with students.

Results are analysed within the framework of cognitive apprenticeship (Collins et al., 1987) in mathematics education and reveal the high potential of GenAI in mathematics education. In addition, our findings highlight the need to think about how these tools can change the way teachers and students interact with the mathematics, and how to conceptualise and analyse the nature of the changes that GenAI brings to mathematics teaching and learning.

Conceptual Framework

To analyse the potential of GenAI as a scaffolding tool, this paper adopts the concept of cognitive apprenticeship grounded on Vygotsky's well-known concept of the Zone of Proximal Development (ZPD) (1972). Vygotsky's theory was extended to the K-12 educational system, by Wood et al. (1976), introducing the notion of scaffolding, according to which teachers provide support, which they call scaffolding, for students to master their learning. Then, when students have mastered the material, teachers remove the scaffolds, much like a structure, and as students learn new material using new scaffolds (tutorials, videos, visual aids, etc.), the ZPD expands outward. Collins et al. (1987) further developed the notion of scaffolding, introducing the model of *cognitive apprenticeship*, designed to make thinking processes visible and explicit in the learning environment. It emphasizes social interaction and the development of cognitive and metacognitive skills to 'use, manage and discover knowledge', through six main processes. The basic processes –modelling, coaching and scaffolding– support the development of both cognitive and metacognitive skills. The next two,

articulation and reflection, are designed to introduce novices to expert-like problem-solving and execution techniques. The final stage, known as exploration, aims to guide the novice towards self-sufficiency and the ability to autonomously solve and recognise problems within the field.

In our study, we analyse a simulated student-GenAI interaction exploring how and to what extent GenAI can perform each of the six steps that characterise cognitive apprenticeship.

Methods

With the aim to investigate the potential of GenAI as a scaffolding tool for students learning, in this paper we focus on the following research question: How can the model of cognitive apprenticeship allow us to investigate the potential of GenAI as a scaffolding tool for mathematical learning?

To answer our question, this paper offers an interpretive a priori analysis: two researchers (the first two authors) investigated the advantages and disadvantages of using GenAI to scaffold undergraduate students learning in a calculus course. The topic chosen for this study –function continuity– comes from a calculus course for biology students taught by one of the authors. Based on the instructor's experience, function continuity is one of the most challenging topics for students in this course, often requiring extensive justification and additional explanation to ensure understanding.

A lecture on the function continuity given in a calculus course for first-year students of the bachelor's degree in biology was audio-recorded and www.turboscribe.ai was used to automatically generate subtitles for the recording. The whole text was uploaded to a GenAI system (Capone & Faggiano, to appear) and, based on the transcription a conversation was developed with GenAI. The questions posed to GenAI during the simulation were based on existing literature and on previous experimentations (which aimed at investigating the common misconceptions and difficulties on function continuity encountered by undergraduate students not enrolled in mathematics courses). In what follows we briefly mention the relevant existing literature.

The learning of the concept of function continuity: related literature

It is well known that students are often unclear about the formal definition of a continuous function (e.g. Jayakody & Zazkis, 2015). A significant part of this difficulty stems from the relationship with the concept of limits which has been proven difficult to learn (e.g. Juter, 2005). Very common is the use of an intuitive (concept) image in which a continuous function is described throughout its domain as a function whose graph can be drawn continuously, i.e. without 'breaks', 'tears' or 'jumps' throughout the fixed domain (Tall & Vinner, 1981). Of course, such a description of continuity should not omit an explicit reference to the continuity of the domain. Students do not always understand how to adequately separate the concept of continuity from its intuitive graphical visualisation. It can happen, for example, that the evaluation of the function continuity whose Cartesian graph cannot be drawn becomes a difficult obstacle to overcome, precisely because it is impossible to visualise continuity or discontinuity through the characteristics of the graph. Moreover, the extensive use of continuous functions in examples and exercises in textbooks can lead to the misconception that continuity is the rule and discontinuity the exception. In other words, the student seems to implicitly associate the concept of 'function' with the property of 'continuity', without realising that a continuous function should instead be considered as a (very) special case of a function. The

interaction with GenAI has been developed taking into account this related literature concerning the learning of the concept of function continuity.

Investigating the potential of GenAI

In this section we report some extracts of the conversation between the researchers and the GenAI system. We then reflect and discuss on what emerged in the light of our framework, seeking to interpret what happened in terms of the different steps that characterise cognitive apprenticeship.

In the following transcript, the sentences attributed to the "User" were written by the researchers, acting like a student who wanted support in her learning. The answers processed by the GenAI system appear as given by "Assistant".

1	User:	Hi, I am enclosing a transcript of a lecture on the concept of continuity in mathematics. [The researcher pasted the transcript of the lesson.]
2	Assistant:	Thanks for sharing the transcript of the lecture. It seems very rich in examples and detailed explanations of the concept of continuity and limits in mathematics. Here is a list of key points from the lesson on the concept of continuity of functions. […] Would you like to make changes, adjust some parts or elaborate further on some specific concept?

We start asking GenAI to present a series of exercises based on the transcribed lecture.

3	User:	Can you give me some exercises on the lesson I gave you?
4	Assistant:	Of course! From the analysis of the lesson transcript, here is an exercise for you. Check the continuity of the function f(x)=|x| at the point x=0.
5	User:	I think the function is continuous at x=0? Is my solution correct?
6	Assistant:	Yes, your solution is correct
7	User:	Can you show me your solution to compare with mine?
8	Assistant:	Of course! […]

The system gives a correct and clear solution and then the researchers tested the system with some question on concepts that were not covered in the transcribed lecture.

9	User:	Yes, thank you, I did not understand one thing: is the function $1/x$ continuous?
10	Assistant:	The function $1/x$ is continuous in its natural domain, which is $\mathbb{R} \setminus \{0\}$, which is the set of real numbers except $x = 0$. However, at $x = 0$, the function is not defined (because you would have division by zero) and is therefore not continuous at that point.
11	User:	But if it is continuous, why can't I draw it without taking the pen off the paper as was said in the lecture?
12	Assistant:	Good point! […] When we say that a function is continuous 'without taking the pen off the paper', we are referring to a function that is continuous over an entire interval. In the case of $1/x$ the problem is that there is a point of discontinuity (i.e., a gap) at $x = 0$. Therefore, the graph has a gap and, to draw it, you would have to take your pen off the paper when you go through […]
13	User:	You told me that at $x = 0$, there is no continuity because the function is not defined. If there is no continuity, how can there be discontinuity?
14	Assistant:	You are right to raise this question, and it is a crucial point in understanding the relationship between continuity and discontinuity […] In summary, in the case of $1/x$, there is no discontinuity in $x = 0$ because the function does not exist at that point.
15	User:	So, if a function is defined at a point, will it also be continuous at that point?

16 Assistant: No, a function defined at a point is not necessarily continuous at that point. For a function to be continuous at a point, three conditions must be met: The function must be defined at that point. The limit of the function must exist when x tends to that point. The value of the limit must be equal to the value of the function at the point. If one of these conditions is not satisfied, the function is not continuous at that point, even though it is defined there.

The researchers then wanted to test the system's ability to generate new examples.

17 User: Can you give me an example of that?

18 Assistant: An example of a non-continuous but defined function is the step function:

$$f(x) = \begin{cases} 1, & if\ x < 0 \\ 2, & if\ x \geq 0 \end{cases}$$

In this case, the function is defined at $x = 0$ (its value is 2), but is not continuous at $x = 0$ because: The left and right limits do not coincide and the limit at $x = 0$ is not equal to the value of the function at $x = 0$, which is 2. Therefore, although the function is defined in $x = 0$, it is not continuous at that point.

As we were unable to provide a correct interpretation of the graph obtained, GenAI has been tasked with constructing a graph in a Cartesian plane with x and y axes.

19 User: Can you show me the graph?

20 Assistant: Here is the graph of the step function you asked for. [Fig. 1 was displayed] As you can see, the function takes the value 1 for x<0 and the value 2 for $x \geq 0$, with an open circle at $y = 1$ in $x = 0$ and a full circle at $y = 2$ in $x = 0$

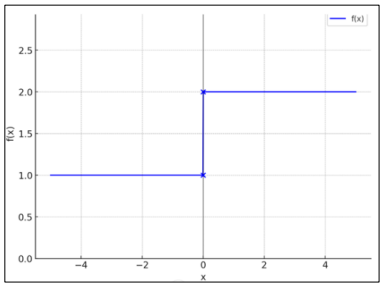

Figure 1. Graph of the step function

The researchers continued to test the capabilities of the GenAI by generating and solving new exercises, introducing variations in the numbers and increasing the level of difficulty.

21 User: Can you assign me some more difficult exercises?

GenAI therefore provides more complex exercises based on the topics discussed, enabling students to challenge themselves and deepen their understanding. A sample solution was then requested, as it could serve as a useful reference for comparison or offer new insights, especially given the increased complexity of the exercises.

GenAI was then asked to generate a summary of the lesson and based on this summary, to pose some questions to the user.

22 User: Finally, can you ask me some questions to verify what I understood of the lesson?

23 Assistant: Of course! Here are some questions to check your understanding:

Definition of continuity: What are the three conditions that must be fulfilled for a function to be continuous at a point c?
Limits and continuity: How can you check whether a function is continuous at a point where the denominator cancels? What do you need to check?
Functions and isolated points: What does it mean if a function is defined at an isolated point? Is the function always continuous at these points?
Graph and continuity: If you cannot draw the graph of a function without taking your pen off the paper, does this necessarily mean that the function is not continuous?
Discontinuities: What are the main types of discontinuities that a function can have? Can you describe one of them with an example?
Try answering these questions and let me know if you have any doubts!

Discussion

In this study, the researchers simulated the actions of a hypothetical student to explore how GenAI could serve as a support tool for their learning. For this reason, in this section, we put the word "student" in quotation marks, as we are referring to them in a hypothetical context. In order to thoroughly analyse the discussion with GenAI in relation to the six steps that characterise apprenticeship learning, we developed and identified a set of categorisation criteria (see Table 1) designed to systematically map the different aspects of the interaction.

Table 1: Identification Criteria for the conversation's analysis

Process	Description	Identification Criteria
Modeling	The expert demonstrates the desired behavior or concept.	Clear definitions, explanations of concepts and the key aspects.
Coaching	The expert provides personalized support and feedback based on the learner's progress.	Adaptive feedback on exercise solutions.
Scaffolding	Temporary support that helps the learner complete difficult tasks, gradually reduced as competence grows.	Breaking complex problems into simpler steps, context-specific suggestions based on particular requirements, progressive guidance that diminishes as the learner gains autonomy.
Articulation	The learner is encouraged to explain and articulate his/her thinking.	Questions that prompt the learner to explain his/her reasoning and justify his/her answers.
Reflection	The learner compares his/her reasoning with that of the expert and reflects on mistakes.	Comparisons between the learner's answers and correct solutions, reflection on choices made during the process.
Exploration	The learner explores independently, solving problems and discovering new applications of the concept learned.	Complex or more difficult problems, decreasing support to stimulate independence and self-directed exploration.

Analysing the conversation between GenAI and the researchers we can see that, when equipped with lecture's transcript as a knowledge base, GenAI can act as a useful *modelling* tool providing a summary of the key points (excerpt 2). Our results also show that GenAI can support individual *coaching* providing some exercises and feedback on their solutions (exc. from 3 to 6). When the "student" asks for support on things she cannot understand on her own (exc. 7, 9, 11, 13), GenAI provide customized *scaffolding* trough contextualized hints and detailed explanations based on their specific needs (exc. 8, 10, 12, 14). In response to requests for explanatory examples and representations (exc. 15, 17), GenAI provides accurate and precise responses, facilitating a deeper understanding of the key aspects (exc. 16, 18). However, it is unclear whether GenAI can always adapt its level of assistance in a manner that is responsive to the evolving competence of the student.

The question thus arises as to whether the assistance provided by GenAI can be gradually reduced as the student becomes more independent and capable of addressing problems autonomously, selecting their own approaches and solutions. When "student" asks GenAI to pose questions about the key conceptual points from the lesson uploaded by the lecturer (exc. 20 and 21), she is encouraged to *articulate* her own reasoning. This process helps her grasp the importance of asking the right questions and thinking aloud, fostering deeper understanding and active engagement. Through this kind of interaction, "student" can develop critical thinking skills and learn to navigate complex concepts more effectively. The request to generate more complex tasks based on the lesson uploaded (exc. 19), and to provide solutions, enables "student" to engage with more advanced problems. This approach allows her to self-assess the skills she has acquired and *reflect* on her own solutions, promoting deeper understanding and independent learning.

Conclusion

This study shows the role of AI within the paradigm of AI-supported education. With the aim to explore the potential of GenAI as a scaffolding tool for students learning, in this paper we attempted to investigate if there is such a potential and how this can be interpreted through the model of cognitive apprenticeship. The findings of this study reveal that when students share the text of a lecture with GenAI, it can provide them with advanced, targeted and personalised support. In fact, we were able to experience the ability of GenAI to summarize lessons (modelling), provide examples (coaching), to develop, solve problems and contribute additional information (scaffolding), simulate interviews (articulation) and propose more challenging activities (reflection). Referring to the six steps of cognitive apprenticeship, the analysis of our results seems to miss the last step, autonomous exploration (exploring). In fact, we were unable to assess this aspect, which is linked to the students' attainment of independence, as our experiment did not involve direct interaction with them.

Although our simulation explored the use of GenAI as a tool to give students the opportunity to explore ideas, ask questions, and receive real-time explanations, we acknowledge that this only represent one step in the broader process of learning a new mathematical concept. Despite the high potential of the tool revealed by this study, further investigation concerning the nature of the changes that GenAI brings to mathematics teaching and learning is needed. For example, we seek to understand how and if different types of prompts—ranging from open-ended questions to more structured guidance—can be used by the learners to support their mathematical learning. We also are interested in exploring the possibility of creating an inclusive learning environment where each student can progress at their own optimal pace with tailored support. To gather more valuable insights on the effectiveness of GenAI as a scaffolding tool, we have already planned additional experiments that directly involve students. This will help us understand how well the AI-supported framework works in a practical classroom environment.

Examination of eye movements of primary school 4th-grade students during mathematical problem-solving*

Çağla Bingül[1] and Yeliz Yazgan[2]

[1]Istanbul Sabahattin Zaim University, Faculty of Education, Türkiye; cagla.bingul@izu.edu.tr

[2] Bursa Uludag University, Faculty of Education, Türkiye

The study aims to examine differences between primary school students' eye movements during routine and non-routine problem-solving. Heat map data grouped by achievement levels were compared for routine and non-routine problems. Eye movement recordings and think-aloud data were coded as 'question-to-answer' and 'answer-to-question'. Problem solving time and number of fixations were also compared. Our findings show a difference between the two types of problems in terms of eye movements.

Keywords: Eye movements, primary school students, problem solving, routine problem, non-routine problem.

Introduction

The eyes are seen as a window to the mind. We perceive the world with our eyes, and almost everything we do during our waking hours involves eye movements (Karatekin, 2008). Eye movements are a vital part of our interaction with the world. They play a crucial role in perception, cognition, and education (Wade & Tatler, 2005). An eye tracker, as stated by Duchowski (2017), is the most used device for measuring eye movements. Eye tracking can detect where users look at a point, how long they look at something, and the path of their eyes (Schall & Bergstrom, 2014). Research by Schindler et al. (2016) showed that eye-tracking provides in-depth information about the processes that students follow when solving tasks. Studies in mathematics education show that eye tracking can provide information about the attentional processes involved in solving mathematical problems (Norqvist et al., 2019).

When classifying mathematical problems, a common distinction is made between routine and non-routine problems. It is challenging to draw a clear line between routine and non-routine problems, as they can vary from person to person. However, the key difference lies in whether the problem requires higher-order thinking skills. Problems involving logical reasoning, inference, or prediction often demand such skills and are likely to be non-routine, which can generally be identified using specific criteria. Routine problems can be solved by applying methods that students have previously learned step by step (Polya, 1957; Woodward et al., 2012). For example, consider the routine problems presented in Figures 1 and 2. These types of problems are structured and familiar, enabling individuals to solve them using their existing knowledge and skills. Since they can be resolved straightforwardly by applying specific formulas or algorithms, they are classified as routine problems. In contrast, non-routine problems, as illustrated in Figures, require individuals to think creatively, tackle unfamiliar

* This research was produced from the first author's master's thesis entitled "Examination of eye movements of primary school 4th-grade students during mathematical problem-solving".

situations, and develop solutions beyond conventional approaches. Solving such non-routine problems demands higher-level skills beyond basic operational abilities, such as organizing and classifying data or identifying relationships (Souviney, 1989). While routine problems can be solved using basic arithmetic skills, non-routine problems often allow for multiple solution pathways (Woodward et al., 2012). Although not classified as “non-routine problems” in the literature, there are some eye-tracking studies that examine such problems (Norqvist et al., 2019; Rożek et al., 2014; Sajka & Rosiek, 2015). There is a limited number of studies that combine eye-tracking techniques and non-routine problem-solving methods. This study aims to address this gap by examining the eye movements of fourth-grade primary school students during mathematical problem-solving. Accordingly, the central research question guiding this study is: "Is there a significant difference in the eye movements of fourth-grade primary school students when solving non-routine versus routine problems?"

Method

The method of this research is a holistic multiple-case study, which is a qualitative research design. The study group consisted of 12 fourth-grade students from a primary school in Istanbul/Türkiye. These students were categorized into three levels of mathematics achievement: high (six students), medium (three students), and low (three students), based on their math grades. All high-achieving students were male, while the medium-achieving group included two females and one male. The low-achieving group consisted of three female students.

Study procedure

The first author conducted the study in a laboratory setting, and participants were informed about the process. During the application, the participants were shown consecutive slides on the computer screen and asked to read the problems aloud and express their thoughts aloud during the problem-solving process. The researcher provided reminders as needed to encourage participants to keep thinking aloud, and the process was recorded with a voice recorder. The research was conducted in two sessions; in the first session, non-routine problems were asked, and in the second session, routine problems were asked. No time limit was imposed on the students during problem solving and the use of tools such as paper and pencil or calculators was not allowed. Due to the non-routine problems with individual differences described in the introduction, one-on-one interviews were conducted with the students after the problem-solving process. The students mentioned that they had not encountered the non-routine problems (from session one) before. In contrast, the routine problems (from session two) reminded them of questions from their textbook or those previously asked by their teacher.

Data collection and analysis

In this study, an SMI eye-tracking device was used. Participants were presented with seven routine and eight non-routine math problems in two separate sessions, and their eye movements were recorded throughout the process. The higher count of non-routine problems is due to one of them consisting of two stages. As part of the initial analysis, heat maps were used both to compare students' approaches to the two problem types and to analyze their performance according to their level of achievement. Heat maps were first compared with participants' success levels to understand the

distribution of their attention and focus areas during the problem-solving process. Since the space limit, only two routine and two non-routine problem heatmaps were provided in Figures 1 and 2. Secondly, scan path videos, gaze replay videos, and think-aloud data were categorized under two predefined codes—'question-to-answer' and 'answer-to-question'—to uncover participants' problem-solving strategies. By coding and analyzing these data, we examined the flow of information in students' problem-solving processes. This analysis provides important clues to understanding students' problem-solving strategies and how they access information. Finally, the comparison of the average durations and number of fixations between the two problem types was conducted to determine which problem type students found more challenging or time-consuming. SPSS version 25 was used to analyze the differences in problem-solving times and the number of fixations between routine and non-routine problems. After confirming that the solution time data were normally distributed, a dependent samples t-test was applied. However, since the fixation data were not normally distributed, the Wilcoxon signed-rank test was used for comparison. These statistical comparisons were part of the quantitative analysis, while the qualitative analysis involved coding and evaluating the eye movement videos. This analysis is necessary to understand how the students' cognitive load and problem-solving speed change according to problem types. In this way, it was possible to obtain information about how the problem types used affect students' thinking processes.

Validity and reliability

The problems used in the study were administered to 85 fourth-grade students who were not part of the application group, and the Cronbach's Alpha coefficient obtained from the reliability analysis of these problems was found to be 0.703.

Results

This section examines how students interact with routine and non-routine problems, highlighting differences in their responses and eye movement patterns across various achievement levels. First, the findings are supported by heat maps (Figures 1 and 2), which illustrate the variations in students' eye movements as they engage with each type of problem. To enhance the clarity of the figures, English translations of the problems are provided before the figures themselves.

English translation of the routine problem in Figure 1:

"314 male parents and 492 female parents attended the PTA meeting. In which of the options is the number of parents attending the meeting rounded to the nearest hundred?"

English translation of the non-routine problem in Figure 1:

"While a tourist was visiting a cave in Antalya, they saw the following code on the wall. He realized that there was a relationship between the top number and the bottom number. However, some parts of the code were left blank. What numbers should go in the blank spaces of the code?"

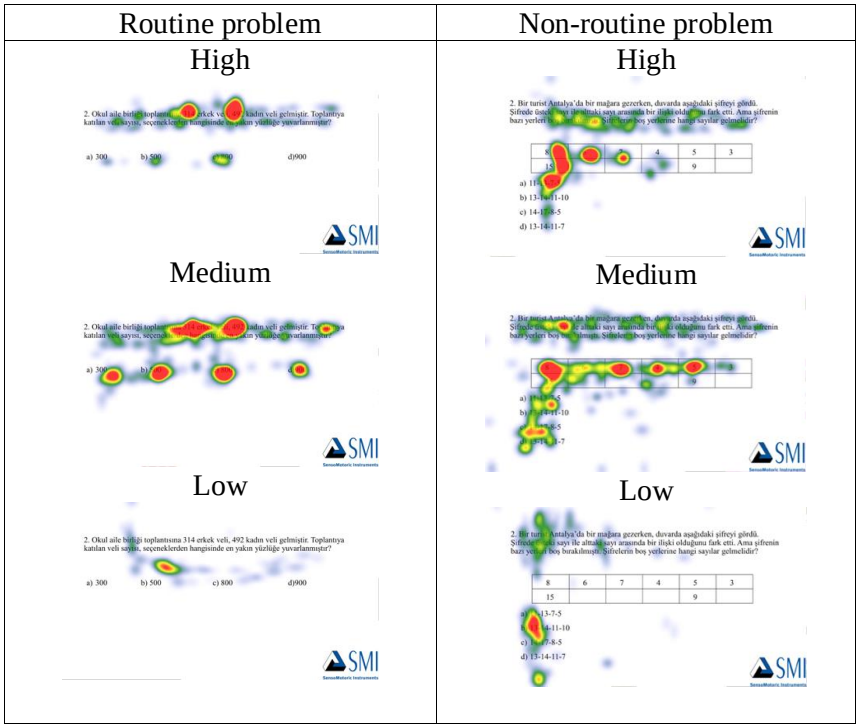

Figure 1: Heat maps of routine and non-routine problems

When the heat maps in Figure 1 are analysed, in the routine problem, the participants at high achievement and medium achievement levels made more fixations on the correct answer to the problem and the relevant statements of the problem. The low achievement level participant, on the other hand, made scattered fixations and did not focus on the relevant parts of the text for the solution of the problem. When the visual attention of the participant at the low achievement level was examined in the non-routine problem, it was observed that although he focused on the expressions "the number above" and "the number below" on the text, his attention on the visual figure was very little and he did not make a correlation between the numbers above and below on the figure. Especially when compared with the other achievement levels, it is seen that the participants at the high achievement level and at the intermediate achievement level looked for a relationship between the boxes at the top and bottom of the visual figure and focused on those parts. When the two problem types are compared, it is seen that participants made more fixations in the non-routine problems. This supports that non-routine problems lead to more cognitive effort.

English translation of the routine problem in Figure 2:

"Ayça and her friends are going to have pizza for lunch. There are 5 pizzas with 12 slices in the pizzeria. If Ayça and her 12 friends each eat 4 slices of pizza, how many slices of pizza will be left?"

English translation of the non-routine problem in Figure 2:

"Using two straight lines, divide the clock face below into three parts so that the sum of the numbers in each part is the same. What is the sum of each of these three parts?"

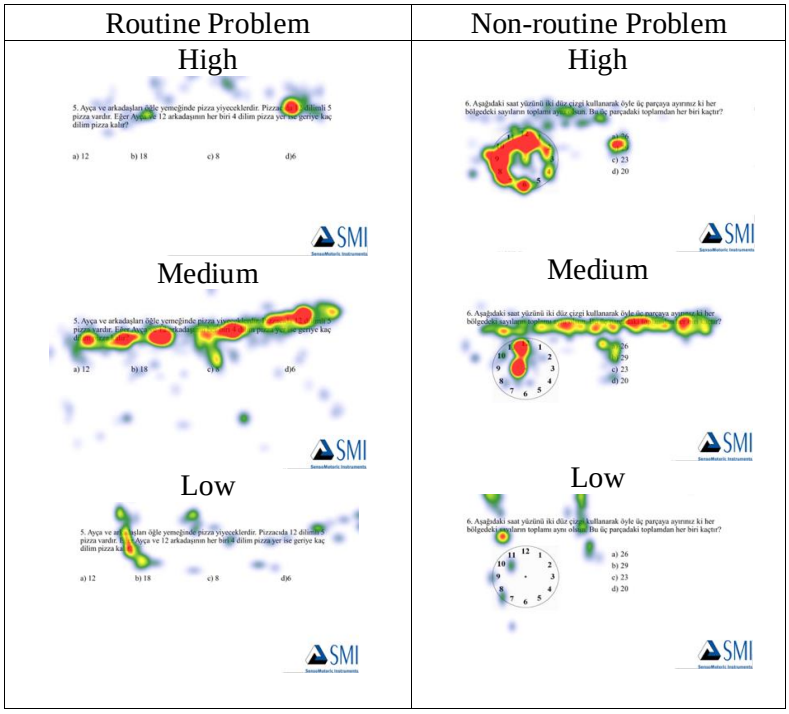

Figure 2: Heat maps of routine and non-routine problems

When the heat maps were analysed, in the routine problem, the participants with high achievement levels focused on the important parts ("12 slices", "Ayça and") of problem-solving. The participants at the medium achievement level focused on many parts of the problem. The low achievement level participant focused on the irrelevant parts of the problem. When the non-routine problem was analysed, the participant at the high achievement level applied the "guess and check" strategy and tried to find the sum of different parts and found the result. The participants at the middle achievement level focused on the problem text and solved the problem with a different strategy. The participants at the low achievement level focused on the irrelevant parts of the problem. When the heat maps were analysed for the routine problem, participants with high achievement levels focused on the critical aspects of problem-solving: the 'three parts' word, the 'same' word, and tried different numbers on the clock as part of the guess-and-check strategy.

This study was conducted to understand the problem-solving strategies of fourth-grade students in routine and non-routine problems. Accordingly, the responses to routine and non-routine problems were coded in terms of "question-to-answer" and "answer-to-question" approaches. The related coding is presented in Table 1. We needed to conduct such an analysis to examine the effects of multiple-choice questions on eye movements and thinking processes and to understand how students adopt different approaches to different problem types.

Table 1: Table on the coding of the answers to routine and non-routine problems from 'from question to answer' or 'from answer to question'

Problem	Routine Problem		Non-routine Problem	
	From question to answer	From answer to question	From question to answer	From answer to question
P1	9	3	11	1
P2	10	2	10	2
P3	12	0	8	4
P4	7	5	12	0
P5	9	3	2	10
P6	8	4	12	0
P7	8	4	12	0
P8			11	1
Total	63	21	78	18

Table 1 shows the classification of responses to routine and non-routine problems under two methods: 'from question to answer' and 'from answer to question.' For the seven routine problems, the participants solved them 'from question to answer' 63 times and 'from answer to question' 21 times. For the eight non-routine problems, they used 'from question to answer' 78 times and 'from answer to question' 18 times.

The paired sample t-test conducted to compare the average time (in ms) required to solve non-routine and routine problems revealed a statistically significant difference. On average, participants took significantly more time to solve non-routine problems (M = 144627,8 ms, SD = 50007,4 ms) compared to routine problems (M = 72251,4 ms, SD = 27041,6 ms). The difference in means was significant, with $t = 5{,}614$ and $p < .05$.

The Wilcoxon Signed Rank Test conducted to compare the number of fixations between routine and non-routine problems revealed a statistically significant difference ($p = 0{,}002$, $p < 0.05$). Negative ranks (routine < non-routine) showed higher fixations for non-routine problems, with a mean rank of 6,50 and a sum of ranks of 78,00. No positive ranks or ties were observed ($Z = -3{,}059$), indicating that non-routine problems demand more attention. Accordingly, more fixations in non-routine problems indicate that there is more cognitive load in solving these problems.

Discussion and conclusions

The heatmaps obtained from the study revealed that participants directed their attention towards specific elements of the problem statements when faced with routine problems, as they were able to predict the solution. This suggests that their focus was concentrated on predictable and specific points. However, participants adopted a more exploratory approach when solving non-routine problems. They carefully examined various elements of the problem statements to explore possible solutions. This indicates that their attention was spread across a wider range, and they developed more flexible strategies during the problem-solving process. These findings are consistent with the findings of Zhu et al. (2022), where it was observed that experts' eye movements covered a larger

area, and they transitioned between different thinking modes more flexibly compared to novices. The increased focus also suggests deeper cognitive processing (Jian, 2017). The flexibility and in-depth attention demonstrated by the participants when faced with non-routine problems support the idea that cognitive processes were more intense.

When the heat maps are considered, and although gender was not a focal point in this study, the observation that high achievement levels were only present among male participants may suggest a potential effect of gender on mathematical problem-solving performance. However, this finding cannot be generalized due to the limited sample size and distribution, emphasizing the need for further research. Another important finding of the study is that as the participants' achievement levels decreased when faced with routine problems, their ability to focus on critical parts of the problem text also diminished. It was observed that participants with low achievement levels struggled to adopt effective problem-solving strategies and could not focus enough on important details in the problem text. This can be explained by the distraction of their attention and loss of motivation when they experienced failure, which negatively impacted their problem-solving processes.

Based on the previously described coding process, routine problems were solved more often by the "from answer to question" method than non-routine problems. These findings indicate that the rate of transitioning from question to answer was higher in non-routine problems, suggesting that participants engaged more in gathering information and exploration during non-routine problem-solving. The results reveal that non-routine problems generally require more complex thinking and advanced problem-solving strategies. Such problems force students to focus on analyzing the problem rather than directly starting from the answer to find a solution.

The study also focused on the solution times and the number of fixations of routine and non-routine mathematical problems. The problem-solving time and number of fixations indicate that non-routine problems require more time and a higher number of fixations than routine problems, as they demand more mental processing. This finding supports the notion that non-routine problems impose a greater cognitive load during problem-solving.

In this study, the data collection sequence was applied in the same order for all participants, which might have increased the influence of factors such as fatigue and loss of attention. For future research, it is recommended to shuffle the order of routine and non-routine problems among participants. Future research could utilize eye tracking as a methodological tool to investigate changes in primary school students' gaze patterns when engaging with routine and non-routine problems, particularly before and after interventions aimed at enhancing mathematical thinking.

Heuristic trees and their fruits

Rogier Bos

Utrecht University, Freudenthal Institute, Utrecht, the Netherlands; r.d.bos@uu.nl

Heuristic trees are hint cards for problem-solving, structured in a tree shape, following specific design principles. Cards near the trunk of the tree show help in a compressed form, and the next cards along the branches decompress the content. Students' use of heuristic trees, implemented in a digital environment, has been studied for several years, and this paper reviews the results of these efforts. In particular, we address how the use of heuristic trees impacts students' engagement, ownership of solutions, problem-solving ability, and metacognitive skills, such as process-structuring and help-seeking.

Keywords: Problem-solving, Heuristic trees, Help-seeking.

"Every good tree bringeth forth good fruit" (Matthew 7:15–20)

Introduction

In this introduction, we argue that technological progress underscores the importance of teaching problem-solving. Heuristic trees to support students' problem-solving constitute the paper's main topic. Increasingly, tasks in daily and professional life can be automated. We believe this has profound implications for education: what was previously taught as a task that required brain and hands can now increasingly be outsourced to technology. Teaching students only to perform tasks and solve problems that can be outsourced to technology would leave those students empty-handed for their future professional lives. This seems to be an old problem: the boundary between outsourceable and non-outsourceable tasks has been shifting with the development of each new technology, from the steam engine to the combustion engine, to the mechanical calculator, to the digital computer. The latter two perform cognitive work, and, with the development of artificial intelligence (AI), the nature of outsourceable cognitive work is increasingly complex. Whereas at first computers could perform strictly delineated calculations based on formal input, with the arrival of generative AI, computers can process a wider range of prompts, including images and natural language. Hence, an important domain of hitherto uniquely human mathematical work, namely (horizontally) mathematizing a problem situation or formalizing a problem, can now to some extent be outsourced. Undoubtedly this outsourcing boundary will continue to shift across the cognitive domain in the future, and education needs to adapt accordingly.

The main response of mathematics educators to the increasing opportunities to outsource complex mathematical tasks is to give more importance to teaching problem-solving (Liljedahl & Cai, 2021). The goal is for students to build skills and experience working in situations where invoking a mathematical routine does not suffice. What is considered routine is subjective: non-routine mathematical tasks become routine as students develop mathematically. What is considered a routine mathematics task in a given society also progresses, as mathematical results and approaches are structured and polished into theories, involving new techniques which after some time are considered routine. Finding an antiderivative was once a non-routine, creative art, but is now a routine if

sometimes complex task. Moreover, this task can nowadays be outsourced to computer algebra systems. This brings us to an important point: there is a close connection between routine tasks and technology: considering a task as routine often coincides with understanding how to outsource the task to technology. When a routine cognitive task requires data processing, this can often be performed by software. Of course, routine, outsourceable tasks are taught in every mathematics curriculum, as they are the stepping stones and building blocks for approaching non-routine tasks. In this light, it is not sufficient to teach outsourceable procedures without some accompanying insight into the concepts and ideas underlying these procedures. This insight is strongly intertwined with the ability to recognize contexts where a procedure is applicable and the flexibility to adapt and apply a procedure to a context (National Research Council, 2002).

We have discussed above how a shifting outsourcing boundary underscores the importance of teaching problem-solving, including the ability to recognize which techniques a problem requires, and the ability to adapt and combine these techniques accordingly, possibly outsourcing routine techniques. The main concern of this paper is how to support students during problem-solving. Two common exclamations of students while working on non-routine problems are: "I don't know what to do!" and "I don't know how to do it!". The first refers to being unable to recognize what general concepts, techniques, or theories apply in a specific problem situation; and the second refers to the challenge of recollecting details and adapting them to the specific problem situation. We hypothesize that these inabilities display a lack of *compression* or an inability to *decompress*. Compression is the cognitive process of reorganizing mathematical knowledge, considering comparable cases as instances of an overarching category, and shifting focus from details of those cases to properties of that category (Sfard, 2008; Tall, 2013). In mathematics, compression applies to concepts, procedures, and statements (Bos & van den Bogaart, 2022a). *Decompression* is the opposite cognitive process: applying a general concept, procedure, or statement to a concrete problem situation: retrieving relevant details or steps, and adapting them to a specific case (Bos & van den Bogaart, 2022a). In a world where the outsourcing boundary shifts at a rapid pace, students should learn to compress mathematical concepts, procedures, and statements, to experience how these compressed constructs can form part of an approach to non-routine problems. This is the more abstract level at which they will work in their future professional life, in many cases outsourcing decompression to digital technology.

This raises the issue of how teachers should foster compression-decompression dynamics during problem-solving. An approach introduced by Bos (2017) suggests promoting this through structured hints in help-seeking episodes. When students are stuck, hints are first offered in compressed form, i.e. applicable concepts, procedures, and statements are shared in compressed form. Further hints, if necessary, are offered in increasingly decompressed form. This idea has been elaborated into the concept of a *heuristic tree*. A heuristic tree offers help on cards placed on the nodes of a *directed tree* (in the mathematical sense: an acyclic, connected, directed graph). The three main branches are labeled "orientation", "making and executing a plan" and "completion", reminiscent of Pólya's phases of problem-solving (Pólya, 1945). Each successive card, moving away from the initial node, decompresses the help offered on the previous card. In the next section, we discuss an example of a heuristic tree in detail.

In this paper, we aim to review four studies on heuristic trees—Bos & van den Bogaart (2022a and 2022b), Stokkermans (2024) and Zwennes (2024)—discussing issues of students' learning, problem-solving skills, reasoning, and ownership, and teachers' design. The motivation for this review is to share the possibilities and challenges of heuristic trees with the international audience at CERME.

Heuristic tree design

Figure 1 shows an example of two main branches of a heuristic tree for the problem: compute

$$\left(1+\frac{1}{2}\right)\left(1+\frac{1}{3}\right)\left(1+\frac{1}{4}\right)\ldots\left(1+\frac{1}{1000}\right).$$

The online version can be accessed here: https://edspace.nl/htree/heuristiekboom.php?boom_id=403.
Cards can only be opened from left to right.

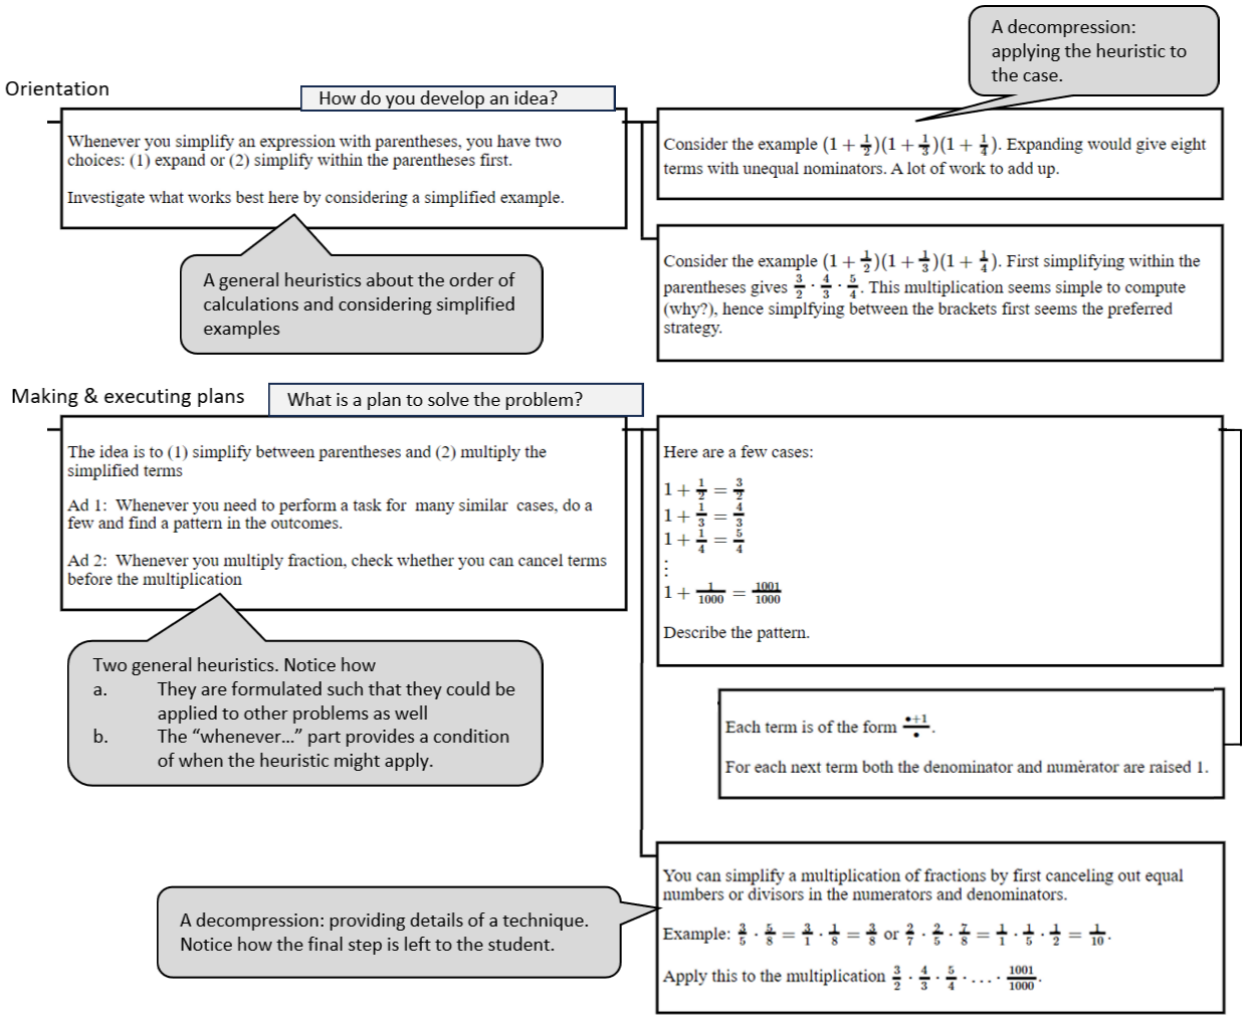

Figure 1: An example of a heuristic tree with all cards opened; with explanatory annotations

A unique heuristic tree is designed for each new problem, though leftmost cards can and should be recycled. The design of heuristic trees is based on six design principles (Bos, 2017):

P1. *Compression-decompression order*: The order along a branch should be from general to more concrete hints, thereby decompressing initial concepts, techniques, and statements.
P2. *Logical order*: The structure of the tree (both along and across branches) should represent a logical order of reasoning within a solution model. It should highlight the main structure of the argument and separate main and side issues.
P3. *Problem-solving phases order*: The branches should be ordered following the phases of problem-solving: orientation, making and executing plans, and completion.
P4. *Independence*: The help offered in any one branch should not require information from any other branch.
P5. *Rationing*: Each card should not give more help than needed.
P6. *Revelation*: The questions that are shown on unopened cards should indicate what help can be obtained along that branch, but not give away any content. In the same way, a hint on a card should indicate what can be expected in the next hint, but not give away the content.

Design principles P2, P3, P4, and P6 aim to facilitate students' navigation of the tree. Heuristic trees are intended to be used by students independently of the teacher. Students need to autonomously decide which cards to open, facilitated by cues on the back of the leftmost cards, and subsequently by cues on the front which indicate what help can be found on the next card. Design principles P5 and P1 aim to promote students' maximum ownership of their solutions. Whenever possible, solution steps and insights are left to the student.

Heuristic trees can be designed and shared with students in our online, interactive environment at https://edspace.nl/htree. Many trees designed by teachers are accessible here, mostly written in Dutch. Two English examples: https://edspace.nl/htree/heuristiekboom.php?boom_id=146 and https://edspace.nl/htree/heuristiekboom.php?boom_id=421. Though heuristic trees could be implemented with paper cards too, the digital version allows easy sharing among teachers and students, improving, and using wherever internet access is available.

Review study 1: students' help-seeking behavior

In a study conducted in 2019-2020, we studied students' help-seeking behavior during work on 55 problems in a number theory course over several weeks, while supported by heuristic trees (Bos & van den Bogaart, 2022a). Data was gathered through a survey, in-class camera observations of two small groups, an interview with those two groups at the end of the course, and an informal teacher's log. The latter showed that students in comparison with previous years posed approximately 90% fewer questions to the teacher while working on the problems, allowing the teacher to spend more time with students most in need of support. The videos showed how students can struggle to self-diagnose whether they need help, and what sort of help they need. However, many successful help-seeking episodes were registered. Sometimes students find that the hint cards confirm their chosen approach and this gives them confidence to continue their attempts. Both in the survey and the interviews, students indicate that they are less inclined to consult answer models and therefore stay engaged with the problem for longer. Also, they confirm that they experience more ownership of their solutions since the heuristic trees do not reveal the solution as a whole, as a model answer does. Finally, the data also support the hypothesis that students develop a more structured approach to problem-solving by being provided with help in a structured way. Their improved engagement, ownership, and problem-solving process are considered central results of the study.

The reviewed paper also addresses the issue of inflexibility in heuristic trees. The solution approach that is presented, the level of that presentation, the notation, and the assumed pre-knowledge are all fixed in the hints, whereas a good teacher can adapt to the student's needs. However, one of the reasons this was of limited impact was that students often sought help before they found a fruitful approach, and otherwise students often did choose the approach presented in the heuristic tree. Moreover, the designer of a heuristic tree (often the teacher) tries to adapt it to the expected approach and pre-knowledge of the students.

Review study 2: teachers' design of heuristic trees

A study in 2022 focused on the challenges of designing heuristic trees (Bos & van den Bogaart, 2022b). A group of teachers followed a workshop on designing heuristic trees given by the two authors of the paper, consisting of two meetings of one hour. In the workshop, the participants were acquainted with the design principles of heuristic trees, the underlying theoretical idea of compression, and a design protocol to shape the design process. The authors analyzed seven heuristic trees (totaling 153 cards in 48 branches) that the participants developed after the workshop. Below we discuss some of the main findings.

Figure 2 shows an example branch from an analyzed tree. The problem involved a geometric situation where a length had to be calculated. The example illustrates some frequently encountered issues. Firstly, the first card is not a heuristic and should have been phrased more generally, for example, "For a geometry problem try introducing a variable for a central unknown length, express the other relevant lengths in this variable, and express a relation as an equation in this variable". The questions "What do you want to find out precisely?" and "What is the consequence?" do not clearly indicate the content of the card to be opened.

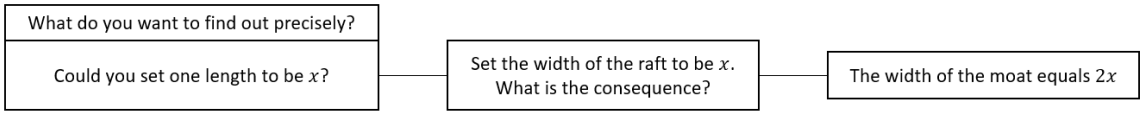

Figure 2: One branch of a heuristic tree designed by a teacher participating in the workshop

Implementing P1 is not straightforward. While 38 opportunities for decompression were taken, 24 opportunities were missed, alongside 12 cases where the first card could have been phrased more generally. A few additional principles should help implement P1 (Bos & van den Bogaart, 2022a):

P7. The first card of a branch should always also apply to other problems; no reference to the concrete problem situation is allowed.

P8. If possible, phrase the first hint on the branch in the form "If [condition], then …". The condition should indicate the class of situations where a certain heuristic or technique applies. Only in the next card is the suggestion applied to the concrete case (a decompression).

A related issue is that teachers tend to use each subsequent card on a branch for the next step of the solution (instead of decompressing anything). Instead, if a technique comprises three steps, then three cards should branch from one, such that students can go immediately to the specific step on which they require help. This inspires another new principle:

P9. Whenever possible, branch out vertically, not horizontally.

Issues with implementing other design principles were observed as well. For example, sometimes a hint gave away part of the solution without announcing this on the previous card, contradicting principle P5. Finally, formulating the hints on the cards proved a major challenge for teachers, as observed in the data (21 occurrences). Teachers tend to formulate in a conversational, somewhat imprecise way, without taking into account that students use the cards without them present to clarify themselves. All in all, the study reveals that designing a good heuristic tree is an art, with many challenges and pitfalls.

Review study 3: heuristic trees support proving

Next, we review the recent master's thesis by Stokkermans (2024), who studied whether and how heuristic trees can support the process of proving in secondary education. On the one hand, finding and writing proofs is just another kind of problem, so why would heuristic trees not help? On the other hand, in proof situations, students find it even harder to diagnose whether their "solution" is correct and whether they need help.

Stokkermans evaluated the students' proof skills based on five indicators:

1. Proof direction: does the reasoning lead to the right conclusions?
2. Assumptions: are assumptions made explicitly visible?
3. Conjunctions: is each step logically connected with conjunctions to the next?
4. Structure of the proof: is a cleaned-up step-by-step elaboration presented?
5. Justification: does each step contain a clear explanation of why it is allowed?

In each of the three iterations, approximately 20 students tried to prove either that the square of even numbers is even or that the sum of the angles in a triangle equals 180 degrees. In the first iteration, students failed on most indicators. A major issue was the lack of generality of their reasoning: many students thought providing a few examples was enough to prove a statement. The main finding of the study was that attention has to be paid to setting proof values and norms (Dawkins & Weber, 2017), both in the introduction to the lesson and again in the heuristic tree. In particular, students benefited from the addition of a fourth main branch representing a fourth phase, namely formulation and finalization. The hints in this branch guide students in formulating their proof, directing attention to the five indicators mentioned above. In this way, students improved their proof-writing skills, in particular in proof direction, conjunctions, and structure. Clarifying assumptions and justification remained a challenge. Stokkermans' work is exploratory and it raised many exciting challenges and questions about the opportunities of supporting proving using heuristic trees.

Review study 4: heuristic trees versus worked-out solutions

Does support from heuristic trees improve students' problem-solving ability? In a recent study, Zwennes and Bos studied this question through an experimental research design. They tested the use of heuristic trees against the use of worked-out solutions, the latter being the most common support during problem-solving in Dutch classrooms. The current paper describes the experimental design and presents the major result. The thesis (Zwennes, 2024) and a full paper (forthcoming) will present the full results, including findings on ownership and engagement.

Zwennes selected two 10th-grade groups that she teaches, with similar group sizes and mathematical achievements. Once a week for six weeks, the groups worked on a non-routine problem from their regular course book in a 15-minute session without the help of the teacher. The problem posed above Figure 1 is one of these problems; a selection of others is shown in Table 1. The experimental group ($n = 27$) was given a heuristic tree with each problem, and the control group ($n = 28$) a worked-out solution. In the seventh week, the students took a post-test, consisting of three problems similar to the ones they had practiced. For the post-test tasks, no help was available.

Table 1: A selection of the problems from Zwennes' study (2024)

	Problem	Link tree
Week 3	René buys fruit for exactly 10 euros. He buys some apples for 40 cents apiece, three times as many pears for 50 cents apiece, and with the rest of the money he buys bananas for 80 cents apiece. How many pieces of fruit did René buy?	#313 Link
Weeks 6	Harry writes down a sequence of numbers. He starts with 1 and the second number is 2. He computes every subsequent number as follows: he divides the second last number by the last number. Write down the 10th number in the sequence as a power of 2.	#322 Link
Post-test problem 2	Mr. van Dijk is 61 years old. He has four sons. Jan is twice the age of Piet. Piet is twice the age of Theo. Wim is five years older than Theo. Mr. van Dijk's age is the same as the sum of all his sons' ages. How old is Wim?	No tree

Zwennes graded the post-test results and Bos acted as the second grader, grading 20% of both groups. A Spearman's correlation was conducted to evaluate the relationship between the results of the first and second graders. There was a significant positive relationship between the results of the graders: $\mathrm{rs}(13) = .94,\ p \leq .001$, for the experimental group, and $\mathrm{rs}(13) = .91,\ p \leq .001$, for the control group. A pre-test was deliberately not included, but instead, the two groups were compared in a test only containing routine tasks on the same subjects as the non-routine problems they had worked on, a week after the post-test.

For the test containing routine tasks the groups had similar results: the experimental group $\mathrm{M} = 5.2$, $\mathrm{SD} = 1.7$, and the control group $\mathrm{M} = 5.2,\ \mathrm{SD} = 1.5$. Indeed, a Mann-Witney test showed there was no significant difference between the mean scores ($\mathrm{M} - \mathrm{W} = 349.5, p = .490$). In contrast, the mean scores on the post-test were as follows: the experimental group (heuristic trees) scored $\mathrm{M} = 6.3$, $\mathrm{SD} = 1.2$, and the control group (worked-out solutions) scored $\mathrm{M} = 4.6, \mathrm{SD} = 2.2$. From a Mann-Whitney test, we conclude that the experimental group scored significantly higher than the control group, $\mathrm{M} - \mathrm{W} = 91.5, p = .008$. This is an exciting result and more can be said to explain it, in particular from our results on the students' engagement and their learning of techniques (Zwennes, 2024).

Conclusion and discussion

From the presented reviews, we conclude that significant progress has been achieved in studying the impact of providing heuristics trees on students' help-seeking behavior and problem-solving skills. Evidence accumulates that promotes heuristic trees to support problem-solving when the teacher's availability is limited. At the same time, new avenues of research present themselves. Experiences during workshops suggest that teachers' scaffolding skills may benefit from designing and discussing heuristic trees with peers: a hypothesis worth investigating. Moreover, though Zwennes' work provides the first quantitative experimental evidence of the eligibility of heuristic trees over worked-out solutions, additional support through a larger experimental setup would strengthen this claim. It would be interesting to see whether heuristic trees could be designed to support more open-ended, explorative problem situations. Finally, while heuristic trees are gaining popularity within the Netherlands, it would be interesting to see whether similar results can be achieved across its borders.

Changes in abstraction levels among undergraduate students during game programming using Scratch

Einav Keisar[1] and Michal Tabach[2]

[1]The MOFET Institute and Oranim College, Israel; peinav1@gmail.com

[2]Tel-Aviv University, School of Education, Israel; Tabachm@tauex.tau.ac.il

Computational thinking (CT) is a fundamental thinking competence strongly related to mathematical thinking (MT). Research shows that CT and MT share underlying skills, including abstraction. The current study aims to examine changes in abstraction levels among undergraduate students by introducing a sequence of programmable games in the Scratch environment. The scripts of these games share repetitive structures that reflect an inverse relationship between motion and rate. The degree to which students' scripts reproduce this inverse relationship throughout the game sequence can be indicative of a change in their abstraction level. The findings show that while most students implemented this inverse relation, their process of abstraction was not immediate. Rather, changes in abstraction were identified throughout the game programming sequence. Hence, this study introduces a novel way to enhance MT in a programming-based CT activity.

Keywords: Computational thinking, mathematical thinking, abstraction, Scratch.

Theoretical background

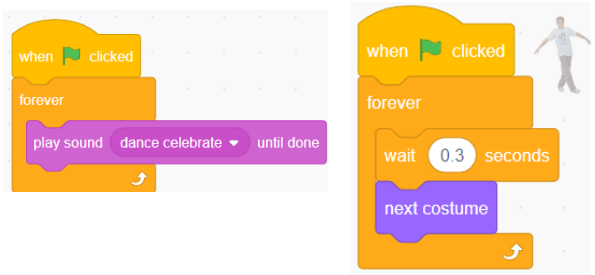
Computational thinking (CT) comprises "thought processes involved in formulating problems and their solutions, so that the solutions are represented in a form that can be effectively carried out by an information-processing agent" (Wing, 2011, p. 20). CT encompasses the development of four fundamental skills: (a) analytical thinking—the ability to analyze problems and decompose them into elements or parts; (b) algorithmic thinking—the ability to plan a sequence of steps to solve a problem; (c) debugging—the ability to monitor and correct errors in the execution of a plan; and (d) abstraction— the ability to decide which details should be highlighted and which can be ignored (Wing, 2011). Abstraction can also be defined as the ability to identify the most significant aspects of a problem and to create generalizable algorithms that make it possible to apply what has been learned in other problems (Montuori et al., 2024).

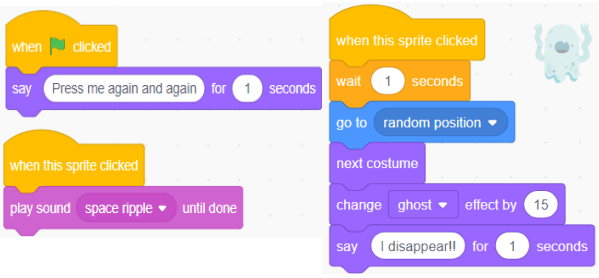
CT is closely connected to mathematical thinking (MT) "in the general ways in which we might approach solving a problem" (Wing, 2011, p. 3717). Studies stress the connection between CT and MT based on their shared skills, one of which is abstraction. Programming activities provide users with an opportunity to implement both CT and MT and to enhance their abstraction skills by identifying mathematical structures and patterns in codes, as described, for example, by Büscher (2025) and Miller (2019). Both studies focused on geometric tasks in elementary school carried out in different programming environments. Büscher (2025) showed that while programming a square, some students identified a pattern, used it to generalize about angles in the polygon, and subsequently applied this pattern to a hexagon. That is, they made an abstraction from the code of the square to the code of the hexagon. In Miller (2019), students were able to analyze repeating patterns when programming the act of drawing a square by inferring the connection between their codes and the

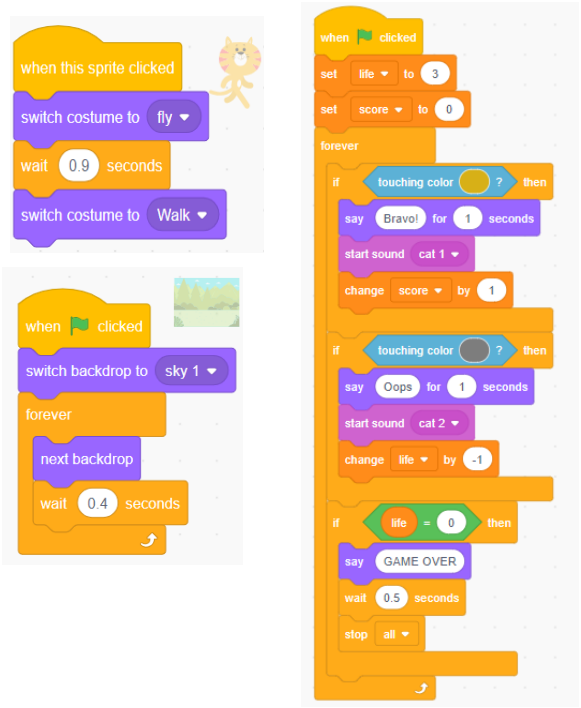
generalized structure of square's perimeter. Thus, through programming students were able to identify mathematical structures and patterns in codes and make abstractions. In addition to the focus on elementary students, a recent study examined in-service teachers' various methods for reusing Scratch code patterns (Ye et al., 2024). Integrating geometric knowledge regarding the parameters of regular polygons (such as size and shape), the teachers expanded their creation from a basic geometric shape made of a single polygon to composite shapes made of several polygons by reusing code patterns. The teachers discovered new ways to create drawings exhibiting rotational symmetry.

As these articles demonstrate, abstraction can be viewed as "the ability to see patterns, recognize the unit of repeat, deduce the pattern and abstract the general structure" (Miller, 2019, p. 924). This view of abstraction is also at the core of current research focusing on changes in abstraction levels among undergraduate students while programming a sequence of games in the Scratch environment. Throughout the sequence, several repetitive structures appear in the scripts, specifically mathematical structures that reflect an inverse relationship between motion and rate. The research examined the following questions: Will undergraduate students be able to express this inverse relationship in their game scripts? And what changes will emerge in their level of abstraction as they implement this inverse relationship throughout the sequence of games?

Methods







Participants and Procedure

The current study is part of a larger study that examines mathematical relations (such as direct relationship between motion and rate) in a sequence of programmable games. This qualitative study, which focuses on the inverse relation between motion and rate, explores changes in abstraction level among 47 undergraduate students majoring in education who were enrolled in a programming course on digital games in teaching and learning. The course included eleven 90-minute meetings. The Scratch environment allows users to program applications, animations and games by means of "blocks" that represent programming commands. Connecting the "blocks" generates a script, according to which the computer performs a sequence of actions. None of the students participating in this course had any prior programming experience in Scratch or in any other programming environment. The data collected at the end of each session included each student's script.

Task Design

The course consisted of a sequence of six games to be programmed in the Scratch environment. The sequence provided an opportunity to identify structures and mathematical connections that could be repeated in the sequence (i.e., abstraction). For example, three of the games (2-Dancing; 3-Ghost; 5-Cody Catches Coins) provide an opportunity to generalize about an inverse relation between motion and rate. The sequence also allows for the gradual use of computational concepts required for script programming (Brennan & Resnick, 2012), such as the use of loops (a command to repeat instructions in the script) and later to add conditions within the loops. Table 1 shows how the scripts of these three games can express the inverse relation between motion and rate.

Table 1: Possible game scripts and how they can express the motion/rate inverse relation

Game name and description	Game scripts	Expressing motion/ rate inverse relation
Dancing The dancer dances to the music without stopping.	Game scripts: Student 17 	Setting the rate of the costume change to a value *lower* than the default time of 1 second will generate a *faster* dance motion.
Ghost Repeatedly clicking on a figure will make it more and more transparent until it eventually disappears.	Game scripts: Student 4 	Setting the rate of disappearance to a value *lower* than the default value of 25% transparency will slow down the disappearance of the figure and make the game *longer* and more enjoyable.
Cody Catches Coins Clicking on the figure (Cody the cat) will cause the cat to jump and collect coins or leap over obstacles.	Game scripts: Student 42 	Setting the rate of the costume and backdrop change to a value *lower* than the default time of 1 second will generate a *faster* and more synchronized jumping and walking motion.

Data analysis

In accordance with the conclusions of Miller's qualitative study (Miller, 2019), we defined three levels of abstraction as reflected in the game scripts. In the current study, these levels described the extent to which the script reflected the inverse relation between motion and rate. Each student's script for each game was analyzed according to these levels.

Level 0: No evidence of abstraction - the script does not include the desired animated motion.

Level 1: Partial evidence of abstraction - the script includes animated motion but does not include any reference to rate.

Level 2: Full evidence of abstraction - the script includes animated motion with reference to rate and describes their inverse relationship.

The data were analyzed in three steps. In the first step, the level of abstraction in each student's game scripts was determined according to the predefined level (0,1,2) for all three games in the sequence (Dancing, Ghost, and Cody Catches Coins).

The levels determined for the Dancing game were as follows: Figure 1a illustrates a script in which the abstraction level was rated 0. This script moved the character 10 steps and 15 degrees to the right without using a Scratch "switch costume" block. Hence, no dancing motion occurred. Figure 1b illustrates a script in which the abstraction level was rated 1. This script incorporated a "switch costume" block as well as a "wait _ seconds" block with a default of 1 second, resulting in a dance movement but at a rate that is too slow. Figure 1c illustrates a script in which the abstraction level was rated 2. This script uses a "switch costume" block as well as a "wait _ seconds" block set at a number lower than the default of 1 second. This script reflects an understanding of the inverse relation between motion and rate, because lowering the wait time between costumes changes the rate of costume changes, resulting in a faster dancing motion.

1a – Level 0 1b – Level 1 1c – Level 2

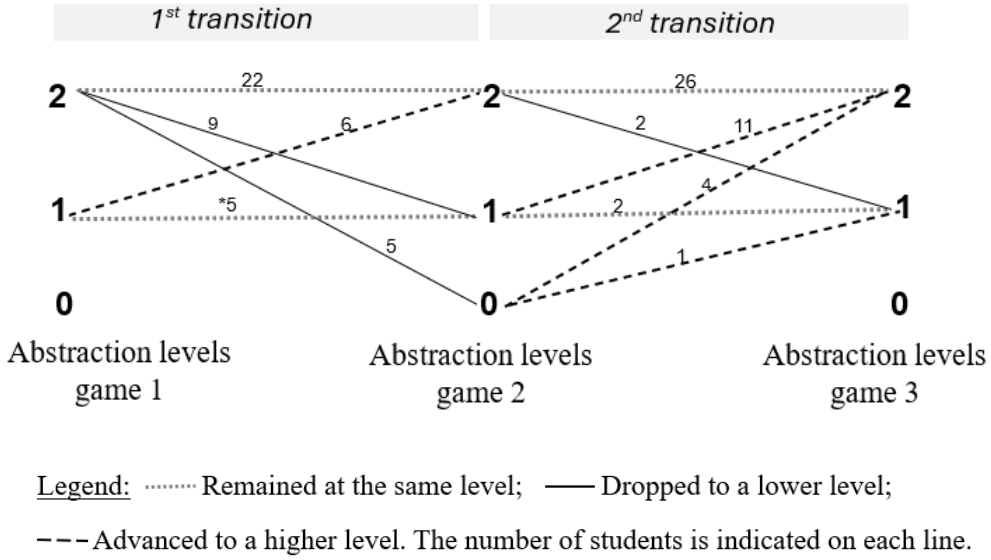
Figure 1: Three levels of abstraction, reflected in the dancing game scripts

At this stage, we also used Cohen's kappa coefficient (Cohen, 1960), to measure intercoder reliability, with the following interpretations: 0.60–0.79, Moderate agreement; 0.80–0.90, Substantial agreement; 0.91–1.00, Almost perfect agreement. Cohen's κ was calculated to determine the level of agreement between two researchers' judgments on three levels of abstraction as reflected in the 34 game scripts. The results indicated strong agreement between the two researchers' judgments ($\kappa = 0.864$, $p < 0.001$).

In the second step of the analysis, each student's sequence of game scripts was examined for changes in level of abstraction. We observed nine general patterns of change in level of abstraction: (a) remained at level 0; (b) remained at level 1; (c) remained at level 2; (d) advanced from level 0 to level 1; (e) advanced from level 1 to level 2; (f) advanced from level 0 to level 2; (g) dropped from level 2 to level 1; (h) dropped from level 2 to level 0; (i) dropped from level 1 to level 0.

In the third step, we examined the patterns of change for each student, first in the transition from the first and second game, and then in the transition from the second and third game. For instance, a level rated 0 in the first game and 1 in the second game establishes a pattern of "progress from level 0 to 1". Similarly, a level rated 2 in the third game creates a pattern of "progress from level 1 to 2". This indicates an increase in the level of abstraction. Based on these patterns, we drew conclusions about the overall change in students' level of abstraction.

Findings



To address the research questions, we analyzed the level of abstraction in each student's game scripts according to the predefined levels of abstraction (0,1,2) for all three games in the sequence. The changes in each student's level throughout the programming sequence are shown in Figure 2 below. The patterns were illustrated through different line representations during two transitions: from the first game script to the second, and from the second game script to the third. Additionally, we provided the number of students who exhibited these patterns during each transition. For example, 28 students reached level 2 in the first transition, i.e., from the first to the second game script (22 of the students remained at level 2, while six others advanced from level 1). Subsequently, 26 of them also remained at level 2 in the second transition, while two students dropped to level 1 in the third game script.

Five of nine patterns of change emerged *in the first transition* (from the first and to the second game script). Patterns d, f and i (advanced from level 0 to 1; advanced from level 0 to 2; dropped from level 1 to 0) were not expressed in this transition, indicating that no student began the sequence at abstraction level 0. *In the first transition* 22 students remained at level 2 and five students remained at level 1. Six students advanced from level 1 to level 2; nine students dropped from level 2 to level 1; and five students dropped from level 2 to level 0. In total, out of 47 students, 28 students advanced to/remained at level 2, 14 students dropped to/remained at level 1, and five students dropped to level 0.

In the second transition (from the second to the third game script), most of the students who remained at level 2 in the first transition remained at level 2 in the second transition (21 students in total), while one student dropped to level 1. Most of the students who advanced from level 1 to level 2 in the first

transition remained at level 2 in the second transition (five students in total), while one student dropped to level 1. Most of the students who dropped from level 2 to level 1 in the first transition advanced to level 2 in the second transition (seven students in total), while two students remained at level 1. Everyone who remained at level 1 in the first transition advanced to level 2 (four students in total). Most of the students who dropped from level 2 to level 0 in the first transition advanced to level 2 in the second transition (four students in total), while one student advanced to level 1.

In summary, 41 out of 46 students reached level 2 in the second transition: 21 who started and finished the sequence at level 2 and 20 who gradually advanced to level 2 during the script sequence. Five students finished the sequence at level 1, whereas none dropped to level 0.

*One of the five students who exhibited abstraction level 1 in the first transition did not submit a script for the third game; thus, the subsequent second transition refers to one student less.

Figure 2: Patterns of change and corresponding number of students in transitions between scripts

Discussion

The aim of this study was to portray changes in abstraction levels among undergraduate students while engaging in a programming activity. The findings indicate that the ability to identify mathematical structures and patterns in codes and make abstractions about the inverse relation between motion and rate was not immediately implemented by the students. Although this inverse relation is within the realm of their mathematical knowledge, not all of them immediately exhibited the ability to identify when and how to use it (i.e., abstraction). Rather, they made gradual changes in abstraction throughout the programming process. Our findings are consistent with studies showing that abstraction may be reflected in geometry programming tasks (Büscher, 2025; Miller, 2019). Moreover, our findings suggest that a sequence of games can be designed to encourage students to implement mathematical thinking (MT) in a programming-based computational thinking (CT) activity, even when they are not explicitly instructed to do so.

This kind of task sequence provides an opportunity to make abstractions, thus addressing the education system's recent focus on CT in the curriculum and the aspiration to encourage students to become problem-solving citizens who can implement different skills (Montuori et al., 2024). While there are still gaps in our knowledge about how CT and MT are interrelated and how they can be intertwined in the school curriculum (Ye et al., 2023), recent study provided in-service mathematics teachers with essential tools to integrate programming into mathematics education, to enhance their teaching practices and support student learning. Similarly, we can infer from our findings that the sequence of games introduced in the study allows students to implement mathematical thinking in programming-based CT activities. Thus, it is highly beneficial to begin programming using Scratch to promote mathematical abstraction as early as undergraduate school of education.

In the future, this kind of task may also provide an opportunity for students to make abstractions about other mathematical relations, such as direct relationship between motion and rate, which involves defining angles to establish their direction of movement. This might provide more information about the way in which CT and MT can be used interconnectedly.

Students' mathematical thinking through programming, animation and 3D printing: Early insights in the case of curvature

Chronis Kynigos and Katia Schiza

National and Kapodistrian University of Athens, School of Philosophy, Department of Educational Studies, Greece; katiaschiza@eds.uoa.gr

We discuss 10th and 11th grade students' ideas about curve and its properties, and their competence in designing 3D curved objects in the programming environment of MaLT2, which supports intrinsically defined curvature animated in space. We consider curvature as a weakly addressed conceptual field in terms of its potential to create environments rich in opportunities to enhance students' mathematical thinking through a restructuration approach. We focus on how students use mathematics for both construction and reasoning when interacting with the digital models through a constructionist approach, and we explore the potential added value of the emerging 3D printing technology in students' mathematical thinking when combined with design through programming.

Keywords: Curvature, intrinsic geometry, programming, 3D design, 3D printing.

Introduction

The rapid evolution of technology in our society is fueling concerns in the mathematics education community about both what mathematics and students' skills are relevant to today's society and how new emerging technologies are being put to use to explore the question. One such case concerns the field of 3D geometry and space (Gravemeijer et al., 2017), along with the emerging technology of 3D printing, which is rapidly entering the field of education, and inviting us to rethink pedagogical practices in relation to this three-dimensional revolution (Ng et al., 2018). The construction and printing of digital 3D models is considered to support the educational process by engaging students with authentic problems, providing opportunities to cultivate their imagination and creativity, and opening a window to develop different skills through prototyping, such as testing and redesign, and design and spatial thinking (Dickson et al., 2021; Coşkun & Deniz, 2022). However, the studies exploring the potential of 3D printing exclusively in mathematics education are limited and mainly focus on the concepts of volume and area, properties of prisms and various 3D solids, while most of them either focus on other areas of STEM/STEAM or use ready-made 3D models, depriving students of authentic engagement with mathematical concepts in both Euclidean and non-Euclidean geometry (Ng et al., 2022), such as curves. Although curvature is a fundamental concept in mathematics and various applied fields, it hasn't found its way (e.g. into the Greek curriculum) for students to explore curves as geometric shapes created by covariational relations. Hence, in this paper we explore the potential of combining 3D design with the emerging 3D printing technology using the programmable tool MaLT2 to support students' mathematical thinking when tinkering with curved objects.

Theoretical Framing

The authors adopt a constructionist approach in their research view and task design, aiming to engage students with the geometric nature of the curve to generate meanings as they construct and tinker with digital models and discuss their mathematical ideas in relation to these artefacts and their behavior

(Kynigos, 2015; Papert, 1980). We discuss knowledge as an active construction by the learner through the exploration and symbolic expression provided by the MaLT2 programming tool, and consider a restructuring of the concept of curve (Wilensky & Papert, 2010) that makes use of the concept of function-as-covariation but does not ignore the actual concept of curvature, as is usually the case in school. With respect to the Greek curriculum, students may learn about the circle, arcs and various conic sections, but they don't have the opportunity to intuitively discover and explore curves as geometric shapes. The mathematical approach to 3D shapes in MaLT2 is through differential geometry, where curvature is described as an intrinsic property of curves and surfaces. In our case, the activity is based on Turtle Geometry (Papert, 1980), a kind of differential geometry linked to movements in which the main ideas are based on the intrinsic properties of geometric models, locality and the expression of mathematical concepts in terms of constructive procedures rather than equations (Abelson & diSessa, 1981). In this way, concepts such as curvature, which are reserved for more senior courses, can be made more accessible through intuitive ideas rather than axiomatic formalisms. Through exploring and tinkering with the 3D digital artefacts using a programming tool with dynamic manipulation of variable values, our intention was for the students to gain a local and intrinsic approach to curvature in space. At the same time, in studying student activity, we wanted to keep a wide lens in terms of the use of their mathematical ideas in the design and construction of 3D curved objects and to consider the concept of curvature in space as a conceptual field (Vergnaud, 1983) rather than as an isolated concept. For example, trying to design a triangle on the surface of a cylinder may involve different concepts such as torsion, rate of change, and the concept of curvature itself as a contrast to non-curved objects or as a property of an object (Stevenson, 1995), which are closely involved with the conceptual field of curvature in space and the intrinsically defined covariation function. Previous research has also explored the concept of curvature using programming through the construction of arcs in 2D space (Kynigos & Psycharis, 2003) and cylindrical helixes in 3D space (Kynigos & Zantzos, 2017), which have shown promising results in creating students' meanings around the concept of curvature, but also students' difficulties over the local nature of a curve (Montoya Delgadillo et al., 2018). Mathematical concepts can be understood in two different ways: structurally (as objects) and operationally (as processes). Learning mathematics results from an interaction between these two elements, while a mathematical concept is formed through a long sequence of transitions from operational to structural concepts, a process known as reification (Sfard, 1991). According to this approach, the use of mathematical concepts leads to a better understanding of them, which in turn leads to finding a wider range of uses for the concepts. In our case, the coding procedure aligns with an operational view of the concept of a curve, as it presents the curved model as a computational process. Conversely, the graphical figure promotes a structural approach, presenting the mathematical concept as a unified whole, with visualization making abstract ideas more tangible and easier to manipulate. It is true that students' learning typically begins with physical objects and later moves toward abstraction. In our case, the use of 3D printing works in the opposite direction, starting with the design of 3D models and ending with physical objects. We suggest integrating both processes in the learning journey, using them as tools to give meaning and structure to mathematical knowledge. In other words, we argue that an axiomatic definition is insufficient to convince a learner of the existence of a mathematical object, or when concepts are either too abstract or not clearly defined in students' experience, they can understand them through other concepts (e.g.

spatial relations or physical objects) through the repetitive cycle of imagining (coding), seeing (figural representation) and touching (3D printed model). In this research, the authors aim to explore the potential of integrating 3D printing with 3D design using constructionist media in the service of mathematics education regarding the concept of curvature in a process from students' meaning making to their mathematical competence in using this concept in different contexts. In this paper, however, the authors' first level of focus is on the study of (RQ1) *What perceptions of the concepts of curve and curvature emerged during students' 3D designs in MaLT2?,* and (RQ2) *How students' mathematical thinking might be enhanced as they use constructionist media for 3D design and printing of curved objects?*

Design of the activity

MaLT2 is an online programmable tool for symbolic representation in mathematical activities through textual programming for the creation and exploration of 3D graphical models with the affordance of dynamic manipulation of variable procedure values (Kynigos & Grizioti, 2018). It provides the following interrelated representations: i. symbolic (code), ii. figural representation (scene), and iii. dynamic manipulation of generalised models in the form of executed parametric procedures (a variation tool activates a slider for each variable of the procedure responsible for the selected linear trace) (Figure 1a). It has recently been extended to include the functionality of 3D printing to enable students to connect the digital models with the physical world and to promote the development of different skills and meaning-making processes for complex concepts (Grizioti et al., 2024). A task was given to the students involving the construction of a cylinder through a curved quadrilateral without reference to the mathematical properties of radius, center or any other external frame of reference. Using only the *forward* move command, and *right* and *down* turn commands, the *repeat* command, and two variables (Figure 1a), the rationale behind the design was to emphasize the local nature of the curve and its construction as a result of its rotation in space, contrasting it with a straight line. Students were challenged to explore the 3D curve created by dynamically changing the values of the variables and to further create their own artefacts on the surface of the cylinder in an intrinsic way. During the intervention, the researcher encouraged the groups to save the different artefact prototypes they were working on, as students could print out any prototype they wanted to see in physical form at the end of each session. The purpose was for the students to use the mid printout as feedback before their final artefact, and for the researchers to gain more insight into the use of 3D printing and its potential added value.

Methods

This study involved five 10th-grade students and three 11th-grade students, divided into three groups. They voluntarily participated in the intervention as part of an after-school Math Club for 4 hours split in 2 sessions. The students had some experience with the MaLT2 tool. In terms of their performance, the groups were mixed to provide extra motivation and support for all. Each group was given a laptop and a notebook. The teacher and the participating researcher acted as facilitators, encouraging the students to share their thoughts openly with the group. In order to have a comprehensive view of students' actions and interpretations throughout the activity, we collected several types of data, including computer screen and audio recordings, students' notes, MaLT2 codes and photos, and we

analysed them using a thematic analysis approach, starting from an initial scheme and remaining open to the emergence of new codes. After we triangulated the transcribed dialogues with the rest of the data, we analyzed the data based on critical episodes (Tripp, 1993) of students' meanings around the concepts of curve and curvature that emerged during their interaction with the 3D models that were relevant to the research questions. To answer RQ1, we looked for incidents in which students expressed their perceptions around concepts closely related to curvature that emerged during their design in MaLT2 and in interaction with their group or the researcher. To answer RQ2, we sought to identify ways in which the 3D design and printing of curved models enhanced students' mathematical thinking using the theory of reification. After coding of the dialogues, we created the main themes of the results. As the intervention was a pilot study for a larger design-based research project (Bakker, 2018), the findings will inform the next cycle of the study and the redesign of the activity.

Results

The thematic analysis revealed four main themes: 1. Approach to curve, 2. Approach to curvature, 3. Characteristics of curve and 4. Challenges. Regarding the RQ1, Table 1 summarizes the codes for each of the above themes, followed by some of the students' quotes during the critical episodes, while in the coding phase we always kept in mind the added value of the technology to the meanings the students generated or the challenges they faced in relation to each code in order to answer the RQ2. For the sake of brevity and clarity, we will describe briefly the 'torsion' code that responds to RQ1 and the 'locality' code that responds in depth to RQ2 using an indicative critical episode.

Table 1: Codes emerged from the data analysis followed by some students' quotes

1a. As a contrast to straight line	St. F: Something that turns, something that is not straight. St. C: Let me think… It's a curved line.
1b. As a property of an object	St. D: Curve is the circle.
2a. Size of curvature	St. C: It's opening up, the curve is widening… Before we wrote down 160/360. Now, we put 50/360. So, the smaller the fraction, the smaller the curvature we have.
2b. As a rate of change	St. D: The [fd 1 down :n/360] tells the bird by how much to turn.
2c. Continuity	St. A: Let's change the step of the slider to 0.1.
3a. Torsion	St. A: The bird has to go up-down, change its direction and also... turn its body.
3b. Locality	Critical episode is quoted below
4a. Orientation in 3D space	St. B: When we say down, I don't understand why we say degrees.
4b. From 2D to 3D	St. B: Can we use the Pythagorean Theorem in curved geometry, in curved space?

Regarding the first research question, the meanings that emerged during the students' engagement with curve models concerned the concept of curve itself which students intuitively encountered as a

contrast to non-curved objects and as a property of an object (Stevenson, 1995), approaches to describe and use the concept of curvature in their designs related to concepts unknown to them (i.e., rate of change, continuity) and characteristics of a curve in 3D space such as torsion, which emerged through the use of the concept of the angle and body syntonicity (Papert, 1980). For example, student A mentally put himself in the bird's position and used not only his hands but his whole body to explain to his classmate his proposed *roll_left* command (Figure 1b), which denoted rotation around the straight line of the bird's movement. Whereas curvature shows how far the curve moves away from being straight, torsion shows how much the curve twists out of the osculating plane in 3D space (e.g. moves away from being flat). Both concepts are associated with a change of direction in space.

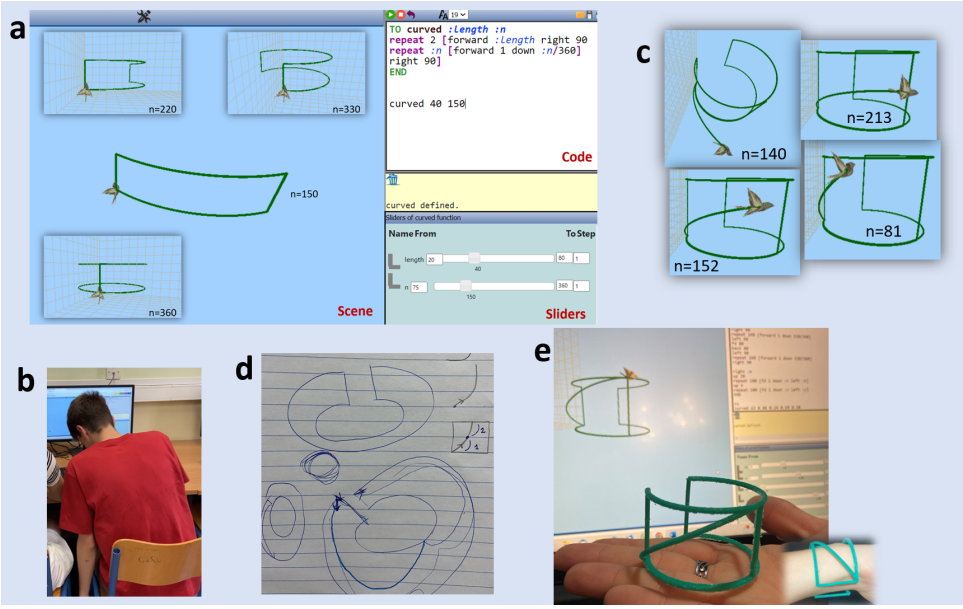

Figure 1: a. The three representations of the microworld in MaLT2, b. Student's use of body connected to his idea of torsion, c. Student's testing using variables, d. Students notes of the 'curtain' idea, e. Final digital and physical model of group B

To address the second research question, we report and analyse one selected case that stood out in combination with the impact of the physical touch of the object. The following excerpt concerns group's B attempt to construct the curved line on their cylindrical bracelet by connecting the bottom point of the vertical line to the top point of the middle one. The challenge that they faced was that the curve was closing towards the inside of the cylinder. After many attempts in changing the code and the values of the variables through the sliders, they decided to print their model. Although up to this point the students had been working on the code using the *forward* and *down* commands in a *repeat* command, they had been concentrating on the twist they wanted to give their curve (torsion) and had not realized, even from the graphical representation of the code in the tool (Figure 1c), that this curve would never reach the end point they wanted. Student C commented when looking at the printout: *"It looks like it wants to go in a circle, whereas we want it to stretch upwards more smoothly"*. This showed that the students had approached the concept of curvature through an operational understanding that was based on the aforementioned commands and their perception of it as a curved line. They had discussed trying a smaller or higher curvature in their model, but they had difficulty

realizing that their curved line would always create a circle with different, but constant curvature, which seemed a challenge for them in approaching curvature structurally. They seemed to had used so far, the concept of curvature as a measure to their curve and as a tool to describe it in their digital model. The next incident in the progress of this group's work was triggered by a student looking around the physical model in her hands.

Student E: The curve we want has the slope of the cylinder and also an upward slope (shows several times the path the curved line should follow with her finger).
Student C: That's right. How can we make the whole line move upward to reach our point?
Student E: What if… (still touches the 3D printed model) What does this move remind you of?
Student D: I don't know. A wave? An uphill?
Student E: A curtain for me. Doesn't the curtain curve upwards like this?
Student C: Yeah, it could. But... The slope at the beginning is steep, and then it tends to be marginally straight.
Student E: That's right! What if we break the movement into 2 curves? What if from the beginning we take it up to about here (i.e. the middle of the trajectory) with a curve that is steeper and from here to the end point with another smoother curve?

Student C's first observation about the circle, combined with the dialogue that followed, triggered the group's discussion around two axes. The first axis concerned the issue of the local nature of the curve, as the students pointed with their hands to specific points along the path of the curve in both the physical and digital model, and proceeded to deconstruct more consciously the code they had created earlier, discussing around the use of the *repeat* command of the code that gives this 'movement' of the curve. The second axis involved the concept of curvature as a property of the curve. They had now focused on curvature as a fixed and perhaps more abstract concept of their model, firstly recognizing the curvature of the circle as a constant and secondly trying to relate curvature to their model as an attribute to describe it. This incident highlights the effect of the 'digital-physical' approach, as this combination led the students to a deeper engagement with the mathematical idea of curvature that might not have happened without the possibility of 3D printing. The process of the construction of a curve with different curvatures or, as they put it, two curves (breaking the bird's movement into two parts) with different curvatures seemed to open the path towards a structural understanding of the concept for the students. The physical model, with its strong sense of touch, prompted students to think of a physical object that resembled the desired curve (e.g. curtain), and to 'break' their curve in one point (Figure 1d) in order to build their final model of a bracelet (Figure 1e). Therefore, it is argued that the alternation between the 'predict-see' approach in the digital model and the 'touch' approach in the physical model could provide opportunities for students to engage with the local nature of curvature and serve as a channel between the procedural understanding and use of concepts around curvature to a more conscious and general one, leading to finding a wider range of uses for them in the models.

Discussion

Students brought to the surface and used, either in the construction of their model or in the justification of their thinking, different concepts involved in the conceptual field of curvature in space, such as the concept of torsion, the locality and the concept of curvature itself. This was mainly triggered by the use of programming commands, the students' body syntonicity and the dynamic manipulation of the models through the use of variables in commands the students wanted to explore

further. The activity of this first cycle was quite open and aimed at discovering students' intuitive ideas and meanings in the field of curvature, since some of the concepts that emerged were either taught in a fragmentary way at school (e.g., curves), or not taught at all (e.g., rate of change), or related only to 2D space (e.g., orientation) in order to inform the design of the next cycle, which will be targeted at specific characteristics of curves and have more cycles of printed prototypes. As for the use of 3D printing, the results showed that it played an interesting role in enhancing students' thinking as the printed model designed by them created a link between abstract ideas and tangible models, giving them the opportunity to engage with the local aspect of curvature. This 'digital physical' alternation acted as a bridge, where the use of curvature facilitated a deeper understanding of it, providing students with opportunities to use concepts related to curvature in both an operational and structural approach. Despite the limitations of this research, it seems worth exploring the possibilities of integrating 3D printing with 3D design using constructionist media in the service of mathematics through repetitive cycles of imagining (coding), seeing (digital figure) and touching (3D printout) to enhance students' mathematical thinking in 3D space.

Opportunities for low-achieving students to learn mathematics through design and 3D printing of usable objects

Laura Levin[1] and Sigal-Hava Rotem[2]

[1]Kibbutzim College of Education, Technology and the Arts, Faculty of Education, Tel Aviv, Israel; Laura.levin@smkb.ac.il

[2] Freudenthal Institute, Utrecht University, The Netherlands

Low-achieving students rarely encounter opportunities to engage deeply with mathematics in ways that connect abstract concepts to tangible, real-world applications. This case study of a 10th-grade classroom examines how 3D design and printing (3DP) activities can offer meaningful opportunities to learn mathematics for these learners. The saved work of eleven students, who used 3D design software to build a biased die, was analysed to reveal the dynamic interplay between concrete experience and abstraction in the activity. We illustrate this process through Nathan's example, who employed an iterative design process, progressing from concrete to sophisticated design by effectively engaging with mathematical concepts such as symmetry, geometry attributes, and spatial reasoning while fostering perseverance and motivation. These findings stress the potential of 3D design and printing to provide low-achieving students meaningful opportunities to learn mathematics.

Keywords: Mathematical modelling, 3D design and printing, opportunities to learn, low achievers.

Introduction

Mathematical modelling entails converting real-world situations into mathematical terms to analyse and solve problems effectively. For students, mathematical modelling is cognitively demanding, requiring continuous transitions between reality and mathematics (Borromeo Ferri, 2018). Although mathematical modelling tasks are typically done on pen and paper, in this study we explore the use of 3D design and printing (3DP) activities as modelling tasks settings.

As a result of recent technological advancements, 3D printers have become popular and can now be found in many schools and households. Although 3DP activities have demonstrated the potential to foster applied mathematical skills and engage students in mathematical modeling and problem-solving (Levin & Verner, 2021), the specific ways in which students learn mathematics through these activities require further investigation. Moreover, low-achieving students' learning through these activities has rarely been studied. This study addresses this gap by exploring the mathematical learning opportunities arising from 3DP tasks among low-achieving students attending a "last-chance" secondary school.

Hence, the goal of this study is to explore opportunities to learn mathematics among at-risk youth through 3DP activities. As a proof of concept, we describe a case study in which a class of low-achieving students at a high school for at-risk youth engage in a 3DP activity. To further exemplify the design and learning process, we describe the example of Nathan, a 10th grade student participating in the activity. Using the students' 3D designs as recorded in the Onshape CAD (Computer-Aided Design) software, we explore the opportunities to learn mathematics that emerged from the activity by examining the following research question: *What opportunities arise for low-achieving students to learn mathematics as they work on a 3D design and printing activity of a biased die?*

Literature review

Mathematical modelling requires identifying and applying relevant mathematical concepts and methods to address real-life contexts (Borromeo Ferri, 2018). Researchers who used authentic tasks that combined mathematical modelling and 3DP activities as an integrative context for real-world applications found that such activities can enhance mathematical learning and help students develop practical application skills (Guler et al., 2019). Creating a 3D printable model requires planning an object that does not yet exist and digitally designing it using CAD software. The students must be able to understand ill-defined problems, collect and quantify relevant data, construct mathematical models and inquire about them using mathematical methods, and derive a solution to the real-world problem from the results of the mathematical analysis. This process demands selecting and defining the geometric shapes that form the design, making decisions that consider technological and task constraints, and evaluating the planned product against the requirements (Levin & Verner, 2021).

Further, when engaging in a 3DP task, students must move back and forth between the physical model they are planning and the mathematics that enables them to carry out their design. That is, students must switch back and forth between abstraction and concrete experiences, which constitutes the relation that "lies in the core of mathematics education studies" (Shvarts et al., 2022, p.3024). This dynamic movement yields meaningful schematizing and algorithmizing, which ultimately turn into mathematical models and formalized rules. Through 3DP, students can apply mathematical concepts to physical objects that they can touch, explore, and use, thereby bridging the gap between theoretical mathematics and its practical applications.

Yet mathematical modelling using 3DP can be challenging for students due to the time-consuming nature of the tasks, the need for group work, uncertainty in the solution process, and cognitive barriers such as identifying unknown quantities and making numerical assumptions (Böswald & Schukajlow, 2023). Educational research indicates that when working on time-consuming tasks low-achieving students tend to exhibit more work avoidance and boredom than high achievers, consequently affecting their engagement and motivation in mathematical modelling activities (Hirt et al., 2021). Nevertheless, we strongly believe that such learning experiences should be accessible to all students. Hence, here we focus on implementing/designing such experiences for low-achieving students enrolled at a so-called "last-chance" secondary school. Building on this perspective, we focus on opportunities to learn mathematics through 3DP activities among those students.

Theoretical perspective

As noted, this research assumes that the emerging opportunities to learn during 3DP mathematical modelling tasks should be accessible to as many students as possible, regardless of teachers' conceptions of students' achievement level.

We define *opportunities to learn* mathematics as "the extent to which genuine opportunities can be created, facilitated, and promoted for different groups of [...] children and young people" to learn mathematics (Ng et al., 2018, p.12). These learning opportunities are realized at the instructional level through the curriculum as delivered by the teacher and at the learning level through student activities. We adopt an enactivist view when considering how students can realize these learning opportunities. Knowing does not arise in the mind from representations of the world but rather through action and interaction with the world (Varela, et al., 1991). From this perspective, if a student designs a model

that "works" in terms of fulfilling its ascribed functionality, this can be viewed as evidence of learning. A 3D designed and printed model constitutes the physical evidence that students know how to use the mathematics underlying the design. In fact, it is "doing that instantiates this knowing" (Abrahamson, 2024, p.158). Consequently, in this study, we examine the learning opportunities emerging from the dynamic movement between abstraction and concrete experiences within a group of low-achieving students who worked on the biased-die task (described below) using 3D CAD software (Onshape). We also provide a detailed analysis of the work of a specific student—Nathan.

Research context – the biased die activity

The biased die activity is part of the DoLearn3D project, an initiative to enhance mathematics learning through 3DP activities for 10th-grade students at a last-chance secondary school. The project includes nine learning units aligned with the low-level mathematics curriculum, covering topics such as measurement, polygons, probability, area, volume, equations, ratios, and spatial orientation. Using Onshape, students design objects, which are 3D printed and analysed for potential redesign. Each design starts as a 2D sketch that is used to create 3D shapes through extrusion. The 3DP activities were described in real-life contexts without explicitly stating the underlying mathematical concepts, thereby encouraging students to apply previously learned mathematics, discover and explore new mathematical connections, and develop original mathematical strategies. The teacher provided targeted support with software use and mathematical concepts while encouraging student autonomy.

This study focuses on the biased-die activity. Students were asked to design and print both fair and biased dice. They then exchanged dice with their classmates, played with them, and attempted to determine which die is biased and which is fair, distinguishing between the dice using the rolling outcomes distribution. The teacher also discussed important concepts connected to dice, such as shape (a cube), symmetry, fairness, chance, and center of gravity. The activity included a worksheet for students that was meant to promote individual work. Figure 1 illustrates Nathan's final design (A), and a cross-section of the biased die that exposes its interior (B).

Several learning opportunities related to the aforementioned mathematical concepts emerged through this activity. One is using the origin of the Cartesian coordinate system as a point of reference for the design. Another is using symmetry to extrude a die symmetrically around its center, which becomes much easier when the die is placed at the origin. A third involves placing the dots on the face of the die. This could be done by measuring an equal length from all sides of the face, which requires using concrete thinking. Another option is taking advantage of the geometric properties of the intersection point of the diagonals in a square and symmetry, which indicate an abstract way of thinking.

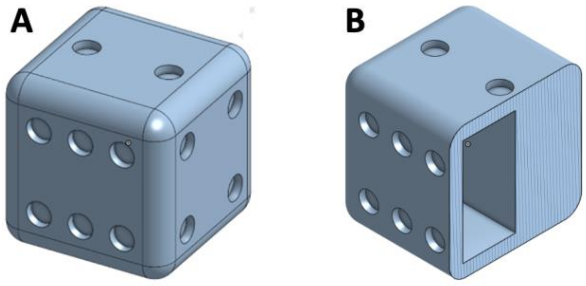

Figure 1: The biased die design and its cross-section view

Methods

To achieve the study goal, we selected the case study methodology (Yin, 2018). The case examined in this study is a group of eleven 10th graders (six boys and five girls, aged 15) with low academic achievement enrolled at a high school in central Israel serving at-risk youth who engaged in the biased die activity described in the previous section. The students used Onshape software to design the objects. Then they 3D-printed, analysed, redesigned, and printed them again if necessary. We selected Nathan's example for detailed analysis as his work illustrated the typical progression we observed across students - moving from basic visual approximations to sophisticated mathematical concepts. His extensive engagement with the task (over 5 hours across 6 days) provided rich data for analyzing the transition between concrete and abstract thinking. Additionally, Nathan's initial struggles and subsequent progress make his example particularly relevant for understanding how low-achieving students can develop mathematical understanding through 3DP activities

Data collection and analysis

The Onshape version used by the students automatically records all data related to the design process, including student interactions and design iterations, and allows teachers to monitor students' progress. This study used the collected data, including the final designs and the students' design process steps, recorded in an audit log format. The platform also provides the option to view historical snapshots of the digital designs for a thorough examination of the design process.

The data analysis was conducted using inductive content analysis methods (Mayring, 2015). To analyse the data, we began by examining the designs and referring to the logs to gain a deeper understanding of the sequence of the design process. We began by collaboratively coding three designs to ensure consistency in our approach and to align our interpretations of the data. Subsequently, each researcher individually coded four additional designs. We then discussed our coding until reaching agreement and presented our interpretations to the class teacher, who provided additional context and information beyond what was visible in the data gathered from the OEE platform. Table 1 presents the final coding schema and the results showing the code's frequency.

Findings

The analysis of students' final designs revealed opportunities to learn mathematics through spatial reasoning, geometric strategies, and functional design. As shown in Table 1, nine students aligned their dice with the origin of the axes (1.4 Center-Origin), demonstrating spatial reasoning, while two placed them randomly (1.1 Random-Placement), highlighting varying levels of understanding of reference points. Strategies for dot placement ranged from mixed geometric methods (3.4 Mixed-Methods-Placement, four students) to diagonal-based precision (3.3 Diagonal-Guides, three students) and visual approximation (3.1 Visual-Approximation, two students). Symmetry was intentionally integrated by nine students (5.2 Symmetry-Integrated), reflecting their grasp of geometric consistency. Six students engaged in biasing their dice (6.2 Biasing-Process), linking their designs to functional outcomes. However, five did not attempt biasing (6.1 No-Biasing-Process), reflecting varied task engagement. These findings suggest that 3DP activities scaffold mathematical concepts, bridging abstract principles like symmetry and spatial reasoning with tangible applications. Nathan's case illustrates how these strategies and learning opportunities emerged in practice, providing deeper insights into the interplay between abstraction and design.

Table 1: Categorization and frequencies of mathematical and CAD processes in students' die designs

Category Name/Description	Code Number, Name and Description	Frequency
Mathematical reasoning and spatial thinking involved in designing the die.		
1. **Placement of die in space**: How die is positioned within the 3D space relative to coordinate axes.	1.1 **Random-Placement**: Die is placed randomly, without specific alignment with the coordinate axes.	2
	1.2 **Corner-Origin**: Corner of die is placed at the origin of the coordinate axes.	1
	1.3 **Bottom-Origin**: Center of bottom face is aligned with origin of the coordinate axes.	1
	1.4 **Center-Origin**: Center of die is aligned with origin of the coordinate axes.	7
2. **Order of working on faces**: Sequence in which student works on each face of the die, arranging dots from face to face.	2.1 **Random-Face-Order**: Faces are worked on in random order, without following any specific logic.	1
	2.2 **Sequential-Face-Order**: Movement from face to face follows numerical order (e.g., 1, 2, 3, etc.).	3
	2.3 **Opposite-Sum-Order**: Arrangement follows die's regular logic, ensuring that the sum of opposite faces equals 7.	3
	2.4 **Idiosyncratic-Face-Order**: Faces are worked on systematically according to another logical order, not related to the sum of opposite faces, but resulting in opposite faces adding up to 7.	4
3. **Placing dots on a face**: Method used to distribute dots on each face of the die.	3.1 **Visual-Approximation**: Dots are placed based on visual approximation without precise methods.	2
	3.2 **Parallel-Guides and Measures-Combination**: Dots are placed using parallel guiding lines and precise measurements.	2
	3.3 **Diagonal-Guides**: Dots are placed based on properties of the square, using diagonals.	3
	3.4 **Mixed-Methods-Placement**: A mixed method, combining several approaches to dot placement.	4
4. **Size of dots**: How size of the dots is determined on each face and across faces of the die.	4.1 **Random-Dot-Size**: Size of dots is randomly determined (every dot is different size).	1
	4.2 **Visual-Dot-Size**: Size of dots is determined visually, without precise measurement.	1
	4.3 **Inconsistent-Dot-Size**: Size of dots is determined by measurements on each face but is not consistent across all faces.	1
	4.4 **Measured-Dot-Size**: Size of dots is determined according to specific measurements.	8
5. **Use of symmetry as part of design process**: How symmetry is applied or ignored during die design.	5.1 **Symmetry-Not-Integrated**: Symmetry is not observed or maintained during design process.	2
	5.2 **Symmetry-Integrated**: Symmetry is intentionally used in design process.	9
CAD Process Related: Aspects related to interaction with CAD software and overall design approach.		
6. **Process of biasing die**: Steps taken to intentionally bias the die, making it unfair.	6.1 **No-Biasing-Process**: Student does not engage in process to bias the die.	5
	6.2 **Biasing-Process**: Student explicitly engages in process to bias the die, making it unfair.	6
7. **CAD design process**: Overall workflow in designing the die.	7.1 **Software-Struggle**: Student appears to struggle with software control, making multiple errors or unnecessary sketches.	2
	7.2 **Iterative-Trial-Error-Approach**: Student makes multiple attempts, often undoing actions and experimenting with different approaches.	5
	7.3 **Systematic-Approach**: Student follows a systematic approach: constructing the die, creating holes, emptying, and filling to bias the die.	4

Nathan's Example. Nathan worked on the biased die activity for six days, for 5 hours and 17 minutes. We describe Nathan's learning opportunities in chronological order as he designed and

printed the die. According to the audit log, on day one (27 minutes of work), Nathan created a rectangular prism, placing its corner at the origin of the 3D coordinate system (1.2 Corner-Origin) (Figure 2A). He initially distributed dots using visual approximation (3.1 Visual-Approximation), starting with one dot and sequentially progressing to adjacent faces (2.2 Sequential-Face-Order). As he rotated the object, he ensured the dots were consistently sized (4.4 Measured-Dot-Size), demonstrating an early attempt at uniformity. Realizing his shape was not a cube, he adjusted its height, disrupting the dots' distribution. The use of symmetry was not manifested (5.1 Symmetry-Not-Integrated). At this stage, Nathan demonstrated a novice approach to 3D design based on visual approximation with little planning and precision.

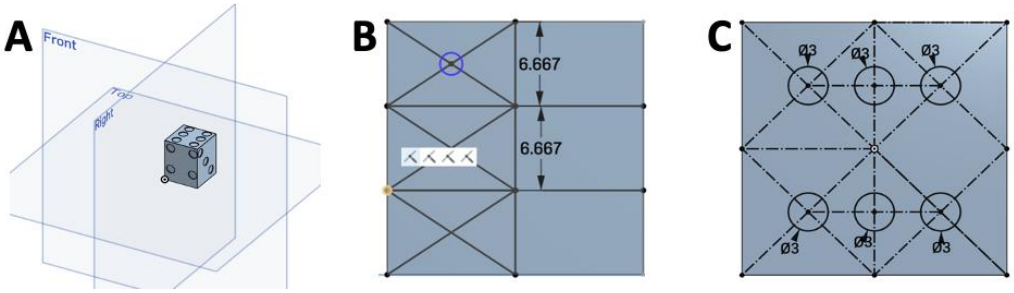

Figure 2: Nathan's designs

On day two (1 hour and 3 minutes), Nathan deleted all previous actions, demonstrating his motivation to improve and awareness of his previous sub-optimal performance. Starting over, he created a die with the corner at the origin of the axes (1.2 Corner-Origin). Initially, he placed dots arbitrarily (3.1 Visual-Approximation) but soon erased them. He sketched equally distanced parallel and perpendicular lines, dividing the face into six equal parts (3.2 Parallel-Guides and Measures-Combination). Then, he added diagonals to determine the center of each part (3.4 Mixed-Methods-Placement) (Figure 2B). This sequence shows Nathan's progression through the design process, incorporating mathematical concepts such as division, measurements, parallelism, and rectangle properties such as the intersection of diagonals. After consulting the teacher, Nathan started over again, sketching a square centered at the origin of the axes (1.4 Center-Origin) and incorporating another mathematical concept: symmetry (5.2 Symmetry-Integrated).

Two weeks later, on day three (37 minutes), Nathan used diagonals to place the dots (3.3 Diagonal-Guides), mirroring their placement for symmetry (5.2 Symmetry-Integrated) and maintaining consistent dot sizes (4.4 Measured-Dot-Size), demonstrating consolidation and application of a previously learned concept. His frequent use of undo-redo actions reflected an exploratory learning approach (7.2 Iterative-Trial-Error-Approach), indicating the ongoing development of CAD proficiency and geometry understanding.

A week later, during day four (2 hours and 3 minutes), Nathan created a dot at the centre of one face, using the origin as a reference after getting teacher assistance. Then, he systematically used diagonals for placing equally sized dots, ensuring opposite faces summed to 7 (7.3 Systematic-Approach, 3.3 Diagonal-Guides, 4.4 Measured-Dot-Size, 2.3 Opposite-Sum-Order) (Figure 2C). Then, Nathan added rounded corners to embellish the die, which was finally ready (see Figure 1A above). To create a biased die (6.2 Biasing-Process), Nathan modified the interior by creating an internal void and adding material to one side (Figure 1B above). This modification represents a mathematical

modelling translation from the digital design to the physical object to be created and used in a real-world scenario, thus showing Nathan's ability to create 3D designs for a specific functional outcome. On days five and six (7 and 9 minutes each plus idle time), Nathan tested different options for discretely marking his biased die, downloaded digital files, and 3D printed them.

Discussion and Conclusions

In this study, we explored low-achieving students' opportunities for learning mathematics when working on a 3DP biased die activity. The class findings revealed varied levels of engagement and success. All the students revealed the application of mathematical reasoning and spatial thinking during the design process. For example, nine of the eleven students demonstrated understanding of the coordinate system, aligning the die' corner with the coordinates origin and a similar number applied symmetry to their designs. On the other hand, only six students created a biased die. Nathan's example illustrated the students' progress during the 3DP activity, from concrete geometric manipulations using visual approximations to precise measurements and then to more abstract conceptual applications of square properties. These findings are in line with previous research showing that 3DP can be combined with mathematical modeling activities to promote mathematical learning (Guler et al., 2019).

This learning trajectory, progressing from arbitrary placement to a more systematic method, occurred organically due to the iterative trial-and-error approach and the teacher's scaffolding and mentoring. The students incorporated various mathematical concepts, such as symmetry, parallelism, and the intersection of diagonals in a rectangle/square. Nathan's design process exemplifies how students discover and apply mathematical patterns, supporting the enactivist framework, which emphasizes knowing as emerging through embodied actions and interactions with the environment (Varela et al., 1991). From this perspective, Nathan's progression shows that he perceived the feedback received from the 3D design software and then improved the model, enacting mathematical concepts through repeated iterations of actions and feedback. Moreover, Nathan's ability to transfer the mathematical patterns across different parts of the design task reflects his evolving mathematical understanding, suggesting, according to the enactivist view (Abrahamson, 2024), that repeated enactment indicates as well as develops a deeper understanding of mathematical concepts. Nathan aimed to create a model that "works", fulfilling its ascribed functionality, and in that sense, his doing reflected his knowing.

Further, Nathan evaluated and validated his 3D model and improved it iteratively. We propose that this assessment, which is an inherent yet often overlooked step in mathematical modelling, was fostered by the concrete and immediate feedback provided by the CAD software during the design process (Levin & Verner, 2021). Additionally, Nathan exhibited notable perseverance and motivation throughout the activity, continuing to improve his designs despite initial struggles. This suggests that 3DP tasks can help students engage with challenging mathematical concepts.

Furthermore, building on Nathan's example we suggest that 3DP tasks can be effective for low-achieving students by providing them with hands-on experiences that bridge the gap between abstract mathematical concepts and tangible applications. We propose that this study makes novel contributions to the field in two ways. First, the use of 3D design and printing among low-achieving students to learn was rarely studied. Second, it shows the unique trajectory by which mathematics was learnt even though it was not explicitly instructed. Nathan did not learn because he was taught

but rather because he experienced. Finally, building on the growing role of 3D printing in industry and STEM education, we suggest further exploration regarding how these activities can be scaled and adapted for other mathematical concepts and diverse student populations.

Acknowledgment

We are grateful to Israel Z. for involving us in this project and for his valuable insights. Special thanks to Achva Academic College and the Alon Fund for Education for providing the necessary resources.

Promoting Euclidean-Taxicab covariational reasoning to enhance understanding of trigonometric concepts in a digital environment

Annamaria Miranda[1] and Loredana Saliceto[2]

[1,2] Department of Mathematics, University of Salerno, Italy; amiranda@unisa.it, lsaliceto@unisa.it

Research in mathematics education shows that activities promoting students' covariational reasoning, as well as the transition from one geometry world to another, favour the meaningful learning of mathematical concepts and the construction of knowledge. In this work, we explore the intertwining of both these educational potentials by engaging undergraduate students in activities aiming to enact covariational reasoning processes within and between two different geometries, specifically Euclidean and Taxicab geometry, in a digital environment. We aim to investigate how students connect trigonometric elements (quantities, functional relations) to identify their covariational positioning within and between the two worlds supported by GeoGebra.

Keywords: covariational reasoning, theoretical covariation, covariational positioning, Taxicab trigonometry, undergraduate university students.

Introduction and conceptual background

Covariational reasoning and the notion of variation or change of a quantity within a scientific phenomenon have been identified by research over the last decades as a powerful way of thinking that helps students construct meaningful learning of a wide range of mathematics concepts (Bagossi & Swidan, 2023; Carlson et al., 2002; Jaber et al., 2024; Moore, 2014; Thompson & Carlson, 2017). The concept has been defined in a variety of ways in the literature, but they all agree that covariational reasoning is the simultaneous coordination and imagination of changes in two quantities. Carlson (1998) describes covariational reasoning as "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354). In Thompson's theory of quantitative reasoning, a person reasons covariationally when "she/he envisions two quantities' values varying and envisions them varying simultaneously" (Thompson & Carlson, 2017, p. 425). Thompson and Carlson (2017) argue that "ideas of continuous variation and continuous covariation are epistemologically necessary for students and teachers to develop useful and robust conceptions of functions" and that "variational and covariational reasoning are fundamental to students' mathematical development" (p. 423). According to Carlson et al. (2002), the development and interpretation of models of continuously changing events are significantly aided by students' covariational reasoning skills. Students' struggles stem from their inability to visualise and coordinate the simultaneous changes in variables or their lack of variational reasoning skills. The mental images they refer to are not limited to visual images but encompass all types of mental representations that represent past experiences, thoughts, emotions, and sensations related to the quantities. Creating mental images is cognitively demanding, requiring the conceptualisation of quantities (quantity in mind, not the real world), quantification (an act of conceiving an object and assigning a unit of measure to one of its attributes), and relationships among quantities. Thompson (1994) asserted that students' reasoning about covarying quantities needed to form a series of mental

images: an image of the change in one quantity, then an image of the coordinated change between two quantities, and finally an image of the two changing quantities covarying simultaneously. Understanding and knowledge should be strengthened when the processes manifest by changing the theoretical world in which to reason and reflect on how to coordinate concept images in different theoretical registers. Research shows that comparing different geometric worlds aids in the advancement of Euclidean knowledge (Kemp & Vidakovic, 2023; Miranda & Saliceto, 2024). In our ongoing experience, university students are involved in exploratory cooperative learning activities within Taxicab geometry (Krause, 1975) using digital tools to better understand concepts in Euclidean geometry. Taxicab geometry relies on an alternative definition of distance to that used in Euclidean geometry. Given two arbitrary points, $A = (a_1, a_2)$ $B = (b_1, b_2)$ the Taxicab distance is defined by $d_T(A, B) = |a_1 - b_1| + |a_2 - b_2|$ and the induced geometry is the totality of notions preserved by Taxicab-isometries. This geometry challenges Euclidean intuitions and encourages reflection on definitions, axioms, and properties. Furthermore, exploring the properties of figures and making conjectures through dynamic geometry software helps to visualise the simultaneous change in quantities and promote students' covariational reasoning. The educational implications of altering the theory within which a concept can be described are seldom ever reported. We argue that switching between geometries stimulates and supports covariational reasoning. We explored the effects of university students' engagement in covariational reasoning in different geometries with the aim of developing meaningful learning of trigonometric concepts and investigating how the use of digital technology supported the covariational processes involved. The aim of this study is to identify the different positionings in students' covariational reasoning emerging from their discourses. We face the issue of promoting undergraduate students' covariational reasoning by giving them theoretical and digital opportunities to explore a trigonometric concept within and between different geometries.

Approaching definitions of theoretical covariation and covariational positioning

From a theoretical perspective, we make a first attempt to define the following notions.

Theoretical covariation. Representations play a fundamental role in the learning of mathematics and are essential for an understanding of mathematical concepts, as they allow students to think mathematically. Moreover, changing theory, exploring the meaning of the concept within each mathematical theory, and transforming from one theory to another makes the semiotic representations set richer and strengthen the understanding of a concept (Duval, 2006). The simultaneous variation of two representations (quantities, relationships, etc.) within distinct theories is said to be *theoretical covariation*. It undoubtedly represents a covariation order different in nature from those already introduced in literature (Bagossi, 2024; Bagossi & Swidan, 2023; Jaber et al., 2024).

Covariational positioning. Positioning theory is the study of how people assign themselves and others a position in discourse (Harré & Van Langenhove, 1999). Wagner and Herbel-Eisenmann (2009) showed that the norm in mathematics education research was to identify students' positioning in relation to mathematics, which is a departure from positioning theory. In line with this research, the idea to investigate how students position themselves in relation to covariational reasoning takes shape. Thompson and Carlson (2017) characterised six different major levels of covariational

reasoning through some mental images and behaviours inducing them: *L5-Smooth continuous covariation*. The person envisions increases or decreases (hereafter, changes) in one quantity's or variable's value (hereafter, variable) as happening simultaneously with changes in another variable's value, and the person envisions both variables varying smoothly and continuously*; L4-Chunky continuous covariation*. The person envisions changes in one variable's value as happening simultaneously with changes in another variable's value, and they envision both variables varying with chunky continuous variation; *L3-Coordination of values.* The person coordinates the values of one variable (x) with the values of another variable (y) with the anticipation of creating a discrete collection of pairs (x, y); *L2-Gross coordination of values.* The person forms a gross image of quantities' values varying together, such as "this quantity increases while that quantity decreases." The person does not envision individual values of quantities going together. Instead, the person envisions a loose, nonmultiplicative link between the overall changes in two quantities' values; *L1-Precoordination of values.* The person envisions two variables' values varying but asynchronously—one variable changes, then the second variable changes, then the first, and so on. The person does not anticipate creating pairs of values as multiplicative objects; *L0-No coordination.* The person has no image of variables varying together. The person focuses on one or another variable's variation with no coordination of values. We call *covariational positioning* the way in which a student positions himself/herself in a mathematical discourse with respect to covariational reasoning; that is, a positioning process (a sequence of positions in the speech) within the mathematical discourse from which it can be clearly deduced that a certain level of covariational reasoning has been or is going to be reached, according to Thompson and Carlson's classification (2017). When someone exhibits a particular level of covariational reasoning, it indicates that she/he can reason consistently at lower levels but not at higher ones. A Position Act PA0, PA1, …, PA5 is one or more sentences in the mathematical discourse from which it is clear that a certain level of covariational reasoning L0, L1,…, L5 has been or is going to be attained, respectively. When the discourse exhibits a reasoning in terms of theoretical covariation, we refer to this act as *theoretical covariational positioning* (TCP).

Research questions

The research started from the hypothesis that shifting geometry enacts covariational reasoning at different orders and positionings. In this paper, we focus on the concept of sine and other concepts related to it (angle, cosine, sinusoid), within the Taxicab trigonometry. Our research questions are:

How do undergraduate students enact reason covariationally when working on knowledge construction involving the shifting of geometries in digital environments? Specifically, which kind of covariational positioning emerges in students' discourses about trigonometric quantities?

Methods

The experiment, which took place at a university in the south of Italy, involved 12 undergraduate mathematics students taking a short course organised in two phases, shifting the students' position from "being a student" to "feeling a teacher". According to the design, each group had access to a vertical non-permanent board as well as a digital environment that included a collaborative tablet, a digital software for design, a collective document in which to place the solution product and process,

and a personal document in which to report on their experiences. Undergraduate students were given a task to introduce and explore the definition of the Taxicab metric starting from a real-life situation:

Model a real-life problem (reasoning on Taxicab paths). Define the Taxicab metric; define Taxicab objects (circles, conics, angles, trigonometric functions), one or more. Choose them and investigate their Taxicab world (relationships, statements) by reasoning on definitions and statements analogous to those already known in Euclidean geometry.

Figure 1: A generic task addressed to undergraduate students

One of the working groups focused on trigonometry concepts. The task, once solved the real-life problem, was structured in instructional episodes described as: I. Illustrate the taxicab distance; II. Explain what a circle is (what is fixed and what varies) and draw an example; write the Taxicab equation of a circle; draw the unitary circle; III. Illustrate the taxicab radian; explain what the sine of an angle is; IV. Graph the sine function; graph the cosine function; V: Investigate the fundamental trigonometric identities; VI. Choose a trigonometry theorem and investigate its validity in the world of taxicab trigonometry. We focus our attention on excerpts from Episodes III, IV, V and VI.

Data collection and Data Analyses

Our collected data, specifically students' audio-recorded discourses and GeoGebra creations, were qualitatively analysed through a systematic identification of some levels of covariational reasoning, labelling the covariational positionings, deriving from Thompson and Carlson's classification (2017), that emerged in their speech acts. Specifically, we only give a taste of the findings selected from the discourses made within a four students group exploring the Taxicab trigonometric world. We labelled through a covariational positioning lens the discursive positioning acts (PA0, PA1, PA2, PA3, PA4, PA5) occurring within a collective discussion carried forward by the working group.

Preliminary findings and discussion

Let us look at the covariational processes stimulated by the transition between different geometric contexts shifting from traditional tools, such as non-permanent boards, to digital tools like GeoGebra. Excerpts were selected from students' recorded discussions related to Episodes III, IV, V, and VI, in which the processes of covariational reasoning, also according to the theoretical covariation and other orders of covariation, emerge through positioning. We discuss here the most significant moments in the discussion in the exploratory immersion in Taxicab trigonometry.

Episode III- Exploring the definition of the Taxicab-radian and envisioning the changes with respect to the Euclidean radian. Students begin with the angles as quantities and identify corresponding quantities in Taxicab and Euclidean geometry through acts of theoretical covariational positioning. The teacher (T) stimulates a correspondence between quantities, the measure of Euclidean radians and the corresponding measure of the same portion of a plane in Taxicab radians (Figure 2), to enact a reflection about the definition of t-radians:

T: When the measure of an arc on the Taxicab circle is one? […] Right! It happens when the Euclidean angle is half of a Euclidean right angle. Why? And, what about the value of the Taxicab angle π_T corresponding to π Euclidean radians?

Student St4 coordinates the value of one variable with changes in another one: (1) pairs of Euclidean-Taxicab angles, producing a discrete relationship, and (2) arc-radius discovering π_T by a ratio (PA4):

St4: […] As a circle of radius 1 has four sides, each of length 2, a Taxi-straight angle π_T is 4. Also, from $2\pi r = circle\ length$ you have $\pi_T = \frac{circle\ length}{2r} = \frac{8r}{2r} = 4$

St2 forms a general image of the relationships between arc, angle, and distances, but without an explicit connection between specific values. He attempts to link geometric concepts such as arc length, angle, and sine qualitatively. This goes beyond the mere separate consideration of variables:

St2: […] A Taxicab radian (t-radian) is an angle whose vertex is the centre of the unit Taxicab circle and intercepts an arc of Taxicab length 1. Look at the figure!! [*pointing by fingers*] So, the length of an arc is the Taxicab distance of that points!! Is the sine of an angle the ratio of the side opposite to the hypotenuse? (PA2)

The discussion goes toward the corresponding definition of Taxicab-angle in analogy with the Euclidean world. The definition subtends the mental coordination of the amount of change of a Taxicab angle with changes in the corresponding Euclidean angle, a discrete set of pairs (PA3):

St1: The measure of a Taxicab-angle θ is the number of t-radians subtended by the angle on the unit circle with vertex in the centre. It's analogous to the Euclidean!!! The definition, but the values are different. Let us take a line through the origin: $\frac{\pi}{4}$ corresponds to 1 t-radian, $\frac{\pi}{2}$ corresponds to 2 t-radian, and so on (PA3).

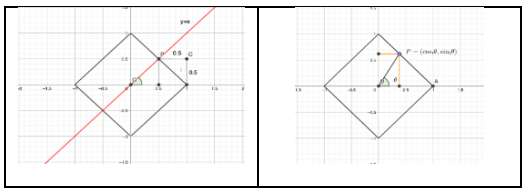

Figure 2: The Taxicab radian, sine, and cosine

The exploration proceeds with GeoGebra (Figure 2), with which students gain awareness. St2 coordinates the variables more deeply than St1, moving from discrete exploration to a more continuous approach, even though the covariation envisioned is not completely smooth (PA4):

St2: The length of the arc must be 1, but the arc is a segment…π/2 becomes 2 t-radians, so π becomes 4 and the circle is 8 radians. See also the values between them! (PA4).

Episode IV - Discovering the Taxicab-trigonometric functions and the related covariations. The exploration concerns the coordination of the t-radian values along the circumference of the unit circle and along the *x*-axis and the coordination of this measure with the sine value. Student St2 expresses clear coordination of the two variables, saying that the sine changes with changes in the radian *x*, and this seems a covariational positioning corresponding to PA4:

St2: When the t-radian value equals the value 0 the sine is 0, the value 1 the sine is 1/2, as the sum of the catheti is 1, and so 2 [*pointing by fingers on the sheet*] (PA4)

St3's speech shows awareness of the sine while considering changes in the Taxicab angle. St3 describes the relationship between variables in terms of simultaneous variations and coordinates geometric and algebraic concepts in a continuous but not yet smooth manner (PA4):

St3: The *sine* of a Taxicab-angle is the Taxicab-distance from the *x*-axis. And when the t-angle changes then the distance from the *y*-axis (and the *x*-axis) changes (PA4).

St1 speech act verbalises that while considering uniform increments of the angle, the rate of change of the sine varies uniformly, increasing or decreasing the function, and this corresponds to coordinating the average rate of change (PA4) anticipating periodicity (towards PA5). The reflection on maximum, minimum, and periodicity suggests advanced reasoning, not yet completely smooth:

St1: If so, let us graph it with GeoGebra!! Oh. [..] It is edgy!! It is not the same, but in the same way, here it increases, then it decreases (PA4). Right at the maximum and minimum points. Better to say angular! Mh… (Figure 3) In this world, the sine function is an open, broken line [*reflecting*]. Is it periodic? (PA5)

Students reflect to define the Taxicab sine and sinusoid (PA3, PA4, PA5). Going back helps students to conjecture the image of the sine graph (PA5) and develop awareness and critical thinking. St2 merely suggests a reflective process without directly considering the variation of values:

St2: So […]. Why don't we reflect on a good definition of sine? (Towards PA5)

St1 coordinates the different sine values in various geometries through a definition.

St1: The simplest is "the distance from the *x*-axis in the unitary circle" […] In Taxicab geometry the sine doesn't take the same values of Euclidean geometry (PA3).

St3 coordinates variations between variables in a continuous but not completely smooth manner, showing an advanced but not global understanding:

St3: If we change the angle length and consider the distance, the maximum is 1, […] is it really getting closer to be a sinusoid? (PA4)

St4 integrates local and global observations, an advanced understanding of the variable relationships:

St4: As the circle is a polygon, the Taxi sine and cosine functions have angularities in the maxima and minima, unlike what happens in Euclidean trigonometry (PA5).

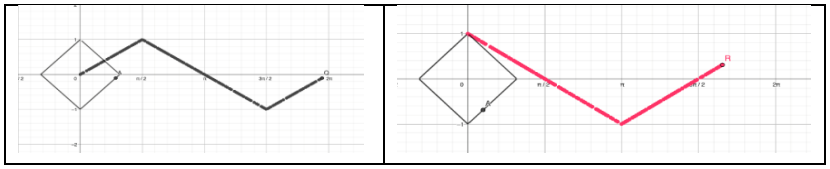

Figure 3: The Taxicab sine and cosine function

Students show awareness of the instantaneous changes in the domain of the functions (Figure 3):

St3: To simplify, I would see sine and cosine while the point moves on the Taxicab unitary circle […] and study its variation [*moving her fingers*]. Let me change the angle *α!* Rather than running through a finite number of points…(PA5)

St4: GeoGebra gives us the possibility to choose a point of the circle, and to make it move on it, visualizing the variation of its distance from the axis […] (PA5)

Episode V - Taxicab sinusoid and cosinusoid. The advanced way of reasoning induced by the shifting helps students engage in covarying sine and cosine (Figure 4), what can be called third-order covariational reasoning (Bagossi, 2024). Coming back to the Euclidean setting, St1 says:

St1: In this world what could be said about fundamental identities? Pythagorean Theorem is no longer valid, so what are the relationships between the sides of the right triangle? [*after a long discussion*] The relation is $|\sin\theta| + |\cos\theta| = 1$. This makes it clear that when sine varies, cosine also varies pointly. Let's graph it!! (PA5)

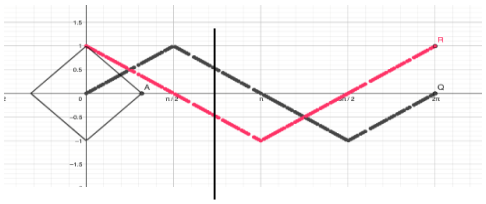

Figure 4: The Taxicab sine and cosine covariation: a third-order covariation

Episode VI - Theoretical covariational positioning in the discourses about Taxicab sinusoids and Euclidean sinusoids. In this episode, students begin verbalising a higher covariational positioning, a double *theoretical covariation* since two measures (T-E-angles) and two relationships (T-E sinusoids) simultaneously covary but in different geometries (Figure 5). St1 and St3 envision a relation between both corresponding angles and function values, both locally and globally:

St1: In this world the same behaviour, when a t-radian varies also the corresponding Euclidean-radian varies. When I move the point on the circles and I imagine representing it on my sheet, I describe the graphs of a function. The sine! (TCP)

St3: We can do the same in the Taxi-world. Let us try to see this in GeoGebra […] But?

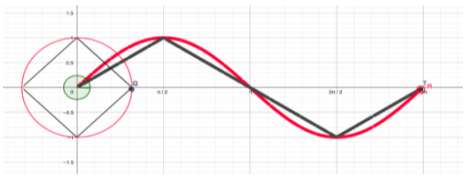

Figure 5: The Taxicab sine and the Euclidean sine covarying: a double theoretical covariation

Shifting to a different geometry opens the construction of new knowledge, reinforcing the old one.

Conclusion

In this experience, the geometrical transition challenges students to reinterpret mathematical concepts, relationships, and representations within a new theory. Such transition stimulates their covariational reasoning by requiring the coordination of analogous quantities across geometries, fostering the ability to observe and analyse how these quantities vary simultaneously. Furthermore, it supports covariational reasoning by encouraging students to create mental images and compare variations, enhancing their conceptual understanding and promoting critical reflection on the properties and definitions that govern each geometry. The reflections stimulated by the transition between Euclidean and Taxicab geometries provide valuable insights into the types of covariational positioning verbalised by students. Across Episodes III to VI, students showed varying levels of covariational positioning, ranging from basic coordination of values (PA3) to higher covariational positioning up to theoretical covariational positioning (TCP). The role of the digital environment in validating covariational reasoning reveals fundamental: students use GeoGebra software to dynamically explore simultaneous variation. They use the slider function to control the independent variables, the animation function to visualise continuous changes, and the trace tool to record the paths of the dependent variables. These tools allow students to observe the continuous changes between quantities supporting covariational understanding through interactive visual representations.

Chat GPT as a didactic tool to improve students' abilities in managing different semiotic representations: a first study.

Giorgia Nieddu[1,2], Maria Cristina Carrisi[2], Maria Polo[2] and Antioco Luigi Zurru[2]

The large multimodal model GPT-4 with the chatbot ChatGPT can operate with text, images etc. With the further aim of understanding how to employ GPT-4 to design a classroom activity, we want to investigate if ChatGPT's multimodal functionalities allow it to effectively handle different (semiotic) representations while solving an assigned mathematical task with operations such as treatment and conversion of data, and provide potentially useful new representations for students. We conducted a qualitative test in which two tasks containing graphs were submitted to GPT-4, and we analysed its responses with a focus on used and produced representations.

Keywords: Artificial intelligence, multimodality, semiotic system, mathematics education.

Introduction

The Large Multimodal Model of artificial intelligence GPT-4 (OpenAI, 2023) with the interface ChatGPT is capable of operating with - and generating - human natural language, programming languages, images, audio etc. interlaced together. Although it does not have didactical purposes and has not been specifically implemented with mathematical knowledge, has become popular in mathematics classrooms, used by teachers and students. It is commonly known that these kind of models are not reliable: the developers reported that "it "hallucinates" facts and makes reasoning errors" (OpenAI, 2023, p. 10), and it is affected by bias and disinformation, which can lead to ethical issues. In computer science field GPT-4 is considered a black box, as it is impossible to see all the processes that conducted to a precise answer; therefore it is a didactical black box, "a system whose inner-workings are (partly) unknown to the user" (Greubel & Siller, 2022, p.1), this representing a limit in education given the importance of argumentation and proper use of sources. Before its release, GPT-4 was tested in question answering with few mathematical tasks with diagrams to be interpreted; developers reported that its capabilities in questions with images are as effective as for text-only inputs (OpenAI, 2023), but we point out that the model's logical and mathematical performances are not solid when images are involved (Nieddu et al., 2024). It is possible that ChatGPT is subject to mathematical biases, which results in greater ability on certain topics than others (due to greater representation in the data used for training) or preference of some solving strategies over others; for example Getenet (2024) in his research involving pre-service teachers finds that GPT primarily relies on algebraic equations and formulas, giving less importance to visual solutions. Variety of representations is a crucial focus in mathematics education, as the emergence of mathematical knowledge is linked to the production of different semiotic representations, for Duval (2006, p.103) "something that stands for something else". We address then the following research question: Can ChatGPT handle different (semiotic) representations

while solving an assigned mathematical task containing graphs and provide potentially useful new representations for students?

Our long-term goal is to design classroom activities in which students work collaboratively with different registers of semiotic representation and interacting with multimodal ChatGPT; This paper constitutes an initial phase of our work, necessary to outline our idea based on the results that we will show here. After a description of the framework(s), we will analyse two tasks performed by ChatGPT with the aid of students' pre-existing data.

Theoretical Frameworks

As we focus on the design of collaborative activities with the use of ChatGPT and mobilization of representations, we employed the theory of registers of semiotic representation (Duval, 2006) and humans-with-media (Borba & Villareal, 2005); the former will help us to recognize the registers used and the relationships between them, the latter will be needed to understand the possibilities that ChatGPT offers in terms of sharing knowledge in a community with technologies.

Theory of registers of semiotic representation

According to Duval (2006), each representation can be generated automatically by a device or an organic system, as a memory image, a reflection or a photograph (non-semiotic) or produced with an organized system of signs as algebraic language, natural language etc. (semiotic). Systems which allow us to describe a representation with operations as treatment (modifying a given representation using the rules of the system in order) and conversion (translating the representation to one into another system) are called registers of semiotic representation. Although ChatGPT's representations are "automatically" generated, some of them could actually be expressed with precise registers of semiotic representation. This relates to our research question.

Humans-with-media

The assumption that knowledge is produced by humans together with the media, whether it is writing, orality or a multimodal technology is the basis of humans-with-media (Borba & Villarreal, 2005): computer technology rearranges human activity in a unique way as in activity theory (Tikhomirov, 1981), allows knowledge to be shared and a collective intelligence to be created (Lévy, 1993). This approach also focus on the importance of representations for mathematics learning: Borba (2012, p. 803) states that "knowing can be understood as coordination of multiple representations" and

> "Based on a combination of images, other kinds of visual feedback, writing and sound, and possibilities for sharing ideas in multimedia environments, multimodal discourse becomes a new means of expression when digital media are readily available in the production of knowledge" (Borba, 2012, p. 803).

Methodology

We selected two tasks from the Italian national INVALSI tests for 10^{th} grade students containing text, tables, pie charts and bar charts as we wanted to include various registers, operations to be carried out and types of questions (and answers to be given). Mathematical contents are mean and

frequency (absolute, cumulative, percentage). We submitted each task to ChatGPT as an image (see Figure 1) with the prompt (in Italian): "You are a student of the second class of a second grade, secondary school. Solve the following task", as it performs better provided with a context (Lee et al., 2023).

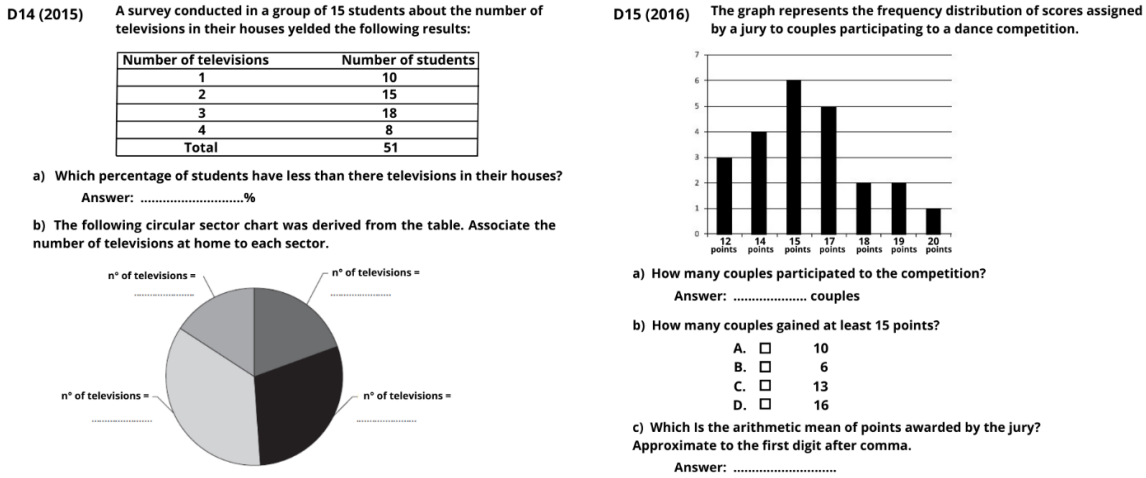

Figure 1: tasks D14-2015 and D15-2016 as examples (original versions are in Italian).

We employed the available pre-existing data (https://gestinv.it/Index.aspx) to understand whether the answers and produced representations could respond to students' potential difficulties. In Table 1 some data about students and ChatGPT (first answers) are collected. A description of GPT's answers and some transcripts follow.

Table 1: General results. Rows 2-3 refer to students' answers.

task	D14-2015 (a)	D14-2015 (b)	D15-2016 (a)	D15-2016 (b)	D15-2016 (c)
Correct	48,3%	61,5%	65,3%	44,8%	24%
Wrong	44,8%	35,1%	29%	51,8%	52,6%
Students' number	27207	27207	33992	33992	33992
ChatGPT	correct	unclear	wrong	wrong	wrong

Task D14-2015

ChatGPT correctly addresses part (a): "In order to calculate the percentage of students with less than three televisions at home, we sum the number of students with one or two televisions"; it calculates 10 +15 = 25 and then the percentage diving by 51 and multiplying for 100. The script for part b) follows:

ChatGPT: [..] we will need to determine the proportion of each category based on the data in the table. Remembering that the sum of the sectors in the graph must equal 100% and that each sector represents a proportion of the students with a certain number of televisions, we proceed to calculate the percentages for each category: [..] we need to associate each sector with the calculated percentages: The largest sector (about one-third of the graph) corresponds to 35.29%, representing students with 3 televisions. The next largest sector corresponds to 29.41%, representing students with 2 televisions. The smallest sector corresponds to 15.69%, representing students with 4 televisions. Finally, the remaining sector represents 19.61%, which corresponds to students with 1 television.

It was sufficient to pick the higher frequency and so forth, without calculating percentages; we also wondered which one is for ChatGPT the largest area it refers to, and asked for more explanations:

Researcher: Are you sure that for part b you need to calculate the percentages corresponding to the various frequencies?

ChatGPT: You are right; [..] since the circular sector graph you provided should already represent the percentage distributions based on the data in the table. Therefore, my goal was more to confirm that the proportions displayed in the graph match the original data. [..] we can rely on the visual distribution to determine which sector corresponds to which category, based on the relative sizes of the sectors. [..] the largest sector should correspond to the category with the most students (in this case, those with 3 televisions), and so on.

Researcher: Can you complete the given pie chart? produce an image of the pie chart where the missing data are inserted.

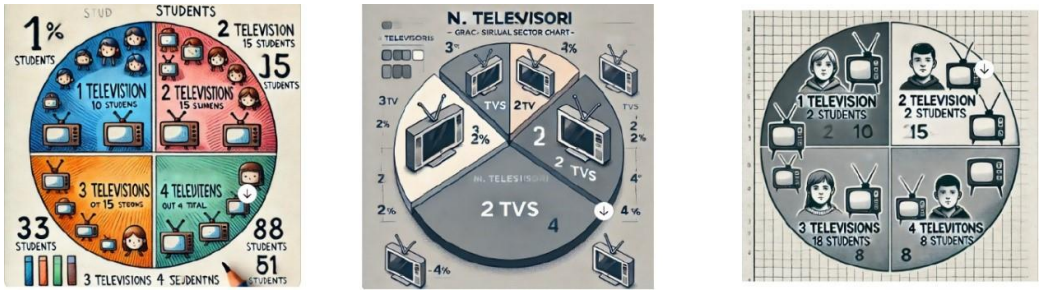

Figure 2: three attempts of ChatGPT to complete the pie chart, task D14-2015, part (b).

We suggested to associate the frequencies referring to sectors' greyscale as in the picture (we asked for the lightest sector, the second, the third and the darkest), but the answer still was meaningless.

Task D15, 2016

ChatGPT misunderstood the frequencies (it uses 1,4,6,6,5,3,1 instead of 3,4,6,5,2,2,1) in the chart.

ChatGPT: In order to determine the total number of participant couples, we will sum the frequencies of points in all columns in the graph: 12 points: 1 couple; 14 points: 4 couples; 15 points: 6 couples; 17 points: 6 couples; 18 points: 5 couples; 19 points: 3 couples; 20 points: 1 couple. Summing these values we obtain: 1+4+6+6+5+3+1=26. So, 26 couples participated to the competition.

For part b), it says: "We consider the couples which obtained 15 points or more", then proceeds to list the data (wrong as before) corresponding to 15, 17, 18, 19, 20 points and sums them. It also states that the result does not correspond to any option. In part (c), it explains "we have to multiply each score for its frequency and divide the total sum of points for the total number of couples". The calculation is addressed correctly (but with wrong data as before), and it also rounds the result as

requested. We asked "are you sure you used the correct frequencies" again obtaining wrong data (but different from the ones before).

Discussion

Using text and image input, one can effectively interact with ChatGPT and obtain new approaches when a mistake occurs. In task 14 GPT shows its understanding of the problem and its ability to find solving strategies, in particular it partially solved part (b) in another way when requested. It does not explicitly use the word 'frequency', this being an adaptation to the language used in the given task or a limitation in the natural language register, which remains colloquial and not specifically mathematical; It could extract the necessary data from the table, showing some handling of the tabular register, a good conversion to natural language and symbolic registers, used explicitly to perform the necessary calculations. On the other hand, 51.7% of the students could not calculate the frequencies for less than 3 televisions, showing some difficulties with the cumulative frequencies. Part (b) was the one solved correctly by the largest number of students, we can assume that it was quite natural for them to proceed assigning the sectors in increasing or decreasing order; ChatGPT initially shows some understanding of the meaning of a pie chart, stating that the sum of the sectors must be equal to 100%; then, it maintains the link between a pie chart and percentages, associating them with the sectors. When we asked about this, it specifies that it is not necessary to calculate percentages. Finally, when asked to complete the graph, it changed the given one, 'forgetting' that the graph must visually represent the percentages (modalities) that it wrote down. It seems that priority is given to the numbers, that is the symbolic register, over the pie chart register.

Dealing with task 15, we can affirm that GPT had a hallucination, resulting in a bad conversion from the bar chart into the natural language and algebraic register. We assume that GPT either misread the chart or randomly generated the data not knowing how to derive them. The natural language and symbolic registers are used in a consistent manner dealing with the concepts of frequency and mean; a weighted mean was not explicitly requested, but GPT was able to recognise the need for it. Furthermore, approximation is carried out correctly using the symbolic register. Students in general obtained better results in part (a); in part (b), it was found that most of the errors were for option B. (39.8% of total answers), corresponding to 6 couples. Being 6 the number of couples that gained exactly 15 points, we can suppose that the cumulative frequencies of 'at least 15 points' might have been mistaken for the frequency of the '15 points' modality; this shows a probable students' difficulty in decoding natural language and in transitioning from natural language register (at least 15 points) to the algebraic register (P>=15). Finally, only 24% of students performed correctly part (c); We can assume that it can largely be attributed to the presence of cumulative frequencies.

Conclusion

Despite GPT-4 not being explicitly designed for didactical purposes, its performance in handling operations such as treatment and conversion between different registers has proven promising in certain contexts, such as processing natural language, tabular and symbolic data. However, limitations remain, as evidenced by its struggles in accurately converting pie charts and bar charts into meaningful representations, leading to mistakes, hallucinations and misinterpretation of data.

Difficulties with pie chart register were both in replication and in analysis, because specific references to sectors in the image are never made, not even when suggested to indicate them using grayscale. It showed no difficulties in recognizing the questions' layout, not even options in question 15 (b). Dealing with the second part of our research question (production of useful representations) ChatGPT provided answers that may or may not be correct, but still well expressed, argued and explained in detail, including the use of bulleted lists, formulas and mathematical symbols used appropriately. This could provide students with useful examples of how a solution is argued and expressed using natural language and symbolic register. It is possible to edit a previously sent message, obtaining two different paths within the same conversation; this ensures the possibility of recalling previous elements or providing new representations to GPT. The model's ability to change its response once it receives a suggestion often turns out to be fictitious, as the second response will be a reworking of the first. When observing ChatGPT outputs, we can see how the model generates - types - its answers word by word, as each one is produced based on the previous one; this constitutes a huge difference between the knowledge produced, for example, by a book, or even a web page, as these media are produced before students' use, and not during it. We argue that, as expressed by Borba and Villareal (2005) in their framework, the media in which a task takes place is relevant, and solving problems with ChatGPT (or other chatbots) is different to do it with every previously known media. It allows students to access information produced, expressed in a certain way, with certain modalities, exclusively for them; as we discussed before, the lack of control on generated contents can be dangerous, and for this reason we believe that teachers should guide students to a fruitful use, and educational research should investigate on best practices.Although the model cannot (and should not) replace human guidance in the classroom, it may enhance learning experiences by offering diverse representations and fostering critical thinking. As argued by Yoon et al. (2024) ChatGPT can be considered as a resource in students' proving process: students were effectively able to take authority in their reasoning through activities such writing a prompt, revising it based on the outcome, evaluating GPT's responses and deciding what to take from them, and finally write a final proof. Barana et al. (2023) explained how ChatGPT supports and activates strategies of critical thinking and problem solving when students use it: as well as being helpful when they could not find a solution approach, students were able to find personal strategies such as dividing the problem into smaller tasks and analysing them with GPT or using it as a confirmation in case one or more solutions had already been found. Dilling et al. (2024) in their research showed how ChatGPT can stimulate interaction among students in various ways such as identifying errors, discussing responses, comparing different solutions; these processes, as the authors affirm, recall and reflect the competences of mathematical communication and argumentation. This is consistent with what we have been saying, but we believe that in order to introduce AI into education, it is necessary to prepare students; as expressed by Arzarello and Robutti (2010), to use effectively the new technologies available in education it is necessary to introduce new methodologies and not simply repeat traditional activities with the new devices. For example, it is necessary to address to students ethical issues, mistakes, hallucinations and other limitations, but also to provide some basic information about how chatbots work, such as the need of asking questions (prompt engineering) in a purposeful way and specifying the context; indeed, as found by Yoon et al. (2024), teachers can influence students' conceptions of genAI and stimulate

constructive use by providing examples of errors and inaccuracies of artificial intelligence and emphasizing its use as a support and not as a solver. We think that various established best practices are suitable for activities with chatbots; for example, it is possible (as we showed) to promote multiple representations, problem solving and collaborative learning: students can be encouraged to conjecture solutions, evaluate and check AI solutions and discuss with peers, for example with the organization of a final discussion to summarize the work done and stimulate the metacognition, focusing on discerning and comparing personal contributions from GPT's ones. Multimodal ChatGPT can be integrated into activities that exhibit a Concrete Pictorial Abstract approach; it could guide the various phases by providing customized cues to reinforce the transition between levels of abstraction; in particular, it can prove a support in the pictorial phase for images and virtual drawings, but also in the abstract phase, since, as we have seen, GPT can consistently handle symbolic register. The practice of scaffolding can also be applied with ChatGPT: the teacher can stimulate students to ask questions (that is writing prompts) to ChatGPT to address complex problems; As the student progresses, ChatGPT support can be gradually reduced, encouraging autonomous responses and using it only at a final stage. Future research should investigate its use in real classroom settings, applying more refined strategies for multimodal learning.

Students' written and oral verbalizations of a numerical pattern using the tool *BookCreator*

Zita Pahlsmeier[1] and Marcus Nührenbörger[1]

[1]University of Münster, Institute for basic and inclusive mathematics education, Germany; zita.pahlsmeier@uni-muenster.de

Numerical patterns are crucial for mathematical learning. However, it is often difficult for students to verbalize their discoveries of a pattern in a generalizing way. In this study, we give insights into a learning environment, in which primary school students are encouraged to verbalize their discoveries on a numerical pattern in both analogue and digital formats using the tool BookCreator. Results from a preliminary design experiment, in which students used a paper-pencil note, a typed text, and an audio recording, reveal differences among these methods, with the digital ones being more generalizing. Every verbalization includes specific information on the pattern. The findings suggest that the BookCreator may offer potential for verbalizing numerical patterns in a generalizing way.

Keywords: BookCreator, numerical pattern, verbalization, generalization, primary school.

Introduction

Mathematical patterns are an important basis for the mathematical thinking of primary school children (e. g., Mulligan & Mitchelmore, 2009; Warren, 2005). Activities such as describing, generalizing, and justifying patterns can make mathematical structures accessible to students, but are often not clearly separated from each other. Therefore, students' verbalizations regarding patterns can include both descriptive and justifying elements (Akinwunmi & Steinweg, 2022). This paper does not aim to differentiate which parts of a verbalization are descriptive and which are justifying. Therefore, we use the term "verbalization" to address all products (written or in a sound record) that the students create when they are tasked to describe a pattern.

Even without any knowledge of variables, it is possible to describe a pattern in a generalizing way, but for young students, it can be difficult due to challenges in the use of (written) language (Akinwunmi, 2012; Coles & Ahn, 2022; Warren, 2005). Research (e. g., Warren 2005) implies, that oral verbalizations may sometimes be more precise than written ones, so working with oral utterances concerning a pattern may be helpful for some students. The use of digital media is one way to fix those oral expressions as a base for further work (Cooper & Warren, 2008; Warren, 2005).

In this paper, we will investigate how students describe a numerical pattern written and orally using analogue and digital media. Therefore, according to the Design Research Method (Nührenbörger et al., 2019), a learning environment with a focus on two numerical patterns was developed and tested in a design experiment. The learning environment uses analogue media and the digital tool *BookCreator*. During the design experiment, two fourth graders produced three different verbalizations that will be analysed by using qualitative content analysis (Kuckartz, 2019). The underlying research question is: *How do students' verbalizations of a pattern differ in paper-pencil notes, typed text, and audio recordings*, and *what impact does the transition between analogue and digital media have on the content and the way of generalization in these verbalizations?*

Theoretical and empirical background

Patterns function as a mediator to understand mathematical structures and are therefore essential for mathematical learning (Akinwunmi & Steinweg, 2022; Mulligan & Mitchelmore, 2009; Warren, 2005). According to Mulligan and Mitchelmore, "A mathematical pattern may be described as any predictable regularity, usually involving numerical, spatial or logical relationships" (2009, p. 34). Discoveries related to patterns can be verbalized orally or in written form, often involving description and justification (Akinwunmi & Steinweg, 2022). Research suggests that verbalizing these discoveries may be challenging for students, particularly when expressing them in written form (Warren, 2005). Oral expression seems easier for students because, for example, it can include gestures and material interactions, elements that are missing in written tasks (Warren, 2005).

As patterns are not limited to specific cases, they can be verbalized in a generalizing way. Such a generalization is important because, for example, it contributes to the development of algebraic thinking (Cooper & Warren, 2008). By using and discussing different representations, students can be supported in abstracting their discoveries and verbalizing them in a general manner (Schifter & Russell, 2022; Warren, 2005). Even young students without any knowledge of symbolic variables can express the general character of a pattern by using a representative example with labelling it such as that, or using their own words as variables, and other (Akinwunmi, 2012; Coles & Ahn, 2022).

Summarizing, students' difficulties with the verbalization of patterns could be rooted in language use, especially when tasked with writing down their ideas. Activities with material seem to support students when verbalizing their discoveries orally (Cooper & Warren, 2008; Warren, 2005); thus the use of representations and the opportunity to work with oral utterances appear to be helpful.

In this study, we use the digital tool *BookCreator* in addition to analogue material to provide these opportunities. The tool enables the creation of multimedia books[1] with features such as text input ("text function"), drawing or handwriting ("pen function"), audio recordings ("sound function"), and photo and video integration ("camera function") (Schäfer, 2023). Integrating videos in *BookCreator* allows the presentation of dynamic processes and activities with concrete material, which can be accompanied by oral utterances, gestures, or notes. As previously discussed, these factors may contribute to oral verbalizations being more precise than written ones (Warren, 2005). While the text and the pen functions allow to integrate handwritten or typed expressions, the sound function enables fixing oral utterances with or without reference to other representations in the eBook. Therefore, when creating an eBook about a pattern, students have several options to verbalize their discoveries. In summary, *BookCreator* as part of a learning environment offers an opportunity to provide students with different representations, even dynamic ones such as videos, or to create these representations themselves. Using multiple external representations in digital media has the potential to enhance mathematical learning (Walter, 2018). Similar to working with analogue media, the students need to actively establish connections between those representations since they are not automatically linked by the tool.

[1] In the following referred to as eBooks.

Method

According to the Design Research method (Nührenbörger et al., 2019), a learning environment focused on numerical patterns was developed and tested in a design experiment. The design experiment involved two pairs of students (grades 3 and 4) participating in three clinical interviews each. The interviews were videotaped and transcribed, and the students' products were collected.

In the following, we provide a brief overview of the learning environment using sample products and recordings from the interviews with one pair of students (Jona and Marco, grade 4). Afterward, three verbalizations produced by the two students in three different formats (paper-pencil note, typed text, audio recording) will be analysed regarding the content and whether there is a general character of the expression recognizable or not. To address the research question, we developed categories using a mix of concept-driven and data-driven development according to qualitative content analysis (Kuckartz, 2019). By classifying smaller parts of the verbalizations, we will focus on the content and the level of generalization within the different products, and examine their differences in terms of both content and general character. Table 1 displays the main categories and subcategories with respect to content. Within each main category, we differentiate between the five subcategories.

Table 1: Categories regarding the content

Name of category: Information about …	**Definition:** The (part of the) verbalization …
Main categories	
I the current pattern	… focusses on the pattern that is currently dealt with, without any information on previous interview sessions or representations that might be used.
II previous sessions	… focusses on previous sessions (e. g. patterns that were discovered), without any references to the current session.
III the current pattern with a reference to previous sessions	… draws a connection between the pattern that is currently dealt with and previous interview sessions (e. g. connection between the patterns that were discovered).
IV the current pattern with a reference to representations	… draws a connection between the pattern that is currently dealt with and a representation that is currently used (e. g. how to recognize regularities of the pattern in a representation)
V other aspects	… focusses other aspects that cannot be assigned to main categories I to IV
Subcategories	
(1) Characteristics of one number	… focusses on characteristics of one number without mentioning characteristics of the other number or the relation to the other number (e. g. the quantity of tens in one number).

(2) Characteristics of two numbers separately	… focusses on characteristic of two numbers without relating them to each other (e. g. the quantity of tens in two numbers).
(3) relation between two numbers	… relates two numbers to each other (e. g. comparison of the quantity of tens in the two numbers).
(4) criteria for matching number pairs	… establishes criteria that must be fulfilled by numbers to match the pattern (e. g. a minimum number of tens that is necessary).
(5) other	… focusses other aspects that cannot be assigned to subcategories (1) to (4).

Concerning generalization, we use category (A) where the general character is not recognizable, or (B) where it is recognizable. Further analyses could explore how exactly the students generalize in the verbalization. However, our focus in this paper is solely on whether the general character in the verbalization becomes clear or not. To categorize a phrase as making a general character clear, we refer to Akinwunmi's (2012) ways of generalization: the use of an example and labelling it as such, the use of several examples, the formulation of conditional phrases, the use of quasi-variables, or the use of variables (Akinwunmi, 2012).

Learning environment

The learning environment consists of three sessions. Figures 1 to 3 show impressions from the sessions, using the example of the interviews with Jona and Marco. The students are tasked with discovering, describing, and justifying numeric patterns using different representations. In sessions 1 and 2, the students work with number pairs such as 25 and 34. In this pattern, the tens and ones differ by 1 and the numbers as a whole differ by 9. In the third session, the students discuss number pairs like 34 and 52. Here, the tens and ones differ by 2 and the difference between the whole numbers is 18. While the students work completely analogue in session 1, they use the tool *BookCreator* to discuss and improve an existing eBook with a focus on the pattern in session 2. This way, the second session gives the students the opportunity to familiarise themselves with the digital tool and its functions on the one hand, and to further develop and question their discoveries on the pattern on the other hand. In session 3, the students build on their previous work by exploring the new number pairs with analogue material and creating an eBook about the pattern.

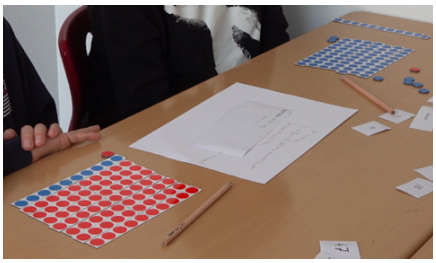

Figure 1: Impression from session 1 - students use counters and stripes of tens

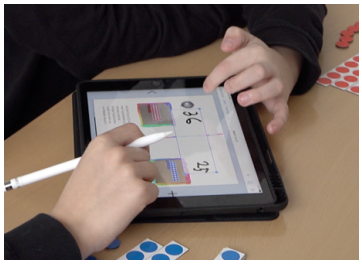

Figure 2: Impression from session 2 - students add a page to the given eBook

Figure 3: Impression from session 3 - the eBook's title page (translated)

Jona's and Marco's verbalizations of the numerical pattern

The verbalizations we will analyse in the following were produced by Jona and Marco in their third interview session. The students discovered the pattern within number pairs such as 34 and 52 and verified it using self-chosen number pairs at the beginning of the session. Then, the students verbalized their discoveries in a handwritten paper-pencil note (analogue), as well as in a typed text and an audio recording on their eBook's title page (digital). These verbalizations were chosen for analysis because they were all created at the point of transition from the analogue to the digital media. Between typing the text and making the audio recording, the students drew an iconic representation (an empty number line with the calculation of plus 20 and minus 2) which is included on the eBook's title page (see Figure 3). Table 2 shows the three verbalizations translated by the authors. The coloured numbers were added to categorize smaller parts of the products.

Table 2: Jona's and Marco's three verbalizations, translated by the authors

Handwritten verbalization	[1] You swap 2 tens and 2 ones. [2] The smaller number has 18 difference to the large one. [3] You swap the 34 becomes the 52 and the 52 becomes the 34. [4] The smaller number has two ones more. But the larger number has 20 more.
Typed verbalization	[1] That with different numbers like 34/52 you can also swap [2] that we had named before as swapping cards [3] but that now it is that you swap 2 tens and 2 ones.
Audio recorded verbalization	[1] We had already made an eBook before. But with this eBook it is like that, before it was with, but the swapping cards were with nine. [2] This time it was simply calculated again plus nine, so two times nine, so that it's eighteen and um, [3] here you can see, that it's twenty minus two and the eighteen and [4] it actually only works with eighteen. [5] And what you also cannot do is, um, now calculate ten plus eighteen, [6] because there has to be a two, there has to be at least a two behind it and or a higher number, because it otherwise, um, because otherwise you can't deduct it so well.

Results

Figure 4 illustrates the categorization of verbalizations into two levels: (A) where the general character is not recognizable and (B) where it is. Both levels assign phrases from the verbalizations into main categories I to V and subcategories 1 to 5.

In the handwritten verbalization (see Figure 4, green parts), most expressions can be understood in a general way. They are not limited on a specific number pair, as the students use their natural language as variables with expressions like "the smaller number". Only phrase [3] is placed at level (A) as it refers to a concrete number pair. Content-wise, this verbalization falls under category I, as it focuses solely on the pattern from the third session without linking to other sessions or representations. On the level of subcategories, the verbalization concerns the relation between two numbers of a pair (subcategory 3), highlighting a swapping process of tens and ones separately (part [1]) and of the

whole numbers (part [3]). With this concept of "swapping", the students have come up in the first session naming their discovery *the swapping theorem* (original "Der Tauschsatz"). As they used the expression "to swap" before, a reference to the first pattern can be recognized but is not explicitly drawn by the students. Part [2] discusses the difference of 18 within a number pair, whereas part [4] compares tens and ones, with tens expressed as "20" rather than "2 tens."

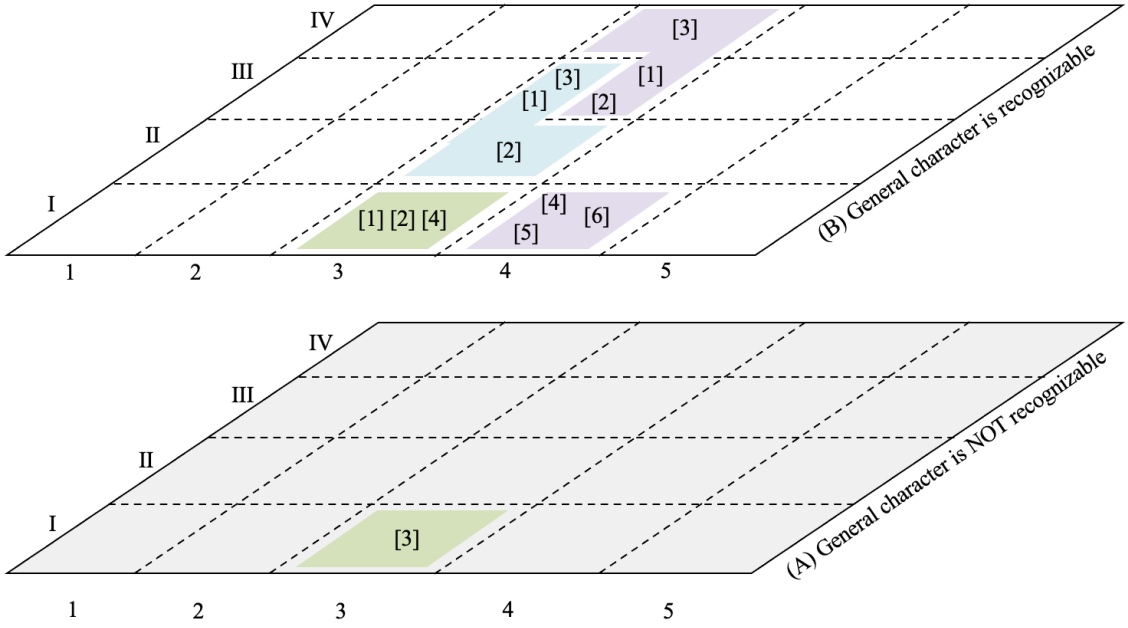

Figure 4: Categorization of the verbalizations (green: handwritten, blue: typed, purple: audio)

The typed verbalization is entirely general (see Figure 4, blue parts). Again, 34 and 52 are used as an example, now labeling it such as that by using the expression "with different numbers like" (part [1]). All parts mention the relation between numbers in a pair (subcategory 3), with swapping processes of tens and ones (part [3]) and whole numbers (part [1]). While part [2] refers on previous sessions alone, parts [1] and [3] draw a connection between the current pattern and previous interview sessions.

The audio recording is again located on level (B) (see Figure 4, purple parts) as all phrases reflect a general character with no specific number references. Phrases [4], [5], and [6] establish criteria for number pairs that are matching to the pattern in the current session (main category I, subcategory 4). Stating that "it actually only works with eighteen" (part [4]), the students underscore the importance of 18 without explication. We suspect that, in part [9], the students try to make clear that the numbers 10 and 10 plus 18 might not fit this pattern, referring to the need for at least two ones, presumably in the smaller number (part [10]). Phrases [1] and [2] draw a connection to earlier sessions (main category III), relating to the swapping process and differences 9 and 18 (subcategory 3). By expressing 18 as *9 plus 9* and *2 times 9* (part [2]), the differences 9 and 18 are set in relation to each other. In part [3], the students express the difference 18 between two numbers of a pair (subcategory 3) as *20 minus 2* with a reference to their drawn empty number line (main category IV).

Comparing the three verbalizations reveals that the handwritten one is less generalizing than the ones in *BookCreator*. The handwritten product focuses on the current pattern itself, discussing the relation

within a number pair (difference of the numbers and of tens and ones, swaps of the whole numbers and of tens and ones) without drawing a connection to prior sessions or representations. The typed verbalization connects ongoing activities to earlier interview sessions and addresses relations between two numbers of a pair. Here, they focus on swaps, excluding the difference of 18. The audio recording again makes links between the sessions, novelly connecting the differences 9 and 18, expressing 18 as *20 minus 2* with reference to the iconic representation, and establishing criteria for number pairs. However, they omit previously mentioned relationships between tens and ones.

In summary, students' handwritten verbalization remained specific and focused, while the digital formats encouraged broader connections and generalizations, with varied emphasis and omissions across media types.

Conclusion and Outlook

In our paper, we presented initial results from a design experiment involving a learning environment focused on numerical patterns using qualitative content analysis (Kuckartz, 2019). We observed differences in content and generalization across three different types of verbalizations: handwritten, digitally typed, and audio recorded.

The verbalizations mostly are expressed in a general way, suggesting that the students do not perceive the pattern as tied to specific numbers. While the handwritten product includes a part that is specifically referring to one number pair, the typed text and the audio recording can completely be understood in a general manner. The handwritten verbalization included key pattern information, while the typed and audio versions referenced previous patterns but varied in detail. Interestingly, in the audio recording, the students established criteria for matching number pairs, which they did not before, and connected to an earlier created iconic representation. The expression of these further ideas is consistent with Warren's (2005) findings that, for some students, oral expression is less challenging and therefore more comprehensive than written expression.

While we cannot definitively link the differences to digital tools, the inclusion of new aspects in each product suggests that creating the eBook inspired new ideas or led to fixation of existing ones. The process of creating fresh verbalizations for the eBook without including their previous products may have enhanced the students' ideas in the digital versions. The creation of a drawing before making the audio recording possibly sparked further ideas captured in the audio. Notably, the audio recording uniquely referenced the empty number line, perhaps due to its production sequence. The written verbalizations omitted such references despite prior use of different representations.

The findings suggest that using *BookCreator* in such learning environments may enhance the ability to verbalize numerical pattern discoveries in a generalizing manner, as it seems to encourage students to articulate ideas that might otherwise remain unexpressed. However, these results are specific to this student pair and context. Our next steps involve further analysis of the verbalizations, refining the learning environment to better encourage generalization and diverse verbalization of pattern aspects, and retesting with more students. In future research it could also be interesting to try elements of the learning environment in a different setting, for example by starting with the digital tool and concluding with analogue media to scrutinize the role of *BookCreator* in our results more closely.

Can you help us? – Task-specific LLM-based support in a digital mathematical escape game

Lisa Rühl[1] and Daniel Thurm[1]

[1]University of Siegen, Germany; ruehl@mathematik.uni-siegen.de

This research explores the integration of large language models (LLMs) into digital mathematical escape games to provide individualised student support during problem-based tasks. The study employs a design-based research approach to develop a task-specific LLM-based assistant for a digital escape game focusing on symmetry. The task-specific LLM-based assistant is shaped by principles of minimal help, multiple representations, enriched language use for conceptual understanding, and cognitive activation. Through analysing student interactions with a task-specific LLM-based assistant, the research aims to uncover effective design principles for task-specific LLM-based assistants, assess the potential and limitations of task-specific LLM-based assistants in supporting individualised learning, and refine the approach for broader educational use.

Keywords: LLMs, digital escape games, support-element, problem-solving.

Introduction

Digital educational escape games represent a form of game-based learning environments that offer various potentials, including a high level of motivation for mathematics education. The games typically include different types of (mathematical) puzzles that students must solve to achieve a goal that fits within the narrative context (Nicholson, 2015). Solving these puzzles can enhance the students' content-related knowledge as well as process-related competencies, such as problem-solving and communication. However, alongside these benefits, there are challenges in using digital escape games in mathematics education. For example, students may struggle to solve a difficult task independently, necessitating additional support. Designing these support elements can be both difficult and time-consuming. An innovative approach to address these challenges is to integrate a large language model (LLM) into a digital escape game, as LLMs like ChatGPT can provide specific responses to students' attempted solutions or queries in natural language. However, current research on the use of LLMs to assist learners in problem-based mathematical tasks is limited, particularly in the context of escape games.

This paper presents a design-based research project focusing on the integration of LLM-based assistants to support learners in problem-based tasks within a digital mathematical escape game. After a brief overview of the theoretical aspects, the paper introduces design principles grounded in theory for developing an LLM-based assistant. Then it presents the results of an initial pilot study.

Theoretical Background

Digital Escape Games

> An educational escape room / game can be defined as an instructional method requiring learners to participate in collaborative playful activities explicitly designed for domain knowledge acquisition or skill development so that they can accomplish a specific goal [...] by solving puzzles

linked to unambiguous learning objectives in a limited amount of time. (Fotaris & Mastoras, 2019, p. 2).

This game-based learning approach has the potential to enhance mathematical learning processes, for example, by fostering students' motivation and collaboration when engaging with problem-based mathematical tasks (Jiménez et al., 2020; Sidekerskiene & Damaševicius, 2023). In this project, we focus on the use of digital escape games for mathematics education, as they offer additional and specific learning advantages. One such advantage is the integration of interactive and dynamic tasks within the digital escape game (see Figure 1) that can enhance cognitive activation and encourage a deeper focus on conceptual understanding. Moreover, digital escape games enable the incorporation of immediate feedback mechanisms (see Figure 1), such as responding to students' solution attempts (Sidekerskiene & Damaševicius, 2023). This feedback can be delivered indirectly, for instance, by preventing progression to the next task until the current one is solved correctly.

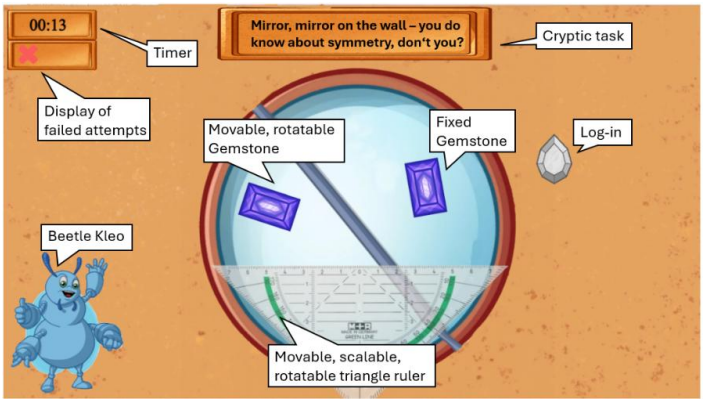

Figure 1: Interactive task with immediate feedback

When such problem-based tasks are integrated into a digital escape game, students may require support when facing the task. Research indicates that adaptive designed educational games can lead to higher learning outcomes and that well-designed learning support in educational games can enhance both learning and student engagement (Shute et al., 2020). However, creating individualised support elements for a digital mathematical escape game is a major challenge. Support elements can be realised, for example, by displaying text. These hints often appear after a predefined time or a certain number of failed attempts. Another option is to employ a pedagogical agent to provide guidance during the task. Wouters and van Oostendorp (2013) show, however, that none of the educational games they analysed integrated a pedagogical assistant to provide support. It can be assumed that the design of such an agent is very complex with previous possibilities (without artificial intelligence (AI)). An innovative approach to enhance the adaptiveness of educational games, including digital mathematical escape games, is the integration of LLMs. The following chapter will explore this in more detail, highlighting the potential of LLMs to offer adaptive support in a digital escape game.

LLMs as support in problem-based tasks

LLMs are a type of generative AI designed and trained to process and produce human language. Recent advancements in LLM technology (e.g., ChatGPT 4.0) have extended their capabilities to

include image and speech processing. The input and output formats can be freely chosen, allowing users to select modes that align with their preferences. Custom LLMs, or "customized GPTs," can be created via prompts, leading to a distinction between generic models (e.g., ChatGPT), education-specific models (e.g., customized GPTs guiding learners through reflective processes), and subject-specific tools (e.g., Khanmigo). Khanmigo, a subject-specific tutor, assists students in solving mathematical problems by avoiding direct answers and instead encourages independent problem-solving through targeted questions and guidance, thereby promoting active learner engagement. Within the category of subject-specific tools, we can further differentiate between three dimensions: cross-topic, topic-specific, and task-specific tools. Generic tools have the advantage of broad applicability across diverse problems, whereas more specialized tools offer potentially more precise support, for example, by taking into account learners' prior knowledge and common misconceptions. In the following sections, these tools will be referred to as LLM-based assistants.

Research on the effectiveness of LLMs and LLM-based assistants in supporting problem-based tasks in mathematics education is limited. While several theoretical studies (e.g., Matzakos et al., 2023) highlight the potential advantages and disadvantages of LLMs, empirical research remains scarce, likely due to the emerging nature of the field. A previously published study conducted with Taiwanese seventh-grade students explored the use of ChatGPT within a digital learning game for physics education (Chen & Chang, 2024). This study examined three groups: The first group ('Game only') used the digital learning game without any LLM-based assistance and served as a control group. The second group ('GameGPT') played a version of the game that incorporated ChatGPT, with adjustments to fit the game context. The third group ('GameGPT_examples') also used a ChatGPT-integrated version but with the addition of context-specific examples and questions provided by the LLM-based assistant. The study found that both experimental groups reported significantly higher perceived competence, and in some cases, experienced a reduced cognitive load. Post-test results revealed that the third group ('GameGPT_examples') achieved significantly better outcomes compared to the control group. It can be assumed that integrating LLM-based assistants could similarly enhance the performance of students working on problem-based mathematics tasks within a digital learning game, such as a digital escape game.

Research Goal and Research Questions

In this research project, we aim to develop and investigate customised task-specific LLM-based assistants that students can interact with during a digital mathematical escape game when they require assistance with challenging task. Employing a design-based research approach (Prediger et al., 2015), we will address the following research questions.

1. What are relevant design principles for a task-specific LLM-based assistant to support the students' working on a challenging task in a digital mathematical escape game?
2. How do students use the task-specific LLM-based assistant working on a challenging task while playing a digital mathematical escape game and which potentials and limitations can be identified?

To address these questions, we will develop task-specific LLM-based assistants for a digital mathematical escape game that focuses on symmetry and reflection.

Development of an LLM-based assistant

Design-principles

For the development of the task-specific LLM-based assistant to support students in solving challenging tasks, four theory-based design principles were derived. The first design principle draws from research in game design, while the remaining four are grounded in research in mathematics education.

1. Non-player characters (NPCs) are in-game characters that players cannot control, often enhancing the immersion of the game world (Ermi & Mäyrä, 2005; Rogers et al., 2018). In the digital escape game, the task-specific LLM-based assistant functions as a NPC, integrated into the narrative context. We assume that this will enhance immersion within the digital escape game, thereby promoting the learning benefits associated with the game flow (Shute et al., 2020).
2. The LLM-based assistant follows the principle of minimal assistance (Zech, 2002). Tips and hints progress gradually, starting with motivational and strategic guidance, and eventually offering more content-specific support. Minimal help is a well-established strategy in mathematics education (Heitzer & Weigand, 2020).
3. Visual aids are employed by the LLM-based assistant to support the problem-solving process. Visualizations can help students to establish connections between mathematical concepts and are particularly crucial for understanding geometry (Hattermann et al., 2023). Presenting multiple representations related to the mathematical task can further enhance conceptual understanding (Prediger et al., 2022).
4. The assistant employs precise technical language while also responding to students' everyday language. The goal is to bridge three language registers—everyday language, educational language, and technical language (Prediger, 2020)—thereby supporting subject-specific language development. Additionally, the LLM-based assistant serves as a linguistic role model by consistently using appropriate technical terminology (Leiss et al., 2023).

Exemplary realisation in a prompt

In the digital escape game, the students find themselves trapped in an ancient temple during a school trip. They are guided by a friendly beetle named Kleo, who lives in the temple and directs them to an alternative exit. However, the doors are locked and can only be unlocked by solving a series of puzzles. Kleo accompanies the students throughout their journey in the temple. One of the puzzles they encounter involves a task (see Figure 1), where students must position a movable, rotatable gemstone in reflection-symmetric with the fixed gemstone. Students have three attempts to solve the task correctly. Kleo provides guidance and encouragement, but solving the puzzles requires students to apply their mathematical knowledge and spatial reasoning skills.

According to Götz and Gasteiger (2019) the difficulty of reflection tasks can vary based on specific features. The task depicted (see Figure 1) includes several difficulty-generating elements: students must reflect a non-adjacent object with no sides parallel to the axis on an oblique axis. Additionally, there is no structured underground (e. g., a square grid), which is assumed to further increase the task’s difficulty. These features suggest that the task may pose a challenge for students.

To assist students who may struggle with the task, a task-specific LLM-based assistant was developed using a customised GPT, guided by the outlined design principles. In the game, this task-specific LLM-based assistant takes the role of the friendly beetle Kleo (see Figure 1, bottom left). At the beginning of the prompt, the task and the task goal are described. Based on insights from a preliminary pilot study conversation starters, specifically prepared prompts to initiate dialogue (e.g., "We don't understand the task. Can you help us?"), were integrated into the task-specific LLM-based assistant. Then the five design principles are implemented:

1. In alignment with *design principle 1*, the role is described (e. g., "You take on the role of a friendly, helpful beetle and act as a tutor.") and the name ("Kleo") is given.
2. *Design principle 2* is implemented throughout the prompt. For instance, the customised GPT is instructed to first offer motivational help ("You motivate the students to solve the task on their own.") before progressing to strategic or content-related guidance. The prompt also requires the customised GPT to refer to the triangle ruler as a mathematical tool to help content-strategical.
3. To incorporate *design principle 3*, the prompt includes instructions for the assistant to offer a content-specific visualization as part of its minimal support. This visualisation intends to encourage students to reflect on the orientation of the reflected object. The LLM-based assistant should direct the learners' focus to the two ladybugs. (see Figure 2).
4. *Design principle 4* is integrated by instructing the assistant to use technical language ("Use the following technical terms for the tips and queries: [...] orientation, rotation, size"). Furthermore, the assistant is guided to respond in short, concise sentences without complex subordinate clauses, ensuring the language aligns with the linguistic capabilities of the target audience.

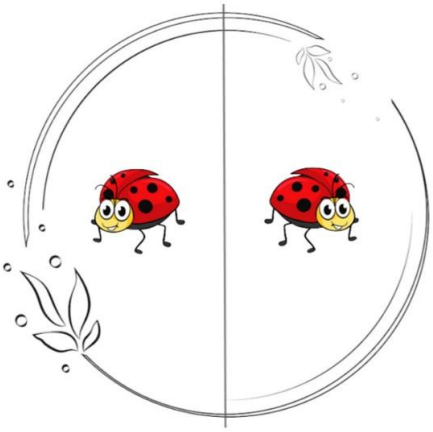

Figure 2: Exemplary visualisation of the LLM-based assistant

Data collection and analysis

The data were collected in July 2024 at a secondary school in Germany, with fourteen 7th and 8th-grade students participating in the study, all participants were video recorded. They attend a school for students with a lower performance in general. This target group was chosen because low-performing learners often require significant support in completing tasks, and the teacher's resources

are insufficient to meet these needs. Therefore, the aim is to specifically address the needs of these learners. The students worked on the task depicted in Figure 1 in a clinical setting at their school, using the task-specific LLM-based assistant previously described. At the time of the study, the LLM-based assistant had not yet been fully integrated into the digital escape game. As a result, students completed the task on a computer screen and used an iPad to interact with the LLM-based assistant. All chat transcripts were recorded, serving as an additional data source alongside the video recordings.

None of the seven groups successfully solved the task. Six of the seven groups utilised the task-specific LLM-based assistant while working on the depicted task. The students were free to choose the input and output format. Communication between students was generally minimal, both among themselves and with the LLM-based assistant. However, a few noteworthy interactions emerged.

Till and Anton, two 7th-grade students, initiated the conversation with the LLM-based assistant using a conversation starter ("We don't understand the task. Can you help us?"). Their prompts were primarily single-word responses, and they spoke little to each other. When the LLM-based assistant presented a visual representation, Till remarked, "*If the beetle sits like this and the other one like this, then the other has to go like this*", then he moved the mouse over the movable gemstone and rotated it to change its orientation to the axis. This marked the first instance where Till took an active role in solving the task.

Jeanette, another 7th-grade student, reflected after working on the task that the task-specific LLM-based assistant helped her to understand the task (‘*Because otherwise, I wouldn't have come up with the task, i.e. that you have to reflect it’*). She and her partner Samuel also communicated little with each other during the task.

Conclusion and Outlook

Working on problem-based tasks (in the context of digital escape games) is challenging for students, so integrating support is an important aspect to assist in completing the task (successfully). Task-specific LLMs, which incorporate didactic dimensions, present innovative possibilities for designing such support in digital escape games. This project aims to identify design principles for task-specific LLM-based assistants to offer support for problem-based tasks and to focus on their use by students with low performance in mathematics and the associated opportunities and hurdles.

Regarding the first research question, it can be assumed that the described design principles can be implemented through prompt design. The task-specific LLM-based assistant largely adhered to the intended structure, utilized the provided technical language, and consistently maintained a friendly, helpful, and motivating tone. This suggests that further design principles could be successfully implemented through prompts, enabling the development of additional subject-specific tools.

In response to the second research question, both opportunities and challenges were identified. As an opportunity, one can see that the interaction with the LLM-based assistant appeared to aid in students' task comprehension and facilitated discourse around the mathematical content. Furthermore, the ability of students to verbalize their difficulties proved important, a task that appears to present a significant challenge for the selected target group. This promotes the described active role in their

learning process, in which subject-specific LLM-based assistants should strengthen the students. Despite the opportunities, several challenges were also noted. Students often found it difficult to initiate conversations with the LLM-based assistant, despite the inclusion of conversation starters. Even when the interaction had already started, communication was frequently limited. It can be assumed that, due to the novelty of LLMs, many students do not yet have the necessary competencies. It seems necessary to learn these competencies explicitly.

The next steps envisage the further development of the existing task-specific LLM-based assistant as well as prompting at least three new ask-specific LLM-based assistants. Based on the results of the pilot study, a training phase is being developed to familiarize the learners with the use of the LLM prior to the data collection phase. During this phase, potential questions and inputs are anticipated together with the researcher. The goal of this training phase is to encourage more effective use of the LLM-based assistant in the digital escape game. One avenue will involve testing a different mathematical task to gather more generalizable data and assess whether the design principles are effective across various tasks. Another focus will be exploring the role of the task-specific LLM-based assistant, specifically investigating how positioning the assistant in a peer role may influence student interaction.

This study reports on findings from an empirical investigation into the use of three different forms of feedback in digital material for learning mathematics: correctness feedback, attention feedback, and explanation feedback. All feedback types are received immediately by the students. In total 267 upper secondary school students used the material during a lesson and data from the system, a questionnaire and observations were collected and analysed. The results show that correctness feedback drives the learners' engagement, while explanation feedback helps learners to build understanding but is often skipped by learners as it is time-consuming. This study suggests that attention feedback, in which the essentials or critical aspects are highlighted without giving all details, is often sufficient in this setting and retains learner autonomy.

Keywords: Mathematics learning, feedback, immediate feedback, digital learning material,

Introduction

At the Akelius Math Learning Lab[1], digital learning materials are being developed to teach mathematics, specifically targeting 7 to 18-year-olds in refugee camps and under-resourced schools in the Global South. The material will be made accessible offline on simple tablets in multiple languages. The digital environment offers educational opportunities to learners with limited access to teaching, ensuring the availability of course materials and feedback. The learners move at their own pace and revisit lectures if they want.

Feedback is considered an important and effective aspect of learning (Black & Wiliam, 1998; Hattie & Timperley, 2007; Shute, 2008; Wiliam, 2016). When creating a digital system for giving feedback there is a need to understand how learners use and benefit from different types of feedback. This study seeks to explore the impact of different feedback forms on learners using digital learning material for learning mathematics. Specifically, we examine learners' interactions with and reactions to the feedback. The research aims to answer the following research question: How do learners react to three feedback forms: correctness feedback, attention feedback, and explanation feedback, in a digital learning environment for learning mathematics?

Theoretical framework

To frame our analysis, we begin by examining the concept of feedback. According to Hattie and Timperley (2007), feedback can be defined as "information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding" (p. 81).

[1] https://www.akelius-math.com/en/about

Meta-analyses show that feedback significantly influences learning (Hattie & Clarke, 2018), but its effect can vary, it can both help and slow down progress, depending on the situation, form, and content of the feedback. It is therefore important to conduct a fine-grained analysis to develop productive feedback adapted to the specific learning situation. In particular, feedback in a digital setting must be tuned in advance, for use in the absence of a teacher.

Effective feedback, as outlined in Hattie´s model, should address three critical questions: "Where am I going?" (the goal), "How am I going?" (current progress), and "Where to next?" (steps to improve). For feedback to be instructional, it needs to offer specific information about the task or learning process, helping to bridge the gap between the learner's current understanding and the desired level of mastery (Sadler, 1989).

The literature differentiates between different forms of feedback (Barana et al., 2021), particularly between elaborate feedback, which provides detailed guidance, and corrective feedback, which merely indicates correctness. Studies suggest that elaborate feedback, such as explanations, reading links, and worked examples, is more effective in enhancing learning.

Barana et al. (2021) conducted a study on student performance in a digital learning environment for mathematics. They analysed results for three types of tasks, with associated forms of feedback: simple tasks with *corrective feedback*, i.e. information on whether the answer was right or wrong, more complex tasks with *interactive feedback*, which provides step-by-step guidance to students who have reached a wrong answer (or have answered right but chosen to verify their answer), and *guided activities*, which lead the student in an interactive exploration process, without building on a previously asked question. Their finding, derived from analysing platform data, show that the tasks with interactive feedback result in frequent improvement when students reattempt tasks they initially failed, whereas corrective feedback only, or guided activities, yielded minimal improvement. The framework developed by Barana et al. (2021) provides a starting point for how we classify different forms of feedback. Similarly to the authors we use corrective and interactive feedback.

Baker et al. (2010) studied, among other things, the impact of boredom, frustration, confusion, engaged concentration, delight, and surprise on students' results in different learning environments. Interestingly, emotions such as frustration seem to have little to no effect on learning outcomes. The authors even suggest that "frustration may not need remediation" (p. 227). This is echoed in the work by Mentis (2007) who suggests that frustration only requires intervention when it stems from factors unrelated to cognitive learning efforts.

Shute (2008) discusses the impact of formative feedback on learning, including how timing affects students' emotions. While the article covers various subjects, mathematics examples are prominently featured, showing how immediate feedback can mitigate negative emotions and enhance learning. Hannula's (2012) study delves into how emotions like frustration and enjoyment influence students' attitudes and behaviour in mathematics learning, highlighting the significant impact of these emotions on student engagement. Fyfe & Rittle-Johnson (2016) specifically examine how the timing of feedback in mathematics tasks affects learning and retention, with a focus on how immediate feedback can help manage frustration and improve problem-solving skills.

The implementation of feedback in the digital learning material

Active learning is one of the pedagogical foundations for the digital learning material used in this study. This approach emphasises that learners should engage in activities beyond listening and reading. They should actively express their thoughts and reasoning (Freeman et al., 2014). Active learning is widely recognised and empirically supported within educational research as a powerful approach to improving learning outcomes (Freeman et al., 2014). This has been implemented in this learning material by abstaining from instruction videos or texts and instead prompting learners to answer questions continuously throughout their learning process. The questions come in various formats such as multiple-choice, sorting objects, connecting objects or asking for a numerical value. Notably, there are no free text questions or questions where the full calculations are asked for. The design aims to guide learners incrementally to facilitate understanding of mathematics through engagement and immediate and varied feedback mechanisms.

The most frequent form of feedback is *correctness feedback*. This is done by showing the learner their answer alongside the correct one. Correctness feedback is given after each question. It does not include intermediate steps or guidance on how to arrive at the correct answer.

At the other end of the feedback spectrum, we have *explanation feedback*. If the learner submits an incorrect answer, they can receive an elaborate and full explanation. This is done in alignment with the principles of active learning. The learners are guided through small intermediate steps by answering questions which guide them through all the steps required for answering the original question. Once the learner completes these steps, they are given the opportunity to attempt the original question again before moving forward. For questions where explanation feedback is available, it is optional for learners who has answered correctly but automatic for those gave a wrong answer.

The objective of explanation feedback is to ensure that learners actively engage with all steps in the solution, find where their thinking was faulty, reflect on their errors, reinforce correct steps and support the consolidation of the whole process. Explanation feedback is similar to what Barana et al. (2021) call interactive feedback. However, since interaction is the core of the digital material we choose to use another name for this form of feedback.

Finally, we have the feedback form *attention feedback*. This is a form of feedback that intends to give the learner some idea on how to find the right answer without giving a full detailed explanation. Instead, attention feedback intends to shift the learner's attention to some critical aspects. In this material, this is done by asking thought-provoking or leading questions or by directing the learner's attention to key features in an image by circling or using arrows. Sometimes only audio is used to highlight some key aspects. The attention feedback does not require the learner to do anything. The learner can disregard it and move on directly. Attention feedback includes correctness feedback, as seen in Figure 1.

For questions where attention feedback is available, it is given to all learners, also to those who answered correctly. The idea is that this form of feedback can ensure those who answered correctly that their thinking, not only the answer, was correct. The learner is free to move on at any time.

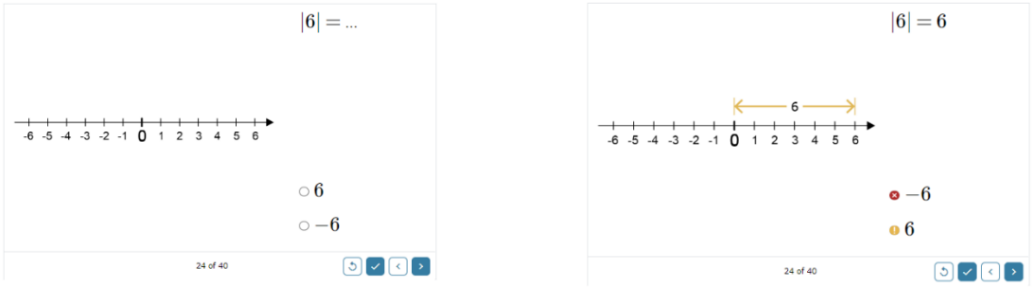

Figure 1: An example of attention feedback. To the left the question is given and to the right the feedback given. A yellow arrow draws the learner's attention to the distance to the origin.

Method

The study's empirical approach involved using the learning material in a classroom setting, allowing for an analysis of how students interacted with the material and responded to the various feedback types. Data was collected in ten classes of 17- to 18-year-old students in upper secondary school in Sweden, during the spring of 2024, with 267 students in total. This was a convenience sample where the respondents were of the right age and appropriate pre-existing knowledge, but from a more homogenous background compared with the intended target group.

Some of the students study mathematics-intensive programs. They worked with lessons about the absolute value, a concept they would normally learn about a few weeks later. Other students studied in programs with less exposure to mathematics. They worked with lessons on systems of two linear equations with two unknowns, something they had not met quite yet. Hence, neither of the groups had been taught the chosen topic in class beforehand. Both groups had in total around 40 minutes to complete as many tasks as possible from the 60 tasks available.

Three types of data were collected. System data consisting of learners' results and time spent on tasks in the learning material, a questionnaire about their experiences with the material, and finally observations in class. The total amount of respondents in the learning material and questionnaire was 246 and 267 respectively.

The questionnaire consisted of 18 questions. In the first section, the respondent consented to being part of this study and entered anonymous code making it possible for the researchers to connect the responses in the digital learning material to the answers to the questionnaire. The second section was on the overall experiences of the material. In the last part of the questionnaire, the focus turned to experiences of separate tasks. Responses to free text questions related to two of the multiple-choice questions are analysed in this report. These two questions are the following (the relevant multiple-choice options will be given in the result section):

Question 17: Sometimes, when you gave an incorrect answer, you entered a sequence with step-by-step explanations on how one can think. What do you think about that?

Question 18: Sometimes you got the option to get an explanation when you had given the correct answer. What do you think about that?

In each class, the observations were made in two different settings: in full classroom settings, where the learners worked individually, and in pair settings, where the learners worked in pairs. In the classroom setting, there were approximately 25 students who worked individually with the learning material on laptops and earphones connected for sound. The observers, consisting of both the authors of this paper and other staff at Akelius Math Learning Lab, walked around and made notes on a protocol focusing on three main themes: how the system was experienced, how the mathematics was perceived and what emotions and reactions were evoked. The protocol was developed by the observers. While preparing for data collection the observers discussed what themes to focus on to ensure reliable and uniform data collection. The classroom setting was used to get many individual reactions from learners using the system in a way that the system most often will be used.

In the pair setting, two students worked in front of a laptop. They were encouraged to collaborate and talk out load about their thinking. This setting was used to get better insight into the respondents' experience by listening to the learners. These groups of students only left the trace of one user on the learning system, while answering the questionnaire individually. This explains why there are more respondents in the learning material than in the questionnaire.

To avoid issues of privacy and integrity, each student was randomly given an anonymous code only indicating which class the student attended. No names or other personal data about the students were collected. The anonymous code was only used to connect the students' results in the learning material with their responses to the questionnaire. Students that worked in pairs both used the same anonymous code when answering the questionnaire.

We used qualitative content analysis to analyse the data from the observations and the written comments given in the questionnaire (Krippendorff, 2018). Two authors participated in coding the data. The procedure for coding started with identifying all questionnaire comments and observations that were related to feedback. These were then categorized into one of the three forms of feedback.

The researchers then searched for recurring themes within each feedback category. This was done inductively. At the end of each phase of analysis, the entire research group validated the categories that emerged from the content analysis. The validation process involved comparisons of the researchers' categorisations, and in cases of disagreement, the categorisation was discussed until a consensus was reached.

Some results

The proportion of correct answers overall was 84 %. Hence, the level of difficulty was such that most students did okay without direct instructions. Nonetheless, some students expressed a desire for more direct instruction and less reliance on feedback.

> Learner Vin44: Some tasks were like "here you get a task, try to solve it" as I said, I think it's better if someone explains how to do it before I make a mistake and not after.

Many learners reacted emotionally strongly when they received *correctness feedback*. They were keen on getting everything right and generally reacted with discomfort when they were incorrect.

> Observer NF: "Facepalm" when he gave an incorrect answer. I got the feeling that he thought it was a careless mistake. He was concerned about getting it right.

The correctness feedback in this learning material do not only show if the answer is correct or not, but also gives the correct answer. Therefore, the material typically does not allow learners to redo the questions they failed, which quite a few respondents wanted.

> Learner Box77: That you could redo the questions you did wrong (What can be improved?)

On the other hand, the observations showed that learners did not always bother to check what the right answer was.

> Observer KT: Clicks past without checking what he did wrong on several pages.

Explanation feedback was only given sparsely in the material. Learners requested more opportunities to receive this type of feedback.

> Learner Tid11: Ask after each answer if you [the learner] want an explanation of what you did wrong.

For those who received the explanation feedback, it often helped them understand the material better. Out of 267 respondents to question 18 in the questionnaire 110 selected the option “The explanation feedback helped me understand”. This was also seen in the observations.

> Observer NF: “Now I understand!" Understood after the explanation feedback.

However, the explanation feedback is time-consuming. For example, at one of the questions that offered explanation feedback, 39 out of 149 learners answered incorrectly. The explanation feedback given consists of five extra questions guiding their thinking before they could answer the original question again. These learners spent in mean spent 80 seconds on this explanation feedback, including redoing the original question.

Some of these would have liked to have continued without explanation feedback.

> Observer AH: They make mistakes but immediately understand why, are still "forced" into the explanation feedback.

Among the remaining 110 learners who answered correctly to the same question, 11 chose to get the explanation feedback. This is mirrored in the questionnaire where 142 out of 267 respondents to question 18 chose the option “I always choose to skip the explanation feedback”. This was the most common respons to this question.

The third form of feedback, *attention feedback*, gives more information than correctness feedback but is less instructive and time-consuming than explanation feedback. Students normally spend just a few seconds looking at the attention feedback and are free to continue at any time.

The data indicated that this was sufficient for many learners.

Observer NF: [The learner …] Continued with only correct answers after looking at the attention feedback on page 8.

For other students, attention feedback was not enough.

Observer SB: They had difficulty understanding the attention feedback given through audio concerning the absolute value of -5.

That the learners could skip the attention feedback had consequences. There were many observations of learners who failed the question but still did not spend much time on the attention feedback. However, data shows that learners that answered incorrectly spent more time, in most cases double the time or more, on the attention feedback.

Discussion

Common types of feedback in a conventional classroom setting are notifying the student if the answer is right or wrong and giving the learner access to the correct answer. In this study we examined the former feedback type, labelled correctness feedback. The results from this study indicate that students view the use of correctness feedback as beneficial and/or helpful.

Explanation feedback is given to students who have responded incorrectly on certain questions. Students' general opinion on this feedback type was quite divided. Some expressed frustration that they were forced into a long loop while others wanted this type of feedback more often. However, the most frequent response was that this feedback type helped students' understanding. Although some students were frustrated that they were forced by the system to stay on this feedback type, it might have been to their benefit. In contrast, students were able to skip the attention feedback type, and this appeared to be a common occurrence, even to the detriment of their own understanding. One student mentioned that they skipped a lot of these feedback types and then realized that they lacked vital information to solve upcoming questions.

Attention feedback was given to all students, regardless of whether their answer was correct or not. Students were provided key insights regarding the studied topic. We considered this feedback type to be an appropriate compromise between correctness and explanation feedback. Some students considered this feedback type to be insufficient, asking for explanation feedback instead. Others thought that they would have liked to have this information before they answered the question – making the information more like a hint than actual feedback. This can perhaps be attributed to how they have been taught mathematics previously. However, an interesting follow-up on this topic would be to compare how students fared when getting the same information before and after responding to a question.

A future iteration should, in the case of an incorrect response, include the possibility of a new chance on the same question after receiving attention feedback. This might encourage students to absorb the information in the attention feedback, knowing they can make use of it.

Student reactions, as observed by the researchers and in the questionnaire responses, suggest that adding a possibility to return to a question that they answered wrong, and correct their answer. could help dissipate the frustration caused by negative feedback. It would be interesting to test a set-up

where students get the possibility to answer a new, similar question to correct themselves in case they have answered wrong. A risk with such a set-up is that some students may not make the effort to try to answer right on their first try, knowing that they will get correctness feedback and a new chance.

Enhancing students' techno-mathematical problem-solving skills: Results from a quasi-experimental study with 5th graders

This paper discusses a teaching experiment aimed at enhancing 5th-grade students' performance in solving mathematical problems using digital tools like spreadsheets, GeoGebra, and Scratch. Employing a quasi-experimental design with a control group, the study assessed the impact of four 100-minute, inquiry-based lessons. Each lesson focused on a problem involving different concepts and employed specific digital tools. The effectiveness of the intervention was evaluated based on students' abilities to grasp the problem situation, implement a techno-mathematical approach, and explain the solution. While the intervention significantly improved students' comprehension of problems and application of techno-mathematical strategies, it was less effective in enhancing their skills in justifying solutions, highlighting strengths and areas for improvement, as well as portraying how the design principles of effective teaching experiments can be grounded in theoretical models.

Keywords: Mathematical problem-solving, Digital tools, Digital problem-solving, Teaching experiment, Quasi-experimental study.

The use of digital tools for mathematical problem solving

There are several ways in which one can address the issue of integrating technological tools in the teaching and learning of mathematics. One of the key distinctions refers to technology as an instrument to engage in mathematical activity, namely mathematical reasoning and problem-solving, versus technology as a device used to outsource procedural routine calculations or perform symbolic operations (Hoyles, 2018). Another division may be found between the utilization made by the teacher, namely for the purpose of presentation, demonstration, or explanation, and the utilization made by the student, consistent with exploring, investigating, and obtaining the solution to a mathematical problem (Drijvers & Sinclair, 2024). In this article we present and discuss a methodological proposal to achieve digital technology integration in the mathematics class, explicitly considering the technological tool being used by the students (5th graders) and aiming to develop their ability to solve different non-routine mathematical problems. Theoretical advances and research results showing the opportunities offered by digital tools to improve students' learning results in mathematics, particularly in solving non-routine problems (e.g. Bray & Tangney, 2017), have driven the study. A background motivation is the growing need to develop students' techno-mathematical fluency (Jacinto & Carreira, 2017a), which means empowering them to effectively interlace mathematical and technological competencies to solve mathematical problems (Liljedahl & Cai, 2021).

Our goal is to assess the impact of a teaching experiment carried out in a Portuguese public school and focused on increasing 5th-grade students' performance in solving non-routine mathematical problems using various digital tools. To measure the impact of the teaching experiment, we targeted

students' ability in: a) grasping the problem situation, that is, finding out how well they understood and framed the given problem; b) implementing a techno-mathematical approach, that is, their ability to apply appropriate methods and technological tools to solve the problem, and c) finding and explaining the solution, that is, knowing how effectively they articulated the reasoning behind their solutions.

The theoretical framework underpinning a teaching experiment on digital problem solving

In today's world, success in solving mathematical problems entails the ability to use appropriate mathematical resources and, at the same time, the ability to use digital technologies as equally indispensable tools (Carreira et al., 2016). The theoretical model MPST - Mathematical Problem Solving with Technology (Jacinto & Carreira, 2017b) aims to describe how students integrate both mathematical and technological knowledge to effectively solve and communicate solutions to mathematical problems. The MPST model comprises ten descriptive processes: *Grasp* (getting initial ideas about the problem); *Notice* (recognize fitting mathematics and useful tools); *Interpret* (considering affordances of digital tools and mathematical approaches); *Integrate* (combining mathematics and technology); *Explore* (using technological and mathematical resources for exploration); *Plan* (outlining an approach to achieve a solution); *Create* (carrying out the plan and recombining tools); *Verify* (explaining and justifying with the resources available); *Disseminate* (presenting the solution and outputs); *Communicate* (interacting with others in solving the problem).

Yet, the model was developed from empirical studies taking place within a beyond-school context, raising the issue of whether and how it could be applied in regular mathematics classrooms. More recently, in a later research phase also fuelled by the operationalization of the MPST model, Jacinto (2023) investigated how to enhance middle-grade students' ability to solve mathematical problems with digital tools by providing moderate mathematical challenges and fostering collaborative work in the Tecn@Mat Club, an online after-school program. The Club fostered the sharing and discussion of strategies and solutions to non-routine problems, with an emphasis on collaboration and closely aligned with an inquiry-based learning approach. Another important feature was the disclosing of several digital tools' affordances in matching the conceptual structure of some kinds of mathematical problems (Leung & Bolite-Frant, 2015; Monaghan & Trouche, 2016). It enabled students to engage in problem-solving, develop proficiency in using technology to find solutions, and enhance their ability to explain and justify them. This movement from researching MPST in the beyond school context (Jacinto & Carreira, 2017a, 2017b) to the after-school program (Jacinto, 2023), made clear that the theoretical model could guide the design of an instructional sequence focused on enhancing students' techno-mathematical problem-solving skills.

When moving towards the implementation in a classroom setting, it became necessary to develop an instrument to measure skill development. Muir et al. (2008) developed a rating scale specifically designed to assess several aspects of problem-solving in educational settings. The scale focuses on evaluating the student's understanding of the problem, the selection and implementation of a strategy, and the accuracy of the final answer. Based on the ten processes established by the MPST model and the assessment rating scale, we devised a rubric for classifying individual responses under three criteria:

i) *Appropriateness* focuses on how well the student grasps the problem, identifies relevant data, and selects the appropriate digital tool for the task. It concerns the initial engagement with the problem and the preliminary strategic decisions made by the student.

ii) *Implementation* involves the adoption of solving strategies, evaluates the degree of tool integration, and the exploration of the results of this integration. The focus is on the practical application of the selected strategies and digital tools, assessing how effectively the student integrates these resources to find a solution to the problem.

iii) *Explanation* examines the student's ability to communicate the solution process and justify the answer, evaluating how well the technology was leveraged to improve understanding or make the solution process more efficient.

The teaching experiment

The teaching experiment was designed to enhance students' problem-solving skills using several digital tools and was conducted by the first author (the teacher of the classes). Embracing the new mathematics syllabus in place for elementary education in Portugal (Canavarro et al., 2021), a set of four lessons for 5th-grade students, each lesson lasting 100 minutes, was planned (Simões, 2024). Figure 1 presents a summary of the teaching experiment conducted in 2023. Table 1 lists the mathematical content and capabilities that were the focus of each task of the teaching experiment.

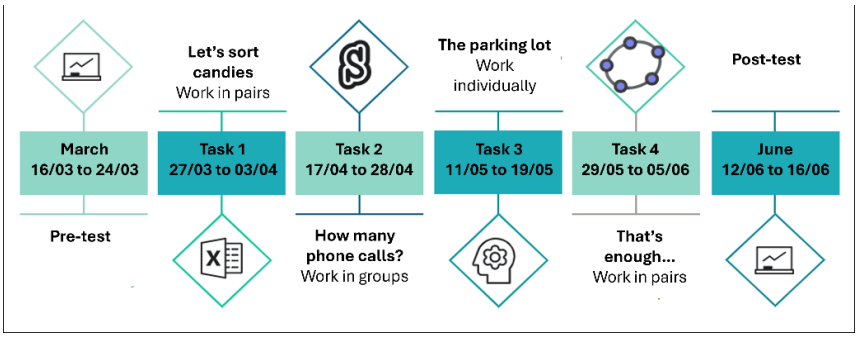

Figure 1: Structure of the teaching experiment

Table 1: Mathematical content and capabilities in focus in each task of the teaching experiment

			Mathematical capabilities					
#	**Task**	**Theme.** Content.	**PS**	**R**	**CT**	**Com**	**Rep**	**Con**
1	Let's sort candies	**Numbers/Natural numbers.** Multiples and divisors. Prime numbers.	X		X		X	
2	How many phone calls?	**Algebra/Patterns and sequences.** Formation rule.	X		X			
3	The parking lot	**Patterns and sequences.** Growth sequences. Formation rule of a sequence.	X		X	X		X
4	That's enough…	**Geometry and measurement.** Construction and classification of triangles.	X	X		X	X	

PS: problem solving; R: reasoning; CT: computational thinking; Com: communication; Rep: representation; Con: connections.

Each lesson adopted an inquiry-based approach: students were introduced to a new problem and worked autonomously for about 40 minutes; then a whole class discussion took place and, finally, the teacher summarized key points regarding efficient problem-solving strategies and highlighted

affordances in the tool used. The four problems involved concepts related to Algebra, Numbers, and Geometry. In three of the problems, students were asked to use a specific tool - Spreadsheet, GeoGebra, and Scratch - and in one of them, they could choose the tool they felt more appropriate. As an illustration, the problem "How many phone calls", related to patterns and sequences, stated: *Five students won a contest. When they got the news, they called each other. Find out how many calls the five friends had to make to congratulate each other. Discover a rule for any number of friends.*

Research method

This study employed a quasi-experimental design with a control group, using a pre-test and an equivalent post-test to assess the impact of the intervention on students' abilities to solve mathematical problems with technology.

The participants in this study were 54 students from three 5th-grade classes attending a school in a rural area of the country. Two classes, comprising 34 students in total, were designated as the Experimental Group (EG), while the third class, with 20 students, served as the Control Group (CG). The majority were 10 years old, yielding a mean age of about 10.2 years. In the interim evaluation, the percentage of students in the EG requiring additional support was 25%, while 35% in the CG were in that situation. Regarding the students' results on mathematical reasoning and problem-solving, more than half of the students in both groups achieved satisfactory ratings. While the groups were not fully homogeneous, efforts were made to ensure the sample size was sufficient to produce reliable results.

The development and validation of the research instruments followed a rigorous process to ensure reliability and alignment with the aims of the study. A pre-test and a post-test were designed to assess students' techno-mathematical problem-solving performance. Both tests included non-routine problems on geometry, numbers, and algebra, and were designed to ensure a good matching (Monaghan & Trouche, 2016) with specific tools such as spreadsheets, dynamic geometry environments, and visual programming platforms. The tests were administered via Google Forms, a familiar platform to the students, facilitating usability and reducing potential technical difficulties.

The classification rubric, designed to evaluate students' techno-mathematical problem-solving skills, comprised three main criteria split into a few indicators: *Appropriateness* – A) interpretation of the problem statement, and B) selection of relevant data and tools; *Implementation* – C) adoption of strategies, D) integration of technological resources, and E) exploration of the results of integration; *Explanation* – F) obtaining the solution, and G) justifying the obtained solution. Each indicator was measured on a scale from 0 to 3, reflecting the level of proficiency in handling each aspect of the problem-solving process.

To validate the instruments, a comprehensive multi-step process was undertaken, beginning with reviews by two experts in mathematics and technology education to ensure that the content and structure were conceptually clear and aligned with the research goals. Feedback was then provided by a mathematics teacher and two 5th-grade students who were not participating in the study, leading to revisions that simplified language and adjusted task difficulty. These collaborative efforts focused on enhancing usability, optimizing timing, and ensuring technical accessibility.

Data collection and analysis

The data collection process began with an adaptation phase, held in December, where students from both the EG and CG engaged in diverse tasks, termed "Adaptation Tasks" using tools such as Excel, Scratch, and GeoGebra. These tasks aimed at helping students become accustomed to the technology and mitigating any potential frustration. Following this phase, a pre-test comprising three non-routine mathematical problems was administered in March, allowing students to use their preferred tools to solve the problems and discuss their solutions. In June, after a 3-month period in which the teaching experiment was conducted, a post-test having a similar structure was applied. The data analysis involved the teacher-researcher classifying each test item using the rubric. The students' scores from both tests were analysed using descriptive and inferential statistics utilizing SPSS.

Results

Table 2 shows the results of the statistical analyses comparing the EG and CG pre-test and post-test scores along with the measures of *Appropriation*, *Implementation*, and *Explanation*. On the pre-test, the mean scores were 18.06 for EG and 14.85 for CG, with standard deviations of 6.84 and 8.1, respectively. The differences were not statistically significant ($t = 1.55$, $p = 0.126$), suggesting similar levels of baseline capabilities to solve problems using digital tools between the groups. However, on the post-test a significant improvement was observed in the EG with a mean of 32.38 compared to the CG's mean of 22.25. The t-test was statistically significant ($t = 3.56$, $p < .001$), indicating a substantial improvement in EG relative to CG, with a mean difference of 10.13.

Table 2: Comparative analysis of pre-test and post-test results between EG and CG

	EG (N=34)		CG (N=20)		Shapiro-Wilk test		Levene test		T-test			
	Mean	**SD**	**Mean**	**SD**	**df**	**Sig**	**Z**	**Sig.**	**t**	**df**	**Sig**	**MD**
Pre-test (T1)[a]	18.06	6.84	14.85	8.1	54	.855	0.304	0.584	1.55	52	0.126	3.21
Post- test (T2) [a]	32.38	11.67	22.25	6.54	54	.461	4.684	0.035	3.56	52	<.001	10.13
Appropriation (APT1) [b]	1.33	0.55	1.21	0.62	54	.037*	0.384	0.538	0.71	52	0.477	0.12
Appropriation (APT2) [b]	2.24	0.64	1.72	0.60	54	.027*	0.060	0.807	2.93	52	0.005	0.52
Implementation (IMPT1) [b]	0.66	0.35	0.54	0.42	54	.014*	0.835	0.365	1.15	52	0.255	0.12
Implementation (IMPT2) [b]	1.42	0.65	0.86	0.28	54	.014*	9.689	0.003	3.68	52	<.001	0.56
Explanation (EXPT1) [b]	0.68	0.24	0.44	0.24	54	.065	0.101	0.752	3.95	52	<.001	0.23
Explanation (EXPT2) [b]	1.02	0.48	0.70	0.26	54	.054	6.458	0.014	2.79	52	0.007	0.32

SD: Standard Deviation; MD: Mean Difference; * p < .05 ** p < .01 *** p < .001
a: classification between 0 and 63; b: level between 0 and 3

The results also indicate that the EG revealed statistically significant improvements over the CG regarding *Appropriation* ($t = 2.93$, $p = 0.005$), *Implementation* ($t = 3.68$, $p < .001$), and *Explanation* ($t = 2.79$, $p = 0.007$), reflecting enhanced proficiency in solving the problems using digital tools. Hence, the data indicate that while the groups started with similar capabilities as shown in the pre-test, the EG showed significant improvements in post-test scores which suggests the effectiveness of the intervention in enhancing their techno-mathematical problem-solving skills.

Table 3 provides a detailed statistical analysis of the results from pre-test and post-test assessments across the multiple indicators within the criteria *Appropriation*, *Implementation*, and *Explanation*. The Shapiro-Wilk normality test is used to assess the distribution of data and the Mann-Whitney Test to compare differences between groups.

Table 3: Comparison between the pre- and post-test results on Indicators between EG and CG

		Shapiro- Wilk Normality test		Mann-Whitney test		
Criteria	**Indicators**	**df**	**Sig**	**U**	**Z**	**Sig**
Appropriation	Indicator A Pre-test	54	.034*	316.000	- .437	.662
	Indicator A Post-test	54	.008*	186.000	- 2.795	.005**
	Indicator B Pre-test	54	.008*	306.000	- .620	.535

	Indicator C Post-test	54	.002*	372.000	- 3.245	.001**
	Indicator D Pre-test	54	<.001***	278.000	- 1.157	.247
	Indicator D Post-test	54	.001**	138.500	-3.672	<.001***
	Indicator E Pre-test	54	<.001***	301.500	- .728	.466
	Indicator E Post-test	54	<.001***	148.000	- 3.514	<.001***
Explanation	Indicator F Pre-test	54	<.001***	165.000	- 3.288	.001**
	Indicator F Post-test	54	.024*	183.000	- 2.870	.004**
	Indicator G Pre-test	54	<.001***	253.000	- 1.651	.003**
	Indicator G Post-test	54	<.001***	243.500	- 1.785	.074

* p < .05 ** p < .01 *** p < .001

Significant improvements were observed in the post-tests for *Appropriation* indicators A and B, with p-values of .005 and .003 respectively, which suggests that the intervention was effective in enhancing skills in interpreting the problem statement and in data selection. The pre-test results showed non-normal distributions, highlighting the initial variability in these skills among participants. The intervention also improved *Implementation* skills, as demonstrated by significant enhancements in the post-test scores for indicators C, D, and E, both yielding p-values of .001, <.001 and <.001, respectively. While the pre-test data reveals existing disparities prior to the intervention, the post-test results indicate a strong impact of the teaching experiment on the adoption of strategies, integration of technological resources, and exploration of the results of the integration. Additionally, there was a significant improvement in *Explanation* skills for indicator F in the post-test, evidenced by a p-value of .004, suggesting effective skill development of the EG in obtaining the solution. However, the changes for indicator G from pre-test to post-test did not reach statistical significance, with a p-value of .074, indicating that this aspect of *Explanation* – G) *justifying the obtained solution* – may require additional focus or alternative instructional strategies.

These results, altogether, suggest that the teaching experiment was particularly effective in enhancing *Appropriation*, *Implementation*, and certain aspects of the *Explanation* skills. These improvements are statistically significant, illustrating that the intervention apparently had a positive impact on students' abilities to apply the learned skills about using technology to solve mathematical problems.

Discussion and conclusion

The results of this study provide solid evidence about the effectiveness of the designed teaching experiment in enhancing 5th-grade students' performance in solving mathematical problems with digital tools. The experimental group showed significant improvements across all three key criteria assessed: *Appropriation*, *Implementation*, and *Explanation*. The improvements were particularly notable in the students' ability to interpret problem statements, select relevant data, adopt appropriate strategies, integrate technological and mathematical resources, and explore results.

The teaching experiment encouraged the use of technological tools combined with problem solving, which led students to interpret statements, select necessary data and appropriate the tools to be used, that is, to find mathematical properties of objects and ways to solve a problem using a certain technological tool (Santos-Trigo et al., 2021). Furthermore, the teaching experiment intentionally led students to recognize the affordances of each tool for each given problem (leading to integration) and to explore the different functionalities of each tool in developing successful strategies for solving problems (promoting exploration). Overall, the results reinforce the potential of the intervention design in enhancing students' ability to leverage digital tools for mathematical problem-solving. While the intervention proved highly effective in most indicators, the results also pinpoint areas needing further attention, particularly the ability to justify the obtained solutions (indicator G). This suggests the need to improve explanation skills through additional or different instructional strategies. For example, more emphasis may be placed on tasks that require students to develop explanations or justifications for their solutions. Additionally, providing opportunities for students to present their solutions and reasoning to the class could further reinforce these skills.

A final important highlight is the observation that the design principles of an effective pedagogical intervention can be rooted in theoretical principles and models, as was the case with the MPST model. The latter was used as a guide for the design of productive problem-solving activities with digital technologies, both in line with curricular topics and with the mathematical skills to be developed in the mathematics classroom.

Analysis of mixed-types in pre-service teachers' argumentation using a digital tool

Julia Marie Stechemesser and Florian Schacht

University of Duisburg-Essen, Germany; julia.stechemesser@uni-due.de

This paper examines pre-service teachers' transition from empirical to deductive argumentation when they work with a digital tool. For this purpose, an interactive book page about the interior angle sum of a triangle was created to assist students in the development of different proof types. Using a structural approach that combines a proof type model and the Toulmin scheme, the pre-service teachers' argumentations were categorized as empirical, preformal and symbolic-generic. The results show that working with the interactive book page encourages students to develop proofs in which argumentation elements of different proof types are mixed. These mixed-types express first deductive approaches and mark an important step in the development from empirical to deductive proving.

Keywords: Geometric proofs, digital tools, deductive thinking, proof types, Toulmin scheme.

Motivation

Numerous studies have highlighted the significant challenges students face when attempting to conduct deductive proofs (e.g. Healy & Hoyles, 1998). A possible approach to support students in the development of deductive proofs can be the use of digital tools (see e.g. Christou et al., 2004). However, current approaches often focus on conjecturing that utilize the empirical nature of digital tools to help students determine whether a theorem is correct or not (Campbell & Zelkowski, 2020). Even so, the research focus on the proving processes of students while working with digital tools can also provide insights into the transition from empirical to deductive reasoning. From a mathematics education perspective, the concept of a proof process can be grounded in the idea that proving can be learned when empirical understanding is a starting point of a proof process and deductive reasoning is built upon it (Brunner, 2014). Thus, a genetic approach is assumed in which empirical argumentation and deductive proving form a continuum, consisting of different proof types (e.g. empirical proofs or preformal proofs). To clarify this, it is more appropriate to refer not just to a proof process, but rather to a proof-type-process. Based on these fundamental assumptions about the developmental process associated with proving and the impact of digital tools on proving, the following research question can be derived:

Which proof types emerge when pre-service teachers work with an interactive book and how do the proof types reflect pre-service teachers' transition from empirical to deductive proofs?

Understanding of the term *deductive* in relation to the Toulmin Scheme

The Toulmin scheme (Toulmin, 2003), which is a tool to structure and analyse argumentation, will be presented in this section, because, for the analysis of different proof types, a structural approach is pursued. Focusing on the Toulmin Scheme also assists in clarifying how deductive reasoning is understood in this study. Toulmin (2003) assumes that argumentation can be structured in a certain way and he distinguishes different argumentation elements. In the Toulmin scheme one infers from

a datum (which is the starting point of the argumentation) to a claim. This connection can be legitimized by a warrant, and the warrant explains the connection between the datum and the claim.[1] The Toulmin scheme could be transferred to mathematical theorems and proving. To illustrate this transfer, Figure 1 gives an example of a mathematical proof structured by a Toulmin scheme.

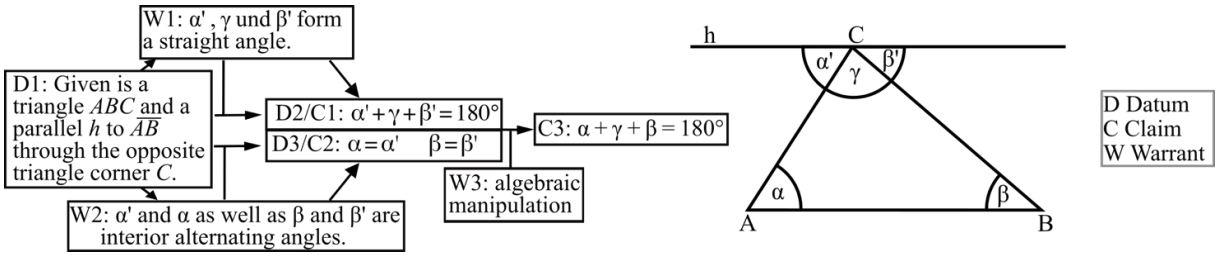

Figure 1: Toulmin Scheme about the proof of the interior angle sum of a triangle

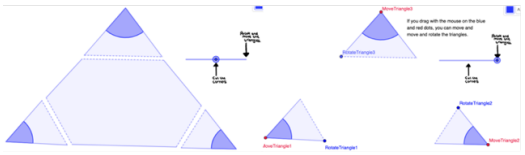
Figure 1 shows the interior angle sum of a triangle, because this geometric proof is focused in this study. The warrants (W1, W2 and W3) of the Toulmin scheme reflect what is meant by deductive thinking in this study, that is the recourse to mathematical theorems, axioms and definitions (see Duval, 1991, for a similar approach). In Figure 1, this is realized by the warrants, which refer to alternating angles (W1) and angles on a straight line (W2). These warrants could also be legitimized by other warrants whereby a deductive network of axioms, definitions and theorems expresses the self-referentiality of mathematics. This structural perspective emphasizes the challenges associated with learning deductive proving, because students not only have to associate the suitable theorem but also have to deploy the mathematical theorem at the correct place in their argumentation. In a rigorous view on mathematical proofs, only the deductive approach counts as acceptable in mathematics, but especially in a didactic context other proofs may exist in which the warrant is not a mathematical theorem, definition or axiom. For example, the warrant of an argument can also be based on experience and perception, which also means that experiences with a digital tool can be used as a warrant (e.g. Hollebrands et al., 2010). This perspective implies that there is not one acceptable proof but different proof types, which are described in the following.

Proof-type-processes applied to an interactive book page

In order to develop a proof type model, which can be applied to geometric proofs for this study, different sources of literature are involved and compared to filter proof types that are suitable for geometric proving with digital tools. The combination of Reid and Knipping's (2010) and Biehler and Kempen's (2016) classifications of different proof types, along with additional literature cited in these sources, lead to three main proof types (adapted to geometric proofs). These three proof types will be explained in the following.

Empirical proof: The empirical proof concentrates on one example which only stands for itself. In geometric proofs, actions like cutting the corners of a triangle and placing them together are often performed. Empirical proofs could be separated into empirical proofs with or without propaedeutic

[1] In the Toulmin scheme there are also the elements rebuttal and qualifier, which are not in the focus in this paper (Toulmin, 2003).



elements. An empirical proof with propaedeutic elements includes elements preparing for the following proof types, which will be exemplified later in the paper.

Preformal proof: In the preformal proof also one or more examples are used and actions are performed. The difference from empirical proof lies in the fact that every step and every argument of the preformal proof can be transferred into a symbolic-generic proof (which is especially demanded in Semadeni, 1984). The preformal proof does not require deductive conclusions but can be translated into them, because it is a concretization of the symbolic-generic proof.

Symbolic-generic proof: The symbolic-generic proof consists of deductive conclusions, but also refers to a figure which is specific for geometric proofs (Reid & Knipping, 2010). An example of a symbolic-generic proof is shown in Figure 1, where for instance symbols are also used to denote equal angles.

In order to illustrate the different proof types, reference can be made to the digital tool used in this study. For the purpose of analyzing proof-type-processes of pre-service teachers working with digital tools, a digital tool was designed that should encourage students to develop proof types in a specific order (from empirical to preformal to symbolic-generic). Therefore, in this study, an interactive book created with the software H5P (https://h5p.org) was deployed. An interactive book consists of different digital pages, and on every page different digital book elements (like videos, drag-and-drop tasks or dynamic geometry software) can be integrated. This study focuses on an interactive book page about the interior angle sum of a triangle. In order to reach the goal of evoking the development of different proof types, the book page follows a certain structure. Apart from a short introductory video, the first task (on the book page task 7) is to find a first argumentation for the theorem that the interior angle sum of a triangle is 180°. This task is open because a GeoGebra applet is integrated in which only a triangle is given. In relation to the proof type model, it is evident that every proof type could be developed for such an open task. This is different for the following tasks (task 8 and task 9), as the development of specific proof types is intended.

a) Second GeoGebra applet (task 8)

b) Third GeoGebra applet (task 9)

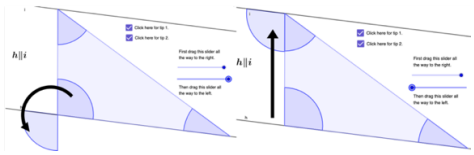


Figure 2: GeoGebra tasks on an interactive book page

In the second GeoGebra applet (task 8, see Figure 2a) a triangle and two sliders are presented. Through the usage of the sliders the corners of the triangle are cut off. Additionally, the students are invited to move and rotate the cut corners. This GeoGebra applet should help students discover that the angles can be placed together to form a straight angle. In relation to the three proof types this GeoGebra applet intends the development of an empirical proof with propaedeutic elements. The propaedeutic element of the proof is that a straight angle could be discovered which is a warrant of the symbolic-generic proof (Figure 1). This points out that this proof can prepare for the symbolic-generic proof. The third GeoGebra applet (task 9, see Figure 2b) should evoke the development of a preformal proof. Here, a parallel is already given and students can move and rotate one angle so it

fits next to the other corner of the triangle (Figure 2b). With the help of this GeoGebra applet students can develop an argumentation, which has the same structure as the symbolic-generic proof, but they do not necessarily have to refer to other mathematical theorems. For example, it is possible to warrant the equality of the alternating angles by referring to the copying and moving of the angles and not to the alternating angle theorem (Figure 2b). At this point, students do not need to argue deductively, but the symbolic-generic proof is prepared, as the warrant of a preformal proof just needs to be replaced by a deductive warrant. Because of the parallel line in the GeoGebra applet, students could also develop a symbolic-generic proof, so both proof types are intended at the third GeoGebra applet. Apart from these specific GeoGebra applets at the end of the book page a solution video is integrated in which the symbolic-generic proof is explained. After this video students are invited to revise their argumentation.

The 'proof-type-structure' of the book page should invite students to develop proofs in a genetic way from empirical to preformal to symbolic-generic proofs. In the results section of this paper pre-service teachers' proof types and their way to deductive argumentation are described.

Methods

In order to answer the research question, task-based interviews (Maher & Sigley, 2020) were conducted with seven pre-service elementary teachers at the university level. During the interviews the pre-service teachers worked (among others) on the interactive book page about the interior angle sum of a triangle, and meanwhile they were invited to articulate their thoughts as a part of a think-aloud process (Charters, 2003). Since the interviews were conducted and videotaped via Zoom, all actions performed by the pre-service teachers in the interactive book (such as a mouse click) could be observed. The interviews were transcripted and afterwards they were structured with the help of the Toulmin scheme (Toulmin, 2003). For this purpose, the different roles in the Toulmin scheme were assigned to the argumentation elements. Next, the entire Toulmin schemes and also the individual argumentation elements were categorized as (part of) a proof type through the utilization of the proof type model described above. To address this, every element of a student's argumentation was assigned to a proof type. An example of a categorisation is shown in Figure 3. Additionally, all proof types of the students were considered in their developmental sequence and they were compared to the structure of the interactive book page. In general, the usage of the digital book elements was consistently examined, taking into account the specific location on the page where students develop their argumentation.

Results

Through the analysis of the Toulmin scheme different proof types could be identified according to the proof type model for geometric proofs. In general, empirical, preformal and symbolic-generic proof types could be reconstructed in students' argumentation. Apart from these expected proof types, mixed-types, in which proof elements of different proof types are integrated in one argumentation, could be identified. The following sections will present these mixed-types, along with a discussion of the complete proof-type-processes of the students, considering the book elements of the interactive book page.

The following figure gives an insight into the mixed-type of a student called Carla. Carla develops the mixed-type at the end of the book page. Initially, with less support from the book page at the open task, she creates an empirical proof without propaedeutic elements in which she argues by halving a square. Afterwards, she develops the intended empirical proof with propaedeutic elements by arguing that the corners of a triangle can be cut off and moved to one point.

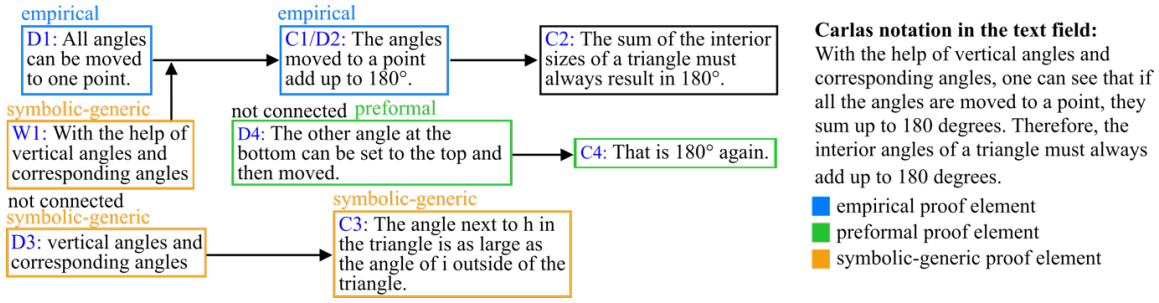

Figure 3: Mixed-type of the pre-service teacher Carla

In Figure 3, Carla combines empirical (D1 and C1/D2), preformal (D4 and C4) and symbolic-generic proof elements (W1, D3, C3) in one argumentation. Carla develops this argumentation while working on the third GeoGebra applet (see Figure 2b) in which the development of a preformal or symbolic-generic proof is intended. Nevertheless, Carla's incorporation of empirical elements into her argumentation (D1 and C1/D2 in Figure 3) becomes apparent, because these argumentation elements reflect the work with the first GeoGebra applet in which all angles could be placed to a straight angle. From this the conclusion can be drawn that the structure of the interactive book page invites students to integrate their previous argumentation from other tasks in the mixed-type. Apart from the empirical elements, there are also first symbolic-generic elements (W1, D3 and C3). Especially the argumentation element W1 expresses that Carla tries to warrant her argumentation with a mathematical theorem. This suggests that the interactive book supports Carla in developing and discovering symbolic-generic proof elements, which is an important step on the way to deductive thinking.

However, the mixture of empirical and symbolic-generic proof elements indicates that students have problems detaching from the empirical part of the proof and that they have difficulties integrating symbolic-generic proof elements and conclusions in their argumentation. This becomes particularly evident when comparing Carla's Toulmin scheme with the text she formulates for her argumentation. Although Carla infers from vertical and corresponding angles on the angles' congruence (D3→C3 in Figure 3), she does not integrate this conclusion in her written argumentation, as she only writes *with the help of vertical angles and corresponding angles*. This can also be demonstrated by the structure of Carla's mixed-type, as two of the symbolic-generic elements could not be integrated into the rest of the argumentation.

The difficulties with incorporating symbolic-generic argumentation elements are also evident in the mixed-types of other students, because many students interpret their discoveries in the GeoGebra applets mathematically, but likely do not understand what their discovery means for the argumentation. This can be seen in the following statements of a student called Amalia.

Amalia: Well, that's when, once—so alternating angles are like a vertical angle shifted. Therefore, this here would now be an alternating angle (points to α') to this one here (points to α). Um, yeah (...) I don't know. Maybe I'm just totally confused right now, but somehow (..) alternating angles, vertical angles (9). Hmm, maybe if you somehow make all three angles (..) into alternating angles, by shifting and rotating them (..), then you get 180 degrees altogether, but that's not really an explanation, so I have no idea.

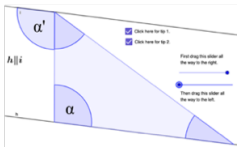

Figure 4: Transcript of the pre-service teacher Amalia

This transcript shows that Amalia associates alternating angles on the basis of the movements revealed by the sliders, but she has problems using the alternating angles and their congruence for her argumentation. This could be regarded as the main challenge in the development of symbolic-generic proofs.

In the following figure, abstracted structures of all mixed-types are considered. This structured analysis highlights that there is not just one mixed-type, but that the mixed-types are constructed in an individual and different way. These individual mixed-types will suggest a fine-graded transition process from empirical to deductive proof types, consisting of different stages.

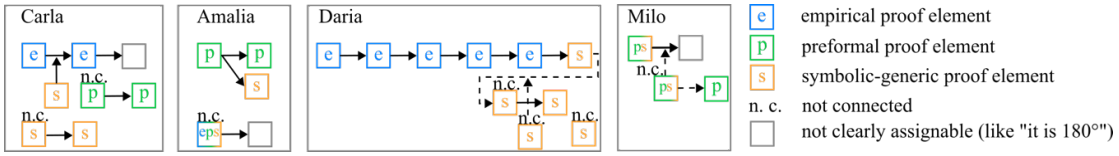

Figure 5: Mixed-type structures of all students

As seen in Figure 5, the mixed-types are mixed differently. While Carla and Amalia mix proof elements from all proof types, Daria connects empirical with symbolic-generic proof elements and Milo connects preformal and symbolic-generic proof elements. Furthermore, the proof elements themselves also can be a mixture. The 'eps-element' in Amalia's argumentation (see Figure 5) can also be seen in Amalia's transcript in Figure 4 in the phrasing 'maybe if you somehow make all three angles (..) into alternating angles, by shifting and rotating them (..), then you get 180 degrees'. The shifting and rotating of (all three) angles reflect the movements in the first and the second GeoGebra applet and can be regarded as empirical or preformal. This emphasizes the deep connection between the different proof types. Focusing on the structure of the Toulmin schemes, further differences can be identified, for example, in the comparison of Carla's and Daria's mixed-type (see Figure 5). The structure of Carla's argumentation reveals a first sign of the integration of symbolic-generic argumentation elements, as Carla attempts to integrate the vertical and corresponding angle theorem in her warrant. In contrast, Daria's approach shows that symbolic-generic proof elements are attached to empirical ones or not completely connected. This does not necessarily indicate a deductive approach in which the connection from data to claim is legitimised by a mathematical theorem. This shows that proving with digital tools can not only be seen as a development of different proof types, but that there are different, finely structured stages of development even within the mixed-types. With regard to the comparison of Carla and Daria, their mixed-type structures suggest that Carla is a little more advanced on the path of developing deductive proofs than Daria, because integration approaches are evident in Carla's proof. At this point, however, further research is needed to categorize such fine-graded stages of development and to derive direct design implications for the interactive book page.

Figure 6 shows not only the mixed-types, but also students' overall development across the book page. This overall development and the inclusion of the book elements in Figure 6 emphasize that students have problems with the development of symbolic-generic proofs, as the mixed-types are developed at the end of the book page and thus at the end of students' proof-type-processes.

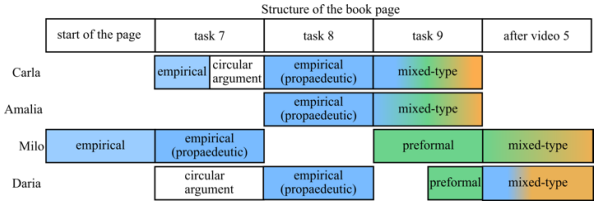

Figure 6: Overview of developed proof types through the work of the interactive book page

A possible explanation for students' development of mixed-types at the end of the book page is that the various findings from the other tasks are combined with each other at this point. With regard to the book elements, the students Milo and Daria develop mixed-types at the very end after video 5. This indicates that despite the fully provided solution in the video, the students develop a mixed-type, even though they could have simply copied the video solution. This again emphasizes that students have difficulties with deductive proofs, even when they are only required to rephrase them in their own words. At this point further research is needed to determine how instructional videos can be designed so that students do not transfer the solution into a mixed-type, but into their own deductive proof. Finally, another similarity of students' proof-type-processes is that their development ends with the mixed-type and that no symbolic-generic proof is developed after that.

Conclusion and Outlook

The analyses reveal different mixed-types that extend the existing proof type model. These mixed-types reflect students' transition from empirical to deductive proofs, as they show students' starting points in deductive thinking. The results of this study indicate that an interactive book with its specific 'proof-type-structure' can evoke the development of mixed-types, which demonstrate the strength of the use of digital tools in proving situations. However, it is not only the structure of the book page that has to do with the development of the mixed-types, because the detailed analyses of Carla's mixed-type show that the features of the GeoGebra applet (angles can be rotated and moved) can help to discover vertical and corresponding angles. In addition, Carla's mixed-type also emphasizes that students try to integrate symbolic-generic proof elements in empirical or preformal proofs. However, Carla's and Amalia's results indicate that symbolic-generic elements were either not incorporated in the rest of the argumentation or in a superficial way. In addition, Figure 5 shows the diversity of mixed-types and their different structures, which suggest a finely graded developmental process with various stages. The individuality of structures also implies that students need individual support and personalized feedback. From this, one can conclude that the use of digital tools at university must be actively supported by a teacher in order to provide individualized feedback. Furthermore, the overall development of students' proof types in Figure 6 stresses students' problems in developing further to a symbolic-generic proof type. This presents new challenges in the use of digital tools, as it is important to not only assist students in discovering the mathematical theorems necessary for a proof, but also to provide individual support in such a way that students perceive these theorems as helpful

for supporting their arguments and apply them as warrants in the appropriate part of their argumentation. This raises the question of how digital tools should be designed to support students in continuing their development beyond the mixed-type. Here, the results suggest that it could be helpful to integrate tips on the book page, motivating students to reflect on the meaning of their mathematical discoveries. Indeed, more research is needed to further develop interactive books.

Learning success while working with (interactive) videos on multiplication derivation strategies

Juliane Wefers[1]

[1] Bielefeld University, Faculty of Mathematics, Germany; juliane.wefers@uni-bielefeld.de

Keywords: Interactive video, primary school children, multiplication, derivation strategies.

Videos are an integral part of our lives and are used as a learning medium. This paper attempts to find an answer to the question, which effect educational videos have on children's mathematical academic achievements compared to interactive educational videos, using the example of multiplication derivation strategies. Do educational videos generally have a positive influence on learning? In order to investigate these questions, the change in performance before and after two different forms of video intervention is examined in a pre-post design.

Introduction

Media education is a part of the primary school curriculum in Germany. Teachers don´t have to understand only how to use media, they must also be able to select suitable media for the individual situation. In my work I focus on the medium of video in the context of learning. The use of video in the classroom is very controversial, which is the starting point for my research desideratum. On the one hand, it is said that videos offer more opportunities for interaction than traditional media (Berk, 2009). On the other hand, it is described that there is a lack of interaction when watching a video and that the viewers are passive recipients (Zhang et al., 2006). However, one study has shown that dynamic and interactive dynamic visualisations have a significantly better effect on learning than static visualisations. As there were no differences between the interactive dynamic and dynamic visualisations, the influence of interactivity needs to investigated (Rolfes et al., 2020).

Theoretical Background

Educational Videos

Children have a lot of contact with (educational) videos outside of school, so schools need to provide guidance on how to use them wisely. In the school context, videos are mainly used to prepare for tests, to help with homework or to revise content that they have missed due to illness, for example. But teachers fear a loss of control and a loss of role (Arnold & Zech, 2019). That's why teachers need to recognise the potential of videos in school. When used sensibly in schools, educational videos should complement rather than replace teaching, as they can provide new learning opportunities depending on the situation (Arnold & Zech, 2019).“Videos materials are supplements to the class session, not a substitute to the class session presentation” (Bento, 2000, p. 111).

Video allows for a change of perspective, internal differentiation, working at your own pace and can present different topics in a very dynamic way (Arnold & Zech, 2019; Modlinger, 2020). Emotions are addressed and actions and three-dimensional facts can be visualised well. On the one hand, videos increase the viewer's motivation, which increases attention. On the other hand, it is said that motivation is high when working with videos because the pupils are convinced that they have to make

less effort (Arnold & Zech, 2019; Clark & Feldon, 2014). Video is often consumed passively as it is perceived as an entertainment medium. (Zhang et al., 2006). This requires a high degree of self-discipline is required, partly because there is no incentive to engage in intensive dialogue, as ready-made solutions are often presented.

Types of educational Video

There are different types of educational videos. In Germany, the names of the most common videos are explanatory videos and discovery videos, which are often have a short duration of usually three minutes. These videos are summarised here under the term *educational video*. These videos often lack real interactivity because the viewers are passive recipients (Römer & Nührenbörger, 2018; Zhang et al., 2006). The supposed interactivity refers to controlling the speed of the video (*control of pacing)*, the Control of the order of performance (*sequencing)* and the (*control of content)* (Merkt & Schwan 2016). These forms of interactivity are merely basic functions of any video. Interactive educational videos are a sub-section of educational videos and are understood here as a sub-category, as the educational videos have been enriched with interactive elements. The interactive learning videos that I have created have been evaluated by an expert rating. They enriched by tasks (multiple choice and drag and drop) and selection options (back, explanation, next). In the latter case, viewers can choose whether they want to see an introductory example again, listen to an explanation of the solution to the task or move on to the next task. Nevertheless, interactive learning videos are intended to activate the viewer, but do not guarantee (Lehner, 2011).

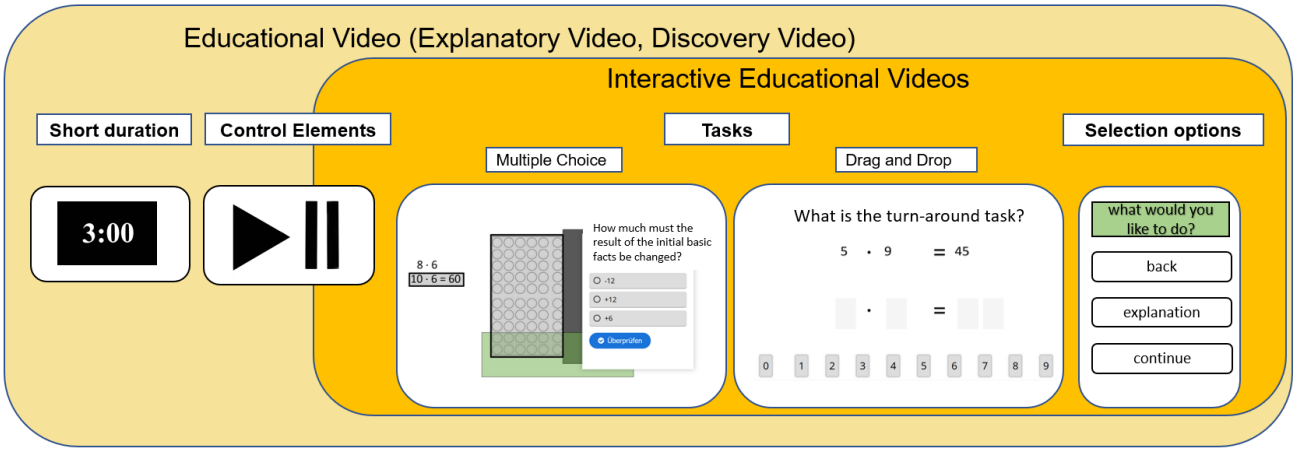

Figure 1: Differentiation of educational video types

Educational videos in primary school mathematics

It has been found that young children's attention is linked to formal features such as movement, voices, fast-paced action or funny scenes and not to themes (Krapp, 2010). Moving images attract more attention than text due to their depiction of movement, but they do not actually carry of the essential information. Teachers can be relieved by the use of video, as video can be used well for differentiation, but only if the passive consumption of video is counteracted. Videos are particularly suitable for dynamic topics and activities. They can be used in geometry lessons to develop spatial

awareness and to visualise spatial relationships. In arithmetic lessons, for example, arithmetic laws can be illustrated well or, in relation to multiplication, consecutive actions can be demonstrated. A static book can only illustrate this dynamic basic idea with several pictures and it is difficult to visualise the derivation of an arithmetic law. Therefore, derivation strategies for multiplication were considered as a suitable example for a content that can/ should be visualised dynamically, what cannot be presented in an appropriate way in textbooks. Furthermore, this is a central topic in the second school year in Germany (Gaidoschik, 2014).

Multiplication derivation strategies

It is not a new discovery that children use many different strategies when working on multiplication problems (Anghileri, 1989). Nevertheless, an exploratory study was able to show that repeated addition was the predominant strategy up to the middle of third grade, especially for lower-achieving children (Köhler & Gasteiger, 2016). As the multiplier becomes larger, children cannot maintain the strategy of repeatedly adding the addends. If different calculation strategies are developed in the class, and they can overcome the unsustainable approach of repetitive addition (Köhler & Gasteiger, 2016). Through the automation of initial *basic facts* (1x, 2x, 5x, 10x and the Square numbers) and the development of operational relationships, children can derive unknown multiplication problems from known ones. It is not sustainable if multiplication is only based on procedural counting (Anghileri, 1989). The systematic development and consideration of interrelationships helps to remember the basic fact tasks (Köhler & Gasteiger, 2016). Even if the long-term goal is to automate all multiplication tasks, it has been shown that a holistic approach produces better results in terms of the transferability of the tasks to larger numbers and in terms of estimation skills (Gaidoschik, 2014). The focus should never be exclusively on finding a result, as this would only distract from discovering multiplicative situations and possible changes in representation (Gaidoschik, 2014). In order to give multiplication a real meaning, the primary aim of multiplication (and division) is to find and discover multiplication situations in the environment.

The derivation of tasks can be illustrated well using a 100-dot field, with two sheets of paper. Dot fields are not only used to represent numbers in different number ranges in relation to the number range extension, they are also suitable for visualizing operations and operational changes and regularities (Kuhnke, 2012; Wittmann & Müller, 2016). Starting from the initial basic fact $5 \cdot 8$ in Figure 2, the task $6 \cdot 8$ can be derivate by moving the transparent green piece of paper one line down. On the left we can see a coloured 100-dot field, for understanding the task. The multiplier indicates shows how many rows there are and the multiplicand shows how many dots are in a row. By moving one or the other of the slips of paper by one or two lines, you can easily visualise the references. Figure 2 on the left first shows how the factors are represented on the 100-dot field. There are 5 x 8 5 rows in the task and there are always eight dots in each row. After understanding the meaning of the factors, the illustration should be shown again in order to direct the focus to a process of change.

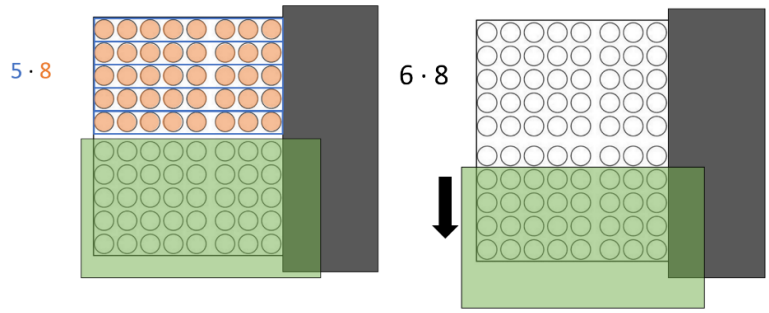

Figure 2: Use the task 5x8 to derive the task 6x8 on the 100-dot field

Aim of research

The theoretical background raises the question of the actual (learning) effect of educational videos. The paper compares the effect of linear educational videos is compared with interactive educational videos and a control group using the derivation strategies of multiplication as the content. The research question is: What is the effect of linear educational videos compared to interactive educational videos on children's performance in multiplication derivation strategies? The focus is not on solving problems, but on understanding derivation strategies.

H1: The group membership (interactive, linear, control) has a significant effect on the test performance of TMU2 (*Time Measurement Unit)*.

Method

The survey period was March 2024 to April 2024. The study analysed 129 second grade children from three primary schools in North Rhine-Westphalia. During the survey, demographic data (mother tongue, gender) were collected, basic mathematical skills were assessed using the *Heidelberger Rechentest* (HRT), and skills in multiplication derivation strategies were assessed using a test specifically designed for the study. Both, the video and the test were validated by an expert rating, consisting of people with doctorates and post-doctoral habilitations. I worked with a pre-post-follow-up design. Therefore, the test for the derivation strategies was used for all three TMUs. Each school was visited for five consecutive days, with the exception of TMU3, which is not discussed in detail in this paper. For logistical reasons, a quasi-experimental design was used.

Figure 3: Procedure for the video groups

On the first day, all children were tested with the HRT and the multiplication derivation strategies test, with the derivation strategies test taking place on both the first and the last day. The intervention took place over a period of 4 days, starting on the second day. The videos are based on the children's prior knowledge, because the children already know the dot-field from school. I use a dynamic visualisation by moving one of the two pieces of paper, as you can see in Figure 2. This shows how the results of the tasks change.

There were three experimental groups that received exactly the same input but processed differently. A group with the *interactive* educational videos (n=41), a group with *linear* educational videos (n=47) and a *control group* (n=41) with lessons, in which the content was presented by the researcher using a document camera. The children worked independently with the eight videos on different facets of multiplication derivation strategies. In addition to the quantitative data from the test results, qualitative data was also collected by examining how the children interacted with interactive educational videos. Screencasts were used to observe patterns in the children's use of the videos and whether they were working with the videos as intended.

I want to elaborate the influence of group membership. The advantage of this *linear mixed model* is that it does not only analyses the differences between the groups, at the same time it also can analyse the individual, random differences between the children. The individual differences of the children, the influence of the mother tongue or the influence of HRT can be integrated into the model. Even if the qualitative data and the covariates of mother tongue and the results of the HRT cannot be discussed in this paper.

Results

In this study, the dependent variable is the children's score in TMU2 and the independent variable is group membership and timing. The interaction diagram can be used to gain an initial impression of how the score of the children in the respective group have changed.

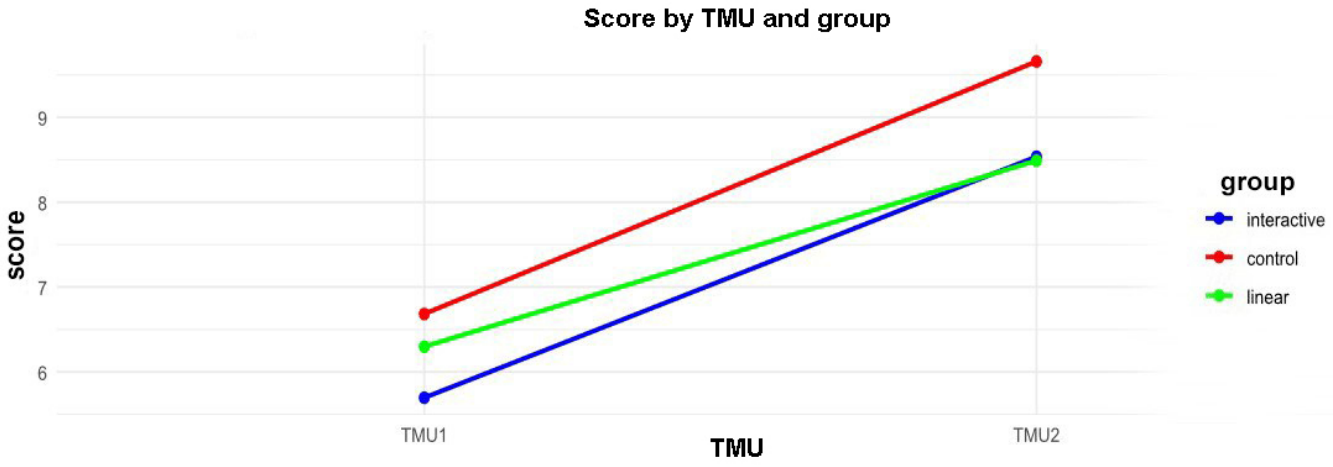

Figure 4: Interaction diagram of the three groups between TMU1 and TMU2

The interaction diagram shows that the starting position of the groups for TMU1 was not quite the same. The interactive group (blue) was weakest at TMU1 and the control group (red) was strongest. The lines in the interaction diagram are not completely parallel. If the lines were parallel, this would mean that there are no significant differences in the interaction effects. However, it can be seen that the line of the interactive group and that of the control group run approximately parallel, which means that the children in the two groups have a comparable performance development. In order to be able to make precise statements about the development of the groups, the dependent variable (test performance) is analysed with the independent variables (group membership and time). The control group is the reference group.

Table 1: Linear Mixed Modell

	Regression coefficient (β)	Standard error (SE)	Confidence interval (CI)	p-value
Intercept	6.6829	0.4331	[5.8394, 7.5265]	0.00***
interactive group	-0.9878	0.6125	[-2.1808, 0.2051]	0.108
linear group	-0.3815	0.5927	[-1.5393, 0.7692]	0.517
TMU2	2.9756	0.3533	[2.2860, 3.6652]	7.08e-14***
interactive group TMU2	-0.1341	0.4997	[-1.1093, 0.8410]	0.789
linear group TMU2	-0.7841	0.4835	[-1.7277, 0.1594]	0.106

*p< 0.05, p**<0.01, *** p<0.001

The intercept (6.6829) shows the points from the reference group for TMU1. It can already be seen in Figure 4, in the section on the y-axis, that the starting position of the values of TMU1 is not the same. The interactive group has a weaker score than the reference group (6.6829 + (-0.9878) = 5.6951). The linear group has an estimated initial value at TMU1 (6.6829 + (-0.3815) = 6.3014).

TMU2 has a significant influence (7.08e-14***) on the reference group. The estimated coefficient of TMU2 (2.9756) describes the average change in the value from the baseline TMU1. This means that the reference group improves by around 3 points. The interaction between the reference group and the interactive group shows that the interactive group does not improve quite as much as the control group (2.9756 + (-0.1341) = 2.8415). Compared to the linear group, the reference group has an estimated beta value of -0.7841. The group also improves, but less (2.9756 + (-0.7841) = 2.1915).

The following standard error (SE) and confidence interval (CI) indicate how accurate the estimated values of the regression coefficients are. The SEs are approximately the same in all areas, which means that the uncertainty in the estimation of the beta coefficients is relatively constant across all predictors. This means that the estimate for these values is relatively accurate. This is also confirmed by the CI values. Looking at the CIs it is noticeable that when comparing the reference group with the interactive group or the linear group, the lower limit ($\beta - 1.96 \cdot SE$) and the upper limit ($\beta + 1.96 \cdot SE$) both contain zero. This means that it is unclear whether the true effect is positive or negative or

whether the effect is actually zero. This means that it is possible that the intervention had no effect. The p-values provide information on how significant the estimated values of the regression coefficients are. When comparing the p-values of the reference group with the interactive or linear group are all non-significant, according to convention ($p<0.05$). Since the p-values are not significant, which could be due to the small number of participants, no statements can be made about the effectiveness of the interventions. In relation to the hypothesis, we cannot give a conclusive answer based on the large p-value. However, a first impression is that group membership seems to lead to different test performances in the TMU2.

Discussion

The first impression from Figure 4, that the control group and the interactive group improved equally, could not be directly confirmed by the data in Table 1 using the linear mixed model, don't indicate significance, which is not yet apparent in the graph. The high p-values are probably due to the small sample size. The power of the study is also limited by the non-randomised groups. Furthermore, the covariates (mother tongue and basic mathematical knowledge form the HRT) were not analysed at this point. The same applies to the long-term effect, the results of the TMU3. Qualitative data were also collected, which cannot be mentioned here in this paper. This qualitative supplement to the quantitative data offers a further explanatory approach for the interpretation of the results. The aim of the qualitative data is to check whether the children in the interactive group used the interactive elements as intended. In addition, this study worked exclusively with multiplication derivation strategies. However, no generalisations can be made about other mathematical topics. Despite the limitations, especially the high p-values, and the restriction to the derivation strategies of multiplication, there is a tendency that linear videos cannot be used as profitably in primary school math's lessons as interactive videos. It could be shown that the mere use of videos in the classroom, at primary school level, does not guarantee learning success. This first approach to the research desideratum should be the starting point for further investigations. Subsequently, the characteristics of a successful use of educational videos in the classroom should be investigated, as there have been no effectiveness studies to date. The main questions to be answered are how the videos are prepared and how well they are embedded in the classroom.

Digital Game-Based Learning in Moroccan Mathematics Education: Insights and Challenges

Tariq Bouzid

Higher School of Education and Training; tariq.bouzid@uit.ac.ma

University Ibn Tofaïl, Morocco

Keywords: Digital Game-Based Learning, mathematics education, Moroccan schools.

Introduction

Employing video games for educational purposes, known as Digital Game-Based Learning (DGBL), offers a promising solution to challenges in Moroccan mathematics education, such as student disengagement, mathematics anxiety, and persistent misconceptions. While educational technology adoption has grown in Morocco (Taam et al., 2024), its integration into mathematics remains limited (Nejjari & Bakkali, 2017). This significantly influences the integration of DGBL in Moroccan schools. This contribution draws on studies of DGBL in the Moroccan context to highlight its impact on mathematics learning outcomes and identify practical pathways for effective implementation.

Key Findings from the Moroccan Context

A systematic review of 38 studies on learning mathematics through DGBL in Morocco reveals its transformative potential:

- Engagement and Motivation: 'JeuTICE', an educational arcade game, provides ludic training in arithmetic, geometry, and measuring - core domains in Moroccan primary mathematics education - increasing pupils' engagement and motivation, though performance gains vary (Tazouti et al., 2019).
- Addressing Misconceptions: 'Didactic Balance', a simulation game, uses the analogy of a balance to approach algebraic equality, allowing pupils to test conjectures, solve for the unknown in first-degree equations, and effectively address algebraic misconceptions (Lhachimi et al., 2022).
- Reducing Anxiety: 'Arithmetic Bomb' generates progressively challenging arithmetic tasks within a time constraint, engaging pupils through competitive play and reframing mathematic anxiety triggers into fun, ludic errors in a sanction-free environment, resulting in enhanced motivation and reduced Mathematics Anxiety. Fostering a positive Mathematics learning (Bouzid et al., 2021).

However, challenges such as curriculum misalignment, limited teacher training, and resource constraints hinder widespread adoption.

Practical Recommendations and Conclusion

- Design and Implementation: Use effective game design models and mobile learning approaches to enhance accessibility and engagement (Bennis & Benhlima, 2017), while addressing cost and complexity barriers.
- Learner Modeling: Tailoring games to individual needs (Hamdaoui et al., 2021) and AI-based adaptive learning (Ezzaim et al., 2023) show promise for personalized education.

- Evaluation and Improvement: Use evaluation tools to assess and improve the effectiveness of DGBL. Intelligent tools can reduce bias and improve assessments (Omari et al., 2021). Consistent tools are needed for the Moroccan context.
- Teacher Training: Train educators to effectively use DGBL to support student learning.
- Curriculum Alignment: Ensure games align with national curriculum objectives
- Resource Allocation: Prepare schools with technological and logistical infrastructure.

DGBL holds transformative potential for Moroccan mathematics education. Success depends on addressing challenges in teacher training, curriculum alignment, and resources. By focusing on these areas, schools can harness gamification to improve student outcomes.

Enhancing mathematics learning through Mixed Reality: The Function Virtuality prototype

Mosè Colangelo, Andrea Ghersi

University of Turin, Italy; mose.colangelo@unito.it

Keywords: Mixed Reality, Virtual Reality, Augmented Reality, Artificial Intelligence.

Research Context

The integration of emerging technologies, such as Mixed Reality (MR), into educational practices is a growing area of interest, particularly in mathematics, where abstract concepts often pose significant challenges to students (Bulut & Borromeo Ferri, 2023; Lei et al., 2018). Recent studies suggest that MR, which includes both Virtual Reality and Augmented Reality, could enhance learning by providing immersive and interactive environments that support cognitive engagement and conceptual understanding. Function Virtuality is a MR prototype developed by Mosè Colangelo within the Widera TransEET1 project (Transforming Education with Emergent Technology). This study is grounded in embodied cognition theory, which emphasizes the role of bodily interactions in cognitive processes within MR environments (Johnson-Glenberg, 2018). This theoretical foundation supports the use of MR to facilitate embodied interactions with mathematical objects, potentially improving conceptual understanding.

The research question is how Function Virtuality, leveraging an embodied approach, enhances the exploration and understanding of mathematical concepts within a MR environment.

Function Virtuality and its affordances

Function Virtuality offers various affordances designed to make the exploration of mathematical concepts accessible and engaging. Within the virtual environment offered by Function Virtuality users can interact with 3D mathematical surfaces in real-time using hand gestures. This embodied interaction enhances the learning experience by allowing users to engage with mathematical functions in a 3D space through gestures and hand movements (Johnson-Glenberg, 2018).

The prototype integrates Artificial Intelligence to support natural language commands, enabling users to easily create and modify mathematical surfaces without needing to rely on complex formulas or syntax. This affordance is particularly helpful for those users who may not be familiar with advanced mathematical notation, making the tool more accessible to a wider audience.

Method

To analyze the impact of Function Virtuality on student engagement and interaction with mathematical concepts, a didactic experiment was conducted with two groups of four undergraduate mathematics students at the University of Turin. Two different approaches were tested: a "sequential activity," where students completed tasks in a fixed order using three different technologies (MR headset, GeoGebra 3D, and pen and paper), each linked to a specific task; a "parallel activity," where students could freely choose the order of the three different technologies. Both activities focused on exploring the same mathematical concepts, such as paraboloids and their intersection with planes.

Feedback on Function Virtuality was also gathered from researchers during the CIEAEM 75 workshop to evaluate the tool's affordances and potentiality. The study utilized qualitative observations and performance assessments to analyze how Function Virtuality, as an emerging technology that lets possible embodied approaches, supports the exploration and understanding of mathematical concepts. Observations focused on student interactions within the MR environment, their engagement levels, and their ability to solve related mathematical problems.

Preliminary results

While the structured approach of the sequential activity helped build a systematic understanding, it limited flexibility and spontaneous collaboration. In contrast, the parallel activity allowed students to switch freely between tools. This flexibility enabled students to engage with the same mathematical concepts from multiple perspectives, using the MR headset for exploration and GeoGebra 3D or pen-and-paper for deeper analysis and verification. In both activities, Function Virtuality facilitated embodied interactions with mathematical objects, enhancing spatial reasoning for a more intuitive understanding of mathematical surfaces and served as an effective exploratory tool, increasing students' engagement.

At the CIEAEM 75 workshop, researchers provided feedback on Function Virtuality's affordances and out of 19 responses, key aspects noted were its interactivity, visual capabilities, multisensory engagement, and embodied experience.

LLMs as a tool for problem solving – A case study on the role of generative AI in the solution of Fermi problems

Marc Herrmann[1]

[1]University of Siegen, Mathematics Education, Siegen, Germany; marc.herrmann@uni-siegen.de

Keywords: Artificial intelligence, Fermi problem, Large language model, Problem solving

Introduction

Since the public release of ChatGPT, generative AI has become a major part of the daily life of young people, especially students. For mathematics education, different studies were able to show the potentials large language models and generative AI offer (Dilling & Herrmann, 2024; Schorcht et al., 2024; Yoon et al., 2024). Among the different technologies within the field of AI, a major focus of current research in mathematics education is on large language models and their implementations in chatbots as ChatGPT. This study looks at Fermi problems, as they require problem solving and modelling skills, while making assumptions about the real world. The capabilities of LLMs for the prior were demonstrated by Schorcht et al. (2024) and giving world knowledge is among the tasks they seem to perform reliably. For these reasons, in this study it is of interest, how students use LLMs while solving Fermi problems (RQ1). Beyond the way they use it, it is also of interest, why they decide to do so. Trying to understand their reasoning, the students' beliefs are analysed (RQ2).

Theoretical framework

According to Schoenfeld (1985) characterizing the mathematical problem-solving performance of students, the four factors *resources, heuristics, control* and *belief systems* are components of knowledge and behaviour suitable to describe the process. Belief systems are "one's 'mathematical world view', the set of (not necessarily conscious) determinants of an individual's behavior" (Schoenfeld, 1985, p. 15) and influence students mathematical processes. This has been shown for beliefs concerning the learning of mathematics (e.g. Witzke & Spies, 2016), which were originally meant by Schoenfeld, as well as technology-related beliefs and their influence on the learning with technology (e.g. Pepin et al., 2024). While there are many different constructs, terms and definitions in the area of beliefs or affective concepts (Philipp 2007), for this study the notions and differences of these will not be discussed. The broad definition of Schoenfeld (1985) shall suffice hereafter.

Fermi problems are a special kind of problem-solving tasks, that require the students to estimate values by making assumptions about problems and the real world. Albarracin & Ärlebäck (2019) describe four activities of students making these assumptions: *Guesstimations*, *experimentation*, *looking for data*, and *statistical data collection*. Besides describing these activities, the authors also link the problem solving of Fermi problems to mathematical modelling, pointing out similarities and differences. Their views on the matter are shared by the author of this submission.

Methods & materials

To answer the research questions an exploratory case study was conducted in December of 2023 in a secondary school in North Rhine Westphalia in Germany. The participants were multiple groups of

students of an 8th class, all of whom participated on their own volition. The students sat around a table in groups of 1-3, on which a calculator, pen and paper and a laptop with ChatGPT 4.0 were placed. They were given basic information about ChatGPT, as the way to interact with it in a chat and that it may produce misleading results. Among other Fermi problems, the students were asked to estimate the amount of water they use per year or how often they blink in one day. The problem-solving process and interviews were filmed, transcribed and analysed with an inductive qualitative content analysis (Mayring, 2000).

Results

Summarizing the results for the first research question, Adam (group 1) used the chatbot by copy-pasting all the problems into the chat and copying down its answers without questioning them any further. The students Berta and Claire (group 2) decided to use the AI as a resource of knowledge for some numerical estimates they used in their calculations. For some problems they decided not to use AI at all and for some they also asked ChatGPT for the full answer after giving up on calculating it on their own. Considering the second research question, all participants stated a high trust in AI and the correctness of its answers, possibility connected to their misconceptions about its operating principle. The self-concept of the students in group 2 seemed to have been the deciding factor for their approach to try and solve the problems on their own as much as possible, only relying on AI as a source of knowledge or once convinced, they could not solve a problem on their own.

Programming to inscribe geometric entities in circle and in sphere: an embodied approach of textual programming towards assembling a new Conceptual Field

Charikleia Korompli

Educational Technology Lab, National and Kapodistrian University of Athens, Greece;
harthekor@gmail.com

Keywords: debugging, dynamic manipulation, Design-based Research, 3D-printing.

Introduction

Digital environments, according to Papert (1980), are fields where, with appropriately designed activities, conditions fertile for rich experiences of meaning-making are ensured. Notable emphasis is put on embodiment, through what he called 'body-syntonicity' and its significance for students' mathematical engagement when working in a programming environment requiring the coordination of one's body posture, physically or imaginarily, with the turtle-vehicle to navigate it and solve geometric problems, drawing upon personal embodied motional experiences. Following this line of thinking, I have started conceiving digital projects and exploratory activities that integrate dynamic manipulation and modelling using a textual programming tool to challenge children to collaborate to debug existing digital models and to produce their own personally meaningful artefacts (diSessa, 2001), posing the question whether -and under what conditions- a geometric entity can be inscribed in another. For this purpose, the Conceptual Field "Inscribability" was assembled, intending to construct a network of related ideas (mainly drawn from Geometry and Trigonometry), representations and problem situations emphasising the interconnectedness of mathematical concepts, arguing against the isolationist approach in education (Vergnaud, 2009). The central objective is to examine how engaging with transformative technologies, redefines learning conditions, affects the production, expression and communication of ideas and, subsequently, how it enriches mental constructions and connections between abstract mathematical ideas and concrete programming implementations. Utilising Design-Based Research (DBR), I mean to iteratively refine the intervention design in real educational settings to enhance learning outcomes and pedagogical practices.

The learning environment

The learning environment MaLt2 (available here: http://etl.ppp.uoa.gr/malt2/#Gr) integrates textual programming with the affordances of dynamic manipulation of parametric procedures, 3D graphics and camera navigation. This online Logo-like tool includes the following interrelated representations: i. Symbolic (code), ii. Figural and iii. Dynamic manipulation of generalised models controlled by procedures with variables (Kynigos & Grizioti, 2018).

Research questions

- What meanings do children construct within the Conceptual Field of Inscribability, while tinkering digital models and linking real-space lived experiences with the embodied turtle metaphor and the symbolic expression?
- How, dynamic manipulation of models, and the parameters that define them, affect the ways in which children **a)** perceive and express Inscribability as a relationship and **b)** explore how it is maintained - or not - as certain parameters are altered within the MaLT2 digital environment?

Study design

This study was designed as a series of open exploratory activities on the issue of "Inscribability" of 2D and 3D objects in a circle and in a sphere, addressed to 9th-grade students (age 15-16) as a task of "Designing the interior space of a crazy ball"; this first pilot conducted with 26 students with prior experience with MaLT2, over two sessions. Initially, children explored given procedures, in which incorrect mathematical relationships were embedded; they worked on 'discovering' these errors and correcting them (debugging) to successfully inscribe the models in a given circle. In the second phase, each group chose a 2D object (e.g. letter, shape) to inscribe in the circle and then in the sphere-crazy ball. The final phase extended to selecting and inscribing a 3D object within the sphere-crazy ball. Their work was documented via screen-recording software and video recordings including audio; moreover, their digital artefacts (codes) were collected and analysed.

Preliminary results and next steps

Students used gestures as a spatial form of action in order to navigate and act in the virtual space and harmonically combined verbal and symbolic expression to interact with the 2D and 3D figural representations, aiming to inscribe one in another. The results gained from this pilot implementation are highly promising suggesting that students' engagement with this Conceptual Field in MaLT2 could create rich opportunities for interconnecting ideas, relating mathematical concepts, properties and knowledge from different contexts. Among these first findings lay the meaningful use of mathematical formalism while modelling and programming as well as the variety of students' creative solutions to the problem. One group, after debugging the given procedure of a triangle, used it as a unit to base on and construct their own star-shaped model by rotation of the triangle. Another group generalized the debugged triangle procedure and created a regular hexagon and a regular decagon, inscribed in the same sphere. For the following cycles of development, I am planning to gradually deepen students' engagement within this mathematical-computational experience by asking them to 3D print their models posing the challenge of creating classes of printable models that could be easily and dynamically modified.

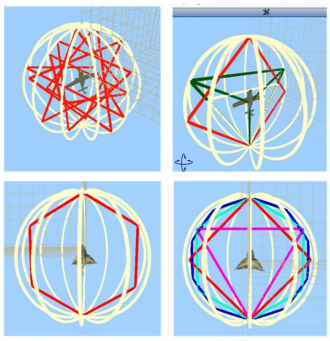

Figure 1: Students' artefacts

The impact of technology-based collaborative learning on enhancing students' fraction comparison skills

Nurit Paz-Baruch[1], Okila Nashif [1], and Iris Schreiber[1]

[1]Bar-Ilan University, Faculty of Education, Israel; nurit.paz@biu.ac.il

Keywords: Learning mathematics with technology, collaborative learning, fraction comparison

Technology-based collaborative learning in mathematics education

Recent technological advancements have significantly impacted mathematical education, prompting schools to integrate technology into teaching to enhance learning and student achievements (Ran et al., 2021). 'Collaborative learning' describes an educational approach wherein students benefit from complete participation in the learning process. Collaborative learning occurs in small groups characterized by mutual engagement and interaction among participants. This enables students to assist one another, exchange ideas, articulate diverse viewpoints, and foster interpersonal social ties (Lahann & Lambdin, 2020). Technology-enhanced collaborative learning environments facilitate student learning in computer and internet-supported contexts via cooperative interactions (Ozdamli et al., 2013). Numerous research has shown that collaborative learning in mathematics improves students' comprehension (Ozdamli et al., 2013). Various studies demonstrated that collaborative learning in mathematics enhances students understanding (Retnowati et al., 2017). These studies described the interactions that occur when students solve math problems in small groups, which include asking questions to get help, confirming ideas, and clarifying progress toward a solution. Previous studies also addressed the positive group synergy when students solve mathematical problems together with technology (Clark et al., 2014; Roschelle et al., 2010). The purpose of the present study was to examine the impact of an innovative technology-based collaborative learning program on enhancing students' fraction comparison skills and to determine whether there is any correlation between gender and knowledge with respect to comparing fractions. Until today, few studies specifically examined the impact of technology-based collaborative learning on students' understanding of fractions. This study can contribute to mathematics teachers by introducing a unique intervention program that combines technology and collaborative learning. The study can make a significant contribution to the field of mathematics education by showcasing how technology-based collaborative learning can improve students' conceptual understanding of fractions comparison.

Method

The study used a quantitative method and involved 125 fifth-grade students (59 boys and 66 girls) studying in a primary school in Israel. Two classes participated in a technology-integrated intervention program, and two classes were taught in the traditional way. The intervention program included three stages: (1) All the students received a preliminary fractions knowledge test; (2) Students in the intervention group were taught about comparing fractions while integrating collaborative technology, while the students in the control group were taught in frontal lessons. The students in the intervention group worked together on various technology-based activities such as solving computerized tasks, playing in computer-based games including real-time competitive quizzes, building a Padlet board with solutions for different tasks, and solving word problems in small

groups and discussing their reasoning in real time through group chats. The intervention duration was about eight weeks. The students solved the tasks jointly in small groups and offered their conclusions regarding rules for comparing fractions using computerized representations. (3) A second test was administered to all the students. Fractions knowledge tests were specially designed for this study and were based on the national mathematics curriculum and a nationwide standardized test. The first test, administered before the intervention began, covered basic fractions knowledge (i.e., understanding of fraction magnitude, identifying numerator and denominator, fraction nomenclature, representing the fraction as an illustration). The second test, administered after the intervention period, focused on skills in fractions comparing.

Results

Repeated measures ANOVA indicated that on students' scores on the fractions knowledge tests both Time and Time × Intervention interaction were significant, [$F(1,121)=33.316$, $p=.000$; $\eta^2=.21$; and $F(1,121)=89.245$, $p=.000$; $\eta^2=.42$, respectively; respectively]. The intervention group significantly improved their mean-score between the pre-and post-intervention [*pre*: $M=67.32$; $SD=21.11$ *post:* $M=76.62$; $SD=19.75$]. In contrast, the control group's mean score remained stable [*pre*: $M=63.22$; $SD=23.36$; *post:* $M=61.07$; $SD=20.45$]. No significant interaction was found regarding Time × Intervention × Gender ($F(1,121)=0.026$, $p=.873$; $\eta^2= .00$).

Conclusions

This study's findings highlight the benefits of technology-based collaborative learning in supporting students' ability to compare fractions. The results demonstrate technology-based collaborative learning has the potential to meet the varied needs of primary students that struggle in studying the subject of fractions comparison.

Moving forward with AR: Effects of augmented reality on learners' solution behaviour in analytic geometry

Xenia-Rosemarie Reit and Valerie Leister

University of Education, Karlsruhe, Germany; xenia.reit@ph-karlsruhe.de

Despite the fact that new technologies are used in teaching there is a need to investigate the impact of Augmented Reality (AR) on learning outcomes in specific areas (Chang et al., 2022). Using AR in mathematics education can be particularly enriching when three-dimensional representations are taken into focus. In analytical geometry, a technical and less descriptive approach is predominant (Borneleit et al., 2001). Starting here, the MalAR (Mathematics learning with AR) app allows users to place mathematical objects of analytical geometry (e.g. points, planes and straight lines in space) together with a coordinate system in one's real environment through the smartphone's camera view. In detail, learners can use MalAR to bodily explore mathematical situations of analytic geometry to either discover given mathematical situations (e.g. textbook tasks) or verify their calculated results (Reit, 2022). Studies using extended reality in STEM education show that learners who moved their bodies to grasp and experience concepts, made learning gains, were more motivated and had more positive attitudes (Lindgren et al., 2016).

Building on these results and the very technical view of the content in the field of analytical geometry described above, the MalAR app was used to investigate the influence of AR support when working on mathematics tasks in analytic geometry. The study described here focuses on two main research questions:

RQ1: What types of body movement related to interaction with virtual objects occur when solving a textbook task in the field of analytic geometry?

RQ2: How does MalAR influence the learners' approach to their written responses?

Method

A video study documenting and analysing the learners' body movements, together with screen recording of the virtual objects used in the MalAR app, was conducted with 25 pre-service mathematics teachers at the University of Education Karlsruhe who agreed to take part in the study in June 2024. The study involved two tasks, adapted from a standard German textbook, on analytical geometry. To ensure that technical difficulties did not have too great an influence on the completion of the tasks, in task one the participants were asked to follow a sample solution to a task step by step and decide whether the solution presented was correct. In task two, the participants were first asked to explore a mathematical situation consisting of 2 points, a straight line and a plane, using the MalAR app. This exploration phase was followed by written solutions to several sub-questions of the task asking to calculate the equations of straight lines using the given points, to determine the point of intersection of the calculated straight line with the given plane and then to analyse the mutual position of the straight line and the plane. Finally, these written solutions were to be verified by exploring the mathematical objects with the MalAR app.

A qualitative content analysis of the videos and screen recordings was conducted to construct a system of movement type categories, drawing upon and extending the findings of Reit (2022). Subsequently, the identified movement types were associated with the virtual mathematical objects that the learner engaged with in MalAR app, addressing research question 1. The quality of the written solutions was analysed to investigate how varying degrees of correctness relate to distinct movement patterns, as outlined in research question 2.

Results and Discussion

The qualitative analysis of the video and screen data revealed that all learners performed various types of body movement while using MalAR: circling objects, verifying intersection points, and manipulating the visibility of virtual elements. These findings answer RQ1 and complement the existing category system of movement patterns (Reit, 2022; Reit & Wachter, in print). An analysis of the learners' written solutions revealed that approximately one-third of the students were initially wrong. After being able to validate their initial incorrect solution with MalAR, they recognised their mistake, recalculated their solution and finally obtained the correct one. This allows to conclude that the support provided by MalAR enables learners to independently assess the correctness of their solution and to make corrections if necessary (RQ2).

Further analyses of the data will show whether specific movement patterns are initiated by the use of MalAR and which of these support learners when solving problems in analytic geometry.

Students' acceptance of the multimodality of the social robot Pepper as an educational technology for learning mathematics

Antonio Vitale[1], Bruno Carbonaro[2], Gennaro Cordasco[2], Umberto Dello Iacono[2] and Anna Esposito[2]

Keywords: Social robot's acceptance, multimodality, educational robotics, mathematics learning.

Introduction

Social robotics is one of the most promising approaches to changing the way that teachers and students interact with mathematics content. Allowing students to have interactive and hands-on learning experiences, robotics can inspire a new generation of mathematics learning (Zhong & Xia, 2020). On the one hand, the use of robots can improve students' understanding of mathematical concepts. In this regard, Baccaglini-Frank et al. (2020) show how the use of the robot GeomBot makes mathematics lessons dynamic and interactive and facilitates students' understanding and visualization of geometric properties. On the other hand, robots can help students see real-life applications and develop lasting practical experience in a social context. Moreover, robots offer new opportunities to support the development of social and cognitive skills and to personalize the educational experience (Belpaeme et al., 2018). Understanding how social robots could enhance the students' learning experience is essential for their implementation in educational contexts. However, there are crucial aspects to be taken into account when using new technologies, such as social robotics. According to Venkatesh et al. (2003), the user perception of a new technology as easy to use is essential for its adoption. Therefore, for the integration of social robotics in the school environment, it is necessary to investigate their acceptance by students in order to have clear guidelines for their effective implementation.

The research study

In our research we are using the robot Pepper. Pepper is a semi-humanoid robot equipped with a tablet display. It is able to speak, move, and relate to the user by reacting in a personalized manner according to what the user does or says. Our research aims to evaluate the interaction between students and Pepper by focusing on multimodality, usability and acceptance in order to investigate students' comfort while interacting with it. Specifically, we are implementing inclusive learning activities in mathematics through storytelling, using Pepper as an inclusive, multimodal educational technology. Pepper is used to improve student engagement and to foster learning. This work is part of a larger project. The focus of this work is to investigate the level of acceptability of the students' interaction with Pepper. Specifically, our research question is: how does the multimodal interaction with Pepper influence its acceptance by students in a mathematics educational context? For an initial investigation, we involved eight students (two from middle school and six from high school) in a learning activity regarding narrative, in particular a story problem on the Pythagorean Theorem. Pepper welcomes the

student and introduces itself. Then it begins to tell the story problem. The student is asked to help the protagonist of the story solve a task. Pepper begins to ask the student questions related to understanding the story problem and provides feedback to her answers. The student begins to solve the problem. If she has difficulty, Pepper provides suggestions. In particular, at the student's request, Pepper provides contextualized examples on the use of the Pythagorean Theorem and properties of right triangles, helping with gestures and pictures that the student can see on the tablet robot. The activity ends with Pepper thanking the student for helping the protagonist of the story and saying goodbye. At the end of the activity, we asked students to answer the Robot Acceptance Questionnaire (RAQ) (Esposito et al., 2019) to investigate the students' interest in talking to Pepper and their emotional involvement during the interaction. In addition to the RAQ, students were asked to answer other questions concerning Pepper's multimodal abilities with the aim to investigate the extent to which Pepper's multimodality affects its acceptance in mathematical educational contexts. For all students, Pepper's comprehension of verbal expressions, its gestures, and the relationship between comprehensibility and gestures were outstanding. All students stated that Pepper had a high ability to understand their spoken expressions. They enjoyed its ability to give appropriate feedback according to their specific requests and to interact in a friendly way, especially in the initial getting-to-know-you process, making them feel comfortable. Moreover, all students stated that they appreciated Pepper's clarity in telling the story problem, its ability to offer personalized support in case of difficulties, and the effectiveness in making mathematical concepts accessible. This study seems to show a high student acceptance of Pepper as an inclusive educational tool in mathematics.

TWG 17: Theoretical Perspectives and Approaches in Mathematics Education

Introduction to thematic working group 17: Centring the function and purpose of theory in mathematics education research

Heather Lynn Johnson[1], Felix Lensing[2], Pedro Nicolás[3], and Amalie Sødal[4]

Thematic Working Group 17 (TWG17) addressed theoretical perspectives and approaches in mathematics education research. To come together amidst a diversity of theories, the TWG17 centred theory as the object of discussion, guided by three main questions around the function and purpose of theory for mathematics education researchers (MERs). The questions were: What motivates MERs' theoretical working and related empirical study? How do MERs' methodological and methodical approaches cohere with their theoretical perspectives? How do MERs' units of analysis relate to their theoretical perspectives (i.e., what counts as material to be studied)? Comparing theoretical approaches and respective research methodologies and methods served as vantage points to initiate dialogue among theories. Implications include the work to broaden audiences for different theoretical perspectives as well as the development of new theories in mathematics education research.

Keywords: Theories, Methods, Research, Mathematics education.

Introduction

At the 14th Congress of the European Society for Research in Mathematics Education (CERME14), the Thematic Working Group 17 (TWG17) responded to the urgent need not only to develop and use theories in mathematics education research, but also to make explicit the reasons for and purposes of choosing specific theoretical approaches. Mathematics Education Researchers (MERs) draw on a diversity of theories to make sense of their respective objects of study. As has been the case for nearly two decades, such a diversity was thus also a defining characteristic of the CERME14 TWG17. To come together amidst this diversity, the TWG17 proposed a change in perspective: Centre theories as the objects of discussion, making *them* (rather than the theorised objects of study) the focal point. This not only made room to discuss specific theories from new angles but also offered space for dialogue between MERs espousing different theoretical traditions.

We wish to relate this change in perspective to MERs' conversations on mathematical objects. MERs have long distinguished between *mathematical meanings* and *objects*. The *concept* of circle, defined, for instance, as the set of all points on a plane equidistant from a given point, can be distinguished from the geometrical *objects*—circles—that are meant and determined by this very concept. The Pythagorean *theorem* can be distinguished from the geometrical *state of affairs* that is meant by virtue of its propositional meaning. Consequently, it is one thing to refer to mathematical objects through their meanings, and quite another to make these meanings the focus of study and attention themselves. To achieve the latter, a meta-mathematical perspective must be adopted, involving the introduction

of new terms. In this regard, Pimm (1993, pp. 261–262) stated: "The term *definition* is one of a handful of meta-mathematical marker terms (others include *axiom, theorem, proof, lemma, proposition, corollary)*, terms which serve to indicate the purported status and function of various elements of written mathematics." And just as meta-mathematical terms such as 'definition', 'theorem', or 'proof' refer to a meta-aspect of mathematical research, our initiative to talk about 'theories as such' points to meta-aspects of mathematics education research. In both cases, the transition to considering meta-aspects gives rise to new questions, which, if addressed, have the potential to affect how the intended and theorised objects are approached in research. This is evidenced, for example, by the case of a preservice teacher reported by Johnson et al. (2014), whose approach to mathematical objects reflected her view on meta-mathematical aspects, namely the function of definitions in mathematical activity. Similarly, MERs' views on meta-aspects of mathematics education research, such as the function of theory-use, has potential to impact their work with theories (see Sinclair & Herbst, 2024).

When meta-aspects of research become objects of discussion among MERs, questions emerge that cut across a range of theories. One question that MERs have asked for some time and have not found consensus is how the concept of theory may be defined in mathematics education research. To look across different definitions, Bikner-Ahsbahs and Prediger (2014) distinguished between static and dynamic views of theory. From a static view, a theory becomes a theory only after it has a developed an organized hierarchical structure and a well-defined field of application that it explains. In contrast, from a dynamic view, a theory is something that evolves through humans' investigation of problems. Bikner-Ahsbahs and Prediger (2014, p. 168) espoused a dynamic view of theory, stating: "Adopting this dynamic view on theory, we are not basically interested in defining what a theory *should be* but in describing how theories *are used* by different researchers and research groups." This interest in describing not just what theories are, but also addressing researchers' interactions with theories foreshadowed questions emerging a decade later. One such question related to how MERs promote dialogue between theories. In a systematic literature review of mathematics education research, Scheiner and Bosch (2025, p. 712) examined *theoretical dialogue*, which they defined as "the intentional and systematic engagement between theoretical approaches that actively informs, challenges, or transforms the delineation and understanding of phenomena in mathematics education." Hence, theoretical dialogue not only connects theoretical approaches, but also impacts knowledge in mathematics education.

One way to initiate such a dialogue would be to ask questions about the function of theory in mathematics education research. It is in the spirit of what constitutes the function of theory in mathematics education research, that we found ourselves in the CERME14 TWG17. To ground our discussion, we posed three broad questions: What motivates MERs' theoretical working and related empirical study? How do MERs' methodological and methodical approaches cohere with their theoretical perspectives? How do MERs' units of analysis relate to their theoretical perspectives (i.e., what counts as material to be studied)? By posing questions that interlinked theory, methodology, and method, we made efforts to examine not only what theory is, but also what theory does.

Extending from Previous Thematic Working Groups

The CERME14 TWG17 rests on the shoulders of the TWG17s that have preceded this group. Our focus on theory, rather than specific theories, grows from the distinction between horizontal and vertical theorising put forward by Bikner-Ahsbahs et al. (2022) at CERME12. A key distinction between these forms of theorising is the object under study. Bikner-Ahsbahs et al. (2022, p. 2916) characterised horizontal theorising in this way: "With horizontal theorizing, researchers focus on the *how* of theory use, for the purpose of illuminating new aspects of complex phenomena." Put another way, with horizontal theorising, MERs use theory to solve problems related to the teaching and learning of mathematics, such as technology use, task design, or classroom practices. In contrast, with vertical theorising, theories themselves are the object of study: "With vertical theorizing, researchers focus on meta-issues of theory use for the purpose of *understanding theories as entities in and of themselves*." (Bikner-Ahsbahs et al., 2022, p. 2916). In our view, Bosch and Scheiner's (2025) definition of theoretical dialogue demonstrates the compatibility between horizontal and vertical theorising. The end goal is not simply to connect different theories for the sake of connecting them, but also to advance knowledge of the teaching and learning of mathematics.

Discussing meta-issues of theory is not trivial, as people need to make efforts to understand and be understood through different theoretical perspectives. Using Lotman's term *semiosphere*, Radford (2008, p. 318) described this shared space as an "uneven multi-cultural space of meaning-making processes and understandings generated by individuals as they come to know and interact with each other." At CERME13, the TWG17 took steps toward discussing meta-issues of theory, and they found that negotiating shared meanings for terms used in English (and in turn terms that do not translate well into English) was essential to making progress (Johnson et al., 2023). If theory, not just specific theories, was to become an object of discussion for the CERME14 TWG17, then there needed to be tangible ways for MERs to communicate across different theoretical perspectives.

Drawing on the work of previous TWG17s, at CERME14 we leveraged theoretical approaches and research methodologies and methods as points of dialogue, to connect discussions of theory to results of research that advance knowledge. To explain what we mean by methodology, we appeal to Tashakkori and Teddlie (2010, p. 276), who state: "We believe that a research methodology is a general approach to scientific inquiry involving preferences for broad components of the research process, whereas research methods are specific strategies for conducting research." From this view, a methodology is something more than a particular strategy; it is an overall approach to research. Not only are MERs' methodologies intertwined with their theories, in a broad sense, methodology functions like theory as a meta-aspect of research.

At CERME13, Johnson et al. (2023) identified theoretical approaches to be fruitful for organizing discussion across theories. One theoretical approach was the networking of theories, useful for drawing connections between different theories for the purpose of solving problems by bringing together different theoretical perspectives (Bikner-Ahsbahs & Prediger, 2010). To broaden discussion, the networking of theories was positioned among a range of different approaches concerning work with individual theories or across theories (Johnson et al., 2023). At CERME11, relationships between theory and methodology were examined (Bikner-Ahsbahs et al., 2019). Chan

and Clarke (2019) offered Gibson's (1986) term of affordance to characterise a mutually beneficial relationship between theory and methodology. Rather than prescribing a methodology given a particular theory, a relationship of affordance means that theory and methodology need to cohere, such that the methodology makes sense in relationship to theoretical principles. By leveraging theoretical approaches and methodologies/methods in our discussions on theory at CERME14, we meant to focus not only on what theories are, but also on what theories do. With this action-focused move, we adopted the caution from Bikner-Ahsbahs et al. (2022), to stay grounded in our discussions of theory, so that we draw on theory to solve problems in mathematics education research.

Call for CERME14

In the call for the CERME14 TWG17, we invited contributions addressing four areas (Johnson et al., 2024, p. 54):

> 1. What approaches are being developed and/or used to navigate a diversity of theoretical perspectives? What practical and/or conceptual problems are solved by the approaches?
> 2. How can theoretical and methodological working be leveraged to disrupt the status quo in mathematics education research?
> 3. How are theories and methodologies being taught in mathematics education? And how are new scholars being supported in learning new theories and methodologies?
> 4. What new theories and methodologies are emerging in mathematics education research? How are they being developed and used?

Underlying each question was the notion of what MERs do with theory (and why they do what they do). The first focused on the approaches and the problems those approaches address. The second focused on the ways in which theory and methodology may impact what counts in mathematics education research. The third focused on new scholars' enculturation into theory and methodology in mathematics education research. The fourth focused on the creation of new theories and methodologies.

What was learned from CERME14

Sixteen papers and one poster were presented. Not only were there a diversity of theories, the topics under study also diverged. Participants theorised around four broad topics, namely mathematical content, the teaching and learning of mathematics, mathematics teacher education, and the practice of mathematics education research. The mathematical content spanned grade levels, including whole number multiplication in elementary school to analysis and topology in postsecondary school. In what follows, we use the three broad questions to organize the contributions from the CERME14 TWG17. While contributions may be organized under more than one question, we chose to present each contribution within a single question, to illustrate how we operationalized the questions in practice.

What motivates theoretical working and related empirical study?

Two contributions illustrated how existing perspectives could be used for new purposes. Lien et al. demonstrated how an existing framework, Skott's Patterns of Participation, was viable for the study of preservice teachers' professional identity. Asenova and Capone demonstrated the utility of category theory for examining interdisciplinarity from a perspective of mathematics (i.e., how

mathematics is employed in other subjects, such as physics). Two contributions showed how a critical theoretical perspective could offer new avenues to examine (or re-examine) mathematics teaching and learning, to disrupt the status quo. Yolcu explained how Foucault's postfoundational theory could be used to reframe what is meant by opportunities to learn mathematics. Xenofontos drew on Foucault's concept of heterotopia to explain how mainstream mathematics classrooms could learn from classrooms outside the mainstream (i.e., special education, gifted education, and prison education). One contribution demonstrated the need to network theories to explain phenomena. Günther et al. reported on a case study in which they networked the Theory of Transformative Education (TTE) and the Anthropological Theory of the Didactic (ATD). By combining theories, they explained a student's transition from secondary to postsecondary mathematics from individual (TTE) and sociocultural (ATD) perspectives. Making explicit the motivations for theoretical working provided new insights into MERs' purposes for their theoretical working.

How do methodological and methodical approaches cohere with theoretical perspectives?

Three contributions demonstrated how theory and methodology/method could work in conjunction. Herbst et al. presented further advancements to their "middle-range theory" of practical rationality, which explains mathematics teaching as a rational, sensible practice. They demonstrated how theory development can go "hand in hand" with the development of instruments to measure theoretical constructs. Drawing on an interactionist perspective, Kollhoff and Gerlach developed a framework that aims to describe and explain the interactive dynamics in which meanings of mathematical representations are negotiated in classroom settings. Bini et al. blended theoretical perspectives from mathematics education and digital sociology to put forward a hybrid experimental design to study students' creation of and work with mathematical memes. Two contributions articulated links between theoretical perspectives and decisions on the use of research methods. Lombard presented methods for ongoing work to archive fundamental resources on the Theory of Didactical situations (TDS) and the ATD. The encyclopaedia will be organized like a thesaurus, linking key constructs to literature explicating those constructs. Drawing on Bachelard's construct of epistemological obstacle, Sebök and Lensing examined the potential of Husserl's eidetic method to examine such obstacles in students' learning of mathematics. Two contributions examined how theory use could connect to the study of the practice of mathematics education research. Shinno and Miyakawa addressed the problem of transposing theoretical and methodological knowledge, from one culture to another. They employed the ATD to explain the transposition from Western culture to Far East Asian culture. Johnson et al. demonstrated the viability of the use of a theory sourced from one tradition to examine a research method sourced from a different tradition. They employed positioning theory to examine the teaching and learning of the research method of task-based interview. The connection between theory and methodology/method grounded our discussions in the work to use theory to solve problems (and what the nature of those problems might be).

How do units of analysis relate to theoretical perspectives?

Units of analysis represent what counts as material to be studied from different theoretical perspectives; these included not only individuals and classroom but also institutionalised knowledge. As evidenced in three contributions, the ATD provided strong grounding for the study of

institutionalised knowledge. Hochmuth et al. examined choices made in a textbook's exposition of an equivalence statement on function continuity. Espín et al. employed diachronic analysis to examine modalities through which research mathematicians studied the real numbers. Nicolás et al. examined the potential for modalities of teaching to promote creativity, illustrating with the use of the derivative to examine the monotony of functions. One contribution demonstrated the utility of quantitative methods for the study of institutionalised knowledge. Drawing on Brousseau's construct of didactic variable and Da Ronch's construct of research variable, Mili et al. examined problems in the official Swiss textbook, to statistically measure the potential of problems to support students' mathematical activity. Another contribution addressed the difficulties MERs often experience when trying to adapt conceptual tools developed in other areas of research for the questions and purposes specific to mathematics education research. In their contribution, Kollosche and Wang dealt with the question of how to conceptualise the relevance that students attribute to their engagement in institutionalised mathematics education. They argued that psychological concepts often employed by MERs to study questions of relevance—such as the concepts of belief, motive, and utility value—cannot account for key dimensions of the subjective relevance of mathematics education. Therefore, they called for a triangulation of psychological and sociological approaches to overcome these limitations. Making explicit our units of analysis offered a different angle to discuss what theories can (and cannot) do in mathematics education research.

Discussion and conclusion

At the CERME14 TWG17, we centred the function and purpose of theories in mathematics education research. Accordingly, this meant that we focused on what MERs do with theory (and why they do what they do). The three guiding questions provided us with tangible ways to dialogue across different theoretical perspectives and across contributions addressing different aspects of the call for proposals. Something new that we made explicit in the call for proposals was the enculturation of new scholars into theories and methodologies in mathematics education research. In our view, the three guiding questions can serve as productive starting points to organize seminars for new scholars. In our discussions, we found the questions to provide footholds for MERs with different degrees of experience with theory to come together, because responses to the questions illuminated our reasons and purposes for our theoretical working.

The three guiding questions led us to consider different roles that MERs may take on with respect to theory, namely *producers*, *consumers*, and *distributors* of theory. By *producers*, we mean those who develop theory, or, to put it another way, those who engage in 'vertical theorising'. By *consumers*, we mean those who put theory into practice to conduct research in mathematics education, or 'horizontal theorising'. By *distributors*, we mean those who expand theories beyond the contexts and cultural traditions in which they were originally developed, providing a broader audience for the theory in question. When we talk about distribution, we do not mean that theories are something that MERs can pick up and "plug in" to a new setting. Theories are rooted in cultural traditions, and it is necessary to honour those traditions in our work with theory (see Jablonka et al., 2013). In addition, we see these three roles as interconnected. If MERs are to use theories specific to mathematics education research, then they need to develop such theories. The contribution from Herbst et al. makes explicit the ongoing work of theory development in mathematics education research. If theories are

to expand beyond the cultural tradition in which they were developed, then MERs need to work to transpose those theories from one tradition to another. The contribution from Shinno et al. provides insights into the work of such transposition. In our discussions, we also critically examined the affordances and constraints of adopting terminology that stems from a different domain (e.g., economics) when seeking to conceptualise possible relationships between MERs and theory.

We provide three implications from the work of the CERME14 TWG17, to advance mathematics education research. The first is to develop points of dialogue among MERs espousing different theoretical perspective. We found theoretical approaches and research methodologies/methods to be productive starting points. For example, our discussions around units of analysis offered a way to examine what counts as material to be studied across different theories. The second is for MERs to make explicit connections between our theorising and our motivations for our studies. The third is to broaden audiences for existing theoretical perspectives, to expand the reach of different theories.

A consequence of our focus on theory as a meta-object of research is a need to be vigilant to ground our conversations so that we do not only discuss theory for theory's sake. We found that moving back and forth between specific theories and broader notions of theory allowed us to ask questions that cut across different perspectives. To illustrate, a feature of the ATD is the use of formal symbolism to articulate theoretical constructs. This feature of a specific theory led us to a broader question about the role of symbolism in theorising, which we left as an open question. While we made strong progress, there is still much work to be done. We close with some comments around future possibilities. One area for future work is to examine what theoretical development looks like in mathematics education research. During a discussion, we considered what progress in theory development might look like if we did not conceptualise it as making finer and finer distinctions. These considerations let us to conclude that there is a need for more guidance around different forms that theoretical growth progress may take. In the call for the CERME14 TWG17, we invited contributions that demonstrated how theory and methodology could disrupt the status quo in mathematics education research. To illustrate, we asked how MERs addressed ontological, epistemological, axiological, and/or ethical dimensions of theorising. We also asked how the power and status of different theoretical traditions among MERs may impact the scope of mathematics education research. We concur with Sinclair and Herbst (2024), that there is a need for more explicit treatment of axiological and ethical dimensions of theorising. We welcome such treatment at future iterations of the CERME TWG17.

Interdisciplinarity in STEM education: A category-theoretical model from the viewpoint of Mathematics

Miglena Asenova[1] and Roberto Capone[2]

[1]Free University of Bozen-Bolzano; Italy

[2]University of Bari Aldo Moro, Department of Mathematics, Bari, Italy; roberto.capone@uniba.it

Interdisciplinarity, especially within STEM and STEAM education, has been emphasized to foster the technical and creative skills required in an innovative, technological world. Despite various models addressing interdisciplinarity, a theoretical framework that explicitly articulates the structure of interactions between disciplines from the perspective of Mathematics remains lacking. This paper proposes such a framework by leveraging fundamental concepts from category theory to provide a structure interpretable across specific contexts. The model employs category-theoretical concepts metaphorically and symbolically rather than formally, intertwining them with the notions of semiosphere and border. The paper introduces and interprets the diagram representing the model and exemplifies its functionality by analysing interdisciplinary interactions in a classroom experiment, highlighting how Mathematics retains its identity through these interactions.

Keywords: Interdisciplinarity, Mathematics, category theory, semiosphere, border, STE(A)M.

Rationale

To answer the formidable challenges of globalisation and the complexity of life on both national and worldwide levels, it is necessary to educate on complexity and overcome separations between disciplines (Lensing & Pilous, 2022). Indeed, the importance of interdisciplinarity has been increasing since 1990, when the acronym STEM has been coined. The Ministry of Education recently issued guidelines on teaching STE(A)M disciplines in Italy. According to these guidelines, the interdisciplinary approach, together with the comingling of theory and practice, is at the heart of the teaching of STEM disciplines, which are particularly suited to fostering the development of technical and creative skills necessary in an increasingly technological and innovative world. Thus, giving theoretical grounding to the interdisciplinary approach is of primary importance. Sanders (2009) introduced the concept of STEM as a 'meta-discipline,' a holistic approach where STEM subjects are integrated and applied in real-world contexts. Kelley and Knowles (2016) proposed a framework that emphasizes the integration of STEM subjects, highlighting the importance of interdisciplinary teaching and real-world problem-solving. In Physics Education, different approaches and models have been developed to address interdisciplinarity (e.g., Satanassi et al., 2023). For instance, in the European research context recently, two projects carried out about interdisciplinarity between Mathematics and Physics, called IDENTITIES Project and FEDORA (Levrini et al., 2021) focus on interdisciplinarity in teacher training, highlighting the identities, the borders, and the forms of integration of the different disciplines reflecting on their epistemological and linguistic structure. Despite various approaches to the theoretical foundations of interdisciplinarity, what is still lacking is a model that can make explicit the abstract relations between the disciplines from the point of view of mathematics. This paper proposes such a model. The theoretical framework is based on the metaphorical interpretation of some basic category-theoretical concepts (Asenova, 2021) that help to

represent symbolically the interdisciplinary interactions in the model's diagram. Indeed, interdisciplinarity is based on recognizing analogies between different areas of knowledge, and category theory provides a language that can grasp analogies between different domains. We focus on such analogies, taking a cue from the category-theoretical terminology. This technical part of the model is intertwined with the concepts of semiosphere (Lotman, 2005) and border (De Luca Picione et al., 2022), which interpret the model's diagram.

The research question we focus on is: To what extent can the model be based on the metaphorical use of category-theoretical tools, semiosphere, and border frame interdisciplinary interactions while keeping the focus on Mathematics?

After presenting the theoretical framework, we describe the adopted method, present and interpret the model's diagram, and exemplify how it works by analysing the interactions between the disciplines in a classroom experiment, keeping the focus on Mathematics and its identity characterisation.

Theoretical framework

The theoretical framework is composed of a first part referring to concepts taken from cultural semiotic (e.g., semiosphere, border, etc.) and needed to interpret the model's diagram, and a second part that focuses on the metaphorical introduction of the technical terms coming from category theory (e.g., category and representable functor) and needed for structuring the diagram.

The notion of *semiosphere*, created by Lotman (2005) in cultural semiotic research, helps us explore interdisciplinary education by focusing on how different subjects interact. A semiosphere denotes the space where different cultural semiotic systems (e.g., Mathematics, Physics, etc.) can subsist and generate new information (Lotman, 2005). Lotman believed that interdisciplinarity, or combining different fields of study, is essential to understanding the complexity of reality. So, he introduced the concept of the border, not just as a dividing line but as a space where things gain meaning. These borders help organise how we understand time, space, and relationships. Lotman also described the semiosphere as a space within these borders, where different cultural codes like language, art, and science coexist and exchange information, defining the disciplines and establishing identities while encouraging translation and understanding of others. What defines a semiotic system is that it allows us to interpret and construct meaning. Lotman (2009) suggests that what turns a structure into a thinking system is its dialogical interaction with the outside world, facilitated by the organisation of borders. The movement between inside and outside involves processes of translation and interpretation. To understand how what exists at the border interacts with its surroundings—and how semiotic systems interact—we can look at the concept of enantiomorphism. According to Lotman, all meaning-making processes begin in a state of symmetry or balance, which becomes more complex over time by creating a mirrored symmetry. For example, one semiotic system, called culture C1, starts in a state of symmetrical balance. When it encounters texts from a different semiotic system, culture C2, it interprets them, breaking them down and reorganising them. Through this process, culture C1 generates an image of culture C2. This image, which Lotman refers to as an

enantiomorphic model, acts like a mirror, allowing culture C1 to see both similarities and differences between itself and culture C2 (Figure 1).

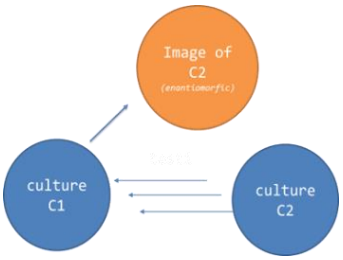

Figure 1: Scheme of the enantiomorphism between disciplines

Imagine Physics as one culture (C1) and Mathematics as another (C2). Physics might take a mathematical formula from mathematics and analyze it to form an understanding of what mathematics is like. This "mirror image" helps Physics compare itself to Mathematics, seeing similarities and differences in their methods and ideas. By doing this, Physics can better understand how to use Mathematics to solve real-world problems. Conversely, Mathematics might take examples from Physics to see how its formulas work in practice, creating its own 'mirror image' of Physics. This exchange at the border between the two disciplines not only helps solve problems from different perspectives but also deepens each discipline's self-understanding through comparison with the other. Working at the intersection of disciplines offers more opportunities than focusing on just one field. This study draws on De Luca Picione and Valsiner's concept of the *border as a metaphor*. They approach the idea of the border not as a fixed entity but, from a psychological standpoint, as a semiotic tool that drives dynamic growth and mental development processes. From this perspective, borders help establish our position within a symbolic field. Aligning with this view, we conceptualise disciplinary borders as psychological tools that support ongoing development and meaning-making processes. Human experience is characterised by a continuous construction of meaning through actions like classification, categorisation, and interpretation, which are essential in shaping behavior, thinking, and relationships. In this context, borders create a symbolic field where these semiotic processes occur, starting with differentiating this field from the outside world. Although borders often represent separation, definition, and closure between distinct disciplines, they also play a crucial role in forming dynamic relationships and structures that encourage comparison, exchange, and dialogue. In this work, we metaphorically connect the idea of the border to the concept of interdisciplinarity (Capone, 2022).

Now, let us come to the technical part of the model. It allows us to schematise the relations between the concepts of semiotic system, translation between semiotic systems, enantiomorphism, border, and semiosphere, taking the cue from the category-theoretical tools category, functor, embedding functor, and representable functor. The diagram resulting from the representation of these technical tools allows us to represent and interpret in detail the relations between the concepts of the involved disciplines and between the disciplines themselves. Our proposal considers the category-theoretical notions involved as universal tools of thought, not as formal mathematical tools (Asenova, 2021; Asenova et al., 2023; Zalamea, 2012). In the following, we explain the metaphorical meaning of each of these technical tools.

In the model, a discipline intended as a cultural semiotic system (e.g., the cultures C1 and C2 in Figure 1) is named 'category'. In this context, a *category* is therefore not a mathematical structure but a relational context where concepts represent the objects and the relations between them represent the arrows of the category, e.g., the concepts involved in a mathematical theorem and the relations between them, explained in its proof, represent such a category. The process representing the translation of aspects of meaning in Culture C1 into aspects of meaning in Culture C2 is named here 'functor'. In this context, a *functor* is not a formal mathematical object but a tool of thought that establishes an analogy from one cultural semiotic system to another, i.e., from one discipline to another, mapping concepts in concepts and relations in relations. This translation between cultural semiotic systems could be complete in the sense that there is a one-to-one mapping between the meanings in the first and the second semiotic system or only partial (e.g., only some elements of mathematical proof can be made to correspond to elements in an experimental proof in Physics). The concept of enantiomorphism introduced above allows us to associate objects belonging to a culture C1 with objects belonging to another culture C2. It is considered a special kind of functor, named 'embedding functor,' that emerges by embedding one cultural semiotic system into another. An *embedding functor is thu*s a tool of thought based on an analogy that allows interpreting a relational context within another relational context and gives rise to a metaphorical use of aspects coming from the first relational context in the second one. In this sense, it is a way to describe the metaphorical use of concepts from a discipline in another discipline (e.g., the physical term 'center of gravity' when dealing with the intersection point of the medians of a triangle in Mathematics). In an interdisciplinary context, the identity of a chosen discipline is characterised by the images sent back from its mirroring in the other involved disciplines through the interactions with them that take place on its border. From a category-theoretical viewpoint, this idea is the core of the 'representable functor' concept. A representable functor is an embedding functor that expresses the relational context it starts from, assuming a particular viewpoint. In our model, a *representable functor* is a tool of thought that expresses the interactions between the concepts belonging to the different disciplines from the viewpoint of one of them, in our case, Mathematics (e.g., when we examine the interaction between a mathematical proof and a physical experiment associated to it, and we assume the point of view of the mathematician who is asking for the meaning of a physical concept). A representable functor focuses on relations rather than on objects. Indeed, it "replaces" the objects, in our case the involved disciplines, by their relations to one chosen object, in our case Mathematics. The concept of semiosphere, where the interactions of the disciplines take place, is modeled by a special kind of category, whose objects are functors and whose arrows are mappings between them. In our model, this special category is the metaphorical space where the interdisciplinary activity takes place and where the representable functor is embedded. The interplay of the technical tools described above allows us to express our point of view on Mathematics in an interdisciplinary context that could be composed of some or all of the STEAM disciplines. More precisely, all the relations that express how a discipline is related to Mathematics within an interdisciplinary approach represent components of a border as a metaphor of interdisciplinarity (Capone, 2022) that can be conceived of as a representable functor.

Methods

In the following, we present the diagram of the model that allows us to frame interdisciplinary settings and provide its interpretation. Then, we describe an interdisciplinary classroom activity from a secondary math classroom and analyse it according to the model.

The model's diagram and its interpretation

The model's diagram (Figure 2) has three main elements: one irregular form named C_{INT} on the left; one rectangular form named C_{INT}^{MATH} on the right, and a curved arrow between them named r_{MATH}.

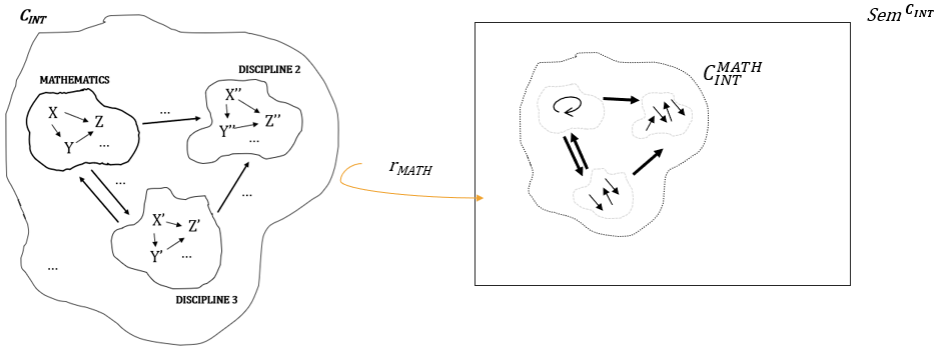

Figure 2: The model's diagram. The interdisciplinary context (C_{INT}) is embedded by the representable functor (r_{MATH}) in the semiosphere ($Sem^{C_{INT}}$) highlighting the borders from the point of view of Mathematics (C_{INT}^{MATH})

C_{INT} is the category representing the interdisciplinary relational context composed of the cultural semiotic systems involved in the activity (Mathematics, Discipline 1, Discipline 2, …) and the relations between them that are relevant to a designed interdisciplinary activity. In each cultural semiotic system, concepts and relations are involved in the activity (X, Y, Z, for Mathematics, X', Y' and Z' for Discipline 2, and so on). $Sem^{C_{INT}}$ stands for the special category representing the semiosphere in which the interdisciplinary activity is operationalised during the classroom activity. Finally, r_{MATH} is the representable functor that embeds a copy of CINT, named C_{INT}^{MATH} in $Sem^{C_{INT}}$. C_{INT}^{MATH} represents the disciplines in C_{INT} and their relations from the viewpoint of Mathematics. So, for instance, if Discipline 1 is Physics, so in C_{INT}^{MATH} it is not defined in itself but as the discipline that uses mathematical results for modeling natural phenomena or other similar relations. This aspect is expressed for each discipline by the straight, thin arrows within the dotted forms in C_{INT}^{MATH}; only Mathematics is expressed by an identity arrow (a loop) that relates it to itself. This underlines that the viewpoint of Mathematics is privileged, and the model aims to characterize its identity by interacting with the other disciplines on its border. The bold arrows between the dotted forms stand for the borders crossed between the disciplines that emerge during the activity in the semiosphere ($Sem^{C_{INT}}$).

An example of interdisciplinary activity analysed according to the model

The interdisciplinary activity presented here is taken from Adesso et al. (2019) and Capone and Faggiano (2024). It focuses on Ceva's theorem. The teaching activity was designed and experimented with 10th-grade students in different schools across Italy. The design of the activity was based, among others, on the following principles: students work in a fixed disciplinary contest but foster the connection between Mathematics and other disciplines; linguistic practices that can be meaningful to

connect the different activities are promoted. The activity was carried out in seven phases. *Phase 1*: Students are provided with the original Latin text of the theorem and divided into small groups; they are requested to translate the text into Italian language. *Phase 2*: Guided by the teacher, students are invited to discuss whether the problem they are faced with is a Physics problem, a Mathematics problem, or both, by answering the following questions: *Which elements of the text can be related to a Mathematics problem? Which elements of the text can be related to a Physics problem?* According to their arguments, they are then asked to identify the strategies and the tools that could be used to give a proof of the theorem. *Phase 3*: Students are asked to prove the theorem with the classical approach and tools of axiomatic Euclidean geometry. The teacher then orchestrates a discussion to bring students' attention to the analogies between the original text of the theorem, the experimental activity, and the geometrical proof of the theorem. *Phase 4*: Students are asked to construct and verify Ceva's theorem using dynamic geometry software. *Phase 5*: Students are invited to choose one of the three approaches to present and prove the theorem. Then, according to their preference, they are divided into three groups and asked to prepare themselves for a debate concerning the reasons for their choice. *Phase 6*: Students in each of the three groups are invited to argue why they consider the chosen approach the best to prove the theorem. The debate is followed by a final collective discussion orchestrated by the teacher. In the following section, we interpret the interdisciplinary activity according to the model presented in Figure 2.

Data analysis and discussion

In the activity presented above, the category representing the interdisciplinary context C_{INT} is composed of Mathematics, Physics, and Latin. The Mathematics context is characterized by four concepts that represent the objects of the related category: the mathematical statement of Ceva's theorem (X), the Euclidean Geometry context (Y), the proof provided in the traditional Euclidean context (Z), the proof in the GeoGebra context (V). Examples of relations between these concepts, as they were conceived by the researcher who designed the activity, are the following: relation from X to Y (X is a theorem in Y) and from Y to X (Y is the theory where X 'lives in'); relation from Z to X (Z is a means to proof X) and from X to Z (X is a part of Z). Further relations between the involved concepts could be singled out. The Physics context (Discipline 2) is characterized by three concepts: the physical statement of Ceva's theorem (X'), the experimental setting context (Y'), and the weight experiment that checks the equilibrium (Z'). Examples of relations between these concepts are: (1) from X' to Y' (X' provides the instructions for the experiment in Y'); from Y' to X' (Y' is the verification of X'). The Latin context (Discipline 3) is characterized by two concepts: the Latin text of Ceva's theorem (X'') and the Latin Grammar (Y''). The relations between Mathematics and Physics are characterized by the assignments formulated by the researchers for the students. Latin to Mathematics and Latin to Physics: read the text and translate the statement from Latin to Italian; Physics to Mathematics: construct a cardboard triangle and apply weights to it that represent the relations of the Cevians. The representable functor r_{MATH} acts as an embedding of the interdisciplinary context C_{INT} within the semiosphere $Sem^{C_{INT}}$, where the interdisciplinary activity is taking place. It expresses the viewpoint on this activity from the perspective of Mathematics. Let us look now to C_{INT}^{MATH} which represents the copy of C_{INT} in the semiosphere $Sem^{C_{INT}}$ assuming the viewpoint of Mathematics. As we stated above, in C_{INT}^{MATH} each discipline is replaced by its relations

to Mathematics, and Mathematics itself is characterised by the images mirrored from the other disciplines. In this sense, examples of images sent back by Physics to Mathematics are the following: (1) Physics provides a concrete and manipulative context for Mathematics that allows one to experiment and thus sends back an image of Mathematics as a discipline that allows to generalise and validate experimental results; (2) the Physics experiment is a way to render more convincing the mathematical relations by experiencing them metaphorically in a concrete context; another image send back by Physics to Mathematics is thus that Mathematics benefits from physical models for being better understood. Images possibly sent back from Latin to Mathematics are the following: (1) Latin provides the opportunity to reflect deeply on mathematical relations by translating them into another language, and thus, Mathematics is a discipline with an abstract language whose understanding can benefit from the interpretation in different languages, including the historically original one. These images are just generic examples of borders crossed during the interdisciplinary activity, emerging through the interplay of the semiotic resources of the involved cultural semiotic systems (the disciplines) in the semiosphere, represented by $Sem^{C_{INT}}$. They are specific to the designed activity and can be nearer defined by analysing the students' points of view. However, the structure expressed in the model's diagram (Figure 2) does not depend on the activity and would always be the same. This characterises the 'syntax' of the interactions of the involved disciplines, keeping a privileged point of view of Mathematics. By syntax, we mean the elements involved in the interdisciplinary interactions and their relations, represented by the symbols associated with the technical tools in the model diagram, while the interpretation that lends the technical tools and symbols related to them with meaning represents the model's semantics. Furthermore, the model allows us to take into account the activity design (the entities and the relations between them in C_{INT}^{MATH}), as well as the analysis of the activity in the classroom, considering the interdisciplinary borders that emerge within the semiosphere ($Sem^{C_{INT}}$).

Concluding remarks

The model presented and exemplified in this paper seems to be able to frame interdisciplinary interactions while keeping the focus on Mathematics, as it makes evident how its disciplinary identity is shaped by its interaction with the other involved disciplines. It allows for clarifying the relations in an interdisciplinary context by expressing them in a symbolic, context-independent manner. We conclude by pointing out that the prioritisation of Mathematics in the model concerning the other disciplines is not necessary. Indeed, we could choose another discipline as a privileged one; in that case, Mathematics would contribute to defining the identity of the privileged discipline. We believe this is not a disadvantage but emphasizes the model's versatility and the generality of the relationships highlighted in it. This aspect represents a possible future research direction pointing to evolving the model towards an interplay between the identities of the involved disciplines, expressed as borders emerging from multiple privileged perspectives within the semiosphere they are interacting in.

On the diachronic analysis of a modality of study

José Ginés Espín[1], Josep Gascón[2] and Pedro Nicolás[1]

[1]University of Murcia, Faculty of Education, Spain; josegines.espin@um.es

[2]Autonomous University of Barcelona, Faculty of Sciences, Spain

The aim of this work is to emphasize the relevance of the diachronic analysis in order to understand a current modality of study of a certain field of knowledge in an institution. This kind of analysis requires the construction of three didactic paradigms to model three modalities of study: the current one, an alternative possible future one and a possible past one. To exemplify a diachronic analysis, we use the case of the study of real numbers in the institution of researchers in Mathematics. Moreover, we suggest that the diachronic analysis is a suitable procedure to tackle a wide range of problems in didactics.

Keywords: Didactic analysis, didactic paradigm, modality of study, real numbers.

Introduction

From the perspective of the Anthropological Theory of the Didactic (ATD), we understand the 'study' in a broad sense: it includes processes of knowledge creation and reorganization, not only those aimed at enabling the dissemination of knowledge but also those designed to facilitate its use in specific situations and within different institutions (Chevallard, Bosch, & Gascón, 1997). We assume that didactics is the science of study and, by extension, of the modalities of study, leading us to consider the following problem: What types of models allow us to characterize the structure and dynamics of a current modality of study in a didactic institution related to a specific field of knowledge? How can such modelling be used to propose possible changes to the modality of study?

In the second section, we introduce some concepts from the theoretical framework that we will use in the work: we explore the concept of the didactic paradigm, as introduced by Gascón and Nicolás (2021a, 2021b), analysing its structure and dynamics. Didactic paradigms serve as theoretical models for certain systems, specifically, those composed by the study of a particular field of knowledge within a given didactic institution (i.e., didactic paradigms model what we refer as *modalities of study*). Our main objective is to propose an expanded approach to the didactic analysis of a current modality of study by examining three didactic paradigms in parallel: a possible past, the current one, and a potential future. This idea, which forms the core of our methodology, is outlined in the third section via the *diachronic analysis*. In the fourth section, we implement the diachronic analysis in the case of the real numbers in the institution of researchers in Mathematics. We conclude the paper summarizing key insights and identifying open didactic challenges.

Theoretical framework: the structure and the dynamics of didactic paradigms

Let us begin by clarifying some key concepts. When we speak of field of knowledge, we do not mean just disciplines (mathematics, history, etc.), but also some specific parts of them (real numbers, French Revolution, etc.). Moreover, the field of knowledge can be quite wide, including everything what is to be studied at a certain didactic institution. When we speak, of didactic institution, we refer to a social institution with the declared aim of studying certain fields of knowledge. A social

institution consists in a set of constitutive1 rules which fixes a series of institutional positions, allowed, compulsory and forbidden actions for each position, and rewards and punishments for certain actions (Searle, 2010). Examples of didactic institutions are Primary Education, Secondary Education, Research in Mathematics, etc.

Social sciences want to understand the working of social institutions. In didactics, we want to understand the working of didactic institutions; that is, given a didactic institution, I, and a field of knowledge, F, we want to understand how the system formed by the study of F in I works. In science, the study of systems is made by using theoretical models. Here, we propose as a theoretical model the idea of didactic paradigm. Specifically, we say that a didactic paradigm for the study of F in I is a triple, $DP_I(F) = [EM_I(F), DE_I(F), DM_I(F)]$, where: the epistemological model, $EM_I(F)$, is a certain description of F (Gascon, 2014), the didactic ends, $DE_I(F)$, are the answers to "What are the reasons for studying F in I?", and the didactic means, $DM_I(F)$, are the actions (which may involve the usage of certain objects, like textbooks) carried out in order to reach the didactic ends.

We thus have a structural description of didactic paradigms. Our use of the term "paradigm" goes back to Kuhn (1962). In our work, a paradigm does not refer to a canonical example to imitate, but rather to a series of shared ideas that strongly conform the way things are being done. Thus, a didactic paradigm DPI(F) aims for being a description of the shared didactic ends, didactic means and epistemological model concerning the study of F in I. However, this is too ambitious and, in practice, instead of aspiring to describe all the shared elements, a didactic paradigm describes just some features, giving rise to a partial didactic paradigm. Hence, there might be several didactic paradigms modelling the study of F in I.

When we use a didactic paradigm to describe the current modality of study, we speak of current didactic paradigm, and we write $CDP_I(F)$; similarly, if we are describing a reference modality of study (i.e., a conceivable modality of study alternative to the current one), we speak of reference didactic paradigm, and we write $RDP_I(F)$.

We will see that to describe the dynamics of a $DP_I(F)$ it is necessary to use the notion of didactic phenomena, $D\varphi_I(F)$. We cannot say what a didactic phenomenon is2. We will simply say that a didactic phenomenon (or study phenomenon) is expressed through a series of features of a modality of study of F in I, modelled by a certain paradigm DPI(F). It manifests through a set of events or processes related to study that are typifiable, regularly recurring under certain circumstances and across different institutions, and are surprising (from a certain perspective), thus requiring an explanation. The events related to the study involve relationships between the different aspects of the modality of study, which translate into relationships between the components of the $DP_I(F)$.

Didactic phenomena should not be confused with praxeological features (features of the epistemological model) that suggest or indicate their existence. For example, interpreting

[1] By 'constitutive' rules we mean they are not merely rules observed within the institution; rather, the institution is fundamentally made up of these rules (i.e., the rules define the institution).

[2] It is not possible to give a definition of a didactic phenomenon, just as it is not possible to define a physical phenomenon.

proportionality as a purely arithmetic relationship between numbers, separating it from other functional relationships (instead of considering it as functional relationship between quantities of magnitude that requires the systematic use of algebraic tools), is a praxeological feature that is surprising from the perspective of the ATD and suggests the existence of didactic phenomena. Among these phenomena, we can mention the following ones: confusion in interpreting language related to ratios, proportions, means, extremes, the rule of three, etc.; systematic technical mistakes in the use of these concepts; the identification of "direct proportionality" with "increasing function"; and, due to the absence of algebraic tools, the difficulties experienced by the school system (and therefore by students and teachers) in interpreting the relationships between "direct proportionality", "inverse proportionality" and "compound proportionality".

As explained in Gascón & Nicolás, (2021a, 2021b), frequently in research we use reference didactic paradigms to describe current didactic paradigm as follows. First, we wonder how to avoid a certain didactic phenomenon3, $CD\varphi_I(F)$, we vaguely detect in the current modality of study. In order to describe this current didactic phenomenon, $CD\varphi_I(F)$, with more precision, we need to specify the current didactic paradigm, $CDP_I(F)$. This, in turn, is done by having in mind an alternative modality of study, described by a reference didactic paradigm, $RDP_I(F)$, which has among its didactic ends the avoidance of $CD\varphi_I(F)$. The constructions of $CDP_I(F)$ and $RDP_I(F)$ are done almost simultaneously, emphasizing their differences. A reference didactic paradigm, $RDP_I(F)$, can be regarded to be an hypothesis as follows: a modality of study ruled by the $RDM_I(F)$ and the $REM_I(F)$ would achieve the didactic ends RDEI(F) and, in particular, would avoid the didactic phenomenon $CD\varphi_I(F)$ which takes place in the current modality of study described by $CDP_I(F)$.

Of course, one can think of the possibility of providing an interpretation of the current didactic paradigm without having explicitly an alternative, a reference didactic paradigm. However, typically, our interpretation of something (a modality of study, in this case) do not rely on obvious and necessary things, but rather are done by pointing out those features that could be differently. For example, when describing a function, we do not point out that it has an input and an output, but rather specify properties such as continuity, differentiability, periodicity or other things that could be differently. In other words, our descriptions seem to be done by keeping in mind, as a reference, a possible alternative reality. This is the role played by the RDP with respect to the CDP.

Since institutions can change a lot along time, in the specification of a didactic institution one has to fix a certain time interval. Indeed, for instance, the didactic institution of University Education in the 12th century in Bologna was very different from the present one. Therefore, it might happen that the current didactic paradigm $CDP_I(F)$ of an institution I was previously a reference didactic paradigm for this very institution I in former times, alternative to the current one at that time. But then, the

[3] The didactic phenomena we study are not always necessarily 'undesirable'. However, our decision to study a phenomenon is motivated, first of all, by the need to explain it, which already indicates that a phenomenon always contrasts with what would be expected from the perspective of our postulates. Secondly, we typically choose to study a didactic phenomenon because we aim to act on the system in which it appears, intending to modify it in some way. Therefore, we tend to choose phenomena that, from our perspective, generate undesirable consequences.

current didactic paradigm $CDP_I(F)$ aimed at that time to avoid certain didactic phenomena that could be described with a certain didactic paradigm current at that time. In this situation, and speaking from present times, we say that the didactic paradigm current at former times is the antecedent didactic paradigm, $ADP_I(F)$, with respect to the current one, $CDP_I(F)$. Hence, we have three didactic paradigms: $ADP_I(F)$, $CDP_I(F)$ and $RDP_I(F)$: $RDP_I(F)$ tries to avoid a certain didactic phenomenon $CD\varphi_I(F)$ which takes place in $CDP_I(F)$, and $CDP_I(F)$ tried in the past to avoid certain didactic phenomena $AD\varphi_I(F)$ taking place in $ADP_I(F)$.

Methodology: didactic analysis as diachronic analysis

With the idea of these three didactic paradigms, the antecedent ADP, the current CDP, and the reference RDP, in mind, we see that the *interpretative analysis* of the current didactic paradigm CDP, can be diachronically complemented by considering $ADP_I(F)$, which explains the origin of $CDP_I(F)$, and $RDP_I(F)$, which points out to a possible change. The links between these three paradigms are the didactic phenomena to be avoided: $AD\varphi_I(F)$ is what $CDP_I(F)$ tries to avoid, and $CD\varphi_I(F)$ is what $RDP_I(F)$ tries to avoid.

Let us show some questions connected to the three different types of analysis:

Interpretative analysis: It consists in providing an interpretation of the $CDP_I(F)$. As said before, this is typically done by comparing it with a reference didactic paradigm, $RDP_I(F)$. In our description of $CDP_I(F)$, we aim to represent the $CEM_I(F)$, the $CDE_I(F)$ and the $CDM_I(F)$, and this would entail to answer the following questions: 'how is the $CEM_I(F)$?', 'what possible elements of F are included in the study of F in I?', 'how is the $CEM_I(F)$ different from the $REM_I(F)$, not only concerning the knowledge involved itself, but also concerning the link of this very knowledge with other fields of mathematics?', 'which are the $CDE_I(F)$?', 'how are the $CDE_I(F)$ different from $RDE_I(F)$?', 'which are the $CDM_I(F)$?', 'are these $CDM_I(F)$ really suitable to reach the $CDE_I(F)$?', 'if these $CDM_I(F)$ are not useful in order to reach the $CDE_I(F)$, how should them be changed?', 'what are the didactic phenomena, $CD\varphi_I(F)$, revealed by $RDP_I(F)$?'

Forwards analysis: It essentially consists in constructing an alternative didactic paradigm, $RDP_I(F)$, and study the conditions that would make possible to go from $CDP_I(F)$ to $RDP_I(F)$. Among other things, the interpretation of $RDP_I(F)$ should show that a modality of study ruled by $RDP_I(F)$ would avoid the $CD\varphi_I(F)$. As said when explaining the interpretative analysis, the construction of $RDP_I(F)$ is done in parallel with the interpretation of $CDP_I(F)$. Thus, some parts of the interpretative and the forwards analysis are done simultaneously. But there is a part of the forwards analysis that can be done before the interpretative analysis. Namely, the study of the features of the institution that would hinder the implementation of $RDP_I(F)$, and how would affect the institution. Those features can appear at different levels of the scale of didactic codetermination (Chevallard, 2002).

Backwards analysis: It essentially consists in explaining the origin of $CDP_I(F)$, and thus, it is connected to the following questions: 'Can $CDP_I(F)$ be regarded as a reaction to a previous paradigm, $ADP_I(F)$?', 'How was this $ADP_I(F)$?', 'How are the didactic phenomena, $AD\varphi_I(F)$ that $CDP_I(F)$ tries to avoid?', 'How to describe $AD\varphi_I(F)$ in terms of $CDP_I(F)$?', 'Are $AD\varphi_I(F)$ really avoided by $CDP_I(F)$?', 'Why are $AD\varphi_I(F)$ non-desirable by the didactic institution I in current times?'

In summary, the didactic analysis of a current modality of study of a certain field of knowledge at a certain institution entails, along with a interpretative analysis, the analysis of a hypothetical past and a possible future, which help to *interpret* the origin and a possible development of $CDP_I(F)$.

Sketch of a diachronic analysis of the current modality of study of the real numbers in the research of mathematics

We will briefly consider the case $CDP_{ResMath}(\mathbb{R})$, where the field of knowledge is that of real numbers, $F=\mathbb{R}$, and the didactic institution is the one formed by Research in Mathematics (included the Degree in Mathematics, regarded as a tool to educate possibly future mathematicians), written I=ResMath. Of course, space restrictions will only allow a sketch of what would be a complete didactic analysis of $CDP_{ResMath}(\mathbb{R})$. In this sketch the emphasis is made on the epistemological model, which is typically the entrance door for the didactic analysis of a modality of study.

Let us first show some features of the antecedent didactic paradigm, $ADP_{ResMath}(\mathbb{R})$, mainly concerning the antecedent epistemological model $AEM_{ResMath}(\mathbb{R})$. We could say that irrational numbers were used, until well into the 19th century, as a *paramathematical* object, in the sense of Chevallard (1985). Indeed, the institution ResMath was happy with a merely practical use of the idea of irrational number, without going deep into the meaning (Edwards, 1979). The use of $\mathbb{R}$ was based on geometric intuitions concerning the magnitudes length and area. However, a worrying didactic phenomenon, $AD\varphi_{ResMath}(\mathbb{R})$, happened. Indeed, the appearance of mistakes and paradoxes, the difficulty in proving some elementary results of mathematical analysis, and the loss of the status of truth of geometry (due to the discovery of non-euclidean geometries), led ResMath to look for a more solid foundation of $\mathbb{R}$. This is how the so-called *arithmetization of analysis* started (Kline, 1990).

Let us illustrate the kind of problems connected to $AD\varphi_{ResMath}(\mathbb{R})$ by showing two mistakes that took place during the 19th century. For much of the 19th century, it was wrongly accepted in ResMath that every continuous function was differentiable at every point, except for, perhaps, at some isolated points. Some books even pretended to prove this fact. In this context, the example presented by Weierstrass in 1861 of a function that is continuous on the whole real line but not differentiable at any point was a great surprise. Apparently, already in 1834 Bolzano showed an example of such a function, but it was overlooked (Edwards, 1979). On the other hand, in a paper published in 1869, Charles Méray pointed out a circular reasoning accepted in ResMath since the time of Cauchy: the limit of a sequence was defined as a certain real number, but, at the same time, a real number was defined to be the limit of a certain sequence of rational numbers (Boyer & Merzbach, 2011).

To avoid the phenomenon $AD\varphi_{ResMath}(\mathbb{R})$ that was taking place in $ADP_{ResMath}(\mathbb{R})$, ResMath constructed the current didactic paradigm, $CDP_{ResMath}(\mathbb{R})$, in which the process of arithmetization of analysis was carried out. The culmination of this was in the year 1872, with the simultaneous publication of four constructions of real numbers in purely arithmetic terms by Dedekind, Cantor, Méray and Heine (Edwards, 1979). These constructions are part of the $CEM_{ResMath}(\mathbb{R})$.

Among the constructions of $\mathbb{R}$, the most extended ones are the Dedekind cuts (due to Dedekind) and the equivalence classes of Cauchy sequences of rational numbers (due to Cantor). As can be checked by consulting the standard bibliography of elementary courses in mathematical analysis in the Degree

in Mathematics (e.g. Apostol, 1991; Rudin, 1976; Spivak, 2008), the introduction of real numbers is as follows: (1) one constructs the field $\mathbb{Q}$ from the set of natural numbers; (2) one proves that $\mathbb{Q}$ is archimedian but not complete (as there are non-empty and upper bounded subsets of $\mathbb{Q}$ with no supremum); (3) one constructs (e.g., by using Dedekind cuts) an extension of $\mathbb{Q}$, called $\mathbb{R}$, which is an archimedian and complete field; (4) one proves that this extension is unique up to isomorphisms. It is also important to mention that the operations in $\mathbb{R}$ are based on those of $\mathbb{Q}$, and, in turn, the operations in $\mathbb{Q}$ are not shown to be as they are due to arguments using magnitudes, but rather they are defined axiomatically. Axiomatic definitions and avoidance of non-deductive arguments are distinctive features of the current epistemological model, $CEM_{ResMath}(Math)$, in ResMath not only concerning $\mathbb{R}$, but the whole discipline of mathematics, Math. This shows that sometimes (we would even say "frequently"), in order to understand a current didactic paradigm for the study of a certain field of knowledge, one has to pay attention to didactic paradigms at higher levels of the scale of didactic codetermination, see (Chevallard, 2002). Hence, in this case, some features we encounter in our analysis of $CDP_{ResMath}(\mathbb{R})$, which is at a sub-disciplinary level, are consequences of some features living at $CDP_{ResMath}(Math)$, which is at a disciplinary level.

The current didactic paradigm, $CDP_{ResMath}(\mathbb{R})$, has among its didactic ends the avoidance of $AD\varphi_{ResMath}(\mathbb{R})$, and this is done. However, a new didactic phenomenon, $CD\varphi_{ResMath}(\mathbb{R})$, appears: lack in the current epistemological model, $CEM_{ResMath}(\mathbb{R})$, of a *raison d'être* for the apparently artificial constructions of $(\mathbb{R}, +, \cdot, \leq)$, with the unanswered question of why decimal expressions are not enough; disappearance of the working with magnitudes in the current epistemological model, $CEM_{ResMath}(\mathbb{R})$; and authoritarian didactic means $CDM_{ResMath}(\mathbb{R})$.

We wonder, as researchers in didactics, how to avoid this didactic phenomenon, $CD\varphi_{ResMath}(\mathbb{R})$, how to construct a reference didactic paradigm, $RDP_{ResMath}(\mathbb{R})$, having among its didactic ends that of avoiding $CD\varphi_{ResMath}(\mathbb{R})$. The idea is that it should be coherent with the idea of mathematics regarded as a modelling activity (Gascón & Nicolás, 2021a), which would allow to connect $\mathbb{R}$ with magnitudes. The $RDP_{ResMath}(\mathbb{R})$ is still under construction, but we already have constructed the reference epistemological model $REM_{ResMath}(\mathbb{R})$. The idea is to understand real numbers as general decimal numbers (finite or infinite, periodic or non-periodic). Positive real numbers can represent measurements of certain objects with respect to specific magnitudes (such as length, area, etc.). These objects may be physical (like a rope) or ideal (like a geometric entity, such as the diagonal of a square). The methods for operating with positive rational decimal numbers, as well as their properties, can be easily explained in terms of measuring magnitudes. On the other hand, one can prove that real numbers (considered as decimal numbers), together with lexicographical order, satisfy the least upper bound property. Using this property, addition (and similarly, multiplication) of two positive real numbers is defined as the supremum of the sums (or products) of the positive rational numbers obtained by truncating the original real numbers. These operations turn out to satisfy the desired properties. When these operations are extended to the entire $\mathbb{R}$ while preserving these properties, the sign rules can be deduced, resulting in a totally ordered complete field (Espín et al., 2024).

This $REM_{ResMath}(\mathbb{R})$ seems to avoid $CD\varphi_{ResMath}(\mathbb{R})$ since: (1) it bases the operations of $\mathbb{R}$ in those of $\mathbb{Q}$ which, in turned, are based in magnitudes; (2) it avoids the artificial construction of $\mathbb{R}$ (for instance, in term of Dedekind cuts on the rational numbers), as it identifies real numbers with certain decimal

expressions. Thus, this $REM_{ResMath}(\mathbb{R})$ seems suitable for a $RDP_{ResMath}(\mathbb{R})$ having among the didactic ends $RDE_{ResMath}(\mathbb{R})$ that of avoiding $CD\varphi_{ResMath}(\mathbb{R})$. Notice that, a priori, many different types of didactic means, $RDM_{ResMath}(\mathbb{R})$, are compatible with this epistemological model $REM_{ResMath}(\mathbb{R})$. Which is the most suitable would depend on the whole set of didactic ends $RDE_{ResMath}(\mathbb{R})$.

It is also worth mentioning that the modality of study ruled by this new paradigm could give rise to new unexpected didactic phenomena, hard to predict now.

Conclusion and open problems

The diachronic analysis of the current modality of the study of a certain field of knowledge F at a didactic institution I not only describe this modality of study, and proposes a change of paradigm, but also explains why the current modality of study is as it is. We have illustrated this with the case of the study of real numbers in the institution of Research in Mathematics. Thus, we have explained why certain apparently artificial constructions of $\mathbb{R}$ are still taught, and why magnitudes are missing, and we have sketched a paradigm to support an alternative modality of study of $\mathbb{R}$.

If we interpret the diachronic analysis as a procedure to investigate modalities of study, a huge range of research problems opens up before us. Let us propose just three examples connected with the investigation of antecedent didactic paradigms that could explain certain didactic phenomena:

- Concerning the current modality of study of *proportionality* in Secondary Education, why is proportionality interpreted as a purely arithmetical relationship between numbers, segregating it from the rest of the functional relationships, instead of considering it as a functional relationship between quantities of magnitude whose study requires the systematic use of algebraic instruments?
- Concerning the modality of study of analytic geometry in Secondary Education, why does it concentrate on the resolution of quasi-algorithmic problems whose data are given in a transparent and unmodifiable reference system, instead of connecting it with the problem of synthetic geometry and aiming at the study of geometric systems expressed with the use of parameters?
- Concerning the modality of study of *differential calculus* in the step from Secondary to Tertiary Education, why does it prioritize technical work aimed at studying the characteristics of a few types of functions, instead of proposing differential calculus as a tool for building functional models of systems of all kinds, working on them, and interpreting the results obtained in terms of the modelled system?

The answer to these questions, and many others of the same type, would require constructing in each case a hypothetical antecedent didactic paradigm to be compare with the current didactic paradigm and to get an explanation for those phenomena.

Crisis-driven transformation in tertiary mathematics – A case study connecting TTE and ATD

Lukas M. Günther[1], Jana Peters[1], Reinhard Hochmuth[1]

[1]Leibniz University Hannover, Germany; guenther@idmp.uni-hannover.de

This paper examines the potential for connecting the Theory of Transformative Education (TTE) and the Anthropological Theory of the Didactic (ATD), with a case study serving as the basis for this investigation. On the one hand, using TTE an individual perspective of a mathematics student in her inaugural semester is taken, whereby specific moments of a crisis and a reaction can be worked out on an individual and socio-cultural level. On the other hand, the mathematical content dimension of the crisis based in the courses Analysis I and Linear Algebra I is analysed using ATD. Based on the findings, assumptions can be made as to why the student fails the crisis and does not undergo a mathematical enculturation.

Keywords: Enculturation, Theory of transformative education, Anthropological theory of the didactic, Networking of theories, Biographical-narrative interviews.

Introduction

As part of a research project at University of Hannover, the socio-cultural transition from school to university mathematics was analysed from the perspective of the Theory of Transformative Education (TTE; Günther & Hochmuth, 2023; Günther, i.p.; Koller, 2023). Here, the transition is understood as a transformation of a culturally shaped relation of an individual to the mathematical world, to others, and to oneself. Individual crisis in the confrontation with the unfamiliar university mathematics culture can override the routines of action familiar to first-year students from school mathematics and can lead to a resignification of experienced explicit, implicit and social school or university mathematics knowledge. In TTE, such crisis are described by Lyotard's discourse theory (1989), with which the experience of crisis can be summarised as a conflict of incommensurable discourses. Using TTE, the mathematical world can be grasped in significant subject-related moments. However, the addressed mathematical actions and knowledge elements remain abstract. This is not a deficit of this specific approach but a general characteristic of educational theories. To further investigate these actions and knowledge, we draw on the Anthropological Theory of the Didactic (ATD) and its notions when concretising relevant aspects of the mathematical world from the perspective of the subjects. In our opinion, this is fruitful because, among other things, ATD and TTE adopt a dialectical view on the relationship between the individual and the institutional-social. We will demonstrate the fruitfulness of a methodological connection between the two approaches using a case study based on an interview excerpt.

In the following, we will briefly introduce our vantage point, TTE and its perspective on university mathematics. A case study that has raised an interesting phenomenon in the context of this theory is then presented and analysed within TTE. This is combined with an ATD analysis of the corresponding excerpt from the teaching materials from the Analysis I lecture. Finally, we will conclude with a discussion on the connections between the two perspectives in terms of an initial local integration (Prediger, 2008).

University mathematics in the perspective of TTE

Based on a range of theoretical perspectives, TTE is an approach widely used in the German educational sciences to describe education (as in the German notion of *Bildung*) as a transformation of a culturally shaped relation of an individual to the world, to others, and to oneself in that world (Koller, 2023). From that perspective and in alignment with a socio-cultural understanding of mathematics (e.g. Prediger, 2004) mathematics is to be understood as a socio-cultural space that mediates dispositions of perception, thought and action required for interactions (Bourdieu, 1985). The subject (e.g. a student) is constituted in this social context of mathematics by replicating the dispositions and hierarchy of social power within interactions (Butler, 2001), thereby acquiring a position in the social space of mathematics relative to others (e.g. peers, lecturers). This positioning determines the subject's possibilities and limits of perception, thought and action (Oevermann, 1991). The constitution of the subject is thereby always contingent upon interactions with others who are part of the mathematical world. The subject's relation to themselves and its dynamic and structuring is on the one hand dependent on the relationship to others, on the other hand marked by a fundamental misrecognition and deception of this dependency (Lacan, 1975). It can be argued that dependence on others must be denied just as much as the difference between oneself and others. With regard to mathematics, this is evident in the constant feedback loops between the subject and others that take place in the various formal and informal interaction spaces and in which each member of the social space must constantly reposition themselves in relation to others and the world (Günther, i.p.). The resulting "condition of possibility for the questioning and shifting of established meanings as well as for the emergence of new meanings" (Koller, 2023, p. 54) opens the possibility of transformation.

Accordingly, a certain mathematical world – it being school, university or academic mathematics – conveys specific mathematical dispositions in the form of explicit, implicit and social mathematical knowledge, and thus can be understood as representing a specific socio-cultural space. The transition between two such mathematical worlds, e.g. from secondary to tertiary mathematics, can be described as an intercultural, processual transformation. But also transitions within such a world, e.g. between different courses or areas of content, can require the adaptation to different cultural knowledge (Hochmuth et al., 2021). The subject must either discard or alter their established dispositions or evolve new ones to develop a system of dispositions that is appropriate to the specific mathematical context and, thus, to become integrated into a new socio-cultural space of mathematics. If this process is successful, we may describe the subject as having been enculturated (Bishop, 1988) into a specific culture of mathematics. This transformation process is initiated by crises (Clark & Lovric, 2008). They emerge through confrontation with problematic situations in which the established mathematical dispositions are overridden and new/other dispositions are required for further actions. Since the subject's engagement with mathematics cannot be fully determined, the emergence of crises is individual and emergent but also unpredictable and uncontrollable from a pedagogical perspective.

TTE allows for various ways of describing crises as triggers of transformations (Koller, 2023). Günther and Hochmuth (2023) used the notion of experiences of foreignness (Waldenfels, 1997), whereby possible reactions of students were described as rejecting, assimilating or (re)productive. Expanding on this, a discourse-analytical perspective will be adopted here. According to Lyotard (1989), "discourses" (p. 9 & 59) are systems of rules governing the combination of sentences,

each serving a specific purpose and involving referent, sense, receiver, and sender. When discourses with distinct sentences and rules interact, they cannot be combined, compared, or reconciled. They are incommensurable, leading to inevitable conflicts, so-called "differend[s]" (p. 9). Lyotard distinguishes those from "litigation" (p. 9), conflicts that can be resolved within the same discourse. He emphasises the importance of keeping differends open and searching for new idioms of expression to avoid silencing the affected party (pp. 32–36). Within TTE crises can thereby be understood as differends of incommensurable discourses which require a productive reaction in the form of a search for new idioms.

Based on this understanding, establishing new mathematical knowledge can be considered a process with three phases: (i) The experience of a crisis initiates a protracted phase of engagement with the differend and a gradual search for new ways of acting and thinking. (ii) This results in the abrupt manifestation of mathematical dispositions in the form of potential actions within the social domain of mathematics that have not yet been actualised. (iii) This is followed by a longer phase of further development and adaptation towards new dispositions of the self-other-world relation. Thus, new mathematical knowledge arises from the divergences between the discourses and can be comprehended as resignification of cultural possibilities for action in mathematics. The advent of new self-other-world relations can be understood as a culmination of social constituted signifying practices that reiterate and adapt established relations in unfamiliar contexts.

Following, we present a case study in which the TTE perspective is used to analyse a problem situation of a student in the first semester of tertiary mathematics.

The case study Johanna

In a series of interviews conducted with first-semester mathematics students at the University of Hannover, the student Johanna (pseudonym) reports on a crisis that was analysed from the perspective of TTE. The following section is part of a longer discussion of the two courses, Analysis I and Linear Algebra I. In brief summary of the interviews, Johanna largely identifies with the discourse of logical and deductive development of theory in Analysis I, whereas she describes the discourse of Linear Algebra I as chaotic and less accessible. Furthermore, Johanna states that both lecturers in Linear Algebra I and Analysis I made references to each other's subjects, which resulted in confusion and a sense of crisis for her (Günther, i.p.).

> Joh.: So maths is somehow still a lot like that, this yes, and then they also do it in a similar way in Analysis, and they do it in a similar way in linear Algebra, and it somehow blurs like that and then somehow not really. And I also noticed that the other day in calculus our professor said, yes, you work with matrices in linear algebra. Why don't you tell me what- what- uh linear function translates to a uh matrix. I look at him like this. What are you talking about, what translates to where? So that has - oh, that has something to do with it? and that's just this – I've also realised a bit... In maths at the moment I'm not looking at how much I enjoy this subject, but how good - how good is the professor (translated by the authors)

In this segment, Johanna refers to what she sees as the two incommensurable discourses in the Analysis I and Linear Algebra I courses, as she has already done in previous sections of the interview series. The professor's attempts to establish links between the subject matters of Analysis I and Linear Algebra I, especially regarding the use of matrices, are met with a lack of understanding by Johanna,

as she makes clear by retrospectively asking the lecturer questions in direct speech. From the perspective of TTE and taking other interview sections into account, the lecturer's attempt to establish a link to Linear Algebra I can be interpreted as an idiom for expressing and advancing the argumentation of Analysis I with the help of Linear Algebra theorems, but also – from a cross-curricular and educational perspective – to illustrate larger connections between the different discourses of mathematics. However, for Johanna, the idiom employed by the professor is unable to establish a connection between her receptions of the discourses of Analysis I and Linear Algebra I, leaving them incommensurable which is made clear by the crisis developing here. At the same time, the link presented is provided with a claim of truth through the representation of the mathematical world by the lecturer. Nevertheless, Johanna's reaction can be interpreted as a transformation of the resulting differend into a litigation in favour of her own perception of the two discourses. Given Johanna's disposition of self-assured demeanour as evidenced in various segments of her interviews, this inability to connect the discourses is attributed by her to the quality of the teaching, rather than to a lack of interest, understanding or enjoyment on her part. The lecturer in particular is to blame for not addressing Johanna's interest or understanding during the discussion of content (cf. Günther, i.p.).

The concise presentation of the TTE analysis illustrates Johanna's perspective in relation to the depicted situation, whereby crises and transformations at specific points in her engagement with mathematics can be elucidated. In the following section, we will examine the content-related aspects of the Analysis I and Linear Algebra I courses that Johanna refers to in the aforementioned segment and led to her crisis, based on the materials presented in the lectures and the perspective of ATD.

The case in the perspective of ATD

ATD is a research programme (Chevallard, 2019) that allows mathematical practices to be analysed from two intertwined perspectives (Winsløw et al., 2014): *The institutional dependence of mathematical practice* states that institutional conditions influence which mathematical actions and which associated mathematical reasoning discourses are appropriate. This allows an external perspective that focuses on those conditions, that can vary across institutions. The internal perspective focuses on concrete mathematical subject matter, which is modelled as *praxeologies* that depend on the respective institutions. A praxeology consists of two interrelated components: The *praxis component* and the *logos component*. Praxis is made of *types of tasks T* and of *techniques* τ, that is, ways of performing the tasks. Logos contains two levels of justification discourse. At the first level *technology* θ describes, justifies, explains, etc. the technique. At the second level, *theory* Φ organises, supports and explains technology. In ATD, institutional conditions are differentiated in relation to certain social levels and modelled with the levels of codetermination (Artigue & Winsløw, 2010). The social mediation of mathematical actions is thus already inherent in ATD but is not further differentiated with regard to the specific organisation of this mediation. The two intertwined perspectives on mathematical practice make a connection between ATD and TTE seem fruitful to us. In the following, we illustrate connections between ATD and TTE using the case of Johanna mentioned above. To illustrate the ATD perspective and for examples of praxeological analyses, we refer to the work of Winsløw et al. (2014). They describe a general praxeological model of the transition from school mathematics to university mathematics and then further within university mathematics. When students transition from school mathematics to university mathematics, the

praxeologies of the student acquired at school must change to become consistent with university mathematics praxeologies. An important part of the Winsløw et al. (2014) model for our considerations here is the new meaning of the logos component of praxeologies for mathematical practices at university. In university mathematics the logos component of mathematical praxeologies must be (further) developed by the student. It can't be compared with school, where it is essentially the teacher who connects mathematical notions through logos aspects. The second transition takes part, when in more advanced courses, former logos elements become new objects of students' praxis.

Definition 35.1. A function $f : D \subseteq \mathbb{R} \to X$ is called differentiable at the point $x_0 \in D$ if there exists a continuous map $A : \mathbb{R} \to X$ as well as a function $r : -x_0 + D \to X$ such that for all h with $x_0 + h \in D$, the following holds:

$$f(x_0 + h) = f(x_0) + Ah + hr_{x_0}(h)$$

where r_{x_0} is continuous at 0 with $r_{x_0}(0) = 0$.

Remark 35.3. We can regard the continuous linear mapping $f'(x_0)$ as a 1×1 matrix (with respect to the bases $\{1\}$ of $\mathbb{R}$ and $\{1\}$ of X) and identify them with its entry $f'(x_0) \in X$. All linear mappings from $\mathbb{R}$ to $\mathbb{R}$ or $\mathbb{C}$ are continuous.

Figure 1: Definition and remark from the Analysis I lecture notes (translated by the authors)

The situation addressed by Johanna in the interview relates to the definition of differentiability formulated in the Analysis I course attended (Figure 1). The version favoured for school mathematics, i. e. the differential quotient, is not used here. In the definition (see Definition 35.1. in Figure 1), the limit value is hidden in the continuity condition for the function r. The expression for the differential quotient can be obtained by dividing the equation by h. In relation to Linear Algebra, the following special features can be identified: (1) The definition speaks of a continuous linear mapping A, which is denoted in the equation by Ah and not by $A(h)$. The expression recalls that a linear mapping from $\mathbb{R}$ to $\mathbb{R}$ can be represented by a real number (in the complex case, i.e. $X = \mathbb{C}$, by a complex number), whereby in $\mathbb{R}$ the canonical basis with basis vector 1 is taken as a basis (technique). (2) Within the standard discourse at school, this would be seen as an inadequate technique. On the one hand, it would be argued that a clear distinction should be made between mappings and numbers, which can also be seen as a permissible criticism of the chosen formulation in university discourse. (3) On the other hand, this was clarified in the lecture (as mentioned by Johanna) by referring to the connection between matrices and linear mappings in Linear Algebra. A corresponding reference can be found on the same page as the definition of differentiability in the Analysis I script (see Remark 35.3 in Figure 1). We will now reflect on the connection assumed in the Analysis I script and presumably explicated in the lecture with the knowledge covered in Linear Algebra I: (1) There, as usual, the relation between matrices and linear mappings is treated in detail. However, no special reference is made to the 1-dimensional case, which is the case here. It may therefore come as a surprise that a number is written as a 1×1 matrix, albeit without matrix brackets, and is therefore interpreted as a linear mapping. (2) Fundamentally, the question of the underlying basis, regarding which the number represents a linear mapping, should also be discussed.

To summarise, it can first be stated that the reference to Linear Algebra I addressed here is not immediately clear and requires independent reflection on content and notation, which can be located in the logos component of mathematical praxeologies. Within the school discourse of mathematics, it is usually the responsibility of the teacher to foster connections within logos components of praxeologies. If such connections are missing, one would speak of a teaching deficit in the school

discourse in view of the hurdle and the effort required to overcome it. In the university mathematics discourse, it represents an (intended) learning opportunity. Fostering such connections becomes a responsibility of the student at university, therefore former logos aspects transition to the praxis component within the university mathematics discourse. With her criticism, Johanna positions herself within the school discourse.

A complementary perspective on Johanna

The helplessness and disorientation expressed by Johanna indicates that she does not see dealing with the discursive difference as a responsibility of herself. From an ATD perspective it is not possible to determine whether she is unable to recognise the gap as a responsibility and therefore does not mobilise any techniques to deal with it, or whether she does not have the techniques at her disposal. Looking back on the TTE analysis of the interviews, Johanna would – in principle – have had the opportunity to elucidate her problem in informal discussions with her fellow students, her tutors or the lecturer. The fact that she does not engage in this approach but instead adheres to the school discourse is a sign of failed or yet not experienced enculturation into university mathematics. This prompts the question of why Johanna possibly failed to capitalise on the opportunity, which, beyond what has already been concluded, is no longer the primary focus of the ATD. With TTE, however, it becomes clear that Johanna's actions throughout the semester are characterised by a distinct self-imposed requirement to work independently. She defines her success at school and subsequently in university mathematics by establishing a clear distinction between herself and her fellow students. She attempts to elevate her positioning within the social space of university mathematics through her achievements. The TTE perspective also indicates that the actions undertaken by Johanna are based on a relatively stable and robust conceptualisation of the nature of mathematics and the characteristics of mathematical activity. This conceptualisation cannot be reconciled with the cultural circumstances of the university mathematics she encounters. The nature of these ideas indicates that they possibly serve as a stabilising force for Johanna. This might be interpreted within TTE in Lacanian terms, as within the hysterical discourse a subject "seeks to be determined by the other, turns to him, desires his desire in order to present himself as his object" (Widmer, 1990, p. 138). As a result, the subject is more concerned with the symbolic value of the object and will never be able to understand its very essence. This becomes apparent as the questioning of Johanna's own dispositions, and the necessary transformation and generation of new ones would be associated with a destabilisation of the established structure. For Johanna this would result in a more profound crisis based on her relation to the mathematical world and herself. Thus, a resignification of existing knowledge (in the sense of praxeological equipment, as shown in the following) cannot take place in this way. For this, in the sense of the first part of the transformation process, the problem would have to be worked through slowly, i.e. in a time-consuming manner, which is not encouraged at school. However, in school it is considered successful if it is done quickly and teaching is considered good if this is prepared accordingly. E.g. the technology is ready with the students and a problem does not have to be prepared technologically, which not only requires having technology, but also having to endure the fact that it is not clear a priori how and what (Winsløw et al. 2014, p. 100). In addition, the discussion and action on the technology level is a new disposition or was demonstrated at school at best by the teacher, less formally and, for example, based on basic ideas (Hochmuth et al., 2024). This also happens at

university. However, the didactic contract applicable to the course stipulates that students understand and critically reflect on this. Ideally, exercises should support this process. However, this would require freedom of studying and time. Recordings from the exercises at least suggest that they are well organised and that so-called face-to-face exercises, which are less technologically demanding, are worked on with the understandable aim of practicing techniques. This at least indicates that the transition to university mathematics not only creates something new but also necessarily resignifies previous knowledge, here in particular aspects of the school mathematics logos component.

Conclusion

We have taken a case study as the starting point for two different perspectives on a problem situation of Johanna, a first-semester mathematics student. By using TTE, it was possible to work out the specific point of a personal crisis in the interaction with mathematics in the extensive material of the interview series and to present Johanna's perspective as well as the socio-cultural context of this problem. The ATD analysis then focused the mathematical content in Johanna's statements in relation to the institutional context. This allowed us to elaborate Lyotard's abstract discourse-related characteristics. The typology of the discourses was then used to emphasise their emerging constellation, which could then be traced back to the mathematical content modelled using ATD. This tracing back and the interrelation of the elements thus revealed in the discourse goes beyond the scope of possible statements within the framework of ATD. On the other hand, the content and the specific institutional context of the discourse could not be reconstructed with TTE alone. Rather, the specific structuring of the discourse represents an institutional-societal possibility. The generalisability of our interpretation is also located at this level: it formulates conditions and restrictions that enable and determine the specific constitution of the mathematical content. TTE and ATD formulate statements at an institutional-social level, which, we can't work out in detail, for reasons of space alone, and appear compatible in this respect. We think that our results demonstrate the fruitfulness of connecting the two.

Didactic transposition of structuralist praxeologies at the interface between analysis and topology: a case study

Thomas Hausberger[1], Reinhard Hochmuth[2] and Erik Hanke[2]

[1]University of Montpellier, Alexander Grothendieck Montpellier Institute, Montpellier, France

hochmuth@idmp.uni-hannover.de

Mathematical reasoning based on structures is important for the transition from beginner to more advanced mathematics: it reflects the epistemology of the body of mathematical knowledge in more advanced mathematics courses that progresses from local reasoning about particular instances of classes of objects to more global reasoning about underlying mathematical structures through historically endorsed abstraction. We examine this type of argumentation in the sense of "structuralist praxeologies" at the interface between analysis and topology, taking as an example the equivalence of the continuity of a real-valued function on the real line with the path-connectedness of its graph. In particular, we identify phenomena of external didactic transposition in the context of options for reasonings and their implementation.

Keywords*: Structuralist praxeologies, didactic transposition, analysis, topology, continuity.*

Introduction

A significant aspect of the transition between calculus and analysis or elementary and abstract algebra is a change in attention from the concrete (e.g., specific functions or arithmetic properties) to the abstract (e.g., theorems about function spaces or abstract rings) (Hausberger, 2018; Winsløw, 2008). A similar issue arises at the interface between analysis and topology. Here, undergraduate mathematics education may foster reasoning based on mathematical structures (e.g., topological properties of metric spaces) rather than merely concretising and thus redeveloping such reasoning locally each time (e.g., arguing for a specific metric space). Emphasising this transition from the concrete to the abstract may thus ultimately raise students' awareness for the relevance of structural reasoning, and this reasoning reflects the historical evolution of mathematical domains such as abstract algebra, real analysis, or topology.

In this paper, we continue our previous work in this direction (Hanke, 2018; Hausberger & Hochmuth, 2023). More concretely, we focus on the role of mathematical structures in *external didactic transposition* (EDT; Bosch et al., 2021): external didactic transposition refers to the process of selecting, adapting, organizing and declaring the knowledge to be taught—beginning from scholarly knowledge and ending with all the teaching materials that can be proposed in a given course. In this process, a series of textbooks, drawing on previous textbooks, can be used to analyse the EDT on specific topics. While Bosch et al. (2021) analysed EDT regarding the organisation of entire study programs in a cross-national comparison, we examine here more local phenomena based on an example at the interface between analysis and topology. Specifically, we analyse the presentation of the following equivalence in a textbook by Ross (2013, p. 182): *for an interval* $I \subseteq \mathbb{R}$*, a function* $f: I \to \mathbb{R}$ *is continuous if and only if its graph* $\Gamma_f = \{(x, f(x)) : x \in I\}$ *is path-connected.*

Occasionally, this equivalence is presented as an exercise in topology courses (for the case of $I = \mathbb{R}$ in Gathmann, 2023, pp. 25–26), and Hanke (2018) examined it in this context (thus considering the next step of *internal didactic transposition*, including the everyday teaching experience, which leads to the actually taught knowledge). However, this task could also be dealt with in analysis courses. It is thus a case for a topic at the interface between analysis and topology, which can arise at different moments in a study programme. As a result, several options for the presentation of the equivalence open up and textbook authors must make choices regarding the selection, adaptation, and organisation of elements of reasoning. To shed light on the role of mathematical structures in the choices made by Ross (2013), we will draw on the model of structuralist praxeologies examined by Hausberger and Hochmuth (2023) and analyse them against the background of further texts for analysis and topology as well as research literature. In doing so, we exemplarily answer the following research question: "Which phenomena in terms of structuralist praxeologies arise in the context of external didactic transposition considering thematical and organisational issues in study programmes (in our case, the interface between analysis and topology)?"

Theoretical framework and method

The *Anthropological Theory of the Didactic (ATD)* analyses relationships to an object of knowledge by praxeologies where the object intervenes at the level of at least one of the following components: "The anthropological theory of didactics considers that, *in the end*, all human activity consists of *accomplishing a task* t of a certain *type* T by means of a certain *technique* τ, *justified* by a *technology* θ which at the same time makes it possible *to think about* it, or even *to produce* it, and which is in turn *justifiable* by a *theory* Θ" (Chevallard, 2001, p. 3, own transl.).

In the context of abstract algebra, Hausberger (2018) introduced *structuralist praxeologies*: these are praxeologies $P_s = [T^g, \tau, \theta, \Theta_{\text{structure}}]$, where T^g is a generalisation of T in a not-yet-structural praxeology $P = [T, ?, ?, \Theta]$ (at least when compared with the structure for P_s), where it is unclear which technique to apply as we signify with ?. Here, structuralist refers to the use of structures in the sense of Bourbaki (e.g., mobilising results about general metric spaces rather than a specific metric space). In the type 1 transition from P to P_s, generally, the rationale of the praxeology P_s is still related to solving concrete tasks from P. We further distinguish between level 1 structuralist praxeologies, where structures mainly appear as vocabulary and through definitions, from *level 2* structuralist praxeologies, where a technique mobilises general results about the structures. A dominant level 1 type of task is "Show that X is Y (or has property p)", which can be achieved with the technique "Show that the definition of Y (or p) is fulfilled". A level 2 task may be to show a theorem about the technology used in a level 1 praxeology. In the teaching and learning of structures, a new stage is reached when praxeologies are based on purely abstract types of tasks that are anchored on reasoning with concepts originating in the logos of previously developed structuralist praxeologies P_s. This is called the type 2 transition, typically situated between the Bachelor's and Master's programmes.

The general view of structures thus allows to demonstrate properties of objects by making them appear as consequences of more general facts (theorems about structures). Conversely, generalisations are put to the test of objects, hence a *dialectical relationship between objects and structures*" (Hausberger & Hochmuth, 2023, p. 3). Through the interplay of didactic variables of tasks

(e.g., functions, domains and their properties) the dialectic of objects and structures is a dialectic of contextualisation and decontextualisation.

In the following, we use this praxeological model to analyse the choices made by Ross (2013) against the background of further literature from analysis and topology. In particular, we discuss options with respect to didactic variables (e.g., connectedness vs. path-connectedness, $\mathbb{R}^n$ vs. metric space, domains or codomains of functions) and reflect on reasons for choices regarding structuralist praxeologies in relation to aspects of the external didactic transposition.

Praxeological analysis of the example

To our knowledge, the equivalence is not widely presented in real analysis or topology textbooks. We will follow Ross (2013), van Rooij and Schikhof (1982), and a post from an online mathematics forum (JOJO, 2020). We also remark that characterising functions in terms of properties of their graph is a topic of still active research in topology and analysis (e.g., Wójcik, 2008), which considers many more properties than continuity and path-connectedness only.

Ross (2013) bases his proof on a characterisation of continuous functions by Burgess (1990) in a journal addressed to university teachers. In the latter, Burgess gives three properties characterising continuous real functions over $\mathbb{R}$, including the *connectedness* of the graph (*not* the path-connectedness) under the assumption that the graph is closed (see Figure 1). In the spirit of the dialectic of objects and structures, he shows that the general statement that connectedness of a graph implies continuity is not valid (1990, p. 339) by taking as a counterexample the function f defined on $\mathbb{R}$ by $f(x) = \sin x^{-1}$, $x \neq 0$, and $f(0) = 0$, which is discontinuous at 0 and has a connected graph. This motivates the additional hypothesis of *closedness* of the graph. Moreover, it is easy to prove that the graph of a continuous real function over $\mathbb{R}$ is closed. Interestingly, closedness is not necessary for the implication of the function's continuity under the hypothesis of path-connectedness. In fact, connectedness is a more general notion than path-connectedness (any path-connected set is connected but not the other way around) with better topological properties (e.g., the closure of a connected subset is still connected, unlike in the case of path-connectedness). This may explain why Burgess (1990), referring to a research paper by Moore (1920), does not consider path-connectedness, so that Ross (2013) had to adapt the proofs.

THEOREM. *If f: $\mathbb{R} \to \mathbb{R}$ has a closed graph in $\mathbb{R}^2$, then the following four conditions are equivalent*:

(a) *f is continuous.*
(b) *f is locally bounded.*
(c) *f has the intermediate value property.*
(d) *The graph of f in $\mathbb{R}^2$ is connected.*

Figure 1: The theorem from Burgess (1990, p. 338)

Ross uses vocabulary from topology (open, closed, compact, …), but the definition of a topological space and thus methods independent from the use of metrics are not developed. This corresponds to a certain learning stage in the analysis path, before topology is taught: multivariate analysis is based on the elaboration of $\mathbb{R}^n$ as a metric space that generalises the real line. Overall, Ross follows praxeologies from the context of metric space topology. This means, that open sets and continuity are characterised in terms of metrics, in particular, continuity is characterised by the well-known ε-δ- or

sequence-definitions. Connectedness is introduced in the last section of the chapter on continuity as an advanced topic (indicated by a star symbol) but it does not serve in any subsequent chapter.

The direct implication of the above equivalence points to an institutional type of task from a topology course T: *prove that a subset Y of a topological space X is path-connected*. Available techniques include τ_1: *show that the definition of path-connectedness* (the technology θ_1) *is fulfilled*, hence a level 1 structuralist praxeology from topology. Ross' (2013, p. 182) proof for this implication follows this line of argumentation: "If f is continuous, then for each $\big(a, f(a)\big)$ and $\big(b, f(b)\big)$ in $[\Gamma_f]$, $\gamma(t) = \big(t, f(t)\big)$ is a path connecting these points. Note that γ is continuous by Proposition 21.2". The latter proposition states that continuity of vector-valued functions is equivalent to the continuity of its component functions. It is based on properties of distances and the ε-δ-definition of continuity. On a higher level 2, structuralist theorems may be used, for example θ_2: *path-connectedness is preserved by continuous mappings*, in relation to the technique τ_2: *show that Y is the image of a path-connected set Z under a continuous mapping F*. With the above notations, we have $Y = \Gamma_f$. To apply the level 2 structuralist praxeology, supposedly the more powerful (economy of argumentation) and enlightening (mathematical understanding), the following values $F = \mathrm{id} \times f$ and $Z = I$ must be assigned. Another key element here is the technology θ_3: *intervals in* $\mathbb{R}$ *are the only path-connected subsets of the real line and vice versa*. A familiarity with product mappings and topologies is needed (a product of continuous mappings is continuous for the product topology), hence supplementary elements of logos from topology. It results from these two proofs that the task t is not a good example to underline the strength of the structuralist methodology: the first proof at level 1 is as economical in terms of length as the other, so that the gain of concepts and abstraction is not clear.

Burgess (1990) divides his proof of the theorem in Figure 1 into three lemmas, in particular (c) ⇒ (a) (lemma 2), and (d) ⇒ (c) (lemma 3), where the closedness of the graph of f is required in lemma 2 only (lemma 1 proves the implication (b) ⇒ (a)). The implication (a) ⇒ (d) (the graph of a continuous real function over $\mathbb{R}$ is connected) is not proved "since there are well-known easy proofs" (p. 338). Here, the author likely refers to the level 2 structuralist praxeology described above where path-connectedness is replaced by connectedness, which is equally preserved under continuous mappings. In the sequel, we continue examining lemmas 2 and 3 since our goal is to study structuralist arguments for (d) ⇒ (a) (a real function over $\mathbb{R}$ whose graph is connected and closed is continuous).

Lemma 3 is proved by showing first that $\Gamma_{f|[a,b]}$ (the graph of the restriction of the function to a compact interval) is connected if Γ_f is connected. However, Burgess (1990) does not give the details for the needed conclusion that f has the intermediate value property (IVP) afterwards. Probably, the previously mentioned level 2 structuralist praxeology is again left to the reader: by projecting to the second coordinate, we get that $\{(x, f(x)) : x \in [a, b]\}$ is also connected (the projection is continuous), hence an interval, so the IVP is fulfilled.

Ross partly follows this sequencing and begins his proof by showing that the path-connectedness of Γ_f implies that $\Gamma_{f|[a,b]} \subseteq \gamma([0,1])$, where $\gamma(t) = \big(x(t), y(t)\big)$ defines a path connecting $\big(a, f(a)\big)$ and $\big(b, f(b)\big)$. He then uses properties of a certain supremum and infimum and the continuity of x to show that $x([\alpha, \beta]) = [a, b]$ for some $\alpha < \beta$ in $[0,1]$ such that $x(\alpha) = a$ and $y(\beta) = b$ (see Figure 2). The application of the intermediate value theorem (IVT) to $y(t) = f\big(x(t)\big)$ yields the IVP.

Let $\alpha = \sup\{t \in [0,1] : x(t) \leq a\}$ and $\beta = \inf\{t \in [0,1] : x(t) \geq b\}$. Thus $0 \leq \alpha < \beta \leq 1$. Since $x(t)$ is continuous, we see that $x([\alpha, \beta]) = [a, b]$. Now we apply the Intermediate Value Theorem again, this time to $f(x(t))$ on $[\alpha, \beta]$. Since $f(x(\alpha)) = f(a)$ and $f(x(\beta)) = f(b)$, we have $f(x(t)) = c$ for some t in (α, β). For this t we have $x(t) \in [a, b]$, so we have verified IVP.

Figure 2: Ross' (2013, pp. 182–183) proof of the path-connectedness of a restriction of the graph[1]

In fact, an affine reparametrisation of $[\alpha, \beta]$ to match $[0,1]$ may be used to produce a path inside $\Gamma_{f|[a,b]}$, which shows that $\Gamma_{f|[a,b]}$ is path-connected. The structuralist input that path-connectedness of graphs of real functions is preserved by restriction of the function to a compact interval is interesting per itself (and equivalent to proving the IVP), but it is not emphasised since the primary goal is the IVP. Moreover, Ross could have used Burgess' proof since Γ_f is path-connected hence connected. It seems that Ross decided to totally avoid connectedness (for reasons see above) although the latter notion brings a simpler proof for the property that relates to restrictions of mappings.

In fact, Burgess explains that he introduced the IVP since he did not find such a characterisation of continuity in textbooks and "it is my main purpose in this note to present an elementary proof" (1990, p. 337). Complementarily, he stresses that, on a more abstract basis, the equivalence of continuity and connectedness and closedness of the graph for real functions "follows from the characterization of a topological line as a locally compact metric space that is separated into two connected sets by each of its points" (p. 337). We see these choices and comments as signs of the didactic transposition operated from the scholarly structuralist practice that serves as a reference, while elementarisation of proofs is a key driver for the didactic transposition. More precisely, Burgess points to a paper by Moore from 1920. Contemporary mathematical research (e.g., Wójcik, 2008) about the characterisation of continuity of functions between topological spaces in terms of properties of their graphs helps to clarify further the situation from a structuralist point of view: topologists define a *connectivity function* by the property that the connectedness of the graph of the function is preserved by restriction of the latter to any connected subdomain (Wójcik, 2008, p. 5). Burgess has then proved that a real function with a connected graph is a connectivity function. Moreover, it is known that a connectivity function $f: \mathbb{R} \to Y$ to any topological space Y has a locally connected graph at a point $\big(x, f(x)\big)$ if and only if it is continuous at x (Wójcik, 2008, Thm. 4). In other words, local connectedness of the graph rather than its path-connectedness enlightens the property of continuity whenever the domain is $\mathbb{R}$ but the codomain is generalised to any topological space.

Burgess' proof of lemma 2 is based on the negation of continuity at a point b to produce a sequence of points of the graph that converges to a point outside the graph (using the IVP) (see Figure 3). The same argument could be applied to the equivalence stated at the beginning of our paper, if we knew that Γ_f was closed. We can find such a proof in van Rooij and Schikhof's (1982) textbook: they provide a similar characterisation of the continuity of a real function by its graph, however, in the case of a compact domain $[a, b]$ (see Figure 4). As a matter of fact, in this case the path-connectedness

[1] In the argument the definition of β must be changed to $\beta = \inf\{t \in (\alpha, 1] : x(t) \geq b\}$.

of the graph implies that it is compact. The key structuralist ingredient is that compactness is preserved under a continuous mapping. As a consequence, the graph is closed and we may conclude that f is continuous on any compact interval, hence globally continuous as well.

Proof. Suppose that f is not continuous at $b \in \mathbb{R}$. Then for some $\varepsilon > 0$, there is a sequence $\{b_n\}$ converging to b such that, for each n, $|f(b_n) - f(b)| > \varepsilon$. For convenience, we assume that each $f(b_n) > f(b) + \varepsilon$. The intermediate value property implies that, for each n, there is a number c_n between b_n and b such that $f(c_n) = f(b) + \varepsilon$. Thus the sequence of points $\{(c_n, f(c_n))\}$ converges to the point $(b, f(b) + \varepsilon)$, contradicting the hypothesis that the graph of f is closed.

Figure 3: Proof of Lemma 2 in Burgess (1990, p. 338)

Van Rooij and Schikhof (1982) prove the three implications in Figure 4 by verifying the properties path-connectedness, compactness, and continuity each time going back to the definition (level 1 structuralist praxeologies). Moreover, their proof uses classical real analysis techniques on sequences and compactness.

THEOREM 8.2. *Let* $f : [a, b] \to \mathbb{R}$ *and let* $\Gamma_f := \{(x, f(x)) : x \in [a, b]\}$ *be*
(α) f *is continuous.*
(β) Γ_f *is compact.*
(γ) Γ_f *is arcwise connected.*
Proof. (α)$\Rightarrow$(γ). Let $(p, f(p)), (q, f(q)) \in \Gamma_f$ and let $a \leqslant p < q \leqslant b$. Let $\sigma : [0, 1] \to [p, q]$ be an increasing continuous function for which $\sigma(0) = p$, $\sigma(1) = q$, and let $\psi : [p, q] \to \Gamma_f$ be the map $x \mapsto (x, f(x))$. Then $\phi := \psi \circ \sigma$ is a continuous map $[0, 1] \to \Gamma_f$ with $\phi(0) = (p, f(p))$ and $\phi(1) = (q, f(q))$.

(γ)$\Rightarrow$(β). There is a continuous $\phi : [0, 1] \to \Gamma_f$ such that $\phi(0) = (a, f(a))$ and $\phi(1) = (b, f(b))$. For $x \in [0, 1]$, let $\phi_1(x)$ and $\phi_2(x)$ be defined by $\phi(x) = (\phi_1(x), \phi_2(x))$. Clearly, $a \leqslant \phi_1(x) \leqslant b$ for all x, and by the (Darboux) continuity of ϕ_1 we see that ϕ_1 maps $[0, 1]$ onto $[a, b]$. But then $\phi : [0, 1] \to \Gamma_f$ is surjective. It follows that Γ_f is compact.

(β)$\Rightarrow$(α). Let $x_1, x_2, \ldots \in [a, b]$ with $\lim_{n\to\infty} x_n = x$. We prove that $\lim_{n\to\infty} f(x_n) = f(x)$. The sequence $f(x_1), f(x_2), \ldots$ is bounded (Γ_f being bounded). Let $\alpha := \limsup_{n\to\infty} f(x_n) = \lim_{i\to\infty} f(x_{n_i})$ for some subsequence $x_{n_1}, x_{n_2}, \ldots$ of $x_1, x_2, \ldots$ Then $(x, \alpha) = \lim_{i\to\infty} (x_{n_i}, f(x_{n_i})) \in \Gamma_f$, so that $\alpha = f(x)$. Similarly we can prove that $\beta = f(x)$, where $\beta := \liminf_{n\to\infty} f(x_n)$. Thus the sequence $f(x_1), f(x_2), \ldots$ converges to $f(x)$.

Figure 4: Proof of the equivalence of the continuity of a function on $[a, b]$ and compactness of its graph (van Rooij & Schikhof, 1982, pp. 52–53)[2]

We highlight that Ross also uses a compactness argument to adapt Burgess' proof of lemma 2: he introduces a sequence $(t_n)_{n\in\mathbb{N}}$ of points in $[0,1]$ and uses the Bolzano-Weierstraß theorem from real analysis (that unfolds to the topological notion of compactness in the topology course). Moreover, Ross (2013, §21) has already proved, that the continuity of the function is equivalent to the compactness of the graph. Thus, he could have adopted the short argument for $(\gamma) \Rightarrow (\beta)$ by van Rooij and Schikhof. We will not trace here the complete argumentation but instead point to an alternative proof (JOJO, 2020) that mimics and combines lemma 2 and lemma 3 from Burgess (1990) shorter than Ross' proof:

> Assuming that f is not continuous at some x_0, the definition implies that there is a sequence $(x_n)_{n\in\mathbb{N}}$ converging to x_0 in some compact interval $[a, b]$ such that $|f(x_n) - f(x_0)| > \varepsilon$ for a given $\varepsilon > 0$ and for all $n \in \mathbb{N}$. Then, there is a path $\gamma: [0,1] \to \Gamma_f$, $\gamma = (u, v)$, with $\gamma(0) = \big(a, f(a)\big), \gamma(1) = \big(b, f(b)\big)$ and $v = f \circ u$. Since u is continuous, the intermediate value theorem yields $t_n \in [0,1]$ with $u(t_n) = b_n$ for all $n \in \mathbb{N}$. By compactness of $[0,1]$, $(t_n)_{n\in\mathbb{N}}$ can be chosen such that it converges to some $t_0 \in [0,1]$. Then, the continuity of v implies that $f(x_n) = f\big(x(t_n)\big) = v(t_n) \to y(t_0) = f\big(x(t_0)\big) = f(x_0)$, which contradicts the assumption $|f(x_n) - f(x_0)| > \varepsilon$ for all $n \in \mathbb{N}$.

[2] We note that van Rooij and Schikhof (1982) use the word "arcwise connected" instead of "path-connected".

For Ross, it may not have been worthwhile to present a shorter more purely real analysis based proof but to maintain the structuralist organisation in Burgess' paper. This and his choice of didactic variables may be interpreted as a sign of the type 1 transition.

Finally, the use of compactness arguments can be understood on a more advanced level with a structuralist result (Wójcik, 2008, p. 13) that replaces both the domain and the codomain of the function with arbitrary topological spaces, the codomain being compact, and reemphasises again the hypothesis of closedness of the graph.

Conclusion

Related to the equivalence of the continuity of a real-valued functions on intervals and properties of their graphs, the didactic transposition, in particular represented in choices regarding didactic variables, achieved by university teachers (Ross, 2013; van Rooij & Schikhof, 1982) seems to prioritise simpler and less abstract arguments, rather than more conceptual structuralist arguments that may be organised in the form of lemmas as in Burgess (1990) when addressing university teachers. Indeed, Burgess (1990) and Wójcik (2008) point to or contain several possible structuralist generalisations of the theorem concerning real functions over a real domain in scholarly works. Each of them enlightens different aspects of more elementary analysis based proofs, and they can be established using structuralist praxeologies from topology. But applying them to deduce the result for real functions nevertheless require praxeologies from real analysis to prove that the hypotheses are fulfilled (such as the connectedness or closedness of the graph of a restriction of the function). The cost to achieve this seems as high as a direct proof of the theorem itself, so that the gain of generality and abstraction is not clear.

In terms of structuralist praxeologies and their evolvement, a struggle between contextualisation (the context of the task and more generally the background of real analysis) and decontextualisation (the development of level 2 structuralist praxeologies based on topological knowledge) can be observed, which arises at least in part from the use of textbooks and the organisation of study programmes. All the structuralist praxeologies applied by Ross (2013) or van Rooij and Schikhof (1982) are level 1. On the one hand, the most elementary proof for the direction "path-connected implies continuous" is not chosen by any of them, but on the other hand, none of the proofs bases the arguments on structuralist principles (this would have required considering abstract domains and/or codomains and connectedness and/or other properties instead of path-connectedness). These observations support the view that real analysis cannot be reduced to its structuralist dimension, but that the fruitfulness lies in the dialectic of objects and structures and in the interplay of real analysis and topology to increase mathematical understanding.

The professional obligations of mathematics teaching: How measurement and theoretical progress work hand in hand

Patricio Herbst[1], Daniel Chazan[2], Amanda Brown[1] & Karl Kosko[3]

[1]University of Michigan, USA; pgherbst@umich.edu; [2]University of Maryland, USA; [3]Kent State University, USA

We discuss the evolution of the professional obligations construct by looking at how the development of operational definitions and measurement instruments has allowed the making of some claims about groups of instructors. We suggest how further refining of the instruments can optimize the way those operational definitions of obligations inform the role that professional obligations play not only as constraints but also as resources for the work of mathematics teaching.

Keywords: practical rationality, measurement, obligations, theorizing, resources, constraints

Middle-range theorizing (Merton, 1967) involves bidirectional traffic between proposed theoretical constructs and empirical research: The former offers lenses for how to read experience and the latter provides justification to propose theoretical distinctions and corrections (Herbst & Chazan, 2022, 2023). We exemplify this using the development of the theoretical notion of professional obligations.

Practical rationality

The theory of practical rationality (Herbst & Chazan, 2003, 2023) aims to describe the grounds upon which mathematics teaching can be understood as a rational or sensible practice. Following Bourdieu (1990), this practice theory avoids reducing an account of teaching either to merely an objectivist or structural perspective, which would account for the work of the teacher as determined by social structures, or to merely a subjectivist or individualistic perspective, which would explain this work in terms of individual goals, knowledge, and beliefs. Instead, practical rationality reconciles both perspectives to account for teaching in ways that require considering both structure and agency: A teacher's position conditions them to act in particular ways, but those positions also allocate individual agency to them that they experience as they make choices and provide reasons for their actions. Their position creates conditions for them to feel disposed to see some actions as desirable; reciprocally, dispositions to act in line with personal inclinations may become defensible if the characteristics of their position afford it. The theory assumes that the practice of teaching is neither determined by structural characteristics, nor a free expression of individual will, but a defensible choice among available possibilities. The theory posits that a habitus of mathematics teaching, a "system of durable, transposable dispositions, structured structures predisposed to function as structuring structures" (Bourdieu, 1990, p. 53) regulates what's sensible for teachers to do.

Practical rationality has developed as a middle-range theory—neither a local theory (i. e., a synthesis of empirically confirmed relationships between specific constructs), nor a grand theory (i.e., a speculative language of description and interpretation that precedes empirical research practice). Merton's (1967) notion of a middle-range theory applies to practical rationality because this theory starts from the identification of a realm of social activity (i.e., the activity of mathematics teaching) and a perspective on social theory (i.e., social activity as practice, action as embodiment of a habitus)

and adds notions that support theoretical development in interaction with empirical research: Empirical research is theoretically motivated and serves as a source of exploration material (to generate theoretical ideas) and as mechanism for theoretical feedback (i.e., provisional confirmations and refutations). A central strategy for theorizing is the development of operationalizations of theoretical concepts that can be used to develop protocols for data collection, including measures.

This paper further advances a component of the theory–the notion that the position of teacher obligates individuals to stakeholders of their work and that such obligations are perceived as dispositions to act (Herbst & Chazan, 2012; Chazan et al., 2016). Four stakeholders–knowledge, the client, society, and organization–are posited as invested in the work teachers do with students and content in classrooms, holding teachers accountable to the stakeholders' interests. This structural claim can be fed by aggregate expectations expressed by classes of people associated with the interests of those stakeholders. *Knowledge* refers to the system of production and use of mathematics and is identified empirically in the expectation that mathematicians and STEM practitioners have that mathematics teachers should represent mathematical knowledge, practice, and applications faithfully. *The client* refers to students and is identified in the expectations that parents and children have that teachers treat students as unique individuals. *Society* refers to the needs and values of society and its communities and is identified in the expectation that prospective employers, politicians, and taxpayers have that teachers foster prosocial behaviors and values in classrooms (e.g., fairness, honesty). *Organization* refers to the institutions that organize mathematics classroom instruction, including departments, schools, districts, and school systems and is identified in the expectation that organization leaders (e.g., government officials, superintendents, principals, department chairs) have that mathematics teachers will be effective and efficient, and operate within the law.

In positing the four obligations, we make a structural claim that these four stakeholders obligate mathematics teachers and that the norms of instruction (i.e., the didactical contracts that are viable in practice; e.g., the expectation that problems assigned to students have all the information needed to be solved and require the use of knowledge recently learned; Brousseau, 1997) result from historical adaptations to the combination of those obligations. The obligations ascribed to the position of school mathematics teacher thus complements prior structural characterizations of the role of the teacher in mathematics instruction, according to which the communication of knowledge to students is regulated by instructional norms (e.g., the claim that a didactical contract exists). In what follows we discuss how these professional obligations have been used in research, how this use has contributed to theory development, and argue for further development of its associated measurement instruments to support further theoretical growth. We develop further the distinction between two empirical manifestations of these obligations so that these can help capture the complementarity between structure and agency of the notion of obligations and support further empirical research on obligations.

Empirical research on obligations–reviewing the first cycle

The proposition that mathematics teachers are obligated to four stakeholders entered the theory as a hypothesis in the mathematical sense. Its origin was as an abductive inference from listening to teachers justify the actions of a teacher who the former saw on video acting in ways that departed from what they expected (Nachlieli et al., 2009). The majority of the studies that have relied on the

obligations construct, have used it to organize the sources of justification that individual practitioners call forth, for example in interviews or focus groups where they consider aspects of someone's practice (Bieda et al., 2015; Webel & Platt, 2015; Lande & Mesa, 2016; Shultz et al. 2021). Practitioners recognize the influence of an obligation in the way they speak about why what they see being done is or is not justifiable. Individual distinctions among practitioners can be made regarding what obligations individuals invoke and how they argue for the justifiability of actions. And the obligations have been used to investigate the various circumstances in which individual mathematics teachers recognize those obligations. In all this, the obligations seem to be resources available to individuals who wield them if they are so disposed, to justify conceivable actions.

But structural empirical questions could also be posed to understand more about the obligation construct and its relationship with other constructs. Our own work inquired on whether further considerations of theoretical structure were needed within each of the obligations. For instance, in the context of the individual obligation, would it make sense to distinguish an obligation to students as cognitive beings from one to students as emotional beings? But alternative structural differentiation could be conjectured too. For instance, could the obligation to individual students distinguish two ways in which a teacher could defensibly recognize this obligation, say as an obligation to cater to the needs of individuals or as an obligation to challenge individuals. Herbst and Chazan (2003) noted how practical rationality could accommodate discussions about the commitments involved in different kinds of teaching precisely by assuming that opposite dispositions (e.g., to coddle or to challenge) could attest to the existence of a common ground (viz., the obligation to the student).

To be clear, though these and other distinctions might make sense and could be used in interpretive work with individuals, incorporating these distinctions into the theoretical account of the obligations required more than consideration of their sensibility. The notion that practical rationality is a middle-range theory suggested instead that the sensibility of those claims, possibly backed up by case studies in which that sensibility was grounded, would need to be tested further against more stringent empirical benchmarks: It became important to further develop the hypothesis that the obligations exist by creating measures that could be used to describe how they are recognized and which could be used to discern how obligations made a difference in making claims at the level of structure.

Even in taking for granted that mathematics teachers would be obligated to the four stakeholders, some structural questions could be formulated empirically and addressed if we had measures. Among those, we could ask whether the obligations hold equally across groups of mathematics teachers from different school levels (e.g., university vs. high school), teachers from different countries, or teachers from different types of schools (e.g., public vs. private). Also, do teachers' recognition of obligations moderate the role that norm recognition plays in teacher decision-making? (Herbst et al., 2016).

The PROB and PROSE measures

To address those questions, we developed two instruments (PROB and PROSE[1]) to be completed by individuals and that posed different questions relating individuals to the sources of justification whose

[1] PROB stands for Practical Rationality Obligations, PROSE for Practical Rationality Obligations Scenario Evaluation.

hold on individuals we wanted to gauge. We operationalized the relationship between individual teachers and each obligation by hypothesizing the construct "recognition of an obligation" to name the extent to which an individual would recognize the existence of specific external expectations on their teaching. PROB (Herbst & Ko, 2017), asked teachers to indicate their agreement with statements that explicitly identified an expectation, sampling from among the various aspects of each obligation statements with which they had to indicate agreement (Figure 1). Respondents had to rate the degree to which mathematics teachers are expected, as professional educators, to act in the manner that the statement describes. The logic of the item responses was that the more likely the respondent recognized themselves as accountable to the obligation in question, the higher they would agree that teachers are expected to act in the manner described. Herbst and Ko (2017) reported on an exploratory factor analysis on item responses that suggested internal factor structure within each of three obligations (disciplinary, individual, interpersonal). For example, items written to gauge recognition of the disciplinary obligation might indicate 3 factors: (1) Obligation to the discipline as member of a community contributing to increase and extend appreciation of knowledge outside of the classroom (9 items) (2) Obligation to the discipline as responsible for its correct representation in study resources (3 items), and (3) Obligation to the discipline insofar as responsible representation in classroom interaction (5 items). Analysis showed poor reliability for the institutional scale, and a variety of significant but low correlations between scores on the obligations and on the various factors of Stipek et al.'s (2001) beliefs instrument, suggesting that obligations and beliefs are different constructs.

Obligation	Statement
Disciplinary	Mathematics teachers describe new procedures to students in ways that a mathematician would endorse.
Individual	Mathematics teachers are responsive to individual student's emotions.
Interpersonal	Mathematics teachers ensure that they address questions from all students.
Institutional	Mathematics teachers assign grades that represent how much of the curriculum students have learned

Figure 1. The PROB surveys

The PROSE instrument attempted to get at whether individuals would recognize opportunities to do something that deviated from a norm as justifiable on account of an obligation they had been primed for. Each item included a priming statement anticipating that the respondent would see a teacher make a decision that considered a given obligation[2] and a scenario such as shown in Figure 2, rendered with nondescript cartoon characters, in which the teacher avowedly acted in response to the primed obligation. After perusing the scenario, the respondent was asked to consider a statement such as "The instructor should stick to the mathematics at hand, rather than take class time to make

[2] The priming statement for the disciplinary obligation at the college level was "In the following storyboard we invite you to consider a scenario in which a college instructor deviates from the lesson in order to attend to issues of mathematical importance." Other obligations were primed using equivalent phrasing.

connections to other mathematical ideas," which indicted the teacher for doing so and to which respondents had to indicate their agreement using a 6-point Likert scale ranging from strongly disagree to strongly agree. As a rule, items had statements indicting the teacher for what they had done and offering instead what would have likely been the norm in a U.S. classroom. PROSE scenarios sampled domains of practice–e.g., in Figure 2, the disciplinary obligation would justify making connections to higher-level mathematics. PROSE items did not directly ask for agreement to be expected to do so, but the question amounted to ask whether the decision was justifiable.

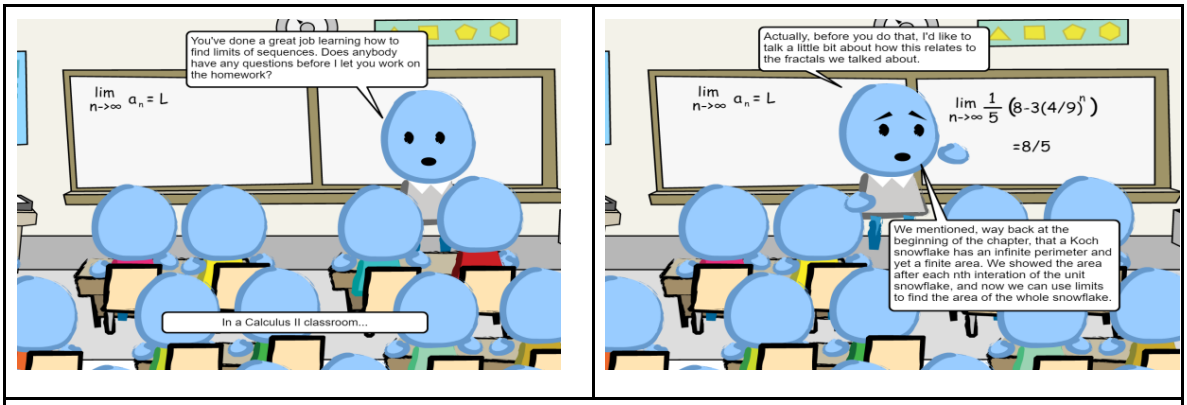

Figure 2. Two slides of the scenario for item A1115, primed for the disciplinary obligation

Sets of parallel items were developed for high school and lower division undergraduate mathematics levels. Matched items across levels would sample the same domain of practice, but the content being handled corresponded to courses in the level of schooling under consideration. Additionally, some linking items were developed that did not show explicit mathematical content and could be included with the other items at all school levels. Ko et al. (2024) used these versions of the PROSE instrument to inspect differences in recognition of the obligations across the undergraduate and high school levels. These examples add to the use of PROB in showing the kind of structural questions that can be asked. In both uses, recognition scores were used to understand empirically what sort of structural claims the obligation construct could help make–that is, the measures were used for basic research and not to make claims about individuals or to inspect any theory of individual differences. At the same time, because recognition of obligations varies and it is arguably a valued asset individual teachers might have that might support the transformation of their practice, one could raise the question of whether an individual's level of recognition is variable or stable, and, if the former, how it varies (e.g., developmentally, situationally). This, in turn, requires us to think carefully about the experience of obligation recognition and the possible variability in individual recognition.

Using obligations measures to make claims about groups and individuals

Despite the productive role that the PROB and PROSE measures have played in confirming that the obligations construct adds to our understanding of mathematics teaching, they could be further improved by refining how their scores are to be interpreted and used. The construction of PROB and PROSE items tap into different operational versions of the obligation construct, to the point that the kinds of claims that each instrument might make possible could contribute differently to improving

the theory of practical rationality. Whereas PROB items elicit recognition of obligations as constraints on individual action, the PROSE items gauge whether recognition of obligations can be resources for justification of actions that might otherwise be seen as problematic. Though both instruments are completed by individuals, the variability in the elicited responses can serve different theoretical ends.

One theoretical end is to better understand what the claim that the stakeholders obligate mathematics teachers means in practice: Does the recognition of obligations by groups of teachers depend on the institutions in which they work, the students they serve, the societies to which they send their graduates, or their relationships with the discipline of mathematics? Among the many different aspects of practice in which such accountability may show up, are there empirically identifiable aspects that may explain variability across groups of teachers? The use of the obligations construct in qualitative research is likely to illustrate affirmative answers to those questions. For example, teachers working in districts where administrators are involved as instructional leaders may experience the institutional obligation differently than those where administrators exercise their supervision through classical means (e.g., test scores, passing rates). Similarly, individual teachers may bring up different aspects of the obligations they recognize as reasons to do or not to do what they do in classrooms. But structurally, some of that individual variability may be explainable in relation to other factors while some other may not. The redevelopment of an instrument like PROB could be oriented to detecting those differences. This instrument could also be used with stakeholders It seems that a next step in the study of whether mathematics teachers are, as a group, obligated to those stakeholders should include a PROB-like instrument being administered to experienced mathematics teachers as well as stakeholders (e.g., mathematicians, students, employers outside of STEM, and administrators who don't know mathematics) to gauge correlations in recognition. A PROB-like instrument could be designed to attend to hypothesized factors within each obligation (either sub-obligations or competing dispositions, or both).

A second theoretical end is to better understand how the obligations become resources for teachers to justify their actions. The PROSE instrument's basic design seems to allow for such detection. Scores on these items not only could vary on the basis of individuals' increasing socialization into teaching (e.g., teacher education, professional development) but also on the basis of individual recognition of events in the class as associated with a particular stakeholder. Indeed, investigation of pilot data with PROSE items (Milewski et al., 2021) documented that individuals varied in their recognition that the circumstances in which a given obligation was applied actually warranted deviation from the norm–oftentimes they thought justification required extra information. Rather than thinking of the source of this variation as item-specific noise, we would like to think of these contexts as avenues through which recognition of the obligation might develop, somewhat in analogy as how weather patterns constitute climate or how mood patterns constitute personality. In other words, a PROSE-like instrument could be sensitive to contextual circumstances, in which recognition of an obligation might not merely be applied if it exists but also be elicited as an agentic disposition.

Conclusion

The pairing of personality and mood is proposed as an analogy with recognition and justification disposition for two reasons. Clearly, both personality and mood patterns develop over time and are

latent traits whose measurement rely on items that indicate them. But personality is stable over longer stretches of time while mood patterns can be more variable not only according to local context but also as those contexts become more pervasive (e.g., with age, changes in financial status). The analogy with obligations suggests that we should use the different constructions of PROB and PROSE as a stimulus to consider two ways in which the obligations are manifest in individual teachers.

On the one hand, teachers may recognize an obligation as a professional constraint or requirement. This recognition may vary across institutions, communities, and cultures and may admit to factor structures that allow for detecting teachers of different groups (e.g., teachers that recognize some dispositions or some sub obligations, etc.). An explicit survey instrument such as PROB could allow us to associate with each practicing teacher a vector of recognition scores that describes their way of being obligated to the stakeholders. This instrument should be able to detect differences between large changes in a teacher's professional life such as before teacher education, toward the end of teacher education, five years into professional practice, and close to retirement. This type of instrument should be usable to examine structural characteristics of the obligation construct and variations in obligations across groups of teachers (e.g., teachers of different countries, levels of schooling, types of schools, teachers with and without strong mathematics preparation, etc.).

On the other hand, teachers may recognize an obligation as a professional resource or support, particularly to justify doing something that feels appropriate at a moment even though it may not be the expected thing to do. A scenario-based survey such as PROSE could be redesigned to include items which differ in regard to both how justifiable a teacher's decision is and in regard to how recognizable the opportunity is to invoke an obligation. This PROSE-like instrument would not measure an individual's recognition of an obligation but rather an individual's present disposition to use an obligation to justify a decision that might need justification. One would expect that this disposition would vary within a timescale smaller than recognition of obligations varies, as individuals accumulate more experiences through practice or professional learning. Thus, the PROSE instrument could be used to detect individual changes over time and possibly also to make claims about the effects of professional learning opportunities, for example those that promote instruction that departs from customary norms.

Using theory as a tool to cultivate and analyse research methods: Theorising positioning to examine task-based interviews

Heather Lynn Johnson[1], Evan McClintock[1] and Robert Knurek[1]

[1]University of Colorado Denver, Colorado, USA, heather.johnson@ucdenver.edu

Researchers use theory to solve problems of practice, which can include problems related to the practice of conducting research. We put forward a use of theory, namely, as a tool to cultivate and analyse research methods in mathematics education. To illustrate, we use the theorising of positioning as a tool to analyse power dynamics involved in task-based interviews. We explain how theorising can contribute to the implementation and further development of research methods, such as the task-based interview. Implications include the training of new researchers in the use of research methods and the interrogation of the use of established research methods.

Keywords: Research problems, Mathematics education, Research methods, Theory use.

Introduction and purpose

In mathematics education research, theories can serve a variety of purposes. One prominent purpose is to provide "*a safeguard against unscientific approaches* to a problem, issue, or theme" (Niss, 2007, p. 1309). This purpose encompasses the use of theories to guide empirical research studies (e.g., drawing on theory to frame a study) as well as to inform the practice of research (e.g., selecting and implementing research methods). Here, our focus is on the latter; we put forward a use of theory to cultivate and analyse research methods in mathematics education.

Two questions frame our approach. First, how can theory use inform the implementation and evolution of research methods in mathematics education? Second, how can theory use inform the training of new mathematics education researchers in research methods? To respond, we start broadly, discussing how theory can be used as a tool to cultivate and analyse research methods. Next, we turn to a specific instance of theory use, namely how the theorising of positioning (Davies, 2023; Davies & Harré, 1990; Davies & Hunt, 1994; Herbel-Eisenmann et al., 2024) can be used as a tool to examine the well-known research method of task-based interviews (Goldin, 1997; 2000). To ground the argument, we provide a vignette to illustrate how theorising can inform the training of new researchers in the practice of conducting research. We conclude with discussion and implications.

Using theory as a tool to cultivate and analyse research methods

Theories are vital for connecting problems of practice and the practice of conducting research in mathematics education (Silver & Herbst, 2007). Problems of practice often include questions or ponderings that arise in the teaching and learning of mathematics (e.g., How may students' reasoning impact their performance on an assessment?). Here, we extend problems of practice to include questions or ponderings that may arise in the practice of conducting research, with a specific focus on research methods, such as task-based interviews.

Theory, whether in the background or foreground (Mason & Waywood, 1996), informs the kinds of problems people may consider as well as potential solutions to those problems. To illustrate, the

research method of task-based interviews involves interaction between an interviewer and an interviewee, in relation to tasks that the interviewer poses to the interviewee (Goldin, 2000). A theory (or theories) guiding researchers' actions informs the interpretations they make when analysing interviews. For example, the theorising of positioning may lead to questions about how young children may use nonverbal actions to communicate their unwillingness (or discomfort) to participate in an interview (see Parks & Schmeichel, 2014). Elaborating on a relationship between theory and problems, Johnson (2024, p. 3121) wrote:

> Theories can bound the kinds of things that people question, and in turn, the kinds of things that can count as answers to those questions (Mason & Waywood, 1996). Put another way, theories shape where people look (or listen) and what they see (or hear), as well as how they make and act on their interpretations.

To explain what we mean by theory, we draw on Radford's (2008) characterisation of theory as a dynamic whole comprising three interrelated aspects. From this perspective, a theory involves a system of basic principles, a methodology that includes techniques/methods that cohere with the principles, and a set of paradigmatic research questions. By using "system" to describe the principles, Radford communicates that the collection is structured, and the structure provides meaning for the principles. While there is not a lockstep relationship between a theory and a methodology, the methodology needs to cohere with the principles and have operability to answer research questions. From this view, it is possible for research methods, such as task-based interviews, to be associated with different theoretical perspectives and related methodologies. Consequently, those methods undergo evolution to cohere with principles underlying the different perspectives.

Like theories, research methods are not static; they evolve as researchers continue to employ them. This evolution includes researchers' use of methods (enacted method) as well as discussion of methods in the literature (intended method). By cultivation, we refer to the nurturing of this evolution. By analysis, we mean the examination of assumptions (tacit or explicit) underlying a "business as usual" approach to the method. Cultivation and analysis can focus on both the intended and enacted method. Analysis of the intended method involves examination of original sources. Analysis of the enacted method involves examination of instances of implementation of the method, which may be retrospective or ongoing. Cultivation of the intended method involves advancement of the method, which may occur through recommendations or further elaboration on the method. Cultivation of the enacted method involves advancements in the approach to the method. Theorising guides cultivation and analysis.

Theories emerge in response to problems, with questions to be answered (Radford, 2008). As theories evolve, the questions also evolve, while marks of the early question remain. Here, we employ this "problem-based" approach, using the metaphor of a tool (Simon, 2009) to describe our use of theory to do a particular kind of work. Our approach responds to a twofold problem—a need to engage in the purposeful practice of research and train new researchers in such practice. We focus on developing expertise in the implementation of research methods more broadly, with a particular interest in task-based interviews. Our author team is composed of researchers (two White men, one White woman) who grew up in different geographical locations in the U.S., in different generations, and in different

social classes. Two have a longer history of designing and conducting task-based interviews and drawing on those interviews as a primary source of data for empirical studies. One is a new researcher, developing expertise in the use of task-based interviews as a research method. As researchers using task-based interviews, our goal is to position ourselves as listeners and to (re)distribute power to participants, communicating our belief that they are the expert in their thinking and reasoning, and our role is to learn from them. Our intention is to foster participants' sense of agency and autonomy, which we have found to be effective to encourage sustained engagement and feelings of success.

Theorising positioning to examine task-based interviews

> The positioning of self in relation to another is not simply or only an act that reveals who that individual has invested him- or herself in being. While it may reveal the investment they have made in one set of values or another, or one discourse or another, it is also, always, an act in relation to the power/knowledge assemblages through which credence in one's own eyes and the eyes of others is accomplished. Positioning is relational, not just the immediate relation with one's interlocutor, but relations with/in the assemblages of power/ knowledge that make up academic/intellectual and everyday life. (Davies, 2023, p. 473)

We intentionally use the phrase "theorising positioning" rather than "positioning theory." Like Herbel-Eisenmann et al. (2024), we do this to communicate that the theory is dynamic, rather than static, having multiple potentialities. In our view, the phrase "theorising positioning" begs the question "theorising positioning in what way(s)?" For our purposes, we adopt the theorising of positioning that Herbel-Eisenmann et al. (2024) put forward; that is, theorising positioning as praxis. With this approach, a relationship between theory and practice is one of reciprocity; theory informs practice and practice informs theory. A reciprocal relationship between theory and practice dovetails well with our use of theory to inform the practice of research. In our view, "theorising positioning as praxis" suggests an active use of theory, something researchers do for certain purposes; it is a verb rather than a noun. We embrace this action-oriented approach to theory.

According to Herbel-Eisenmann et al. (2024), when researchers theorise positioning as praxis, they engage in five commitments, acknowledging that their list is neither exhaustive nor entirely mutually exclusive. The commitments are to "historicize," "reflect on positionality," "foreground/honour participant perspectives," "address tensions," and "acknowledge hopes and fears" (p. 291). Next, we elaborate on these commitments, appealing to ideas presented by Herbel-Eisenmann et al. (2024). To "historicize" involves learning histories of people involved, which can happen in different scales and scope. This work entails understanding that histories, like positions, are something negotiated and contestable. As researchers, to reflect on our positionality means examining how "our histories, languages, experiences, and cultures relate with our participants and give an account of how tensions shape our interactions and interpretations" (p. 294). By foregrounding/honouring participant perspectives, researchers attend to how participants may experience or interpret positionings, which may continue to evolve and can happen at different scales. To address tensions means not to oppose or squelch them; in contrast, it entails welcoming and navigating tensions as part of the process, and these tensions can include acknowledging participants' hope and fears. We view these commitments to embody early work around positioning. In their study, Davies and Hunt (1994, p. 392) describe

their efforts to "reveal the positions from which and from which we have struggled to gain some understanding of the positioning of marginal students."

Storylines are a key construct to the theorising of positioning, and people's hopes and fears frame their stories (Herbel-Eisenmann et al., 2024). Storylines refer to "the ongoing repertoires that are already shared culturally or they can be invented as participants interact" (Herbel-Eisenmann et al., 2015, p. 188). Like positioning, storylines are dynamic, rather than static, and they constantly evolve. Storylines also can operate at different scales (Herbel-Eisenmann et al., 2015); they may happen moment-to-moment, and they can be products of accumulations of experiences.

Wagner and Herbel-Eisenmann (2009, p. 2) have called for researchers' attention to positioning in their practice: "The way a researcher theorises positioning (the way she sees and thinks about it) affects the way she interprets actions, including her own." When researchers describe and implement research methods (intended and enacted methods), they create conditions that result in sources of data to be interpreted. When research methods, such as interviews, involve communication acts between researchers and participants, both contribute to the enactment of the method. In this vein, Solomon (2012, p. 177) contends that interviews are something more than "a giving up of information by Joanne and Roz [participants], but are joint constructions in which I played a part". We concur with Solomon (2012)'s characterisation of interviews as "joint constructions" between at least a researcher (interviewer) and participant (interviewee), and view this to be applicable to the mathematics education specific research method of task-based interviews.

Task-based interviews have a long history as a method in mathematics education research (Goldin, 1997; 2000; Maher & Sigley, 2020), being used primarily to understand students' thinking and reasoning while solving problems. Thus, it is not surprising that many research studies employing task-based interviews are framed by cognitive theories (Goldin 1997; Maher & Sigley, 2020). Yet, social aspects are inherent within the method, as evidenced by Goldin's identification of questions for researchers to provide explicit consideration in advance of conducting task-based interviews:

> What constraints or limitations are imposed by the social, cultural, and psychological contexts of the interviews? How may the student's expectations, presumptions, apprehensions, and intentions interact with mathematical cognitions and affect (and with task variables) to influence the interview outcomes? (Goldin, 1997, p. 42)

Parks and Schmeichel's (2014) study illustrated how researchers may theorise positioning to respond to Goldin's questions, as they examined how a researcher (interviewer) and student (interviewee) worked to "position themselves and each other" during task-based interviews used for assessment purposes. A purpose of the study was to draw on students' embodied actions to provide a way to analyse power dynamics that can unfold when researchers from dominant populations interview participants from nondominant populations (in their case, young children). As a result, Parks and Schmeichel (2014) advocated for researchers to develop awareness of their positions of power, to allow more nuanced reporting that may provide insight into how children felt during the interview.

Theorising positioning can uncover power dynamics, as both the researcher and the participant(s) co-construct task-based interviews, and their interactions can manifest a range of storylines. Johnson et

al. (2024) have identified three researcher-participant storylines that emerged during an interview: expert-novice, questioner-answerer, and listener-expert. If the "expert-novice" storyline dominates a task-based interview, it has potential to be problematic, because the storyline preserves the *status quo* power dynamic of researcher as expert and participant as novice.

We distinguish the theorising of positioning from the theorising of decentring, a theoretical construct widely used to examine researcher actions during task-based interviews. Decentring, the "ability to see a situation as perceived by another human being" (Confrey, 1990, p. 108), is crucial for researchers conducting task-based interviews. It includes researchers' active efforts to make sense of situations from a student's perspective, in the moment or retrospectively (Hackenberg, 2010). Through the theorising of positioning, researchers can examine power dynamics at play during task-based interviews, even when researchers are actively engaging in decentring.

Using theory to inform the training of new researchers: a vignette

The questions that frame our approach ask how theory use can inform the practice of research (i.e., the implementation of research methods, specifically task-based interviews) and in turn, the training of novice researchers in such practice. We contend that the theorising of positioning demonstrates promise to inform the training of researchers to learn to implement task-based interviews. To illustrate the potentiality for such theorising, we share a vignette of Roger, a new researcher developing expertise in leading task-based interviews, during multiple cycles of preparation, implementation, and reflection. Across the cycles, in the implementation phase, there is a back and forth between Roger's roles as observer and interviewer, guided by reflection on the implementation.

To prepare to implement task-based interviews for his dissertation study, Roger apprenticed with his dissertation advisor. This included acting in the role of observer for task-based interviews his advisor conducted, as well as watching videos of existing interviews with tasks similar to those he intended to implement. Roger and his advisor discussed key principles (intended method), including ways in which he may decentre, to make sense of students' perspectives on tasks, which may be different from his own. Along with this, Roger planned questions (and follow-up questions) to guide task-based interviews he would conduct. To practice, he interviewed a few friends and family members. While on the surface, Roger's enacted method followed the principles of task-based interviews, after the interview, one person said that they were trying to remember what they thought they were "supposed" to do. Others said they felt the interview was very formal, like an evaluation, and they were self-conscious about getting the right answers. This created space for Roger to reflect, and talk with his advisor, thinking that if people with whom he was close felt this way, student participants he did not know as well likely would feel uncomfortable, perhaps even more so. Across conversations with a colleague, Roger's advisor came to wonder if Roger's positioning during the interview might be perpetuating an expert-novice storyline, in which participants may be trying to figure out what Roger (the expert) thought would be appropriate for them (the novices) to say/do during the interview. In response, Roger and his advisor hatched a plan, in which Roger would observe his advisor conduct new interviews, for the purpose of supporting him to (re)distribute power to students. In these observations, focus shifted between interviewee and interviewer. First, Roger observed an interview with a focus on what the student said and did, considering how long the student's responses were and

how comfortable the student seemed to feel during the interview. Second, Roger observed another interview, this time with a focus on follow-up questions that his advisor asked in response to student's statements. Then, Roger applied the different foci to each of the interviews. These targeted observations were intended to allow for an exploration of conditions under which students might feel safe and welcomed to engage in the vulnerable act of sharing their thinking during an interview.

In response to the observations, Roger described his emerging awareness of power dynamics during interviews. First, he began to consider how interviewer-interviewee interactions could communicate who holds power during an interview. He wrote that he could feel how an interview became more comfortable and "low-stakes" as it continued. Second, his debriefs with his advisor after the interviews allowed him to share things that he noticed, and made room to discuss the intentionality behind those moves to (re)distribute power to students (e.g., If a student says that they don't know, one follow-up question could be to ask them if there are things they are wondering about.). Third, Roger watched and reflected on his own interviews, catching times when he might sound judgmental, or jump in too quickly, and making notes for future interviews. In Roger's words:

> The more interviews I conduct, and the more comfortable I get with asking students questions, the more I realize how complex and rich their thinking is. When students feel comfortable and in control during an interview, they really can "open up" and provide deep insight into their thinking.

Discussion and implications

At the outset, we asked how theory use can inform the implementation and evolution of research methods in mathematics education. In turn, we asked how theory use may inform the training of new mathematics education researchers in research methods. We argued for a use of theory as a tool to cultivate and analyse research methods, both intended and enacted. To illustrate, we theorised positioning to analyse task-based interviews, demonstrating how the theorising could make explicit power dynamics having potential to impact the course of an interview. Through Roger's vignette, we illuminated the utility of such theorising not only for the advancement of research methods, but also for the training of new researchers to viably implement research methods.

Analysing research methods from different theoretical perspectives can create opportunities to problematise the intended and/or enacted method. Drawing on Radford's (2008) notion of theory, a theory's principles inform the logic underlying a research method. When a research method is developed in one theoretical tradition, then imported into a different theoretical tradition, the logic of the method carries residue of the theory in which it was generated. From this view, research methods (e.g., task-based interviews) may only be viable with respect to certain theoretical principles. Different theories can illuminate aspects of research methods that otherwise may be tacit.

Focusing on the research method of task-based interview, we sourced a theory outside of the tradition associated with the development of the method. We view this use of theory to be consistent with Scheiner's (2020) mode of juxtaposing potentially competing explanations, to reveal conflicts and tensions. While decentring explains researchers' active efforts to understand participants' perspectives, theorising positioning explains power dynamics that can be at play during interactions between researchers and participants. Despite Roger's efforts to decentre, power dynamics present in

interviews (enacted method) remained tacit for him. Theorising positioning, together with cycles of observation/implementation and reflection, made room for those dynamics to become explicit. The navigating, rather than squelching, of this theoretical tension also aligns with commitments to the theorising of positioning, as laid out by Herbel-Eisenmann et al. (2024). In our view, embracing the tension is a key aspect of the use of theory to cultivate and analyse research methods.

In conclusion, we return to a purpose of theory put forward by Niss (2007); that is, to guard against unscientific approaches to problems. A crucial aspect of scientificity is the ethical application of research methods. Theorising positioning to analyse power dynamics in task-based interviews has potential to enhance the ethical ways in which researchers act (see also Parks & Schmeichel, 2014), and to centre the humanity of researchers and participants in task-based interviews.

An interactionist perspective on the negotiation of meaning of mathematical representations

Sebastian Kollhoff[1] and Kerstin Gerlach[1]

[1]Bielefeld University, Institute of Didactics of Mathematics, Bielefeld, Germany;
sebastian.kollhoff@uni-bielefeld.de

This article presents the theoretical and methodological framework of an empirical research programme that aims to develop an interactionist perspective on the question of how representations acquire meaning in the context of interaction in mathematics classrooms. In order to address this question, we propose a conceptualisation of the interpretation of representations as situationally established rules that are negotiated in classroom interactions. By way of an illustrative example, we demonstrate that the processes of interaction in the classroom manifest on two levels: the interactional negotiation of the meaning of a mathematical representation, which is orientated towards norms that are in turn shaped and established in the process of interaction.

Keywords: Representation, Norms, Symbolic Interactionism, Interaction Analysis

Representations as tools for doing mathematics

Mathematics is an abstract science. In contrast to other sciences, we cannot experience the objects of mathematics empirically or directly with our senses (Duval, 2000). It is therefore particularly important for the learning of mathematics to visualise the abstract mathematical objects with representations, e.g., illustrations, diagrams or symbols, that mediate between the abstract objects of mathematics and the learner's world of experience. In this way, learners can utilise representations to discern mathematical objects, experiment with them, develop hypotheses about them, verify and justify them. Through the utilisation and manipulation of representations, learners may be enabled to experience abstract mathematical objects with their senses (visually and, if appropriate, also haptically) to conceptualise them and mentally anchor them as ideas regarding flexible application (Kollhoff, 2022; Finesilver, 2022; Tiedemann, 2020). Representations thereby become a means of doing mathematics, of understanding and of being understood (cf. Bauersfeld, 2002).

However, representations are generally not self-explanatory. There is no direct, isomorphic correspondence between representations and their associated mathematical objects. Representations do not convey mathematical objects; rather they represent mathematical objects through an assigned similarity between the object and its representation. In many instances, mathematical discourse employs the use of symbolic artefacts that have been specifically designed for the purpose of facilitating mathematical communication, in the sense of didactical materials. Such representations refer to entities that do not exist in the physical world (Sfard, 2008). Duval (2000) characterises this discrepancy between the abstract nature of mathematical objects and the concrete nature of representations as the "paradoxical character of mathematical knowledge" (Duval, 2000, p. 61). The use of mathematical representations to represent abstract mathematical objects results in the creation of essentially artificial artefacts. Consequently, learners must develop an increasing awareness that mathematics education operates with representations and not with the represented objects themselves (Duval, 1999).

The interpretation of a representation involves a process of abstraction from the surface features of the representation itself (cf. Söbbeke, 2024; Kollhoff, 2022). This interpretation of meaning is an individual and constructive process, whereby learners interpret a representation on the basis of their individual previous experiences. Furthermore, the mathematical objects and relations depicted in representations are often initially unfamiliar or unknown to learners, and their individual interpretations frequently diverge from the normatively intended ones. In order to utilise representations for the purpose of mathematics learning, it is essential that learners develop the ability to interpret representations in a way that is aligned to the intended interpretation as closely as possible. Söbbeke (2024) characterises this necessity for the learners as an epistemological conundrum: On the one hand, learners require the concrete quality of a representation to facilitate the conceptualisation of mathematical objects. Conversely, learners must also abstract from this concrete quality to interpret the underlying mathematical object represented.

From an interactionist perspective, we put forth the argument that such learning necessitates intersubjective negotiations of meanings between the learners and the teachers. Consequently, representations become "social products" (Blumer, 1969, 2013), which are negotiated situationally in and through the interpretations and defining activities of the interacting individuals.

Negotiation of meaning from an interactionist perspective

From an interactionist perspective, as applied in mathematics education research, particularly in interpretative research (e.g., Bauersfeld et al., 1988; Krummheuer, 2011; Schütte et al., 2019; Kollhoff & Gerlach, 2023), mathematics learning is understood to transpire within and through social interaction. The fundamental assumptions of this approach are derived from the sociological theory of symbolic interactionism (Blumer, 2013), as well as from approaches to collective learning (Miller, 1986) and ethnomethodology (Garfinkel, 1967).

Blumer posits that human coexistence is constituted by symbolic interactions, whereby the actions of the individual are always based on the previously interpreted actions of the other person. In addition to the concept of interaction, the concept of interpretation and the meaning resulting from these interpretations form the basis of symbolic interactionism. In consequence, the meanings of mathematical objects, operations, and representations in particular, can be characterised as 'social products' that are generated in reciprocal collective interpretation processes (Blumer, 2013, p. 67; cf. Fetzer & Tiedemann, 2018). By engaging in such collective processes of meaning-making, individuals can transcend their limited individual abilities to construct meaning, thereby establishing a foundation for individual mathematical learning (Schütte et al., 2021). From an interactionist perspective, however, it is a fallacy to assume that learners enter collective negotiation processes devoid of prior experience and knowledge, and that they construct only situation-specific concepts in these processes. Consequently, at the outset of an interaction, all learners establish preliminary situation-specific interpretations of the situation in which they find themselves, termed *situation definitions*, based on their individual experiences and knowledge (Krummheuer, 2011).

In order to facilitate effective communication and collaboration, those engaged in the negotiation processes invariably prepare the definitions of the situation in anticipation of potential interpretations by their counterparts. These are then modified or adapted during the process of mutual negotiation of

mathematical meaning (Krummheuer, 2011). In this process of mutual alignment of individual definitions of a situation, a moment of 'interpretive agreement', that is an instance of shared interpretation between the learners, can be achieved. This is referred to as an 'interpretive interim' by Schütte et al. (2021). The term is also discussed by Voigt (1995) in the context of 'taken-as-shared' understanding.

In line with Miller's (1986) perspective, the interpretive interim has the potential to be a source of innovation for the individual, enabling them to transcend their existing interpretive capabilities in a systematic manner. From the perspective of an interactionist understanding of learning, the interpretive interim can be seen as a source of 'stimulation potential' for fundamental, situation-transcending cognitive construction and restructuring processes at the individual level. Consequently, a one-time collective construction of an interpretive interim does not necessarily lead to individual cognitive construction or restructuring processes. Rather, it may be more accurate to view this as a process that requires repeated negotiation of the same interpretive interim, potentially in different groups of learners.

The underlying situation definitions of the individual that led to the production of the interpretive interim can be considered to 'converge' into more *standardised* and *routinised* retrievable situation definitions (Schütte et al., 2021). These enduring cognitive edifices, or their reorganisation, are referred to as the construction or modification of *frames* in accordance to Goffman (Goffman, 1957; Krummheuer, 2011). On the basis of such frames, learners reinterpret the situation (here: the representation) in subsequent mathematical negotiation processes, thereby acquiring altered opportunities for participation. In the context of classroom discourse, it is to be expected that this convergence of individual interpretations – cf. 'conception-frames' as introduced by Salle and Schütte (2023) – of representations towards a conventional normative meaning will be driven by the negotiation of sociomathematical norms.

Norms and Processes of standardisation

Sfard (2008) categorises rules and norms in mathematics education into two different types. On the one hand, she identifies 'object-level rules', which orientate the content level of a conversation, and on the other hand, 'metadiscursive rules', which orientate what to do, when and how (Sfard, 2008). Sfard uses the following example of an object-level-rule: "To divide a by b, you have to find a number c such that $b \cdot c = a$" (Sfard, 2008, p. 201). The metadiscursive rules are no longer concerned with the content of a verbal utterance, but with its situationally appropriate integration into the course of a classroom discussion, such as 'Always explain how you arrive at the result of a calculation'. Sfard (2000, p. 166) identifies sociomathematical and social norms as instances of metadiscursive rules. These provide a promising foundation for the examination of interpretation-related norms as pursued here.

Voigt (1994) and Yackel and Cobb (1996) employed the same data set to reconstruct sociomathematical norms. Voigt (1994) posits that sociomathematical norms serve as value criteria for mathematical activities within the classroom setting. These norms, he asserts, do not function as definitive rules within the social dynamics of the classroom; rather, they typically operate as implicit orienting principles (ibid., p. 107). A sociomathematical norm, for instance, may delineate the

parameters of an acceptable interpretation, a desirable linguistic description, or a successful operational modification of a representation. As Voigt asserts, the criteria in question are negotiated within the classroom setting and cannot be reduced to the expectations of the teacher or the individual objectives of the students. As Voigt (ibid., p. 106) notes, learners typically regard the teacher as a knowledgeable representative of mathematical culture and, as a result, tend to take the teacher's presumed expectations into account when formulating their own statements (cf. ibid., p. 106). However, he emphasises that mathematical norms are not constraints imposed upon the students by the teacher (cf. ibid., p. 106f.). While teachers have the opportunity to indicate their demands through their assessments, it is ultimately up to the students to decide whether they orientate their actions and interpretations accordingly. For Voigt (ibid., p. 105), only those rules that are recognised as valid by both sides are considered norms.

Yackel and Cobb (1996) emphasise that the norms are always contingent upon the specific actors involved in the given situation: "[…] what becomes mathematically normative in a classroom is constrained by the current goals, beliefs, suppositions, and assumptions of the classroom participants" (p. 460). The negotiation of norms through interaction enables the development of a shared interpretative frame of reference, or an interpretative interim, which facilitates the joint interpretation of representations.

Two challenges for classroom interaction

An interactionist perspective on the interpretation of representations poses two fundamental challenges that must be addressed to facilitate effective mathematical learning through representation in classroom interaction:

1. The negotiation of meaning: Representations do not convey mathematical content. Therefore, it is necessary to interpret abstract mathematical objects into representations or to ascribe meaning to representations.
2. The establishment of value criteria for the interpretation of representations: The purpose of introducing representations is typically to represent a specific abstract mathematical object. In the context of classroom interaction, the negotiation of value criteria is significant for determining if an interpretation of a representation is appropriate in a given situation.

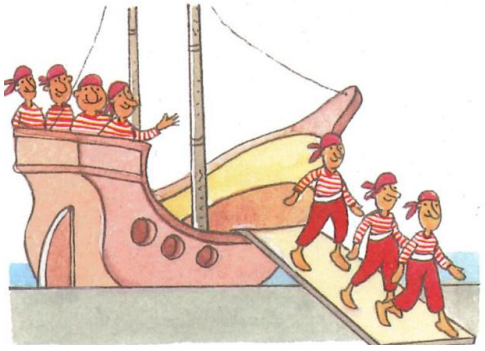

Figure 1 taken from the textbook „Welt der Zahl 1" [World of Number] (Rinkens et. al, p. 40)

We would like to exemplify these two problems using an illustrative representation. This illustration, depicted in Figure 1, appears in a widely used German mathematics textbook in the section on the introduction of subtraction. This indicates that the editors and authors of the textbook consider this representation to be an appropriate means of conceptualising the concept of subtraction of natural numbers and of identifying and developing corresponding mathematical structures within it. From an objective standpoint, it is evident that the depicted action can be interpreted in a multitude of ways.

For instance, it can be expressed as 7-3, 4+3, 4-3, and so forth. Conversely, the objective of the authors or instructor is for the learners to discern that, of the seven pirates on the ship, three pirates disembark, leaving four pirates on the ship. The discrepancies between the feasible and the intended interpretations of the representation can be contemplated in the context of the tension between the representation and the abstract mathematical concept. In consideration of the position in the textbook, it becomes evident that there is meant to be a single appropriate interpretation, accompanied by a multitude of situationally inappropriate ones. This necessitates the negotiation of value criteria that determine which interpretation is preferable in the context of the classroom interaction in accordance with the requirements of the present situation. The following example of a classroom interaction serves to illustrate this assumption.

Illustrative Example: Reformulation

The following scene is taken from a classroom observation of a second-grade lesson on the introduction of multiplication.

Teacher:	My aim in the weeks before the March holidays is to make sure that you understand what a multiplication task is. So, who's going to go ... six times and get two cubes each time? (02:46-06:02) Okay, what do you see in the centre now? ... Hannah.
Hannah:	That's twice as many as six.
Teacher:	Mmh. That's quite interesting information. Liam.
Liam:	A bunch of cubes.
Teacher:	Mmh. What do you see in the centre? ... What is there? ... Emma.
Emma:	That's ... um ... That's six times two. So there are always two cubes, but if you put them together, there are always six.
Teacher:	Well, what would the plus task be called, a suitable one? (...) Jakob.
Jakob:	Two plus two plus two plus two plus two plus two plus two.
Teacher:	[writes '12' on the whiteboard] But now it's like this and you've already said 'Phew, that's quite long!', that's too tedious for me and it could be written differently, namely as a multiplication task. ... Stevan.
Stevan:	You write down six. Then one point. And two.
Teacher:	Exactly. Great. [writes '$6 \cdot 2 = 12$' on the whiteboard] So, these six twos become six times two. (...)

Figure 2 Six times two cubes

The scene opens with the staging of a representation, for which the instructor requests that a student retrieve "six times [...] two cubes" and place them on a table within the view of the entire class. The teacher provides precise instructions regarding the repeated addition of two cubes, enabling learners to build on their existing knowledge and interpret the enacted representation within the context of addition as "adding". After preparing the representation, the teacher requests an interpretation of the representation (Figure 2): "Okay, what do you see in the centre now?". In consequence, she does not respond to the multiplicative interpretations put forth by Hannah and Emma, but rather concretises her expectation: "Well, what would the plus task be called?" She makes an intermodal alteration of the representation from the concrete cubes to the symbolic term by noting the repeated addition of 2 on the whiteboard. She requests the result, "12", and repeatedly emphasizes that this calculation is

"too lengthy" and "too tedious", thus sociomathematically motivating a shorter and more concise method of writing the equation.

Subsequently, the teacher initiates an intramodal alteration of symbolic representation by indicating the corresponding multiplication task associated with the repeated addition and explicitly articulating the transformation of representation: "$2 + 2 + 2 + 2 + 2 + 2 = 12$" becomes "$6 \cdot 2 = 12$". Although the teacher provides the additional clarification that "these six twos become six times two", she does not offer a reinterpretation of the additive structure as a multiplicative structure in the cube representation, thereby omitting any substantial justification for the reformulation of the equation.

Discussion

This scene on the interactive standardisation of representations is to be understood as an illustration of a key insight. The process of developing shared meanings from individual interpretations is inherently complex. It is shaped by the interplay between learners' prior experiences, teachers' normative guidance, and the negotiation of sociomathematical norms within collective argumentations.

The teacher's reactions to the learners' contributions and her own argumentative behaviour in this scene indicate her expectations. In particular, the enacted representation should be interpreted as a case of repeated addition. Although she appears to accept the learners' divergent interpretations and acknowledges them by marking them as "interesting information", she largely disregards the learners' interpretations of the representation and explicates the intended meaning as the foundation for further thematic development. In doing so, she makes a decisive change to the object of study, abstracting from the cube representation to the symbolic notation of the calculation, which from then on is at the centre of the discussion. There is no explicit connection made between representation and term, which would be desirable in terms of understanding the concept of multiplication. Instead, the term is reformulated on a symbolic level. On this note, the teacher introduces the objective of maintaining terms in the shortest possible format.

From a methodological standpoint, the theoretical framing of norms for the interpretation of representations as situationally negotiated binding rules allows us to reconstruct thematic developments on both levels: the negotiation of meaning and the negotiation of value criteria to characterise a situationally appropriate interpretation. The observation-based assumption that the reconstructed processes exhibit a certain regularity in terms of interaction patterns motivates the conceptualisation of the interactional negotiation of representation meaning as a discursive practice from a functional-pragmatic perspective. A discursive practice is defined as an always situated, socially regulated linguistic-interactional procedure for solving a repeatedly occurring interactional problem (cf. Tiedemann, 2020). In this case, the problem arises from the necessity of interactively establishing representations in mathematics lessons in a manner that ensures their interpretation is sufficiently similar by teachers and learners. The rationale behind the development and utilisation of such practices can be attributed to the existence of discrepancies between the learners' individual interpretations and the normatively intended interpretations of representations (cf. "conflicting interpretations" in Schulz and Tiedemann (2020); "deviating subjective interpretations" in Kollhoff (2022)).

From this perspective, processes of sociomathematical standardisation in classroom interactions are not merely situational solutions; they also represent an opportunity to establish rules for interpreting representations in the field of tension between mathematical conventions and individual constructions. This allows for the interactive stabilisation of scientific consensus in the classroom, thus facilitating the resolution of tensions between mathematical conventions and individual learners' construction processes.

Conceptualising subjective relevance of mathematics education

David Kollosche[1] and Chiara Nadine Wang[1]

[1]University of Klagenfurt, Klagenfurt, Austria; david.kollosche@aau.at

In this essay, we understand subjective relevance of mathematics education as the relevance that students attribute to their engagement in institutionalised mathematics education. After presenting reasons for studying this concept, we ask how to conceptualise it. We propose to test possible theories, all of which have already been used in publications in the field, against a list of features of subjective relevance. Here, we discuss the suitability of the concepts of beliefs, motives, and utility value. We conclude that these concepts may be promising to capture some cognitive aspects of subjective relevance but fail to explain the developmental nature of subjective relevance. Also, these concepts struggle with explaining the social entanglements of subjective relevance and do not facilitate reflection on the role of subjective relevance for mathematics education as a social institution.

Keywords: Subjective relevance of mathematics education, beliefs, motivation, expectancy-value.

Introduction

The last decades have seen a growing interest in the relevance that students see in mathematics education. For example, Kislenko et al. (2007) compared two Likert-scale questionnaire studies with Norwegian students from grades 6 and 9, including questions on their "own evaluation of importance of mathematics" (p. 352), and found that students mostly agreed to the statements that "mathematics helps those who make important decisions" and that "good mathematical knowledge makes it easier to learn other subjects", but not that "mathematics helps me to understand life in general". Dobie et al. (2021) collected questionnaire and interview data from 84 US-American seventh-grade students, analysed it with the concept of "perceived utility", and found that utility was predominantly associated with the use of mathematics in daily life. They highlight the case of Liliana, who finds mathematics useful for money-related activities and sees relevance in learning mathematics in order to be able to help friends and family with money-related challenges. However, Liliana also expressed "some scepticism, as she worked to make sense of whether math was truly useful" (p. 419). Chronaki and Kollosche (2019) studied subjective relevance as an aspect of identity work of students of mathematics in order to make sense of the case of Anja, a ninth-grade student from Germany who denied any relevance of mathematics education for her life.

In this paper, we understand "subjective relevance of mathematics education" as the relevance that students attribute to their engagement in institutionalised mathematics education. One could just as well study "subjective relevance of mathematics" as related to the academic discipline in broader terms. We decided for the narrower focus on mathematics education, because our main research interest lies in understanding mathematics education as a social institution. Especially, we refuse to narrow "engagement" down to "learning", as students can find mathematics education relevant for very different reasons (see, e.g., Kollosche, 2017), including the self-discipline that mathematics requires, the objectivity of mathematical knowledge, and the utility of mathematics in daily life, in targeted vocations, or in society in general. The categorisation of such reasons is subject of a different essay (Wang & Kollosche, 2025). Nonetheless, while this distinction serves conceptual clarity, it

becomes blurred when put into practice: On the one hand, experience and our (yet unpublished) data show that most students identify the discipline of mathematics with what is happening in their mathematics classrooms. On the other hand, even if someone is able to distinguish mathematics as an academic discipline from mathematics education in school, it is fair to assume that subjective relevance of mathematics and subjective relevance of mathematics education would interact strongly. This blurriness is present when reporting on empirical studies in the field which use different concepts to frame their results, for example, Kislenko et al.'s (2007) concept of "importance", which could mean subjective relevance in our sense just as well as societal instead of individual importance.

The subjective relevance of mathematics education is worth studying for various reasons:

- We can ask in how far a student's subjective relevance fits to what is offered in mathematics education. Different studies from Western countries (e.g., Sachdeva & Eggen, 2023) have repeatedly shown that students have very limited and fragile accounts of the relevance they see in mathematics education. Studies show that a lack of subjective relevance constitutes an obstacle to identifying with or becoming motivated for mathematics education (e.g., Chronaki & Kollosche, 2019). If more aspects of the relevance of mathematics education were available for students, they might face better conditions to productively engage with mathematics.
- We can also ask in how far what is offered in mathematics education fits what students find to be relevant for them. Such a perspective might reveal that mathematics education includes offers for some interests but not for others – for example, offers for students who want to follow rules and experience flow in batteries of exercises, but no offers yet for students who want to work on complex problems collaboratively (e.g., Andersson et al., 2015). Ultimately, an awareness of possible aspects of the relevance of mathematics education would be a condition for emancipating students to express what they expect from mathematics education.
- Eventually, subjective relevance can be seen as a functional part of mathematics education as a social institution, helping as a device to train specific subject positions towards mathematics. For example, if students disengage from mathematics because they have learned to find it irrelevant to them, then they become more easily subjected to socio-political decisions which are allegedly supported by mathematics (Fischer, 1984). More generally, such an institutional perspective on subjective relevance can help us reflect on the roles that mathematics and its education play in society, for example, concerning the question if it is a function of mathematics education to train and measure the ability to concentrate. A deeper understanding of such functions might also prove important to legitimise school mathematics.

We hope that this short introduction to the nature and importance of the subjective relevance of mathematics education convinces the reader that this concept is worth studying. However, although it has been touched upon in various studies under different terms, there is no common conceptual basis for what we understand as the subjective relevance of mathematics education. Kislenko et al. (2007) framed their research along the concepts of *belief* and *attitude* in mathematics education. Dobie et al. (2021) used the psychological concept of *utility value* to inform their approach on "perceived utility", and other concepts from motivational psychology, such as the concept of *motives,* appear promising to illuminate the motivational aspects of subjective relevance. Vollstedt (2011) approached subjective relevance through the concept of meaning (German: *Sinn*). Chronaki and

Kollosche (2019) understood subjective relevance as a part of students' mathematical *identities*, which are constantly developed within a social discursive field. Given this variety of theoretical framings, we ask *what these theoretical frameworks offer to conceptualise the subjective relevance of mathematics education and where its limitations lie*.

The search for a helpful theory is not straightforward. In fact, it could be that there is no fitting theory at all, which can easily be adapted to explain what subjective relevance is. More likely, we will find that some theories serve well to explain some aspects of subjective relevance but not others. But how to determine that? We propose to lay down some key features of the concept of subjective relevance. A theory fits if it does not contradict these features, and it helps all the more if it is able to explain them well. This process does not have to be chronologically linear. In fact, a feature of subjective relevance might not be striking until facing a theory that contradicts it, whereupon this feature can be described and serve as a basis to judge that theory. In our written presentation of the results of such processes, in order to have a basis on which to judge the suitability of such theories, we first present key aspects of the subjective relevance of mathematics education, which a suitable conceptualisation will have to capture. Due to space limitations, we will only discuss the concepts of beliefs, motives, and utility value here. This approach not only provides insights into which aspects of these concepts can help to conceptualise subjective relevance, it also helps us to further develop the features of subjective relevance and allows us to judge the fruitfulness of this approach in general.

Features of subjective relevance of mathematics education

Past research has shown that there are features of the concept "subjective relevance of mathematics education" that a theoretical conceptualising should be able to address. These include:

1. Subjective relevance of mathematics education has both a *cognitive* dimension in that it describes what individuals think and how they behave on that basis as well as a *social* dimension in that it is constructed in a field of social discourses.
2. A conceptualisation of subjective relevance should address its importance for motivation (in providing reasons to engage with mathematics education), emancipation (by allowing to formulate expectations in mathematics education), and our understanding of mathematics education as a social institution.
3. Between individual accounts of the subjective relevance of mathematics education, there are differences, but also recurring patterns, which can be described as *dimensions* of subjective relevance. Such dimensions include the idea that mathematics education is relevant because mathematical qualification will help oneself in private life. Students hold different sets of such dimensions, and the dimensions can be formulated as ideal types to study them further.
4. Different dimensions of subjective relevance can be based on one and the same feature of mathematics education. For example, some students find mathematics education relevant because mathematics "knows only right and wrong", while other students find mathematics education irrelevant for the same reason (Kollosche, 2017). A conceptualisation of subjective relevance will have to consider that different people judge similar experiences differently.
5. Subjective relevance of mathematics education develops (e.g., within an interview) and can be fragile (e.g., notwithstanding spontaneous questioning) (Chronaki & Kollosche, 2019).

Mathematics-related beliefs

Subjective relevance of mathematics education has been studied in research on *beliefs* in mathematics education research. In their seminal "quest for conceptual clarity and a comprehensive categorization", Op't Eynde et al. (2002) arrive at the definition that "students' mathematics-related beliefs are the implicitly or explicitly held subjective conceptions students hold to be true about mathematics education, about themselves as mathematicians, and about the mathematics class context" (p. 27). They shortly refer to cognitive theories of learning, which identify "conative and affective factors […] as constituting elements of the learning process" (p. 14), and offer a categorisation where beliefs stand side-by-side with knowledge, heuristics, metaknowledge, and self-regulatory skills as factors influencing learning. Further elaborations of how beliefs integrate into cognitive theories of learning are scarce, but there are studies illuminating how beliefs influence problem-solving activities in mathematics education (Schoenfeld, 1989).

Although Op't Eynde et al. (2002) stated that "a person's beliefs about what counts as a mathematical context and what (s)he finds interesting or important will, as such, have a strong influence on the situations (s)he will be sensitive to, and whether or not (s)he will engage in them" (p. 15), and although prompts such as "I find mathematics important" had been studied in beliefs research (p. 24), their quest for a categorisation shows that subjective relevance was no explicit focus of beliefs research, nor was it in any way conceptualised. Nevertheless, a few studies use the concept of beliefs to address such issues (e.g., Kloosterman, 2002, see below). Other studies did not prove relevant here and usually only refer to the concept of beliefs to loosely locate their research within a research field without using the features of the concept (e.g., Gijsbers et al., 2020).

We will use the above features of the subjective relevance of mathematics education to judge how fruitful it is to understand subjective relevance as a part of students' mathematics-related beliefs. Beliefs research allows to understand recurring dimensions of subjective relevance of specific beliefs and acknowledges that students hold different beliefs. However, while beliefs are often considered to be enduring and difficult to change, the same cannot be said about subjective relevance, which has been found to be able to change quickly and drastically. The description by Op't Eynde et al. (2002) proposes that beliefs might be suitable to capture the cognitive aspects of subjective relevance, but the cognitive features of the concept of beliefs are not well developed, for example, by expanding an existing psychological theory. A definition of beliefs as "subjective conceptions students hold to be *true* about mathematics education" (Op't Eynde et al., 2002, p. 27 emphasis added) would be a serious problem, as we might hold something to be true (e.g., that cigarettes are bad for us) and still not act accordingly. Likewise, it might be possible to hold it to be true that mathematics education is relevant for oneself for a specific reason, but this idea might have no influence on how one engages with mathematics education. A possible social dimension is not discussed, and their categorisation of factors influencing learning does not refer to the social environment of students. Further, beliefs research does not provide useful methodological input, as most studies in beliefs research use closed instruments such as Likert-style questionnaires and would thus not be open to the identification of new dimensions of subjective relevance, nor do the minimalistic answers to such questionnaires allow for a study of the social circumstances and implications of specific dimensions (Kloosterman, 2002). Eventually, even qualitative studies on beliefs focus on the manipulation of students in order to

improve learning outcomes (e.g., Kloosterman, 2002) and neither problematise this goal nor take any emancipative or institutional perspectives. We conclude that understanding subjective relevance of mathematics education as a part of students' mathematics-related beliefs would dramatically curtail our understanding of what we want to conceptualise.

Motives and expectancy-value theory

Motivation is the willingness of an individual to perform an action, such as learning mathematics or refusing to learn mathematics. Motivation theory assumes that motivation is negotiated not only by the situation where individuals are urged to act, but also by their motives, which are features of the individual. Reiss (2016) understands motives as "universal goals that motivate significant behavior" (p. 576), and Wigfield and Rosenzweig (2016) point out that "motivation and cognition influence one another" (p. 571). On the one hand, motivation influences how far a person engages in cognitive activities, which cognitive resources this person activates, how persistent this person is, and how much this person can learn. On the other hand, how people think about certain actions, goals, and about themselves will influence their motivation.

Motivation theory is a field with dozens of partly conflicting and yet prominent theoretical offers. It is clear that we cannot cover these offers here, but we want to highlight two very active strands in the field: First, there are a number of theories which Wigfield and Rosenzweig (2016) argue "have had strong social cognitive foci in that individuals' beliefs, values, and goals are the major components of these theories" (p. 570). They list Weiner's attribution theory, expectancy-value theory, Bundura's social-cognitive theory, and self-determination theory as examples. Second, there is a research strand focussing on universal needs of humans – universal in the sense that these needs appear frequently among humans. Reiss (2016) speaks of 328 different goals discussed in the literature, including, for example, such needs as acceptance ("the desire for positive self-regard"), curiosity ("the desire for understanding"), dominance ("the need to control and lead others"), infavoidance ("the need to avoid failure/shame"), or nurturance ("the need to protect the helpless") (p. 577).

Different from the basic needs, whose significance for mathematics education has, as far as we know, not yet been studied, theories from the strand that Wigfield and Rosenzweig (2016) refer to have already been applied to mathematics education research, for example, by Kloosterman (2002). He assumed "that motivation is a cognitive activity and that students make specific choices about how and when they apply effort to learn" and that "these choices are based on students' beliefs" (p. 248).

For an exemplary look into one special theory, we will discuss the expectancy-value theory. In their study on how students perceive the "utility" of mathematics, Dobie et al. (2021) referred to the concept of utility value. Alongside attainment value and intrinsic value, utility value is one category of values in expectancy-value theory (Eccles, 1983). In its simplest form, this theory assumes that achievement motivation is a function of both the probability of success and the values associated with the goals of action in question. Thereby, the attainment value is understood as the importance for someone to do something well, the intrinsic value is understood as the pleasure that an individual feels while performing an activity, and the utility value is understood as the importance of an activity in order to achieve future goals. Since its introduction by Atkinson in the 1950s, expectancy-value theory has seen further conceptualisations of expectancy, such as self-concept of ability, perception

of task difficulty, perception of other's expectations, and causal attributions of success, as well as further conceptualisations of value (ibid.). Dobie et al. (2021) use the theory to theoretically attest the importance of utility values. This perspective would be too narrow for a conceptualisation of the subjective relevance of mathematics education, as not all of its dimensions are directed at future achievements. However, expectancy-value theory, in general, would be open to include further values in order to cover dimensions of subjective relevance beyond utility.

Again, we will use the above features of the subjective relevance of mathematics education to judge in how far it is fruitful to understand subjective relevance through motivation and expectancy-value theory. The dimensions of subjective relevance can be understood as motives for engagement in mathematics education. It has become clear that motivation theory offers different approaches to understand the cognitive dimension of subjective relevance, for example, through expectancy-value theory. Also, there are motivational theories that acknowledge that motives can be socially influenced (Kumar, 2016). Nevertheless, in descriptions of motivation theory (e.g., Eccles, 1983; Kumar, 2016; Reiss, 2016; Wigfield & Rosenzweig, 2016), the question of how the social environment influences motives is not central, if posed at all. Also not central to motivation theory is the question of how motives develop and in how far they can collapse. Instead, motives are often regarded as more or less stable properties of the individual (Reiss, 2016). Eventually, though not surprising, it has to be noted that motivation theory does not easily allow to focus on emancipation through mathematics education or on the understanding of mathematics education as an institution. Although it seems fair to assume that motivation theory has this potential – that, for example, a better understanding of students' motives would allow us to change mathematics education for the better or at least to understand its institutional confinements –, critical psychology points out that the predominant goal of motivation theory is to manipulate workers to be better workers, students to be better students, etc. (e.g., Osterkamp, 1975).

Conclusion

First of all, it proved fruitful to depart from features of subjective relevance of mathematics education as a basis to judge the suitability of possible theories for the conceptualisation of this concept. During the process, some features were found to be irrelevant, while others had to be added or elaborated. This allowed us to develop judgements that we hope to be transparent.

The list of features helps us to understand what we mean by subjective relevance. Where easily possible, we included references to studies where the relevance of certain features has been established. More references could be added for all listed features if space limitations allowed.

It appears to be possible to understand dimensions of subjective relevance as "beliefs" in the sense of subjective conceptions students hold to be true about why mathematics education is relevant for them. The concept of beliefs might allow to capture the cognitive aspects of subjective relevance, but the benefits of such a conceptualisation are not easily visible as the concept of beliefs appears not to have a strong theoretical foundation. Likewise, it appears to be possible to understand dimensions of subjective relevance as "motives" for one's engagement with mathematics education. This approach is more promising, for there are many theoretical offers on motivation theory, which have been developed over decades. Expectancy-value theory would be one such offer. Its strength lies in not

only focusing on motives as values but also on expectancy, which is largely influenced by the experiences in the mathematics classroom. Concerning values, the distinction between attainment, intrinsic, and utility value does not appear to be sufficiently accurate, but different approaches in motivation theory might allow the development of a more detailed categorisation of possible motives (Reiss, 2016).

Both beliefs research and motivation theory seem unfit to explain the fragile and developing nature of subjective relevance, as their concepts are considered to be more stable and difficult to change. Further, both fail to describe the social dimension of subjective relevance and its importance for students' emancipation and the understanding of mathematics education as an institution. This might not come as a surprise, as both theories are psychological in origin and thus focus on an understanding of the individual. From such a perspective, social questions are only relevant as long as they allow for a better understanding of the individual, but not for their own sake.

An alternative might be to use sociological theories. For example, Chronaki and Kollosche (2019) used discourse theory to understand subjective relevance of mathematics education as a part of the discourse that an individual develops about the relationship between the self and mathematics. Locating subjective relevance in such a discursive field allows to better understand the fragile and developing nature of subjective relevance (as discourses are easily changeable), its entanglements with the social environment (e.g., with stereotypes about mathematics), and its functions for mathematics education as an institution (e.g., concerning the question which sentiments towards mathematics are developed in school). Yet, such a sociological theory might leave open questions concerning the conceptualisation of the cognitive dimensions of subjective relevance, which might, in the end, call for a triangulation of psychological and sociological approaches.

Pre-service teachers' developing professional identity as mathematics teachers – a theoretical perspective

Beate Lien[1], Amalie Sødal[1], Jorunn Reinhardtsen[1] and Martin Carlsen[1]

[1]University of Agder, Faculty of Engineering and Science, Kristiansand, Norway;
beate.lien@uia.no

In this paper we will launch the theoretical perspective Patterns of Participation as a lens to study pre-service teachers' developing professional identity as secondary mathematics teachers, through the notions of being, becoming, and belonging. It is documented in the research literature that pre-service teachers experience a gap between the university and the school as learning contexts. In our study we address tensions that manifest themselves in the development of professional identity, as the pre-service teachers participate in these two learning contexts. Furthermore, we introduce the idea of a resource bank, theorised as a boundary object between these contexts. Drawing on an example from another study, we argue that by reflecting on the content of a resource bank, one pre-service teacher testifies her being, becoming and belonging.

Keywords: Communities of practice, patterns of participation, pre-service teachers, professional identity, secondary school

Introduction

In this paper we will launch the theoretical perspective Patterns of Participation (Skott, 2013, 2019) as a lens to study pre-service teachers' (PSTs) developing professional identity as secondary mathematics teachers. The importance of studying professional identity formation among pre-service teachers has been advocated by Arvaja and Sarja (2021). Skott (2019) argued that teachers draw on previous and current practices as they participate in classroom interactions. Unlike in-service teachers, PSTs engage in practices both at the university and in schools through school placements. Their professional identity develops across these two learning contexts, distinguishing them from in-service teachers whose identity is primarily shaped within the school context. Moreover, it is well documented in research that the PSTs experience a gap between the university and the school as learning contexts (Goos, 2009; Jenset, 2020). In our study we address tensions that manifest themselves in the development of professional identity as mathematics teachers, as the PSTs participate in these two learning contexts. Furthermore, we build on the idea of a resource bank, hypothesised as a boundary object (Star & Griesemer, 1989) between these contexts.

These tensions stem from the particularities in the teacher education that the PSTs in question participate in. In Norway, those PSTs who are becoming mathematics teachers in secondary school, follow a teacher education in which the mathematics subjects are separated from educational and didactical aspects of mathematics teaching and learning. These PSTs also study mathematics subjects together with undergraduate students in mathematics. Furthermore, the school placement part of their teacher education is more spread compared to primary teacher education. We argue that these PSTs' professional identity formation as mathematics teachers deserve attention in research. Thus, we launch a framework for studying identity formation in this context adopting Patterns of Participation (PoP) (Skott, 2013, 2019) as a lens, accompanied by the construct of boundary object.

Below we will give a theoretical account of Communities of Practice (CoP) (Lave & Wenger, 1991;

Wenger, 1998), as well as PoP, since PoP take CoP as its theoretical point of departure. However, we will first give an account of (mathematics) teacher education in Norway, its regularities and expectations. We also introduce the idea of a resource bank for PSTs to bridge their experience from the two learning contexts university and school.

Teacher education for grades 8–13 in Norway

According to the National Council for Teacher Education (NRLU), the teacher education for grades 8–13 is "integrated, professionally oriented, research based, and experience based and offer the student professional deepening within two school subjects" (2017, p. 4, our translation). For PSTs for grades 8–13 in mathematics, the first or second year of their studies consists of mathematics as a discipline subject, which means they study mathematics alongside students from other study programs. In the third and fourth year, PSTs encounter mathematics education courses and general education courses. During their studies, PSTs must spend at least 100 days in school placement, where they will teach mathematics and another chosen subject (Subject 2). It is the institution's responsibility to organise the school placement so that it contributes to a coherence in the education. That requires collaboration between PSTs, mathematics teacher educators both in the institution and in school, to plan, implement and evaluate school placement. The content of the school placement should be connected to pedagogy and didactics, and build on the PSTs' knowledge in mathematics and Subject 2, to develop their professional knowledge through both theory and practice. Through school placement, PSTs should "gradually be introduced to various aspects of the teaching profession and strengthen their development of a professional identity" (NRLU, 2017, p. 15).

Following the national guidelines presented above, Norwegian teacher education for grades 8–13 should be both research-based and practice-oriented. Moreover, the PSTs are expected to learn and develop professional identity from consolidating experiences in school placement and in university coursework. However, research indicates that PSTs tend to view the two sites as separate and unconnected, appraising practical experience as more valuable than theoretical aspects (Bjerke et al., 2013). In Norway, the disconnection between theoretical and practical aspects of teacher education is a persistent criticism and there is a call to better prepare PSTs to take on the practical work in classrooms (Jenset, 2020). This experienced disconnection also causes deficits in the PSTs' developing professional identities as mathematics teachers.

During the teacher education programme, PSTs participate in the practices of the university site and the school site. When participating in these practices, PSTs are both students themselves and (novice) teachers. The two roles sometimes hold different expectations for and images of teaching mathematics (Goos, 2009). Norwegian teacher education programmes tend to operate on the assumption that laying a foundation of theoretical principles that PSTs are to apply in practical situations will sufficiently prepare them for the practice of teaching (Solomon et al., 2017). However, Gainsburg (2012) observed that PSTs struggle to connect theoretical and practical principles of teaching if not supported in this process.

Resource bank as a potential boundary object

A recent study introduces a resource bank for teaching mathematics, exploring how the resource bank can support PSTs in connecting experiences from the practices at university and the practices at school placement (Sødal, 2023). The approach builds on Gueudet et al. (2019), who theorise teacher learning

and professional development through interaction with resources. Sødal (2023) inquired into how a resource bank may support PSTs in connecting experiences from coursework and school placement, thereby bridging the gap between the university site and the school site. Each PST developed a resource bank which contained for example mathematical tasks, activities, lesson plans and research related to mathematics teaching. Moreover, experience from interactions with students, mentor teachers, peers and teacher educators were also considered and potentially included in the resource bank through entry-slips (short reflections on why a resource was included and how it was to be enacted). The resource banks were developed both in connection to coursework and during school placements, and in this way, they were developed on a continuum across the boundary between university and school. Sødal (2023) studied how the practices of university and of the schools shaped the PSTs' process of developing the resource bank. The resource bank mediated PSTs' learning across practices, for example as the PSTs updated their entry-slips following the enactment of a resource.

We thus propose the idea of a resource bank as a means to explore PSTs' development of professional identity as they participate in different university and school practices. Star and Griesemer (1989) launched the analytical concept of boundary object to address scientific objects that encompass intersections between different social worlds. The authors argue that boundary objects "have different meanings in different social worlds" (p. 393). We hypothesise that the PSTs' resource bank may become a boundary object between different practices. At the university site, the resource bank (including resources from courses and school placements) serves the purpose of operationalising theoretical ideas, while at the school site the resource bank serves the purpose of implementing these operationalisations into the classroom practice.

In their review of boundary crossing and boundary object, Akkerman and Bakker (2011) identified four learning mechanisms in crossing boundaries: identification, coordination, reflection, and transformation. Identification addresses central demarcations between the intersecting practices of university and school. Coordination allows means and procedures to be used across the intersecting practices. Reflection is "coming to realize and explicate differences between practices and thus to learn something new about their own and others' practices" (pp. 144–145). Transformation involves confronting the tensions that emerge between the intersecting practices, resulting in changes in the practices. All four mechanisms play a role in developing professional identity as mathematics teachers. As we will argue, professional identity development may be viewed through the lens of Patterns of Participation (PoP), as being, becoming and belonging (Skott, 2019).

Professional identity as a social construct

Wenger (1998), in his seminal book 'Communities of practice. Learning, meaning, and identity', gives an account of what he calls a community of practice. As we, in this study, address the development of professional identity amongst pre-service mathematics teachers for grades 8–13, the communities we are talking about are the varied social constellations that pre-service mathematics teachers participate in during their education and the practices are what these communities do.

According to Wenger (1998), a community of practice is characterised by mutual engagement, a joint enterprise, and a shared repertoire. It is beyond the scope of this paper to do full justice to making explicit these features. Nevertheless, we would like to mention that mutual engagement is what defines the community, «what makes a community of practice a community is mutual engagement»

(Wenger, 1998, p. 75) – in our case the PSTs' participation in the community of mathematics, mathematics education, teaching and learning of mathematics in the classroom, etc. In order for a community to be sustainable, a joint enterprise is needed. Despite plausible disagreements, participants still invest their energy into discussions aiming for some agreement. In a community, participants make efforts to achieve agreement on the essence of the enterprise, since «defining a joint enterprise is a process» (Wenger, 1998, p. 82). In this process, a separate discourse develops comprising terminology, expressions and metaphors, use of tools and actions. This discourse is 'local' in the sense that each community will be characterised by 'local' negotiated expressions and metaphors, some of which overlapping with more general ones. Wenger calls this a shared repertoire. "The repertoire of a community of practice includes routines, words, tools, ways of doing things, stories, gestures, symbols, genres, actions, or concepts that the community has produced or adopted in the course of its existence, and which have become part of its practice" (Wenger, 1998, s. 83).

In the process of developing mutual engagement of a joint enterprise, characterised by a shared repertoire, Lave and Wenger (1991) argue that participation takes place at various levels. However, among several constituents of a community, Wenger (1998) emphasises that the development of personal identity plays an important role in a person's participation in a community. Due to space limitations, we cannot possibly give a full account of identity as a construct. However, we adopt Wenger's point of departure, that identity is profoundly connected to a practice entailing "the negotiation of ways of being a person in that context" (p. 149), in our case the practice of mathematics teaching. Furthermore, "our identity includes our ability and our inability to shape the meanings that define our communities and our forms for belonging" (p. 145). Thus, identity is characterised as negotiated experience, membership in a community, a learning process, and membership of multiple communities in which belonging is globally and locally negotiated.

Skott (2013, 2019), in his framework Patterns of Participation, draws in part on social practice theory (Wenger, 1998; Holland et al, 1998) to understand the teacher's role in classroom interactions. Rather than seeing the teacher in the classroom as a strategic individual acting from a firm set of beliefs, knowledge and skills, the teacher is seen as a reflexive responder to pupils' needs and the evolving classroom situations, drawing on previous experiences of being, becoming and belonging, again providing new experiences that allows for continues transformations of the teacher's role. Thus, for Skott (2013, 2019) identity is not static but in flux.

A teacher is and has been participating in a multitude of practices that may form his reflexive acts in classroom interactions (Skott, 2013), including local communities of practice such as mathematics classes in school, courses in teacher education, professional development programs, colleagues at former and current schools, mathematics clubs, etc. While participating in these different practices, the teacher may also have encountered cultural and more generalised practices. For example, reformed mathematics teaching or ideas from theories of learning, such as zone of proximal development, the importance of student talk, and conceptual learning. To incorporate such practices Skott used the concept of figured worlds drawing on Holland et al. (1998). They argued that identity is the views one has of oneself in worlds of action and involved two contexts of activity: (1) the immediate here and now interaction; and (2) figured worlds, i.e. socially and culturally constructed realms of interpretation inhabited with actors, significations of acts and different values assigned to different outcomes.

Thus, considering the many practices and figured worlds that may form a teacher's role in classroom interactions, Skott (2013) argued that social practice is not sufficient as the unit of analysis, which is often used within social practice theory. Therefore, he argued, a recentring of the individual is necessary to understand how a teacher's professional identity take form as PSTs or teachers move in and out of different social constellations. To do so, Skott incorporated the idea of self. The self is simultaneously the process and product of action and reflection on action and has two phases: the *I* that act; and the *me* that takes the attitude of others and interpret the acts instantaneously. Participating in interaction consists of two processes, one of acting including indicating others' action, and one of interpreting others' actions symbolically and ones' own actions in terms of models of others' perspective. Action and meaning are inherently linked and are informed by previously established norms and histories. The unit of analysis is the individual in discourse, including current and previous practices and figured worlds that are actualised as generalised others.

Skott (2019) argues that professional identity develops through "shifting experiences of being, becoming and belonging as they relate to the profession" (p. 469). In terms of PSTs, this may include experiences of being competent or challenged in using resources for teaching mathematics, experiences of becoming autonomous as a mathematics teacher in the classroom, and the experiences of (not) belonging to a community. In the development of a professional (mathematics teacher) identity, several tensions can emerge.

According to Pillen et al. (2013), novice teachers face three main categories of tensions: "(1) the change in role from student to teacher; (2) conflicts between desired and actual support given to students; and (3) conflicting conceptions of learning to teach" (p. 660). In their study, they found that these tensions usually were accompanied by significant emotions experienced by the novice teachers. Thus, as Skott (2019) argues, to study the development of (professional mathematics teacher) identity, it is vital to study (mathematics) teachers' experience as they draw "on a multiplicity of prior and present practices and figure worlds when facing the challenges" (p. 472) or tensions emerging in their profession.

Approaching the development of professional identity as mathematics teachers

As mentioned in the introduction, we aim to address the tensions that manifest themselves in the PSTs' development of professional identity as mathematics teachers, as they participate in practices at university and school. In a Norwegian context, this may involve studying PSTs from the beginning of their teacher education when they study undergraduate mathematics and make initial experience with school placement as well as educational and didactical issues with respect to mathematics teaching and learning.

To exemplify how to identify tensions in PSTs' development of a professional identity as mathematics teachers, we will provide an example from data collected for a different purpose than ours. Nevertheless, the analysis of excerpts from a questionnaire and an interview of Ingrid, a primary school PST, testifies that Patterns of Participation shows promise for addressing PSTs' developing identities as mathematics teachers, despite not providing insights into all aspects of being, becoming and belonging (Skott, 2019).

Example

Ingrid worked with her personal resource bank in her fourth year of teacher education. She included

resources from different practices, some were adapted from her previous school placements while others were developed based on inspiration from fellow PSTs or lecturers at the university. During school placement (five weeks), Ingrid struggled to put the resource bank into use, partly because she experienced her mentor teacher to be fixed on a particular resource for teaching mathematics (a textbook called Dragonbox school). This led to a tension between what Ingrid wanted to do and what she was allowed to do in her teaching (experience of not belonging to the same community as her mentor teacher). Ingrid was concerned about her students' learning of mathematics, and in her opinion the chosen textbook material did not encourage learning ("drag and drop" which instantly gave feedback on whether the answer was correct or not, thus allowing the students to guess).

Prior to school placement, Ingrid was particularly concerned with including manipulatives in her teaching (exemplifying her being). Most of the resources in her resource bank included the use of manipulatives. After her school placement, the use of manipulatives was still important for Ingrid, but now she also stressed the importance of not being dependent on a textbook, but rather being able to develop her own teaching content (testifies her becoming):

> What's important for me when I start working as a mathematics teacher is to have manipulatives available and not be dependent on the textbook. I want to be able to do things my own way, following the curriculum and competence aims without having to follow the textbook to the letter (our translation).

It may seem that Ingrid's lack of freedom and pressure to use Dragonbox school in her teaching, has given her clarity on how she does not want to be as a teacher, in addition to possibly reinforcing her positive perspective on the use of manipulatives in teaching. She also reflects on her own school experience and how her teachers mostly had students work with problems from the textbook. This also reinforces Ingrid's desire to put the textbook aside, and she notes that the resource bank will be valuable for facilitating other teaching activities. She points out that working with the resource bank has helped her become aware of the type of mathematics teacher she is (testifies her being):

> Because I actually thought I was very much … just following the book. But I see that I have become better at not following the book to the letter and at using other things, and that I use a lot of manipulatives. I haven't really noticed this until I started writing down these tasks. I really enjoy using manipulatives, and it helps me in my teaching. I find it easier to explain [the mathematics].

Concluding remarks

In this paper we have made efforts to address tensions in PSTs' developing professional identity as mathematics teacher through the lens of Patterns of Participation, through the notions of being, becoming and belonging. Furthermore, we have attempted to theorise the gap in the PSTs' participation in various practices at the university site and various practices in school placements, materialised through the boundary object of a resource bank. As a participant (being and belonging) in various practices (seminar sessions with the subject teacher and fellow PSTs, and in school placement with mentor teachers), we argue that Ingrid was inspired to develop her resource bank, which in turn made her more aware of her own development as a mathematics teacher (becoming).

We have argued that professional identity development may be viewed through the lens of PoP, as being, becoming and belonging (Skott, 2019). Akkerman and Bakker's (2011) four learning mechanisms in crossing boundaries (identification, coordination, reflection, transformation) may be

linked to Skott's definition on professional identity. Identification addresses how teachers acknowledge demarcations between different practices and figured worlds, while transformation involves confronting the tensions that emerge between these practices. Ingrid was dragged between the practice of using Dragonbox school for teaching, and what she wanted to do in her teaching. This led to a tension, as Ingrid experienced that she did not belong to the same practice as her mentor teacher. Coordination includes Ingrid's experience of belonging to the various practices. Based on the analysis, there was a lack of coordination, in that she could not use many of the resources she had collected at the university. Reflection is about realization (being) and about broaden one's perspective (becoming). Ingrid realized that she was particularly concerned with including manipulatives in her teaching, and during school placement, she stressed the importance of being able to develop her own teaching content.

The framework discussed in this paper, we argue to be appropriate for studying PSTs' professional identity as secondary school mathematics teachers as they participate in various practices. A particular research scope may be to examine the tensions that arise as the PSTs engage in these various practices and reveal insights into their development of professional identity. By providing such insights, perceived disconnections within mathematics teacher education programmes might be mitigated.

Rationale and methods for an archive and encyclopaedia of "fundamental didactics"

Nathan Lombard[1], Marianna Bosch[2] and Claire Margolinas[3]

[3]Université de Clermont Auvergne, Clermont-Ferrand, France

"Fundamental didactics" designates a line of development of didactics of mathematics which appeared in France in the late 1960s, before being developed around the world. Despite its historical importance, complete bibliographic and documentary resources do not exist yet. This is the main raison d'être of the recent project of elaborating its archives and encyclopaedia. Carried along by a group of researchers under the supervision of a scientific committee, it aims at assembling a body of works together with its commentary, to give an account of the genesis and development of fundamental didactics up to the present day, for expert as well as novice readers. Above and beyond, this project raises the question of how a research community can make progress, by showing how its results can cumulate into a coherent body of conceptual and methodological resources.

Keywords: Fundamental didactics, Theory of Didactical Situations, Anthropological Theory of the Didactic, Reference materials.

Introduction

"Fundamental didactics" designates a line of development of didactics of mathematics, otherwise referred to as the "epistemological programme" (Gascón, 2003), which appeared in France in the late 1960s before being developed in Spain and around the world. It was initiated by Guy Brousseau as the Theory of Didactical Situations and was later characterised by him as the "science of the conditions for the production and dissemination of mathematical pieces of knowledge useful to societies and human affairs" (Brousseau, 1995, p. 2, our translation). In line with this project, Brousseau and his successors have stressed the importance of developing this fundamental facet of research in didactics of mathematics. Assuming certain theoretical and experimental detours, it aims at developing theoretical and methodological means to study didactic phenomena per se, as independently as possible from the direct and sometimes pressing demands of society.

In this spirit, Brousseau inaugurated the Centre for Observation and Research on Mathematics Teaching (COREM in French) in 1972, a kind of "didactic accelerator or didactron" (Barquero & Bosch, 2015, p. 258). Such an observational device quickly enabled previously undetected phenomena to be brought to light, while an intense theoretical work was conducted to account for them. Two connected theoretical frameworks thus emerged in the French context, the Theory of Didactical Situations (TDS) and the Anthropological Theory of the Didactic (ATD, initiated by Yves Chevallard in the 1980s). The result today is a coherent set of concepts and methods for analysing the phenomena of dissemination of knowledge, with an important bibliographic collection. Its function as a fundamental science of didactics makes it very distinctive in educational research.

However, despite its historical importance, complete and well documented bibliographic and documentary resources on fundamental didactics do not exist yet. Consequently, the exact historical

(conceptual and sociological) roots of this significant way of doing didactics of mathematics are not always well known. Half a century after its birth, at a time when the main players in its development are gradually withdrawing from the scene, the preservation of this scientific heritage is at stake. Even if this line of scientific research is still vivid nowadays, worldwide, some of its constitutive texts and concepts remain poorly spread, because they are not available in digital form and are mostly written in French. Furthermore, the notions involved are numerous, representing a vast and interconnected conceptual network, of which today's researchers can for the most part only catch a glimpse.

This is the main raison d'être of the recent project of elaborating the archives and encyclopaedia of fundamental didactics. Carried along by a group of researchers, under the supervision of a scientific committee, it aims at assembling a body of works together with their commentaries, to give an account of the genesis and development of fundamental didactics up to the present day, for expert as well as novice readers. The project raises, however, several questions. What is the exact extent of fundamental didactics? Where to find its original sources and how to make them accessible? Given the corpus we are dealing with, how to design and then write an encyclopaedia reflecting it? More generally, and beyond the strict scope of fundamental didactics, we want to address the question of how a research community can make progress, by taking advantage of the different approaches developed throughout the years and letting the ensuing results cumulate into a coherent body of conceptual and methodological resources.

What is "fundamental didactics"?

As we mentioned already, "fundamental didactics" refers to the ambition, embodied and then formulated by Guy Brousseau to establish an autonomous science of didactics of mathematics, in a context where psychology and linguistics were the predominant disciplines in the field of mathematics education. Brousseau started out as a primary school teacher, with a deep interest in mathematics and its social relevance. In the late 1960s, he gathered a team of colleagues at the IREM[1] of Bordeaux (France) to enquire about issues posed by the teaching of mathematics from an epistemological point of view, particularly at primary school. Through the support of colleagues at both French and European levels, he managed to create the Centre for Observation and Research on Mathematics Teaching (COREM, 1972-1999), associated with the primary school Jules Michelet (Talence, France). There, through a vibrant theoretical-experimental work, together with his team of teacher trainers and school teachers, he elaborated a novel experimental method for mathematics education based on the didactic engineering of situations, the theory of which was carefully worked out (see for instance Brousseau, 1997, p. xv and p. 275; and also Artigue et al., 2019, section 2.1.2; Barquero & Bosch, 2015, section 8.2.2). This experimental method, together with its theoretical grounds, enabled a new scientific practice which raison d'être was to answer fundamental questions on what school mathematics is and how it disseminates, hence the term "fundamental didactics".

Didactics of mathematics in France thus "emerged with the aim of building a genuine field of scientific research and not just a field of application for other scientific fields such as mathematics or

[1] The *Instituts pour la Recherche sur l'Enseignement des mathématiques*, French for Institutes for Research on the Teaching of Mathematics, were founded in 1970 to bring teachers of all levels together with mathematics researchers to discuss issues related to the teaching of mathematics.

psychology." (Artigue et al., 2019, p. 14). Of course, France is not the only country where such an enterprise took place (for instance, see Blum et al., 2019, for the Czechoslovak and German cases). However, due to its size and scope, we have decided to restrict ourselves for the time being to the corpus of the branch of fundamental didactics which originated in France (and has been widely developed internationally since its creation). In the French context, besides the seminal work of Brousseau's group in Bordeaux, another channel of development of fundamental didactics was made possible by Yves Chevallard's breakthrough on didactic transposition phenomena and their subsequent formalisation in anthropological terms. Indeed, the ATD was born from the close collaboration of Chevallard (born in 1946) with his elder Brousseau (1933-2024) around 1980. Since then, the two frameworks evolved in parallel, while always sharing the same theoretical foundation, as Brousseau (2005) himself pointed out during his opening plenary at the first International Conference on the ATD:

> I have the feeling, a priori, that there is no contradiction between their statements, which means that they can be associated. They could even prove to be equivalent: the axiom of choice has a large number of expressions whose equivalence is not obvious. What differentiates them, then, is the choice of the objects they mainly deal with and those they seem to neglect. If none of them contains the other, they should at least be able to "complement" each other (Brousseau, 2007, p. 50, our translation).

Chevallard also explicated in what respect the ATD is grounded in the TDS: "anthropological sensitivity is, as opposed to what one might think, constantly present in the work of G. Brousseau, and has been from the start — even if it is often situated slightly in the background compared to explicitly formulated analyses." (Chevallard, 1992, p. 137). Today, the TDS and the ATD form the bulk of the "epistemological programme" in didactics of mathematics (Bergsten, 2020; Gascón, 2003), which, following Brousseau, we call in this text "fundamental didactics".

Methods and outlook

The goals of our project include a better understanding of the historical interplay between the TDS and the ATD as well as the subtle conceptual differences in their epistemological constructs. As such, it should contribute to identifying a research paradigm (in the sense of Kuhn, 1962). However, many questions arise, as this ambition touches upon the making of an epistemological and social history of a field of knowledge. To go beyond Lakatos' programmes and Kuhn's paradigms, we may rely on the sociology of knowledge constructed by authors such as Norbert Elias (2009) or Pierre Bourdieu (2004). Of course, Gaston Bachelard (2002) himself is also a reference when it comes to studying the epistemological history of a scientific community. Given the size and scope of the corpus at hand, such analyses could be performed by different people. So, the goals of our project also include collecting, sorting and presenting what we consider the necessary sources for such historical and epistemological studies of fundamental didactics, though they may be carried out by others. We consider such surveys to eventually contribute to the development of fundamental didactics itself and its dissemination. However, our undertaking goes beyond the sole case of didactics of mathematics. This project actually raises the question of how our research community in mathematics education can make progress, which is an especially sensitive issue in contemporary social sciences (Lahire, 2023, chapter 2). By assembling this archive and encyclopaedia, we wish to tackle the problem of integrating past results in mathematics education and going forward from a scientific

point of view. Indeed, our project should lead to an in-depth structural work on a huge corpus, which could very well foster new insights on our research methods and theories. Over the years, it could question our research practices at a wider scale. Not necessarily by adherence, but because of the questions it will raise for other approaches as well: What are their roots and rationales? What are their conceptual histories? How do they permit to ground subsequent research practices?

In the following, and to substantiate the previous claims, we will develop the facets of the work as it was launched last year, how it goes on, and what are its prospects for the future.

The stages of the archival work

The historical evolution of the publication of the major texts in the TDS and the ATD followed a similar pattern. In their first years, many (sometimes hand-written) documents were printed on the occasion of a research seminar, the National Seminar of didactics of mathematics (starting in 1978) or a Summer School of didactics of mathematics (starting in 1980). Some of them where then edited by each university's own IREM, and only rarely would they also be published in academic journals. This way, Guy Brousseau and his team in Bordeaux published most of their works until the 1980s at the IREM of Bordeaux, followed by Yves Chevallard and his colleagues at the IREM of Marseille. At that time, the French journal *Recherches en Didactique des Mathématiques* was founded and published by *La Pensée sauvage* in Grenoble (France), where several books were published as well (Brousseau, 1998; Chevallard, 1985).

Fortunately, each one of the two lead authors built and maintained a website, which, though not complete, give an idea of the scope of the corpus at stake. Brousseau's personal webpage (guy-brousseau.com) comprises more than a hundred papers for a total of circa 1,500 pages, while Chevallard's website (yves.chevallard.free.fr) features around 300 articles for some 2,500 pages. From the 1990s, the text written by the numerous contributors to each of the frameworks have been published in research journals, which they have since made available in digital form. Another aspect greatly facilitating our archival work is the growth of open archives such as the French online repository HAL[2], where many of the previously mentioned contributions may be found.

However, given their historical conditions of production, some of these texts are neither on the above-mentioned websites nor otherwise online. Three possible locations then exist. First, some references may still be found in the libraries of French universities, especially in the libraries of the IREMs, despite regular storage space savings. The Centre for Resources in Didactics of Mathematics (CRDM-Guy Brousseau), hosted by University Jaume-I in Castelló (Spain), is a second location where the teaching and learning material coming from the Centre for Observation and Research on Mathematics Teaching (COREM) was archived, by Pilar Orús and her team. Many master's and PhD theses from the 1970s may also be found there. Though its purpose makes it focused on a particular period (1972-1999) and place (the COREM), the CRDM is a significant place for the history of fundamental didactics. Thirdly, a crucial archive is constituted by the personal libraries of the researchers themselves. Indeed, some documents concerning scientific events from the 1970s and 1980s may only be found there. Therefore, what may be important contributions to the early history of fundamental didactics sit in attics or basements somewhere in France, waiting to be sought for. This is even more important that, at that time, foundational issues were discussed, which resonate

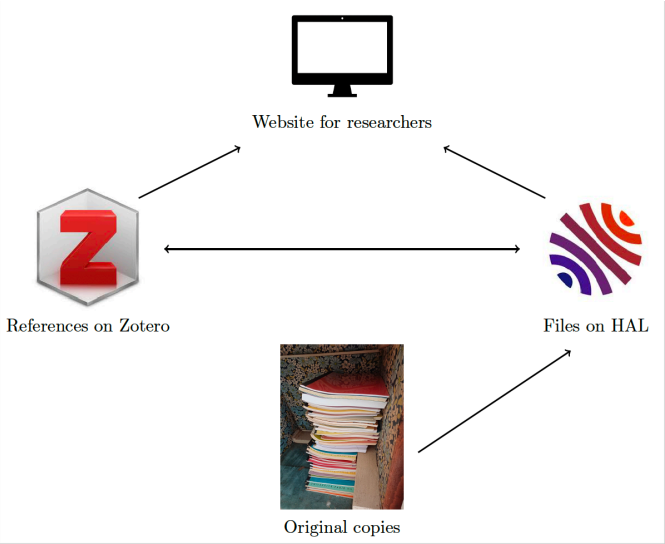
[2]*Hyper Archive en Ligne*, which means "hyper online archive" in French (https://hal.science/ HAL).

well with current debates on methods in our community. Finally, pieces may have been lost. At best we can then identify them by their reference in the bibliography of other documents.

After having recovered existing source texts, the archival work will then consist in preparing a digital version of them to be uploaded on an open archive (the French online repository HAL, in our case). Secondly, a mirror archive will be constructed thanks to a reference management software (Zotero in our case) for the users to better navigate it. Given the extent of the archival work, the practical value of the previously mentioned twice-restrictive hypothesis might be better understood: first, to assimilate fundamental didactics in the French context to the coupling of the Theory of Didactical Situations and the Anthropological Theory of the Didactic; secondly, to focus primarily on the works of their respective lead authors, Guy Brousseau and Yves Chevallard.

So, the stages of the making of the archives are the following: 1) collect all the texts written by either Brousseau or Chevallard, 2) reference them in the Zotero library, 3) create their digital version (when it does not already exist), 4) upload them on HAL. Other kinds of documents (audio recordings, videos, photographs) would require a special treatment, which we will not detail here. Then, the same kind of work is to be done on the collective events which punctuated the scientific life of fundamental didactics in the XX century. In particular, the still-ongoing National Seminar (1978 to the present) and Summer Schools (1980 to the present) could be quite momentous at the time, triggering the production of significant texts (courses or seminar articles). The last and open-ended stage of the making of the archive is the adjunction of the complete works of other contributors than Brousseau and Chevallard, starting in chronological order. It is a practical necessity, to organise this vast archival work. Based on the already known literature, together with the crucial testimonies of the colleagues who participated in it, a first historiographical model of the early development of fundamental didactics should be established.

This is why a scientific committee was asked to oversee this archival work. Such a collective, through its combined expertise and perspective, should indeed compensate for the limitations of decision-making by the small group of individuals initially implementing the project.



Writing an encyclopaedia: why and how?

The overall aim of this project is to produce digital resources accessible via a website and providing both an overview and the contents of half a century of contributions in fundamental didactics. But the mere library of articles, plethoric, would not be of much help for colleagues investigating, were it merely displayed in chronological order. When writing a paper, one often needs the literature just on a given topic or concept. So, in the case of fundamental didactics, one would rather need a thesaurus, together with references to the most important articles elucidating each term. These are the grounds for the development of the encyclopaedia.

Both the TDS and the ATD put at play a large number of concepts organised as dense conceptual networks, which exhibit a high level of internal coherence. These are crucial epistemological features, when it comes to designing their thesaurus. Of course, each of these terms have been shaped by its epistemological and social environment, in the course of time. Consequently, the stages of the encyclopaedic work are the following: 1) select the entries of the thesaurus; 2) for each entry, compile a list of extracts from the archived corpus reflecting the development of this notion and its possible facets; 3) redact a presentation of these extracts, adapted to both specialists in fundamental

didactics and less experienced colleagues. Concretely, each article (e.g. “institutionalisation”) will have three parts: an introduction aimed at non-specialists (young researchers, teacher educators, teachers interested in research in didactics of mathematics); a presentation of the historical development of the term; a selection of excerpts from the main sources relating to it, lightly discussed. Some terms, which are widely used by other research communities (e.g. “model”, “knowledge”) should have their meaning specified in relation to their most prominent uses in mathematics education. The articles of the encyclopaedia will naturally be linked when they are conceptually related, but also when they need to be clearly distinguished. Finally, we could think of articles dedicated to individuals (bibliographical notes) or historical episodes (a given Summer School, a famous controversy, etc.).

Figure 1: Organisation of the encyclopedia in relation to the archives

Two legs of the same project

Clearly, only by meticulously collecting the sources of fundamental didactics will we be able to properly reconstruct the historical development of its notions and present them in their full extent. So, the archival work is a necessary stage on the path to writing the encyclopaedia. On the other hand, the texts of the encyclopaedia will discuss excerpts of the articles of the archives. In particular, they should feature hyperlinks to consult them directly on the open archive online (HAL), or to visualise the collection of papers relating to a given notion on the reference management software (Zotero). So, the encyclopaedia is also a portal towards the archives. This tight link between the website of the encyclopaedia, HAL and Zotero (figure 1) is made primarily to facilitate the investigation work of colleagues.

Conclusion

This project of establishing an archive and encyclopaedia for fundamental didactics has a main objective: to produce a privileged source for anyone whose personal investigation leads them to come

across concepts or works in the field of fundamental didactics. In addition to its function as an overview and search engine for researchers in didactics, it should also be aimed at a wider public and provide an image of this particular approach to mathematics education. However, as we have seen, it also raises numerous issues, at both technical and epistemological levels, which go beyond the project and affect the future evolution of the field of mathematics education.

First, the very definition of fundamental didactics, even restricted to the French context, is problematic. For the time being, equating it with the duo formed by the TDS and the ATD seems sufficient, because accurate enough and practical. However, further historical studies would be in order. This raises the important issue of how the different branches, areas or domains of a field like mathematics education are defined and by whom. Then, most of its original sources, if they still exist, are accessible in France and Spain. Technical solutions exist to make them accessible, via an articulated use of an open archive (HAL) and a reference management software (Zotero). Even if this question can appear as only practical at first sight, the language used in the development of research frameworks and its dissemination among the international community in English as lingua franca requires a specific attention, especially to prevent negative effects coming from the dominance of English-speaking communities.

Regarding the encyclopaedia, a significant research work is still necessary, in order to list its entries and to select the most relevant excerpts from the literature. But this necessarily collective work, supervised by our scientific committee, might also lead to very fruitful debates, historical or etymological discoveries, and further writings. In this sense, this project is also a way to further develop the theory and practice of fundamental didactics.

Ultimately, this project deals with the problem of integrating past results in mathematics education, and going forward from a scientific point of view. By presenting in one place a comprehensive network of the concepts of fundamental didactics, coupled with a collection of articles both defining them and exemplifying their use to probe didactic phenomena, this project will help researchers build their investigations on this amassed, common ground. Because starting from scratch would become absurd, this project should foster truly cumulative contributions, which is an essential sign of doing science. Furthermore, this project raises the question of how a research community can make progress. This article indeed indicates another way to bring out “solid findings” in mathematics education. Instead of being declared directly, we suggest they can also emerge from the body of knowledge produced by a given community of researchers, that bespeak the accumulation of its results into a coherent body of conceptual and methodological resources.

Combining a theoretical framework and a statistical measure to assess the reliability of didactic criteria in the analysis of large corpora

Ismaïl Mili[1], Mickaël Da Ronch[2] and Marie-Line Gardes[3]

[1]University of Fribourg, Faculty of Educational Sciences, Fribourg, Switzerland; ismail.mili@edufr.ch

[3] University of Teacher Education Vaud (HEP-VD), Lausanne, Switzerland

The aim of this article is to present the articulation of a theoretical framework and a statistical measure using Fleiss' Kappa to assess the reliability of didactic criteria. These didactic criteria have been developed within the framework of the analysis of a corpus of consistent resources and aim to evaluate the potential of problems enabling students to develop a mathematical activity of research. The results show that the criteria constructed are reliable, with significant inter-coder agreement, and provide interesting perspectives for the analysis of resources in the context of teacher training.

Keywords: Mathematical activity, problem, data analysis, reliability, Fleiss' kappa.

Background and research question

Internationally, recommendations from research and the field suggest that the teaching and learning of mathematics should take place through problem solving, preferably linked to the activity of the mathematician (see in particular OECD, 2014; Ministère de l'Education Nationale, 2019; National Research Council, 2001). But what is the reality? Do the resources available to teachers encourage such activity? And how can we identify that a teaching resource has the potential to encourage mathematical research activity? Our contribution aims to propose a theoretical framework and a methodological tool for analysing the potential of resources to encourage mathematical activity.

This contribution follows on from an article published at CERME 13 (Da Ronch et al., 2023), in which initial criteria for assessing the potential of school level problems were defined. Since that prospective study, these criteria have been revisited, broadened and refined, and the corpus studied extended. The research question now focuses on methodological aspects: can these criteria be considered "reliable" (in the sense of concordance between ratings made by several coders, see Sim & Wright, 2005)?[1]

To do this, we begin by defining mathematical research activity and the notion of problem. In the second part, we detail the development of criteria for identifying, within a teaching resource, whether a mathematical problem is likely to encourage mathematical research activity. In the third part, we put these criteria to the test by applying them to the analysis of a corpus from French-speaking Switzerland, in order to test their reliability. Finally, in the fourth part, we open up perspectives on

[1] In our view, this is an essential step before testing the reliability of the criterion in terms of predicting student activity.

measuring the validity and reproducibility of these criteria, as well as their reinvestment in teacher training.

Theoretical Background

Da Ronch's (2022) epistemological study of the notion of mathematical activity as a human activity shows that for most mathematicians and mathematics didacticians, this activity is strongly linked to problem-solving (see Brousseau, 1997; Chevallard, 1998; Da Ronch, 2022; Gardes 2013; Halmos, 1980; Perrin, 2007; Thurston, 1994). During this activity, there is no question of limiting oneself to the use of definitions and theorems for the sole purpose of applying them to specific situations (Brousseau, 1997). Neither is the production of a mathematical result the ultimate goal of this activity. It is above all the processes involved in solving the problem that are indicative of genuine mathematical activity. The finished product, *i.e.*, the result of the problem, is in itself only a secondary objective of this activity (Chevallard, 1998). Consequently, mathematical activity involves different processes leading to the elaboration of a finished product, as the result on the problem, which are linked to the dialectics, which Brousseau qualifies, of action, formulation and validation. This means proposing problems that allow us to articulate, during these phases, "the reasoning of plausibility, purely inductive, and that of the necessities attached to deductive reasoning" (Da Ronch, 2022, p. 11) in the search for mathematical truth and its explanation in order to answer the problem. Doing mathematics therefore requires solving problems and accepting a certain form of scientific responsibility in the face of the challenge of truth and the need for proof (Da Ronch, 2022; Da Ronch et al., 2023). These different dialectics emerge if, and only if, specific knowledge is mobilized in the resolution of a problem (e.g., Da Ronch, 2022; Da Ronch et al., 2023). For example,

> […] the mobilization of specific knowledge linked to the practice of the mathematical activity. For example, entering into the resolution of a problem by studying particular cases is a knowledge linked to the experimentation process. The formulation of conjectures resulting from the study of these cases, the change of the register of representation of the mathematical objects at stake, sometimes leading to modelling premises, are examples of knowledge linked to the formulation process. Finally, validation is based on hypotheses (e.g., law of excluded middle, law of noncontradiction) and rules of logic (e.g., *modus ponens, modus tollens*) which allow, thanks to different mathematical reasoning (e.g., direct implication, contradiction, induction, counterexample...) to enter into the argumentation and proof process and thus to rule on the truth or falsity of a mathematical statement. This knowledge is therefore knowledge related, this time, to the validation process […] (Da Ronch et al., 2023, p. 97).

Furthermore, the processes of action, formulation and validation and their associated knowledge are indicative of a real articulation between inductive and deductive reasoning, testifying to a genuine experimental approach in mathematical activity (see, Da Ronch, 2022; Gardes & Durand Guerrier, 2016; Giroud, 2011; Perrin, 2007).

These processes are visible only through the encounter with a problem and the proven need to solve it for those who intend to investigate it (Da Ronch, 2022). The etymological and epistemological study carried out in Da Ronch's work (2022, chap. 2) has enabled us to characterize a problem according to a double aspect, syntactic and semantic. The syntactic aspect concerns the structure of

the problem presented in the form of a general question and a set of instances, in reference to Garey and Johnson (1979).

> For our purposes, a problem will be a general question to be answered, usually possessing several parameters, or free variables, whose values are left unspecified. A problem is described by giving: a general description of all its parameters, and a statement of what properties the answer, or solution, is required to satisfy. An instance of a problem is obtained by specifying particular values for all the problem parameters. (Garey et Johnson, 1979, p. 4)

The general question refers to the existence of a search variable (Grenier & Godot, 2004; Da Ronch, 2022), *i.e.,* a problem parameter whose value is not fixed and which is therefore the responsibility of the problem solver.

The semantic aspect of a problem refers to its epistemological quantity, determined by a detailed mathematical analysis of the problem (Da Ronch, 2022). This quantity can be identified by proximity to other related problems and by changes in the scope of the question and instances of the problem studied. The proofs used are also indicators of proximity to other problems that mobilize similar invariants in their resolution process (Da Ronch, 2022; Giroud, 2012; Da Ronch et al., 2023). All this highlights the non-isolated nature of the problem and its richness. To carry out such an analysis in order to determine the epistemological quantity of a problem, we pointed out a deficiency in the method of conduct to be adopted. Indeed, during the preliminary analysis (Artigue, 2015), no method of conducting a mathematical analysis with a view to building solid didactic engineering, with real consistent problems, leading to real mathematical activity was made explicit. This has led to the development of a method for carrying out such analyses (see Da Ronch, 2022; Da Ronch & Gravier, 2024). However, this method is relevant for the construction of didactic engineering, but remains too complex and not very operationalizable to evaluate the mathematical potential of problems on large corpora of data. Indeed, it is not possible to carry out such fine analyses for a wide variety of problems. This calls for the development of a new pragmatic evaluation tool that can effectively analyse a large corpus of problems for their potential in the implementation of mathematical activity.

Development of didactic criteria

In order to determine the potential of a problem to foster mathematical activity as we have defined it, we use the concepts of research variable (Grenier & Godot, 2004; Da Ronch, 2022) and didactic variable (Brousseau, 1997).

As mentioned in the previous section, a research variable is a problem parameter that is not initially fixed in the statement. It is up to the problem-solver to set different values for this variable. For example, if we wish to determine whether a rectangle of size p×q can be tiled with 1×2 dominoes, the search variable here is the size of the grid, which is not fixed in the statement. It is therefore up to the subject to appropriate it, *i.e.,* to set its own values in the process of solving the problem. The existence of a search variable thus guarantees that the problem is syntactically correct and semantically rich. When solving the problem, the problem-solver's mathematical activity is focused on the study of particular cases (as sub-problems) and then on generalization.

A didactic variable is a parameter of a learning situation that the teacher can vary to influence the way students interact with the proposed problem. The choice of a didactic variable value by the teacher can thus enable him or her to encourage mathematical activity in the pupils, in particular to take them gradually from the study of particular cases to the study of the generalization of a problem (see Figure 2).

The analysis of a problem's potential to encourage mathematical activity is based on a four-level criteria, relating to the nature of the variables present in the problem statement. We have formulated and coded them as follows:

- *Code 3: existence of a search variable in the problem statement*

For example, in the exercise Ribambelle[1] (see Figure 1a), the research variable is the number of "men" (where "man" is the basic figure created with the matches and then reproduced iteratively). It's up to the student to make this number of men vary, in order to study a few special cases that will enable him to determine a general formula.

- *Code 2: presence of a didactic variable with several values set by the problem statement*

For example, in the exercice Les étapes[2] (see Figure 1b), the number of steps is a didactic variable that the statement makes vary (20, 50, 100) to encourage students to study particular cases in order to determine the general formula.

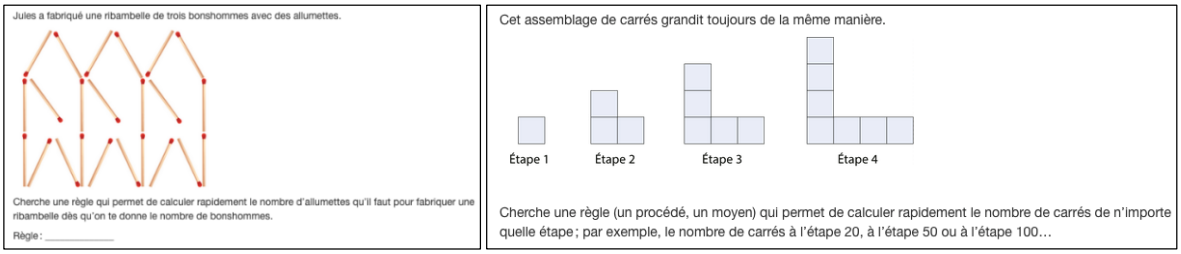

Figure 1: Statement of "Ribambelle"[2] (1a) and "Les étapes"[3] (1b) – fifth grade textbook in french-speaking Switzerland

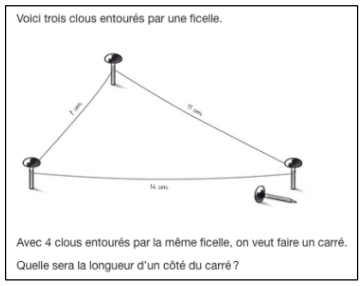
- *Code 1: presence of a didactic variable with a value fixed by the problem statement, but which can be modified by the teacher.*



For example, in the exercice The string (see Figure 2a), a didactic variable is the length of the string. The teacher could vary this to study different cases and guide the students' activity towards a more general question, e.g. what are the triplets of three numbers such that the perimeter of the triangle is equal to the perimeter of the square?

[2] Jules made a string of three men out of matches. Find a rule to quickly calculate the number of matches needed to make a string once you've been given the number of men.

[3] This set of squares always grows in the same way. Look for a rule (a process, a way) that allows you to quickly calculate the number of squares in any step; for example, the number of squares in step 20, step 50 or step 100...

- *Code 0: no didactic variable*

For example, the exercise Achats (see Figure 2b) is a verbally stated problem that can be solved with simple arithmetic operations. There is no didactic variable that would enable us to develop a mathematical research activity in our meaning of the term.

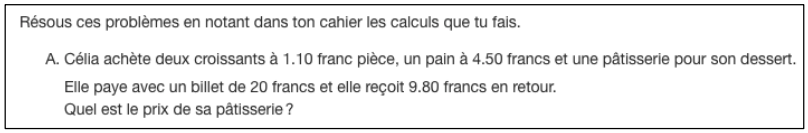


Figure 2: Statement of "La ficelle"[4] (2a) – fourth grade – and "Achats"[5] (2b) – sixth grade

Testing criteria on a corpus, choice and method

In addition to the fact that the authors work in Swiss institutions, the French-speaking Swiss corpus was chosen for the following three reasons. Firstly, because of the country's administrative structure, only one "official" teaching resource (textbook and book) is available to teachers: the Moyens d'Enseignement Romands (hereinafter MER). Although teachers have pedagogical freedom to supplement these MERs according to their needs, they are compulsory at ministery level, as they have been designed, developed and written to cover the subject content of the official curricula, grouped together in the Plan d'Études Romand (hereafter PER). This uniqueness of resources makes it possible to quickly get an overview, without having to analyse several different manuals. Secondly, some of the PER's injunctions are similar to our definition of mathematical activity. Indeed, in the "General comments" of the "Mathematics" domain presentation text, we find that

> "[Mathematics] promotes [...] an attitude of research through trial-and-error, generalization, conjecture and validation. In this way, the practice of mathematics develops the ability to imagine strategies, and to organize and structure knowledge" (free translation, General comments on the MSN field, CIIP, 2024).

This is in line with the components of mathematical activity presented above. Other recommendations are along the same vein, such as the organization of scientific debates in mathematics, the formulation of questions, the development of reasoning, the use of trial and error to reconstruct a thought process and understand missteps, and the analysis of the relevance and limitations of a chosen model, among others (see "Contribution au développement des Capacités Transversales", CIIP, 2024)

[4] Here are three nails surrounded by a string. With 4 nails surrounded by the same string, we want to make a square. How long will one side of the square be?

[5] Solve these problems by writing down the calculations you make in your notebook. A. Célia buys two croissants at 1.10 francs each, a loaf of bread at 4.50 francs and a pastry for dessert. She pays with a 20-franc bill and receives 9.80 francs in return. How much does her pastry cost?

Thirdly, a section of the MER entitled “Aide à la Résolution de Problèmes” (Problems solving support, hereinafter ARP), distinct and circumscribed and constituting around 1/5 of all the statements, is explicitly intended to “work on problem solving”. The editors justify this section by pointing out that “it is not enough to let students find problems and then correct them on the basis of those who have succeeded, for everyone to learn to solve problems”, and that it is “necessary to put in place real teaching in problem solving” (free translation - ARP comments, CIIP, 2024).

Using our criteria, we analysed the entire Cycle II ARP corpus (students aged 8 to 12). The analysis was carried out in parallel by the three authors on a corpus of 312 items, with an initial sampling of 10 items per level (over 4 levels) to calibrate the coding. Inter-coder similarity, an indicator of criterion reliability, was measured using the appropriate Fleiss' Kappa coefficient (see Fleiss, 1971). It measures the agreement between several coders when they classify items into discrete categories. The Fleiss' Kappa coefficient ranges from 0 to 1, where 0 indicates a match equivalent to that expected by chance, and 1 corresponds to a perfect match between coders. A medium match is considered to exist when $\kappa > 0{,}41$, and a large match when $\kappa > 0.61$. The fact that four categories are available increases confidence in the interpretation of the coefficient obtained. Moreover, testing it on a wide range of problems (312) reinforces this confidence (Fleiss, 1971; Landis & Koch, 1977; Sim & Wright, 2005).

Results and discussion of the reliability of the criteria used and research perspectives

The results of our study show the reliability of the didactic criteria obtained by calculating Fleiss' Kappa coefficient. The latter indicates a significant concordance value ($\kappa \approx 0.7$) according to Landis and Koch's (1977) table. Indeed, of the 312 problems coded in triple blind according to our four criteria, 44 obtained a different coding with each time exactly 2 coders in perfect agreement out of the 3 with only a deviation of 1 in the coding. Thus, 268 problems obtained perfect agreement in coding. Consequently, the results show that the criteria constructed are reliable, with significant inter-coder agreement. This paper has thus presented a reliable method for processing and analysing resources in order to identify the potential of problems enabling students to develop a mathematical research activity. This method of conducting research is based on epistemological and didactic criteria for categorizing problems in the study of a corpus involving a significant quantity of resources. Finally, our criteria-based processing and analysis method seems effective for analysing the potential of problems to generate mathematical activity in students, since it enables us to process a large corpus of data, without having to carry out an exhaustive *a priori* analysis of the problems to measure their epistemological quantity.

A first perspective provided by these results is to pursue the articulation of our theoretical framework with the use of statistical measures to question the validity of the didactic criteria developed, as well as the reproducibility of their use. Validity could be assessed through an analysis of student activity during problem solving, showing that the nature of the variables involved does indeed have an impact on students' mathematical research activity. With regard to reproducibility, initial results suggest that these criteria are sufficiently precise and operational for other coders to take them up and use them on different data corpora. However, this remains to be proven. A second perspective is to deepen the

analysis of the corpus studied. We can already state that this corpus includes few problems that allow students to develop a mathematical activity of research. Indeed, there is only one problem with a search variable (Ribambelle, see Figure 1a) and five problems with a statement proposing several values for a didactic variable. We can thus see that the MERs do not really enable teachers to implement the PER injunctions concerning problem-solving. Indeed, with the exception of these six problems, the statements do not propose any work on the formulation and proof of conjectures, generalization is little worked on, the issue of truth is absent, as are discussions on the existence of solutions, their multiple or universal nature. A third perspective is to consider the use of these didactic criteria in teacher training, for analysing resources or designing situations. Indeed, since the institutional resource only partially addresses the requirements of curricula regarding mathematical research activity, teachers must be able to identify problems that allow students to engage in mathematical activity. The developed didactic criteria could thus be a relevant tool for refining their didactic analyses.

Didactic paradigms to promote creativity in the study of mathematics

José Ginés Espín[1], Josep Gascón[2] and Pedro Nicolás[1]

[1]University of Murcia, Faculty of Education, Spain; pedronz@um.es

[2]Autonomous University of Barcelona, Faculty of Sciences, Spain

This paper asks what it means to be creative in mathematical activity, why one might want to promote creativity in mathematics education, and how this might be achieved. For this we use the notion of a didactic paradigm, consisting of didactic ends, didactic means and an epistemological model. We show how including the promotion of creativity among the ends affects the means and the epistemological model.

Keywords: Creativity, didactic paradigm, didactic ends, epistemological model, didactic means

Introduction

The aim of this work is twofold. On the one hand, it aims to explore how the study of mathematics could be planned to promote mathematical creativity. On the other hand, it aims to carry out an analysis of the very idea of creativity in mathematics. This analysis should contribute to a better understanding of how creativity can be promoted. Thus, beyond its theoretical importance (e.g. as an aspiration to the understanding of certain notions), the practical importance of the second aim lies in the practical importance of the first one. As for the practical importance of the first goal, it lies in the fact that the aims of education should include not only the acquisition of certain knowledge, but also of certain skills and attitudes. Indeed, it seems that formal education is aimed at maintaining (or even increasing) the welfare state of our societies. In turn, it seems clear that this state of well-being is due not only to the accumulated knowledge itself, but also to the fact that some members of our society have attained this knowledge at some point. The attainment of new knowledge for humanity, when it is not a rare case of serendipity, is obtained through an act of creativity.

In order to achieve these two goals, we will use the theoretical framework provided by the Anthropological Theory of the Didactic (ATD). Of course, it would be interesting to compare the way in which we address questions about creativity in ATD with the way in which they are addressed in other approaches in mathematics education. Unfortunately, the limited space available prevents us from doing so. Instead, we address the two objectives in sufficient detail to show the challenge they pose to the mathematics education research community.

Didactic paradigms rule didactic institutions

Didactic institutions are those social institutions stablished with the aim of studying something. In order to analyse how didactic institutions work, we will use the notion of didactic paradigm as introduced by Gascón and Nicolás (2019, 2022). Given a didactic institution, I, and a certain field of study, F, in I, we say that a didactic paradigm for F in I is made of: didactic ends, which explain the purpose of studying F in I, an epistemological model of F in I, written $EM_I(F)$, which provides a description of F, and didactic means, which state what is done in order to study F in I.

Of course, there should be strong links between these three components. For instance, the didactic ends should determine to a large extent the epistemological model. The didactic ends should also determine the didactic means, because different ways of teaching boost or complicate the acquisition of certain types of knowledge or attitudes or skills which might be among the didactic ends. This is also the reason why there is a strong relationship between the didactic means and the epistemological model, or, in other words, between how to study and what is studied. In what follows, we will show how to include the promotion of creativity among the didactic ends affect the epistemological model (the way knowledge is organized) and didactic means (how this knowledge is studied).

Epistemological models

As said before, in a didactic paradigm the epistemological model describes what is specifically studied about F in I. For this we use the notion of praxeology. This is a fusion of the terms praxis (related to the idea of procedural knowledge) and logos (related to the idea of propositional knowledge), and it has been used in different places in social sciences. Following Chevallard (1999), we say that a praxeology is a 4-tuple Π = (T, τ, θ, Θ), were: T is a family of types of tasks, τ is a family of techniques (typically described in terms of actions), devoted to carry out the types of tasks, θ is the technology (that is, the logos of the techniques), devoted to explain why the techniques of τ work, and to assess the scope, the economy and the reliability of those techniques, and Θ is the theory, devoted to specify everything else concerning the knowledge of F in I.

In order to specify certain ingredients in Θ we will use the general description proposed by Gascón and Nicolás (2024), according to which a theory would have, at least:

- An ontological component, denoted by $\mathcal{O}$, which provides the language L used to speak of the field of study F, and a list of axioms, which are statements we assume to hold without any supporting argument beyond the evidence of 'experience'.
- A nomological component, denoted by $\mathcal{N}$, made of theorems. Each theorem is a statement expressed in terms of L, and, contrary to what happens with axioms, theorems are not a starting point in the study of F, but the conclusions of valid arguments with true premises (either because they are, in turn, theorems, or because they are axioms).
- An epistemological component, denoted by $\mathscr{E}$, which states what kinds of arguments are valid to support theorems. Notice that, depending on the institution, certain kinds of argument might not be allowed. For instance, a drawing is not regarded as an argument in the institution formed by professional mathematicians, but it can be taken as a proof in Primary Education (for instance, we make a draw to show that in the case of an acute triangle, the three heights lie inside the triangle). Moreover, a single institution might have, at different historical periods, different criteria of validity for arguments. Indeed, the institution of professional mathematicians has considerably narrowed the family of allowed arguments after Hilbert's proposal (Zach, 2023), as a way of fighting the crisis in the foundations of mathematics (Snapper, 1979).

Therefore, in order to specify the epistemological model $EM_I(F)$ for the study of F in I, to describe what is specifically studied of F in I, we need to describe a certain set of praxeologies, Π = (T, τ, θ, Θ), with Θ = ($\mathcal{O}$, $\mathcal{N}$, $\mathscr{E}$) and with $\mathcal{O}$ = (L, Axioms).

Didactic means

In a didactic paradigm, the component devoted to the description of how the study is carried out is called didactic means. In our view, a good way of conceptualizing it is by using the idea of game, very much in the spirit of mathematical Game Theory (von Neumann & Morgenstern, 1944; Luce & Raiffa, 1957). The idea of game as a tool to understand the working of certain social situations goes back to Wittgenstein (1953). Games are useful in order to describe the dynamics of situations governed by prefixed rules, where several agents (players) take part, where there might be something that (some of) the agents want to get (so that they can lose or win), and where the actions of the agents affect each other. Thus, in order to describe a game, one has to specify which are the players, which are the allowed moves for each player, which are the rewards and punishments (if any) for each move, and what does it means for a player to win the game. The use of games in didactics started with Brousseau (Brousseau, 1986, § III) and Hintikka (1982), who used the notion to describe the wide variety of interactions that can take place in a classroom between teacher, Y, and students, X, around the study of a certain field F. Here, however, we prefer to distinguish between different, more specific, types of games: imitation games, argument games and inquiry games.

An imitation game consists in the teaching of a certain technique (in the sense of ingredient of a praxeology) by putting it into practice with examples (ideally covering all cases). An example of imitation game could be the teaching of the technique for solving a quadratic equation by means of solving particular cases. The students are then encouraged to solve other cases themselves in a similar way to the teacher's approach.

An argument game consists in Y showing X valid arguments to justify a certain proposition. In argument games, although Y seems to be the only participant, X is supposed to complete the argumentation with Y, actively collaborating in the development of the game, so that Y can observe if X follows the steps of the argumentation. We could even come up with an alternative definition of argumentative games: X is the one who has to win the game by understanding the premises used by Y and why those premises can have the initial assertion as a conclusion.

Finally, in an inquiry game students X are challenged to answer an initial question by probing and being guided, to a greater or lesser extent, by the teacher Y. Inquiry games have a high degree of uncertainty, both for the students (who are less guided than at other times) and for the teacher (who does not know in advance how the students will act). In any case, imitation games and argumentation games can also be extremely difficult for the teacher. Choosing the examples to imitate and the steps to take in the arguments requires a deep understanding of mathematics.

What is creativity in mathematics

We have used praxeologies to describe epistemological models, and the ingredients of praxeologies point out in how many different ways one can be creative in mathematics:

- Creativity in proposing open problems, for instance, conjectures
- Creativity in developing techniques, which cannot be overestimated in maths.
- Creativity in proving theorems, which cannot be overestimated either!

- Creativity in setting axioms. We can think of Euclid's Elements, the foundation of Euclidean Geometry by Hilbert (2015/1899), or the axiomatization of Set Theory by Zermelo and Fraenkel (Zermelo, 1908, 1930; Fraenkel, Bar-Hillel, and Lévy, 1973/1958).
- Creativity in the description of the ontological component of the theory. Of course, there are really extraordinary occasions where some people are creative enough to propose a completely new ontology. This was the case with the study of sets and their relationships, which was created at once by Cantor (1874), and was used to set the foundations of the whole contemporary mathematics. This is also the case of Grothendieck's creation of the theory of schemes and topos theory in his series of works called Éléments de géométrie algébrique, which entailed a great unification of Number Theory, Geometry and Topology, previously cut off from each other.
- Creativity in setting the epistemological component of the theory. Among the most sharp mathematicians there is, actually, a constant reflection on the validity of methods of proving the validity of statements. For example, Euclid's distinction between axioms and theorems, and his carefully way of deriving theorems out of the axioms, started a new way of thinking for the whole humankind, beyond mathematics. Concerning the strict realm of mathematics, there have been some proposals originated at the beginning of the 20th century as a response to a crisis in the foundations of mathematics. The most prominent are logicism, intuitionism and formalism (Snapper, 1979).

Didactic paradigms that allow creativity

Promotion of creativity as one of the didactic ends

It is well known that, from the very beginning, formal education has to do with the transmission of knowledge to future generations, but also with the transmission of beliefs, attitudes and skills from which society in general can benefit. Among the skills that deserve to be encouraged we can think of creativity. But we have to keep in mind that genuine mathematical creativity requires to carry out a systematic, rigorous, patient and long-term work. However, current didactic paradigms, in order to entertain and not eliminate pupils from the school system, disregard many of these aspects of mathematical work, needed for creativity to appear. Therefore, in practice, real creativity is replaced with an apparent one, staged through a continuous change of activity. As a consequence, there is a mismatch between didactic ends (which include promoting real creativity) and didactic means (which only promote fictitious creativity), giving rise to the creativity paradox pointed out by Chevallard, Bosch and Gascón (1997). Thus, the question is: How to avoid the phenomenon of creativity paradox and how to encourage real creativity while teaching knowledge well established in advance?

Epistemological models that allow creativity

There do not seem to be magic formulas for promoting creativity, but there are epistemological models more or less likely to leave room for creativity. Teaching of mathematics is based on an epistemological model previously designed (or at least assumed) by the teacher. An epistemological model is a way of organizing the knowledge to be taught, and that organization may be more or less conducive to the creativity of those who learn. Thus, in order to favor creativity in the learning of mathematics, the epistemological model should include the possibility for the students of conceiving

new types of tasks, developing their own techniques to solve types of tasks, reflecting on the ontology they are dealing with, questioning and making explicit the basic properties assumed, proving new results (linked to the nomological component), and reflecting on the way they prove results (linked to the epistemological component). But, for this, there must be a previous design of the epistemological model, conceived in a diachronic way. Let us explain it further.

One can use a single (possibly big) praxeology to provide a synchronic description of $EM_I(F)$, that is to say, a description in one go of all that students must learn along the study process. In a synchronic description there is, in general, no space for types of tasks that cannot be accomplished, or defective techniques, or bad candidates for being theorems, or mistaken proofs, since they are not supposed to be learned. But it is surprising not to include all these features in our study processes, since they are innate to real mathematical activity, and they really foster creativity.

Therefore, if one wants all these features to take place in the study of mathematics, one has to use a diachronic description of $EM_I(F)$, taking into account the order in which the steps could be achieved along the study process. For this, one might use a directed graph, where the nodes are praxeologies, and the arrows indicate that the praxeology in the tip is a single step evolution of the praxeology in the tail. Such a diachronic description of $EM_I(F)$ is said to be a diachronic epistemological model of the study of F in I. In a diachronic epistemological model, we have what we call initial praxeologies, which are those praxeologies which are not in the tip of any arrow, and final praxeologies, which are those praxeologies which are not in the tail of any arrow. Among final praxeologies, we can distinguish between failed praxeologies, which are discarded attempts to advance in the study of F in I, and successful praxeologies, which provide the answers we were looking for at the beginning of the study process. Those praxeologies which are neither initial nor final are called transition praxeologies. Progressing through a diachronic EM involves finding praxeologies that offer increasingly better solutions to the issues raised by the initial praxeologies. Failed praxeologies represent dead ends in the study process, while successful praxeologies offer conclusive solutions. Of course, not every collection of praxeologies placed in the nodes of a directed graph is capable of describing the praxeological development of a possible study process. On the contrary, there must be some kind of epistemological plausibility in the passage from one praxeology to another. However, once one has organized knowledge through a diachronic epistemological model, it is easy to see where are the opportunities to foster creativity in a study process based on that model. The proposal of basing the study of mathematics on diachronic epistemological model is very much in the spirit of Lakatos' proposal (1976).

Didactic means that allow creativity

In an imitation game there is space for a certain degree of creativity. This is mostly the kind of didactic games and the kind of creativity currently observed in lessons in Primary and Secondary Education in Spain. However, it seems clear that inquiry games allow a huge degree of creativity. These games may aim to have students reconstruct pre-established knowledge through an inquiry process or to develop enquiry skills like creativity. It is natural to wonder to what extent it is feasible to get students to carry out a successful inquiry without the teacher's inevitable inference distorting it. Indeed, inquiry is a process in which a complex interplay between deductions and questions takes place, and

in an inquiry game not all the questions can be asked at any moment. Fortunately, Genot and Gulz (2015) explain how the teacher can strategically manipulate what they call students' range of attention, so that they can pose the right questions in the course of the research, and bring it to fruition.

Let us sketch now two different ways of teaching the use of derivatives to study the monotony of functions: One way could be to explain first how to calculate the derivative of a function (via an imitation game), and then, how to use this derivative to find the extremum of the function (again, via an imitation game). Note that in the course of these imitation games, pupils will have learned new types of tasks (finding the derivative of a function; using it to find the extremum), the corresponding techniques (including the derivatives of elementary functions; derivative of the composite function, etc.), will have enlarge their nomological component (incorporating, for example, a theorem saying that the derivative vanishes in the extremum of the function), and will have enlarge also their ontological component (incorporating to their language the notions of extremum of a function and the notion of derivative). In addition, in the course of these games, students can employ a certain degree of creativity in imitating the teacher. For example, if the teacher says that the derivative of $f(x)=x4$ is $f'(x)=4x3$, students can creatively imitate it and deduce that the derivative of $g(x)=x5$ is $g'(x)=5x4$. However, the monotony of functions can be studied in a way that promotes much more creativity. Let us very briefly outline a diachronic epistemological model for this. One could start by seeing that to check whether a linear function $f(x) = mx + n$ grows in a certain interval [a, b], it suffices to look at the sign of $f(b) - f(a)$. This incorporates a new notion to our ontological component, the rate of change, $RC(f, a, b) = f(b) - f(a)$, which tells us whether $f(x)$ grows in [a, b] and how much it grows, and we can compare growths of different functions. However, to compare the growth of $f(x)$ relative to the length of the interval [a, b], we must consider the average rate of change, $ARC(f, a, b) = (f(b) - f(a))/(b - a)$. This, which is a new ingredient in our ontological component, works perfectly well for linear functions, and for monotonic sections of any function. But it is not useful to detect monotony in intervals with monotony changes. So, for example, if $f(x) = x2$ we have that $ARC(f, -1, 2) = 4 - 1 = 3 > 0$, but $f(x)$ is not increasing in [-1, 2]. Once it is observed that the reason for the failure is that the interval [-1, 2] is too large, because a monotony change occurs within it, one can consider the option of dividing [a, b] into smaller intervals, and then calculate the ARC of $f(x)$ in those smaller intervals, in the hope of reducing the probability of encountering a monotony change within those smaller intervals. However, the teacher can direct the students' attention to functions and intervals for which such a division of the interval does not guarantee that ARC solves the problem. Indeed, such an interval splitting before knowing the monotonicity of the function cannot guarantee a solution, because it is not known how to choose suitable subintervals that avoid a change of monotony. The solution could come from the idea of regarding x and $f(x)$ as representing amounts of magnitudes. Let $f(x)$ be the polynomial $f(x) = ax + bx2$ describing the height $f(x)$ of an object as a function of time, x, along a certain trajectory. When working with magnitudes there is, in practice, a degree of precision. Well, to study the monotony of $f(x)$ near a point $x=c$ one could choose a number h such that bh is a negligible amount of length, i.e. less than the degree of accuracy. We can then use ARC to see the monotony of $f(x)$ in the interval [c, c+h]. Indeed, $ARC(f, c, c+h) = a + 2bc + bh$ m/s. This means that $a + 2bc + bh$ meters is travelled in 1 second. As bh is a negligible amount of meters, we can say that $ARC(f, c, c+h) = a + 2bc$ m/s. Thus, for those c where $a + 2bc > 0$ the function will

be increasing, and for those c where a + 2bc < 0 the function will be decreasing. We could say that ARC, with h small enough, is an instantaneous rate of change. We can use this method to say that f(x) = 6x - x2 is increasing for x < 3, and decreasing for x > 3. We obtain the same result if we study the behavior of f(x) only a little to the left of x = c, that is, in the interval [c-h, h]. This is how our inquiry game on the study of the monotony of a function can naturally lead us to enlarge our ontological component with the idea of rate of change, average rate of change and instantaneous rate of change (derivative), to consider new types of tasks (is ARC useful for non-linear functions?, does it make sense to arbitrarily divide the interval?, can the degree of accuracy help us in our study of monotony?, what is the derivative of a polynomial of degree n in general?, etc.), and new techniques (together with its technology) that provide answers to these types of tasks. The same enquiry can be extended beyond rational functions, by considering questions as the following one: is there anything like the techniques used for, say, f(x) = sen(x)? It seems clear that this game of enquiry, full of possible dead ends, but with students asking questions and checking their conjectures against examples (sought by them or suggested by the teacher), is more conducive to creativity than a game of imitating certain unfounded procedures showed by the teacher and leading in a straight line to the resolution of types of tasks that appear out of nowhere.

Conclusion

The use of the notion of praxeology to analyse mathematical knowledge helps us to understand the different ways in which one can be creative in mathematics. By using the notion of didactic paradigm for the analysis of the functioning of didactic institutions, we have seen to what extent what is taught (the epistemological model) and how it is taught (the didactic means) should be conditioned by the raison d'être of what is taught (the didactic ends). Thus, if promoting creativity in the study of mathematics is assumed as one of the didactic ends, the choice of the epistemological model and the didactic means must be made accordingly, being a diachronic epistemological model most appropriate, and being the use of inquiry games advisable.

On the concept of epistemic obstacles and its significance to mathematics education (research)

Kata Sebök[1] and Felix Lensing[2]

[1]University of Vienna, Austria; kata.seboek@univie.ac.at

[2]Free University Berlin, Germany

Obstacles to learning mathematics are of natural interest to mathematics education research. In this paper, we examine a particular strand of research which has its origins in Gaston Bachelard's concept of epistemological obstacle. The paper is divided into two parts: In the first part, we start by giving a brief historical sketch of how the concept found its way into mathematics education research, and then focus on a specific subset of these obstacles which we will term 'epistemic obstacles'. The second part of the paper presents examples of results that can be obtained from analysing such epistemic obstacles and argues for their significance for mathematics education (research). We conclude by discussing the potential of Edmund Husserl's eidetic method for a systematic analysis of epistemic obstacles.

Keywords: Obstacle, epistemological obstacle, epistemic obstacle, epistemology, Husserl.

Introduction

Mathematics education research seeks to identify the conditions under which the teaching and learning of mathematics can be successful. In this context, however, it is repeatedly confronted with the fact that many students do not learn the mathematics that is taught. Hence, it seems natural to look at the processes of mathematical learning and teaching from the perspective of obstacles that may stand in the way of students acquiring mathematical knowledge.

In this paper, we would like to take a closer look at a strand of research that originated in Gaston Bachelard's (2002) work on epistemological obstacles. To do this, we first provide a historical sketch of how the concept has found its way into mathematics education research, and then focus on a particular subset of these obstacles, which we propose to call 'epistemic obstacles'. In the second part of the paper, we illustrate the kinds of results that can be gained by investigating epistemic obstacles by providing some examples, aiming to show the relevance of such results for mathematics education (research). Having done this, the methodological question of an appropriate methodical approach for conducting investigations of epistemic obstacles remains, and so we conclude the paper by briefly outlining how Edmund Husserl's eidetic method could provide the basis for such an approach.

Epistemological obstacles and mathematics education research

When analysing obstacles to learning and knowing, the adjective 'epistemological' is often used to distinguish one's research interest from the investigation of obstacles that also hinder knowledge, but which do not originate in characteristics of the knowledge being sought after. Examples of such non-epistemological obstacles to mathematical knowing would be mental obstacles such as learned helplessness (Yates, 2009) or social obstacles such as socioeconomic status (Valero et al., 2015).

Bachelard (2002) introduced the term 'epistemological obstacle' in 1938, while "looking for the psychological conditions in which scientific progress is made" (p. 24). He identified obstacles like *opinion*, *conservative instinct* and *explanatory preferences* such as animism or substantialism as causes of inertia and stagnation in the genesis of scientific knowledge.[1] While Bachelard (2002) looked to the history of science to identify the mental tendencies that could obstruct acts of knowing, as an epistemologist, he insisted on taking a normative stance, rather than choosing the descriptive methods of a psychologist or historian: "[Epistemologists] have to evaluate [historical] documents from the standpoint of reason and indeed from the standpoint of developed reason for it is only now that we can really judge the errors of the mind's past" (p. 27).

In the 1970s and 80s, Brousseau (2002) transferred the concept to mathematics education research. He observed that many errors that students make in the process of learning mathematics „are not only the effect of ignorance, of uncertainty, of chance, […] but the effect of a previous piece of knowledge which was interesting and successful, but which now is revealed as false or simply unadapted" (p. 82). Such obstacles are considered pieces of knowledge (as opposed to a lack of knowledge) which produce responses that are appropriate within some typical contexts but inappropriate outside of these. Pieces of knowledge that are obstacles in this sense appear to be resistant to the occasional contradictions they cause and continue to reappear persistently even after their inadequacy for a more universal understanding has been recognised (Duroux, 1982, as cited in Brousseau, 2002).

While obstacles, in general, "are made apparent by errors" (Brousseau, 2002, p. 84), epistemological obstacles understood as this kind of illegitimate transfer of knowledge to new domains can be distinguished by the fact that the later established system of knowledge will bear signs of the obstacle that had to be overcome in order to reach it. In these kinds of obstacles, Brousseau and his followers thus see a constitutive part of the mathematical knowledge which students should learn. As a consequence, such obstacles should not and cannot be avoided and the role of the teacher is to provide didactic situations in which students apply their previous beliefs to a more general problem, realise its limitations and modify their beliefs by incorporating the obstacle into an adequate generalisation. One approach to this kind of 'didactical engineering' can be to selectively restore some of those conditions in the historical development of a concept that have "disappeared in curriculum processes such as decontextualization and sequentialization of knowledge" (Bergsten, 2020, p. 502).

Typical methods of uncovering epistemological obstacles include reconstructions of the history of mathematics and content-focused analyses of common teaching challenges, since aside from the pervasiveness of an obstacle, the role it plays in the knowledge system of mathematics is crucial. In the next section, we shall argue that one can add to this strand of research by introducing further distinctions within the sphere of epistemological obstacles and that for a subset of these obstacles, a different method of analysis is required.

---

[1] Even though Bachelard explicitly excluded mathematics from his investigations (see Bachelard, 2002, p. 32), we believe that the 'generic extension principle' (Tall, 1991), according to which properties of objects in a restricted context are assumed to be more generally valid, could be considered an obstacle of a similar kind in the mathematical domain.

The nature of epistemic obstacles and how to identify them

In the broadest and most literal sense, any obstacle that prevents a subject from coming to know could be called an epistemological obstacle. However, besides didactic obstacles and ontogenetic obstacles, for example, which are contingent upon specific characteristics of the teaching situation and the developmental level of the students, one can identify certain obstacles of "really epistemological origin" (Brousseau, 2002, p. 87).

These can be found among the obstacles that mathematicians had to overcome in history in order to open up certain areas of mathematical knowledge or the obstacles that students of mathematics face again and again as they acquire certain pieces of mathematical knowledge. Epistemological obstacles are obstacles that are not a result of suboptimal conditions (e. g., if mathematicians in a certain region of the world and at a certain point in history were not familiar with a particular set of mathematical methods, or if a topic is presented to students at an age in which the necessary cognitive skills aren't sufficiently developed) but specifically those obstacles which have been empirically shown to occur even in processes of knowing that are ultimately successful.

However, when obstacle seeking reconstructions of the genesis of mathematical knowledge remain grounded in mathematical knowledge as it was *actually* discovered or is *actually* acquired, this leaves room for certain contingencies. For it does not follow from the fact that certain obstacles have arisen in the history of mathematics, or repeatedly arise in educational contexts, that their arising could not have been avoided. For example, a student might expand their understanding of multiplication as repeated addition to include an understanding of multiplication as scaling in order to make sense of an expression like '$0.75 \cdot 0.4$'. In this instance, the previous understanding may well be an obstacle, which, once engaged with and overcome, can be contextualised and incorporated into a correct system of knowledge (see Brousseau, 2002, pp. 109–110). Yet it is by no means clear whether this – the path which leads through this understanding which can become an obstacle – is the path which must be taken *en route* to the multiplication of rational numbers.

In light of this observation, one might wonder whether there are any obstacles which not only have factually prevented certain groups of human beings from knowing, but *that would necessarily prevent any rational subject from attaining the piece of knowledge in question*. Accordingly, we set out to identify those obstacles to knowing which make acquiring mathematical knowledge of a particular kind impossible. To distinguish this subset from epistemological obstacles in Brousseau's sense, we will use the term 'epistemic obstacles'.

Note that empirical observation cannot yield answers to such questions of strict necessity, which means one has to find other methodically controlled ways of investigating them. We will return to this methodological issue toward the end of our paper. First, we will provide some examples of the kinds of results that a *rational epistemic obstacle analysis* can arrive at, and thus illustrate its relevance to mathematics education and its research.

Epistemic obstacles and their significance for mathematics education

In order to get a better impression of which obstacles to (mathematical) knowledge can be called 'epistemic obstacles' in our sense, we will now, in the second part of the paper, discuss some

examples. A large group of such epistemic obstacles can be summarised under the formula of 'the failure to distinguish the different'. This formula refers to the numerous cases where distinctions that are necessary for progress in the act of knowing are overlooked. We shall now show how a *failure to distinguish between the meaning and the object of a mathematical expression* can become an epistemic obstacle in the depicted sense.

We start directly with a mathematical example and develop the necessary distinctions along the way: In 'What is mathematics?', Courant and Robbins (1996) write about division by zero: "Expressions such as 1/0, 3/0, 0/0, etc. will be for us meaningless symbols" (p. 56). Although they acknowledge that it may be useful in some cases to replace "such expressions by the symbol ∞ (read, 'infinity')" (ibid.), they immediately go on to add that one should not then try to deal with "the symbol ∞ as though it were subject to the ordinary rules of calculation with numbers" (ibid.). If one were to do this, after all, one could infer, for example:

$$3 = 0 \cdot \infty = (0 + 0) \cdot \infty = 0 \cdot \infty + \ 0 \cdot \infty = 3 + 3 = 6$$

The assumption that 3/0 = ∞ thus – by applying the distributive law – results in a contradiction. From a *mathematical* point of view, this is an ordinary permanence argument: One demands the permanence of certain laws (here: the 'ordinary rules of calculation with numbers') and then shows, by deriving a contradiction, that the operation of division cannot be extended to the divisor zero under the demanded condition. From an *epistemological* point of view, however, it is illuminating to take a closer look at the explication that Courant and Robbins provide for their own mathematical activity. For this passage shows quite clearly the difficulties in mathematical knowing that can result from not distinguishing between the *meaning* and the *object* of a mathematical expression.

We may first observe that every mathematical expression has a certain meaning and by virtue of this meaning, it relates to ('means') an object. "In meaning", writes Husserl (2001), "a relation to an object is constituted" (p. 201). Note that "it makes no difference whether the object exists or is fictitious or even impossible" (ibid.). That the mathematical expression relates to a mathematical object through its meaning therefore says nothing about the existence of the expressed and meant object. Rather, it only indicates that the expression relates to its respective object *by* the particular meaning. However, this then leads to the important consequence that the question of the *existence of the object* corresponding to the mathematical expression must not be confused with the question of the *existence of its meaning*. To put it another way, the *meaninglessness* of an expression is something quite different from its *objectlessness* (see Husserl, 2001, p. 202).

"But if one" – as Courant and Robbins (1996) seem to do in the passage above – "gives a very rigorous interpretation to the proposition that an expression, in so far as it has meaning, relates to an object, i.e. in a sense which involves the existence of the object, then an expression has *meaning* when an object corresponding to it exists, and it is *meaningless* when no such object exists" (Husserl, 2001, pp. 201–202).

We will now show that this view is not tenable. While Courant and Robbins (1996) deny expressions such as '3/0' or '1/0' any meaning, they paradoxically also use the meanings of these expressions to justify their statement that they are meaningless. After all, to deduce a contradiction, one has to

interpret division as the inverse operation to multiplication and further demand that this purported operation satisfy the 'ordinary rules of calculation with numbers'. In doing so, a meaning *is* assigned to the expressions involved, namely a meaning which could be formulated as follows in the case of '3/0':

'3/0' means as much as 'the number which, when multiplied by 0, gives 3'

And only by utilising *this* meaning is it then possible to show that the number that the expression '3/0' means is determined in a contradictory way and that this purported number therefore cannot exist (see the proof above).

We now want to show that such considerations are not merely epistemological quibbles, but that we are dealing with an epistemic obstacle that can have tangible consequences for the teaching and learning of mathematics. For this, we build on an example stemming from Hans Freudenthal (Freudenthal, 1973, p. 232): Imagine a mathematics class which is dealing with the extension of the natural number domain to the integers. Sooner or later, the class will face the question of why the multiplication of two negative numbers yields a positive result. On this occasion, the teacher starts from the paradigmatic example $(-3) \cdot (-4) = 12$ and presents the following argument for it:

'We know that -a is the number which, when added to a, gives 0, so we know that the following two equations hold:

$$(-3) + 3 = 0 \text{ and } (-4) + 4 = 0$$

If we now multiply the first equation by 4 and the second by -3, we get

$$0 = \big((-3) + 3\big) \cdot 4 = (-3) \cdot 4 + 3 \cdot 4$$

and

$$0 = (-3) \cdot ((-4) + 4) = (-3) \cdot (-4) + (-3) \cdot 4.$$

This allows us to deduce that

$$(-3) \cdot 4 + (-3) \cdot (-4) = (-3) \cdot 4 + 3 \cdot 4.$$

And therefore:

$$(-3) \cdot (-4) = 3 \cdot 4 = 12.'$$

The teacher finishes off this presentation with the conclusion: "Of course, this was no proof, it was a mere plausibility argument, because in our so-called proof we have been so reckless as to use the distributive law for negative numbers which we never proved" (Freudenthal, 1973, p. 232).

Freudenthal (1973) analyses the situation as follows: "The teacher denies that what he has done was a mathematical activity though the pupil must have received the impression that it was rather profound mathematics. The pupil is right. In denying it, the teacher causes harmful confusion" (p. 232). But where exactly does this 'harmful confusion' come from? And on what basis may the teacher have arrived at their mistaken conclusion? *One* way of making sense of the teacher's actions is to build on the previous considerations: The teacher could be led to their conclusion because they failed to distinguish between meaning and object of the mathematical expressions involved. How so? Well,

having this issue in mind, the teacher's comment might be indicative of a correct intuition that *something* remains unproven, namely the existence of the realm of negative numbers and the operations upon them – but this does not mean that nothing is proven at all.

The argument shows that *if* there exist negative numbers and an operation of multiplication upon them that satisfies the ordinary laws of arithmetic, *then* this operation necessarily must yield 12 in the case of -3 and -4. This constitutes a *proof*, and not only a plausibility argument. But it constitutes a proof that is played out entirely on the *level of meaning.* Whether the expressions '-3', '-4', and '·' relate, through their meaning, to *existing* objects is not at issue in the proof. It is not a proof of existence, but only a proof of uniqueness, so that the proof for the existence of mathematical objects with properties satisfying all the demanded conditions remains to be given. But the proof does unfold the implications of fixing the meanings of the expressions involved in this specific way.

The fact that proofs based on the principle of permanence do not allow for positive conclusions about the *existence* of the expressed and meant mathematical objects in question hence does not mean that no 'progress' is made in terms of knowing. On the contrary, in these kinds of extension problems, one must *first* analyse the desired meaning of the new expression and find out in which way the object in question is determined by this meaning. This can lead, as the analyses above have shown, for instance, to the result that said object is determined in a unique way. In these cases, then, a proof of existence remains to be given and is, as Freudenthal (1973) notes, fundamentally important; but it comes second, "both as regards the temporal succession, and as regards the importance" (p. 234).

In the example, the teacher's unawareness of this necessity of dealing with the task of elucidating the *meaning* of an expression before advancing to the question of the existence of its *object*, leads to an ill-structured presentation followed by a misleading conclusion. As such, a *didactic* obstacle in the instructional situation might occur that could stand in the way of students' own epistemic processes.

Concluding and looking ahead

Conceptualising certain constitutive elements of the mathematical knowledge being sought as potential 'obstacles' to knowing has a longstanding history (see Brousseau, 2002; Prediger, 2008) within mathematics education research. In our paper, we aimed to present a case for the potential of considering a more narrowly defined category of *epistemic obstacles*. These are not dependent on any specific past or present circumstances of acts of knowing or characteristics of real or imagined knowing subjects. As such, epistemic obstacles are relevant to all students of mathematics. As we have mentioned, a rational inquiry into such conditions for knowing mathematics and the resulting obstacles to knowing mathematics poses a certain methodological question (see Kollosche (2023) on the need for a methodology for rational didactic content analyses): How can one analyse mathematical knowing in a purposeful and systematic manner to arrive at conclusions about epistemic obstacles?

In the analyses we have conducted so far, we found that the "eidetic method" (Husserl, 1960, p. 71) might provide an answer. Its core idea is to 1) *hold a* (perceived, remembered or imagined) *instance of an act of knowing in one's mind,* while 2) *systematically varying* features of the act, carefully paying attention to when the altered act stops being an act of knowing. Features which can be altered without the act ceasing to be a knowing act cannot lead to epistemic obstacles in our sense. However,

some features seem to be necessary for us to still consider the modified act an 'act of knowing'. Whenever those features are absent, an epistemic obstacle occurs.

To illustrate the working of the eidetic method, let us now retrospectively provide a firm foundation for our analyses from the last section. In order to get our analysis off the ground, we began by introducing some distinctions that, we believe, are relevant to all acts of mathematical knowing. We first distinguished between a *mathematical expression* and that which it expresses. Then, on the side of what is expressed, we distinguished between the *meaning* of the expression and the *object* to which it relates through that meaning. Using the eidetic method, it can be shown that these conceptual *distinctions* are actually grounded in objectual *differences* in the sphere of mathematical acts.

The starting point of the eidetic analysis is a mathematical act in which these three aspects – expression, meaning and object – are given. Imagine that I, Kata Sebök, am confronted with the expression '12' and interpret it as a numeral within the decimal system. '12', then, is construed by me as a mathematical expression that has the same meaning as '$1 \cdot 10^1 + 2 \cdot 10^0$' and that thus, through that very meaning, relates to the number twelve. To 'hold this act in one's mind' now involves considering this act not as an event that occurred at a certain point in time and space in my specific mind, but rather conceive of it "merely as exemplifying a pure possibility" (Husserl, 1960, p. 71). And the eidetic insight that expression, meaning and object are actually distinct features of this possible act can be obtained by systematically varying the act. First, it becomes evident that the expression does not impose its meaning on me, but rather that the meaning can be varied while adhering to the expression. I could, for example, also interpret the expression '12' in another place value system, for example base 3. '12' would then have the same meaning as '$1 \cdot 3^1 + 2 \cdot 3^0$' and would thus relate to the number five. However, it is also evident that the expressed object is not necessarily altered by different interpretations of a mathematical expression: For example, the expression '3', when interpreted in place value systems of bases 4 and 10, relates to the same object, the number three, but does so via different meanings, namely the respective meanings of '$3 \cdot 4^0$' and '$3 \cdot 10^0$'. In other words, it is possible to retain the expression and the object, but vary the meaning. Yet, it is also possible to retain the meaning and the object while varying the expression. I could, for example, use the English word 'five' or the German word 'fünf' and thereby use different expressions to relate to the same number via the same meaning.

This series of variations, which could of course be taken further, shows that expression, meaning and object are really three different aspects of mathematical acts. In the last section, we developed some of the problems which can arise when these crucial differences in mathematical acts are not taken into account – or, as we have put it succinctly: if a subject *fails to distinguish the different*.

It is important to point out that, while varying the components of mathematical acts in such a way takes us away from any particularities of a situation, the results of this kind of analysis have the benefit of applying to any human activity with the aim of performing such acts. Rather than being interested in a particular group of students with specific characteristics, the level of abstraction serves us in achieving results that apply to a most diverse range of students of mathematics.

Mathematics education researchers have already recognised that an awareness for the results of epistemological analyses of the mathematics being taught and learned can be of benefit both to

researchers as well as teachers in mathematics education (Prediger & Hefendehl-Hebeker, 2016). Rational epistemic obstacle analysis can reveal the *common* obstacles which students of all backgrounds and in all educational contexts can always face. As such, it complements empirical research that seeks to identify effective ways in which educators can help individual (groups of) students overcome these obstacles given specific sets of resources.

Transposition of research knowledge: From the West to Far East Asia

Yusuke Shinno[1] and Takeshi Miyakawa[2]

[1]Hiroshima University, School of Education, Japan; shinno@hiroshima-u.ac.jp

[2]Waseda University, School of Education, Japan

Theories and methodologies in mathematics education are disseminated into different international contexts. In this paper, we aim to explore conditions and constraints underlying the transposition of theories and methodologies from the West to East Asia (Japan in particular). Reflecting on two case studies in terms of the anthropological theory of the didactic, we discuss some cultural specificities of researchers' work in Japan that contrast with those in the West: regarding the relationship between researchers and teachers, the nature of theories in relation to the practices, and so forth.

Keywords: Diversity of theories, transposition, culture, language, research knowledge

Introduction

Theories and methodologies in mathematics education are seen as 'research knowledge (scholarly knowledge)' produced by a community of researchers. We assume that any theory in mathematics education cannot be seen as an absolute or finished product but can evolve and change over time through its use and adaptation to the different local contexts in which researchers work. However, it is often implicit what conditions or constraints may underlie local educational contexts or scholarly traditions, which are more or less invisible to those outside them. This is also the case for methodologies in mathematics education. The variations in the methodological frameworks may bring diversity to researchers' theorising work (García, 2019). Although there have been many discussions of the diversity of theories at international conferences such as CERME and ICME, most are about the theories that emerged in the West, in particular, within the European tradition of didactics (Blum et al., 2019). Indeed, different scholarly and cultural traditions exist within the West (Gascón & Nicolás, 2017; Jaworski et al., 2018). However, there are few contributions from East Asian colleagues to such discussions. Theories and methodologies originating from the West are often imported and disseminated into mathematics education research in East Asia. Traditionally, East Asian researchers have translated seminal books and papers for dissemination in their local communities. However, research knowledge sometimes undergoes changes when adapted to a country with a very different language and culture (e.g., Far East Asia such as Japan), due to issues of linguistic and cultural origins. In this paper, we conceptualise such theoretical or methodological dissemination as the *transposition of research knowledge* and illustrate conditions and constraints that may affect the transposition. For this purpose, we use two case studies that the authors have recently worked on. One case illustrates the transposition of a theoretical framework (Documentational Approach to Didactics; hereafter DAD; Trouche et al., 2020) developed in Europe. The other demonstrates the transposition of a methodological framework (design research) that is also well developed in the West (e.g., Gravemeijer & Prediger, 2019). To explore the cultural specificities of research knowledge under the influence of transposition, in the first case, we reflect on the researchers' translation works on the terminologies of the DAD, and in the second case, we consider local theories produced from design research. This theoretical paper makes a new

contribution to the extant literature on the diversity of theories from cultural and institutional perspectives. To this end, we draw some concepts based on the Anthropological Theory of the Didactic (hereafter ATD). One of the reasons for adopting ATD is that it is a research programme with a basic assumption that admits the 'institutional relativity of knowledge' (Chevallard, 2019), which could be suitable to achieve the purpose of this paper.

Theoretical perspectives

Understanding different researchers' works on theories is challenging but promising (e.g., Sierpinska & Kilpatrick, 1998). For instance, Bishop (1992) introduced the notion of research traditions and distinguished three traditions: the pedagogue, the empirical scientist, and the scholastic philosopher traditions. Thanks to the initiative to develop mathematics education as a scientific discipline, the scientific progress of our field has shown a multi-faceted nature of scholarship over the last five decades (Niss, 2019). As the field has developed, theories per se have become more intensively discussed; for example, the roles of theories (Silver & Herbst, 2007), the networking of theories (Bikner-Ahsbahs & Prediger, 2014), and the dialogue between scholars (Gascón & Nicolás, 2017). However, there are far fewer contributions from East Asian colleagues to those discussions. This is not only because they use non-dominant language, but also because they work in a very different research tradition. This is what we would like to explore in this paper.

Some perspectives from ATD

In this section, we offer three perspectives based on ATD (*didactic transposition*, *praxeology*, and an *ecological perspective*) to explore and illustrate the cultural specificity underlying transposition.

Transposition. Didactic transposition conceptualises diffusion of certain mathematical knowledge across institutions, such as in a community of mathematicians (scholarly knowledge), an educational system (knowledge to be taught), a mathematics classroom (taught knowledge), or a community of study (available knowledge) (Chevallard, 1985/1991). Although most existing studies have focused on the transposition between 'knowledge to be taught' and 'taught knowledge', the relativity of 'scholarly knowledge' is rarely discussed. However, scholarly knowledge also varies according to institutions: it is obvious that there is different scholarly knowledge in the history of mathematics. The concept of transposition can be extended to the transposition of research knowledge (Wang et al., 2023). Research knowledge refers to the scholarly knowledge in researchers' communities of mathematics education. In this paper, we assume that research knowledge exists in different research institutions and consider the transposition between contemporary institutions from an international perspective. In particular, we focus on the transposition from the West to Japan. It should also be noted that the transposition does not necessarily lie in one direction, but both directions are possible.

Praxeology. To better characterise research knowledge, we draw the praxeology, which is a model of human activity (know-how) and knowledge (know-why). Artigue et al. (2011) applied this notion to researchers' practice and knowledge. This praxeology is called *research praxeology* (hereafter RP), and it consists of a *praxis* block describing research problems and research methods, and of a *logos* block providing a rationale and discourse to explain and justify the praxis blocks. Certain didactic theories (e.g., DAD) and methodologies (e.g., design research) are considered parts of the logos block

of RP. Developing mathematics education research in international contexts, those RP can then be transposed into different research institutions. The focus of this paper is on the transposition from Western to Japanese research institutions. In fact, the transposition of the logos of RP is an important work that constitutes RP in East Asian countries, such as China and Japan (Wang et al., 2023).

Ecology. In an institution, praxeology is shaped by *conditions* that support its organisation and *constraints* that hinder it. Those conditions and constraints constitute the ecology of lived praxeology (Gascón & Nicolás, 2019). In the case of RP in the West, the logos block is developed within the research institution, which is subject to its ecology (e.g., European traditions of didactics). In Japanese research institution, RP exists with some specificity shaped by ecology in its local contexts. Exploring such conditions and constraints underlying the transposition allows us to understand the cultural specificities of research knowledge in each institution.

Reflecting on two case studies

Case 1: Transposition of DAD

DAD is a theoretical framework in mathematics education that aims to understand teachers' interactions with the resources used and designed in/for their teaching practice (Trouche et al., 2020). The internalisation and the diversity of researchers working on this theory have led to the DAD Multilingual Project (Trouche et al., 2023). One of the aims of this project was to deepen and diversify didactic theory by adapting it to different local contexts. We were involved in this project and engaged in the Japanese translation. One of the outcomes of this project was published in the special issue of ZDM, in which we contributed with Chinese colleagues (Wang et al., 2023). In the following, we summarise some principal aspects of our work in terms of the transposition of DAD. Translation involves different issues, including not only the linguistic aspect but also considering the possible understanding of concepts in the target institution. We therefore assume that "the translation work of a didactic theory is considered a process of transposing a logos block of research praxeology from one research institution to another" (Wang et al., 2023, p. 707). We have experienced various difficulties during translation at different levels. At the linguistic level, there are four main issues: 1) the development of new terminology; 2) multiple meanings and candidates; 3) phonetic expression; and 4) the rules of derived words. These issues stem from the distance between the Western and Japanese languages. Therefore, the translation is not always equivalent to the original term because the choice of the term is strongly affected by the researchers' perspective.

Regarding issues related to cultural origin, the translation of technical terms of DAD is affected by the local educational contexts in which teachers and researchers work when choosing terms. For instance, the word resource is a key term in DAD, and our Japanese translation is リソース(risōsu) which refers to a phonetic expression of the original term (but cannot retain the English connotation '*re-source*' suggested by Adler (2000)). In professional communities in Japan, most teachers are not very familiar with this term. One of the reasons for this is that other terminologies are more commonly used in the communities. An example is the term 教材 (kyōzai), meaning teaching material, which is sometimes used similarly to the term resource in DAD. Kyōzai is the one that is usually provided to students, not teachers. For instance, mathematical tasks and textbooks are seen as kyōzai as well as resources for students' learning. However, curricular documents such as teacher's guides on national

curricula are not considered kyōzai. Additionally, the use of the term kyōzai is practice-oriented without theoretical underpinning, in contrast to the term resource in DAD. Therefore, the use of the term リソース(risōsu) in Japan is not necessarily the same as in the West. There are some Japanese terms that refer to teachers' work with resources. For example, the term 教材研究(kyōzai kenkyū), which denotes studying kyōzai (teaching materials), could be viewed as teachers' documentation work with different resources. The term kyōzai kenkyū is often used to describe teachers' lesson preparation work, including task design and lesson plan drafting. During kyōzai kenkyū, teachers work on various curricular resources; for instance, textbooks and their supplementary materials are very influential in teachers' lesson planning in Japan. Most Japanese educators and educational researchers acknowledge that kyōzai kenkyū is a promising activity for developing teachers' professional and mathematical knowledge for teaching. Although kyōzai kenkyū is a well-known terminology used to describe teachers' practice, the use of the term has no theoretical underpinnings. From a research perspective, kyōzai kenkyū is an object of study that can be analysed or characterised through a particular theoretical lens such as DAD. Consequently, the translation work went beyond the linguistic issues, leading to an understanding of the extent to which the target texts would be evident to them in an institution (see further examples in Wang et al., 2023).

Case 2: Transposition of the design research

Design research is a methodological framework developed across disciplines. In the field of mathematics education, different variations of design research have been developed in different scholarly traditions: such as *instructional design research*; *design experiment*; *topic-specific design research*; *didactic engineering*. One of the reasons for this diversity or dissemination is that design research is a methodology that combines the practical aim of improving designs with the theoretical aim of generating theories (Prediger, 2019). It seems that the implementation of design research is therefore strongly influenced by the local and cultural contexts in which the researchers and teachers work. This is also true for task design research in mathematics education. In the following, we report and reflect on some results of an ongoing project in Japan (Komatsu, 2024; Tsujiyama & Kato, 2022).

This project aims to develop task design principles (TDPs) that allow researchers to design mathematical tasks that make proving activities explorative and collaborative (Komatsu, 2024). Komatsu (2024) defined TDP as follows: "theoretically and empirically grounded prescriptions that guide the design of tasks for specific learning contents or activities" (p. 2). This project adapted a design research model from the West (e.g., Gravemeijer & Prediger, 2019) and offered a research framework comprising the following elements: 1) specifying the learning goal, 2) constructing TDPs, 3) designing tasks, 4) implementing the tasks, 5) analysing the implementation. This framework also includes two fields: "research" and "context (of the implementation)". "Research" is a scientific field in which researchers refer to relevant theoretical references to provide the underpinnings of designs and contribute to the literature. "Context" is a practical field in which the designed tasks are implemented. The project also offers a task design format that allows researchers to work on elements 1, 2, and 3. The following presents examples of learning goals and TDPs taken from Tstujiyama and Kato (2022) during the project.

- Learning goals: Realising explorative proving activities that allow interactions between 'statement (conjecture)', 'proof', and 'looking back'
- TDP1: Use tasks whose conditions are purposefully implicit, in order to allow the production of a conjecture whose hypothesis is implicit. TDP2: Provide a problem that considers if the conjectured statement is true, in order to allow the production of proofs with 'irrational' diagrams. TDP3: Increase students' recognition of the contradiction between the 'irrational' diagram and the valid proof, in order to allow the revision of the statement and the proof

Specifying learning goal(s) and designing tasks are researchers' or teachers' activities that contribute to the practical aim of the design research. There are various methods to design tasks such as 教材研究(kyōzai kenkyū). A set of TDPs supports their task designs to realise learning goals. The development of TDPs is considered a research-based activity because some theoretical references are used to justify TDPs. In terms of the theoretical aim of design research, a set of TDPs produced during the cycle could be the main outcome. TDPs are considered prescriptive theory elements (Prediger, 2019) that guide task design to achieve learning goals. To generate such elements, the theorising steps (e.g., connecting, transforming, refining) are crucial (Prediger, 2019). For example, Tsujiyama and Kato (2022) stated that "when teaching proof problems with diagrams through Lakatosian style, it is difficult for some students to distinguish if one can construct a diagram and if one can prove" and justify this statement with the reference. In terms of the categorisation of the theory elements (Prediger, 2019). This statement is considered an explanatory theory element generated by connecting it with some descriptive elements that they identified in the preliminary classroom practice. This element is then transformed into a conjecture for a prescriptive element "to provoke students' awareness of a contradiction 'while the diagram is irrational, the proof is valid'" (Tsujiyama & Kato, 2022, p. 154). This element was then refined and incorporated into one of the TDPs (see TDP3 above). Those successive steps of theorising (connecting, transforming, and refining) contribute to the generation of TDPs, which are prescriptive theory elements.

Discussion and conclusions

Conditions and constraints underlying the transposition of research knowledge

Reflecting on our transpositive works on research knowledge in the two case studies illustrated in this paper, common conditions seem to support transposition, and common constraints hinder it. A close relationship between researchers and teachers may constitute a condition underlying the transposition. In the first case, some DAD terminologies were translated into Japanese with reference to Japanese professional terminologies. Teachers' documentational work corresponds well to the practice related to classroom teaching in Japan, and Japanese terms already exist to denote such practices. In the second case, a well-established system in Japan allows researchers and teachers to work collaboratively. Thanks to the tradition of lesson study, which is similar (not identical) to the practical aim of design research, the implementation of the cycle in design research seems to work naturally in the school context in Japan. In this case, the framework of the project described earlier is not seen as a product of the 'one-directional' transposition from the West but rather as a product of the 'double' transposition (cf. Cabassut, 2009). As will be mentioned later, mathematics education research in Japan has a strong orientation towards development and practice. This orientation may

constitute a constraint that a theoretical framework is received as a prescriptive or normative one that can be used for developing, designing, and improving educational practices, rather than for understanding phenomena. In the first case, although DAD is a didactic theory to understand teachers' work with resources, it might be conceived as a strategic approach to improving teachers' practice such as kyōzai kenkyū. In the second case, the generation of TDPs (a set of prescriptive theory elements) is the main theoretical outcome, however, this is also an explicit contribution to improving designs. This is because TDPs as prescriptions seem to be acceptable outcomes of research in Japan. In terms of the dialectic between the theoretical and practical aims of design research, the TDPs in the project have two interwoven aspects: TDPs were first produced to support task design and then discussed how these principles could contribute to the theoretical aim of design research. However, this is not the case in other countries' research projects on task design or didactic engineering (García, 2019).

Research praxeology in different research institutions

What is the nature of the logos block of RP in the West? There are many earlier works for developing mathematics education as a scientific discipline (e.g., Sierpinska & Kilpatrick, 1998). The evolution of this discipline requires the creation of new scientific knowledge and terminologies in the theoretical world other than those spontaneously developed in the practical world (see also Margolinas, 1998). To get a deeper understanding of didactic phenomena at stake, the use and role of such theoretical terminologies constitute the logos of RP in the West (e.g., the European tradition of didactics). In other words, there is an *epistemological rupture* (Bachelard, 1938/2002) between theoretical/scientific terminologies, comprising RP in the West, and practical/professional ones, comprising teaching (didactic/paradidactic) praxeology. In this regard, Gascón and Nicolás (2019) offer a clear view on didactics as a science that "is legitimised to present, as results of research, neither normative prescriptions nor value judgments of any kind" (p. 42). In contrast, in the East Asian tradition of mathematics education research, teachers and researchers often share and develop terminology for collaborative work. Hirabayashi (1987), who obtained the first PhD in mathematics education in Japan, stated: "Mathematics education research is, in a sense, a practical science. Its problems are always identified within the educational practice, and its results should always be reflected in the educational practice" (p. 28; our translation). Consequently, RP in Japan has been strongly oriented towards the improvement of teaching (see more examples; Shinno & Mizoguchi, 2023), in which teaching and research ends share the same sphere of educational research. Our contribution could open a new dialogue between scholars working in different research institutions, which can be exposed when research knowledge is transposed from one institution to another.

Mathematical heterotopias: Lessons for the mainstream classroom

Constantinos Xenofontos[1,2]

[1]Oslo Metropolitan University, Oslo, Norway

[2]University of Agder, Oslo, Norway, konstantinos.xenofontos@uia.no

This paper explores the application of Michel Foucault's concept of heterotopia to mathematics education, examining alternative learning environments such as special needs classrooms, gifted education programmes, and prison education. These "mathematical heterotopias" challenge traditional educational structures, fostering inclusive and flexible approaches to learning. By highlighting the potential of these environments to inspire critical thinking and personalised instruction, this paper emphasises the importance of reimagining mainstream mathematics education. The insights gained from these alternative spaces offer valuable lessons for creating more empowering and inclusive learning environments in mainstream classrooms.

Keywords: Mathematical heterotopias, special needs education, gifted education, prison education.

Introduction

This paper draws on the concept of heterotopia, rooted in Michel Foucault's framework of spaces that exist outside conventional social norms yet remain closely tied to them. Through an exploration of special needs classrooms, gifted education programmes, and prison education as "mathematical heterotopias", I stress the potential of these spaces to challenge dominant narratives and foster inclusive, critical approaches to learning. The theoretical importance of this paper lies in its application of Foucault's heterotopia to mathematics education, revealing how these alternative environments not only disrupt traditional pedagogies but also offer insights that could transform mainstream education. Through this lens, I argue that these spaces present a model for more inclusive, flexible, and empowering learning environments, ultimately suggesting a reconceptualisation of how we approach mathematics education within conventional classroom settings.

Foucault's concept of *heterotopia*

Michel Foucault's concept of *heterotopia* refers to real, physical spaces that exist outside conventional social and cultural norms, yet remain closely connected to them (Foucault, 1986). Heterotopias are spaces that mirror and invert societal structures, representing a kind of "otherness". Unlike utopias, which are idealised or imagined places, heterotopias are real locations that serve specific roles within society. For Foucault, heterotopias are defined by several principles. Firstly, every society creates them, although their forms and functions vary across cultures and time. Secondly, they combine multiple spaces or meanings within a single location. For instance, a garden might represent nature, while also being a constructed, controlled space. Thirdly, heterotopias often play a role in managing time, such as museums or cemeteries, which preserve objects or people for the future. Fourthly, they are spaces that are both accessible and restricted, with entry governed by specific conditions. Finally, heterotopias often reflect or challenge dominant ideologies, offering spaces of deviation or critique, like psychiatric hospitals, prisons, or even carnivals. These spaces serve as mirrors, reflecting a society's norms while also providing an alternative view. Through

heterotopias, Foucault invites us to consider how spatial organisation can reveal the power dynamics and tensions that shape our everyday lives.

Classrooms as heterotopias

Classrooms have often been described as heterotopic spaces where dominant narratives and traditional structures are challenged, offering opportunities for critical engagement and transformation. In this context, Zembylas and Ferreira (2009) describe classrooms in conflict-ridden societies as spaces where students engage with their identities beyond entrenched conflict narratives, allowing for reimagined forms of belonging. These heterotopic spaces resist normative identities grounded in polarised trauma, fostering new possibilities for understanding identity and coexistence. Similarly, Liddle (2021) reveals how a British classroom became a space to question war and the normalisation of military values, enabling students to critically examine dominant discourses around conflict. This classroom, functioning as a heterotopia, facilitated deeper discussions that contrasted with mainstream school environments. Focusing on physical education, Larsson et al. (2014) explore how classrooms become spaces where gender norms can be disrupted. By challenging the traditional masculine and feminine roles typically reinforced in such settings, these spaces provide opportunities for students to explore non-normative identities. In the same vein, Gourlay (2015) discusses educational spaces as heterotopias of compensation, where gaps in mainstream educational practices can be addressed. Classrooms are not merely spaces for conventional learning but dynamic environments where normative structures can be questioned, fostering intellectual and personal growth.

Three examples of mathematical heterotopias

In the context of mathematics education, the mainstream classroom is often viewed as a normative space, structured by traditional pedagogies, standardised assessments, and prescribed curricula. While some may argue that it functions as a heterotopia due to its controlled and regulated environment, I consider it the norm from which alternative learning spaces deviate. In this article, I discuss three distinct heterotopias where mathematics learning occurs outside the mainstream classroom, focusing on the positive and empowering lessons they offer. These spaces challenge traditional structures, foster inclusivity, and encourage critical thinking in ways that can enrich the mainstream classroom. Although I acknowledge the potential negatives and shortcomings of these heterotopias, my focus will remain on the opportunities they present to improve mathematics education within the mainstream classroom setting.

The mathematical heterotopia of the special needs classroom

Teaching mathematics in special education settings presents unique challenges and opportunities. Students in these classrooms often have a diverse range of needs, from learning difficulties to cognitive disabilities like dyscalculia, which can make even basic numeracy skills difficult to grasp. There is sometimes a tendency to set lower expectations for these students, resulting in a diluted curriculum. Instead of being encouraged to engage with challenging content, they are frequently assigned tasks that are overly simplistic (Kurth et al., 2024). In some cases, classrooms spend an

excessive amount of time on basic concepts such as counting or letter recognition, neglecting more complex, age-appropriate material (Cascales-Martínez et al., 2017).

Recent technological advancements are helping to bridge these gaps in mathematics education. Tools like augmented reality (AR) have been shown to enhance engagement and learning outcomes significantly. By making mathematical concepts more visual and interactive, AR allows students to understand better practical ideas like financial management (Cascales-Martínez et al., 2017). For example, AR can transform abstract concepts like percentages and fractions into visual, manipulable objects, making them easier to comprehend. However, when students with special educational needs are integrated into mainstream classrooms, they often face additional hurdles. The pace in general education is usually too fast, and these students may require more time to process and internalise new material. McCarthy and Shevlin (2017) observe that mainstream classrooms frequently lack the necessary repetition and explanation needed for these students to fully grasp mathematical concepts. This emphasises the importance of differentiated support, ensuring that all students, regardless of ability, have the opportunity to succeed.

Mainstream classrooms can benefit greatly from practices commonly used in special education, particularly in personalising instruction and fostering inclusive environments. One notable practice is co-teaching, where a general education teacher and a special education teacher collaborate to deliver lessons. This approach ensures that students with a range of abilities receive the support they need within the same classroom. Rexroat-Frazier and Chamberlin (2019) argue that this method allows teachers to combine their expertise to better address diverse learning needs, and its implementation in mainstream classrooms could be especially beneficial. Another important lesson is the value of maintaining high expectations for all students. In mainstream education, there is often a tendency to lower expectations for students perceived as struggling, but this can have detrimental effects. Kurth et al. (2024) emphasise that when students with disabilities are provided with grade-level content and the necessary support, they often rise to the challenge. This suggests that rather than simplifying material, mainstream mathematics teachers should focus on offering appropriate challenges while providing the necessary scaffolding for students to succeed.

Technology, which has proven transformative in special education, also holds promise for mainstream classrooms. The use of AR, for instance, has been effective in helping students grasp complex mathematical concepts. Expanding the use of such tools could benefit not only students with special needs but also those who struggle with more traditional teaching methods (Cascales-Martínez et al., 2017; McCarthy & Shevlin, 2017). Finally, the principle of inclusion, central to special education, should be more widely embraced in mainstream classrooms (Roos, 2023). In special education, individualised lesson plans such as Individualised Education Plans (IEPs) are tailored to meet each student's unique needs. While this level of formal individualisation may not be feasible in general education, teachers can still adopt more flexible and differentiated strategies to support all learners. Techniques like differentiated instruction, continuous assessment, and small curricular adjustments can ensure that every student is given the opportunity to succeed (McCarthy & Shevlin, 2017).

The mathematical heterotopia of gifted education programmes

Mathematics education in gifted programmes often focuses on both acceleration and enrichment to accommodate the advanced cognitive abilities and unique learning styles of gifted students. These programmes provide opportunities for students to engage with abstract and complex problems that require higher-order thinking, creativity, and independence. Students in these settings benefit from instructional approaches that introduce deeper mathematical content earlier than their peers, fostering creative problem-solving and a more advanced understanding of mathematical concepts (Dimitriadis, 2016). Koshy et al. (2019) also highlight the importance of recognising individual learning speeds in mathematics, encouraging students to move beyond routine tasks and engage in conceptual and creative thinking.

A key element in these programmes is allowing students to create their own problems rather than simply solving existing ones. As Matsko and Thomas (2014) concluded, when gifted students generate their own mathematical problems, their engagement, motivation, and metacognitive skills are enhanced, helping them see mathematics as a creative and dynamic discipline. This approach not only deepens their understanding but also allows them to explore mathematical concepts in a more personal and meaningful way. Mainstream classrooms can learn valuable lessons from these practices, particularly in fostering creativity and autonomy in mathematics. Encouraging all students to create their own problems, as is often done in gifted programmes, can lead to a deeper understanding of mathematical concepts and greater engagement in the learning process.

Acceleration, that is, enabling students to progress through the curriculum at a faster pace, is another strategy proven effective for mathematically gifted students, in allowing them to cover content more efficiently and keeping them engaged by offering appropriate levels of challenge (Maggio & Sayler, 2013). However, the success of acceleration depends heavily on carefully assessing students' readiness and providing the necessary support throughout the process. Differentiation, a central aspect of gifted education, is also highly applicable to mainstream settings. Grouping students by ability or offering tiered assignments based on their readiness allows for more personalised instruction. Koshy et al. (2019) point out that teachers need to be aware of the varying levels of mathematical ability in their classrooms and adjust their teaching methods according to these diverse needs. Acceleration can also be implemented in mainstream education, allowing students who are ready to progress through mathematical content at a pace that aligns with their abilities (Maggio & Sayler, 2013).

Inquiry-based learning and enrichment activities, commonly used in gifted education, can also enhance mainstream mathematics instruction. Leikin (2021) discusses how mathematically gifted students benefit from enrichment tasks that promote deep thinking and challenge them beyond the standard curriculum. Incorporating such activities into mainstream classrooms can encourage all students to engage more creatively with mathematics, fostering engagement and the development of higher-order thinking skills.

Finally, maintaining high expectations for all students is an important principle that mainstream classrooms can adopt from gifted education. Research shows that when students are presented with challenging tasks and given the necessary support, they often rise to the occasion, showing improved performance and confidence (Smedsrud, 2018). Instead of simplifying content for students who

struggle, mainstream teachers should aim to provide suitable challenges along with the support needed to help all learners succeed.

The mathematical heterotopia of prison education

The constraints of incarceration and the specific educational needs of inmates often shape a unique set of challenges and opportunities for mathematics education in prisons. Prison classrooms often serve individuals with diverse educational backgrounds, many of whom have disengaged from formal education early on. Incarcerated students frequently enter prison with significant gaps in basic skills, particularly in mathematics, a subject often associated with frustration and failure in their past (Chrysikou et al., 2023). As a result, prison educators must address both the academic and emotional barriers students bring to the classroom, making it essential to adopt alternative teaching methods tailored to this population (Vasquez, 2017).

Creating a supportive and empathetic learning environment in prison classrooms is vital, often referred to as a "pedagogy of care". When incarcerated students are treated with respect and humanity, they are more likely to engage meaningfully with the subject matter (Wolf, 2020). This approach is especially important in mathematics education, where students often feel inadequate or fear failure. A caring, student-centred approach can help build confidence and change their relationship with mathematics, encouraging them to view it as a tool for personal growth rather than another hurdle to overcome. Moreover, peer learning plays a crucial role in prison mathematics education. Stathopoulou et al. (2024) describe a project in Greece where young prisoners worked collaboratively with prospective teachers to co-create mathematical knowledge. This collaborative approach not only improved the mathematical understanding of all involved but also fostered a sense of community and mutual respect. Such initiatives show the potential for mathematics education to be empowering, helping incarcerated students reclaim their identities as learners and thinkers.

When it comes to teaching methods, hands-on, discovery-based learning has shown great promise in prison settings. Battaglia and Ferrarello (2021) discuss the use of the Mathematics Laboratory approach in Italian prisons, where students engage with mathematical concepts through physical manipulation of objects and collaborative problem-solving. This method, known as "horizontal teaching", places teachers and students on equal footing, encouraging a partnership in the learning process. In this model, students are encouraged to explore mathematical ideas at their own pace, which has proven particularly effective in restoring a sense of agency and self-worth in incarcerated learners (Ahl & Helenius, 2021).

The experiences of teaching mathematics in prison offer valuable insights that could benefit mainstream education. One of the key lessons is the power of a supportive, student-centred approach to teaching mathematics. In prison classrooms, where many students have been let down by the traditional education system, creating a caring and empathetic learning environment is essential for re-engaging them in the learning process (Wolf, 2020). Mainstream classrooms could benefit from adopting similar teaching principles, recognising that students thrive when they feel supported, respected, and treated as capable learners, regardless of their past academic performance. Another important lesson is the value of hands-on, discovery-based learning. The success of the Mathematics Laboratory approach in prisons, where students engage with mathematical concepts through practical,

real-world applications, highlights the need for more experiential learning opportunities in mainstream education (Battaglia & Ferrarello, 2021).

Mainstream classrooms can also learn from the role of peer learning in prison education. In prison settings, students often rely on each other for support, working together to solve problems and build mathematical understanding (Chrysikou et al., 2023). This collaborative learning model can be just as effective in mainstream classrooms, where students with different strengths and abilities can help one another succeed. Encouraging peer learning fosters a sense of community within the classroom and promotes active engagement with the material, leading to better outcomes for all students. Finally, prison education highlights the value of personalised, flexible learning pathways. In prison, students benefit from individualised instruction that meets them in their mathematical development, allowing them to progress at their own pace (Ahl & Helenius, 2021). Mainstream education could adopt similar strategies by offering differentiated instruction and flexible pacing to accommodate diverse learning needs. By moving away from a one-size-fits-all approach, mainstream classrooms can create a more inclusive environment where every student has the opportunity to succeed.

Conclusions - Moving forward

Considering the concept of mathematical heterotopias offers an insightful perspective on how alternative learning environments can contribute valuable lessons to mainstream education. The heterotopias explored, ranging from special needs classrooms to gifted education programmes and prison education, each presents a distinct context. Yet, they converge in their capacity to challenge conventional educational structures and introduce innovative, inclusive pedagogical practices. The common thread across these environments is the capacity for flexible, responsive teaching that prioritises the individual needs and abilities of learners. These settings exemplify the limitations inherent in uniform instructional models within traditional classroom settings, by embracing individualised and personalised approaches

A particularly noteworthy aspect is the role of creativity in fostering autonomy and engagement, as observed in gifted education. This invites us to reconsider how student potential is conceptualised within mainstream education. Providing opportunities for all students to explore stimulating, problem-solving-oriented mathematical tasks has the potential to spark curiosity and critical thinking, irrespective of prior experience or ability levels. Equally significant is the relational focus in prison education, where care, collaboration, and mutual respect are foregrounded. These elements have transformative potential, particularly for re-engaging marginalised learners through peer learning and experiential methods, an approach that could significantly enrich traditional classroom settings.

The insights gained from these unique spaces draw attention to the need to rethink how we approach mathematics education, placing inclusion, diversity, and emotional well-being on an equal footing with academic achievement. These lessons have the potential to transform the mainstream mathematics classroom into a space that meets students' diverse needs, but also empowers them in ways traditional approaches often overlook. The future of mathematics education lies, in my view, in moving beyond rigid, standardised methods towards a teaching that values every student's potential to engage with challenging and meaningful content. Future research could benefit from deeper, more focused investigations into specific heterotopic environments. In-depth ethnographic studies within

a single heterotopia could explore the lived experiences of learners and teachers, examining how mathematics is taught, understood, and valued in these settings. This could provide richer insights into the specific conditions that enable effective mathematical learning outside mainstream structures. Another promising avenue is longitudinal research tracking learners who experience mathematics in heterotopic environments. For example, a study could investigate whether students who engage with mathematics in gifted education, special education, or informal learning spaces carry these alternative approaches into later academic or professional contexts. Furthermore, future research should consider broadening the definition of mathematical heterotopias to include less commonly studied spaces, such as mathematics within Indigenous knowledge systems or apprenticeship programmes. A wider scope could refine our understanding of how mathematical learning operates across different cultural and professional contexts, potentially revealing overlooked yet powerful pedagogical models.

Reconceptualizing opportunities to learn mathematics through postfoundational theories

Ayşe Yolcu[1], İ. Elif Yetkin-Özdemir[1], Emine Gül Çelebi[2], Gökçe Ursavaş[1]

[1]Hacettepe University, Turkey; ayseyolcu@hacettepe.edu.tr

[2]TED University, Turkey

This paper is a theoretical reworking on the concept of opportunities to learn mathematics. Drawing on postfoundational approaches, particularly Foucault's work, the relationalities between systems of thought and pedagogical practices for school mathematics are investigated through teachers' statements. This theoretical approach decentres individuals but foregrounds the materiality of knowledge as normalisations of mathematics education and society. Our reconceptualization reveals the relationalities between organisation of school mathematics and the inscription of kinds of children, and makes visible normalised practices in mathematics teachers' everyday lives in schools.

Keywords: Learning opportunities, Foucault, systems of thought, pedagogical practices, in/equity.

Introduction

The concept of opportunities to learn has widely been used to understand teaching and learning situations in mathematics education. It is taken up by transnational studies that attend equity issues, as students' mathematics achievement disparities are explained through unfair distribution of opportunities to learn (OECD, 2016). Beside large-scale comparative research, opportunities to learn mathematics are also taken as an analytical tool for classroom studies in which student learning, teaching practices and mathematical tasks are considered as the main pillars (Cai et al., 2020). Despite the utility of the concept opportunities to learn in relation to immediate research and practical needs of mathematics education, the field acknowledges that this concept is vaguely defined and yet to develop a comprehensive theorization driven from the practice.

This paper aims at reconceptualizing opportunities to learn mathematics through postfoundational theories, particularly Foucault's analytic approaches. Part of a larger ethnographic project with mathematics teachers in Turkey, our purpose is to produce a new understanding of opportunities to learn mathematics, accounting for relationalities between systems of thought and pedagogical practices embedded in teaching and learning situations. As we explain later, the focus is not on the individuals and their intentions, but on the prevalent discourses that govern ways of thinking and acting in the social sphere of school mathematics. In doing so, our goal is not to develop a fixed and stabilised framework that is applicable in everywhere. Rather, we aim to foreground the relationalities and to make visible the taken for granted discourses and practices. Unpacking the normalising effects in mathematics education offers crucial implications for issues of equity and access.

Opportunities to Learn Mathematics in the Literature

The concept of learning opportunities has occupied the educational literature for more than a half century. Influenced by the psychometrics, the concept is first formulated as the actual time spent in the instructional activities to learn a topic (Carroll, 1963) and the content taught in the classrooms (Husen, 1967). Several studies discussed opportunities to learn by increasing the number of school

days or lesson hours (Wiley & Harnischfeger, 1974), as well as extending the scope of mathematics content and curriculum (Törnroos, 2005). Later, in mathematics education, Tate (2005) pointed to the quality in addition to the time, as predictive of opportunities to learn mathematics in relation to access and equity. For Tate, the quality of instructional activities includes pedagogical methods, techniques and strategies positively affecting students' learning. In relation to this, the bulk of research has worked for the quality of instruction such as cognitive demand of mathematical tasks (e.g., Hadar, 2017) or using daily life examples to improve access to mathematics (Andrews, 2003).

Mathematics education research considers mathematical learning opportunities not only through the quality of mathematical tasks but also in a classroom interactional level, including participation structures, roles and positions of students and teachers during teaching (Gresalfi, 2009). Relatedly, studies direct attention towards how to educate teachers with an equitable vision, including high expectations for historically marginalised groups and asset-based views for students' mathematical thinking (Flores, 2007). Research focuses on changing authority relations by positioning students as producers of knowledge and as capable of doing mathematics (Christiansen et al., 2023).

The concept of opportunities to learn mathematics has been subjected to constant change with the needs of educational research and practice and it is modified in relation to the access and equity concerns. Different conceptualizations offer immediate solutions to the existing inequalities, the research has yet to provide long term alternatives. Despite the equitable intentions and inclusive efforts of teachers providing equitable learning opportunities, classroom participation structures of students are still differentiated based on gender, race or immigration status (Reinholz & Shah, 2018). Particularly, the research exclusively focuses on quality of mathematical tasks, students' participation structures or teachers' positionalities, moving away from holistic approaches that account for teachers, students and mathematical tasks altogether. This separation yields to the individualistic explanations for the current inequity problems in mathematics education, where the unintentional result is blaming individuals or individual groups of students or teachers (Chen & Horn, 2022). Additionally, the recent studies reported that a culture of exclusion emerges in relation to normalised notions of mathematical ability and competences even in the classrooms of equity-committed mathematics teachers (Louie, 2017). These limitations urge us to rework on the concept of opportunities to learn mathematics, a term historically familiar to the mathematics education community. This paper reconceptualizes opportunities to learn mathematics through Foucault's (1995) analytics and aims at opening up new understandings and possibilities of actions.

Theoretical Approach and Analytical Strategies

This paper reconceptualizes opportunities to learn mathematics through postfoundational theories. Postfoundational theories challenge taken-for-granted understandings, systems of thought and normalised practices in social and material settings. We consider postfoundational theories are not anti-foundational, rather similar to how Butler (1995) directs attentions to the eventuality of current understandings and practices that are built on the contingent foundations, which simultaneously excludes or forecloses. In this sense, postfoundational theories rework on the shortcomings and limitations of traditional modern concepts that explain realities and seek to develop new associations and relationalities among thoughts and things that are usually taken for granted.

Drawing on Foucault's (1995) work, this paper aims to make visible the normalised understanding and practices that constitute a regime of truth embedded in practising mathematics teachers' statements regarding learning opportunities. Particularly, our postfoundational approach is concerned with the systems of thought that make, differentiate, classify and order particular kinds of people on the hierarchy (Hacking, 2007). System of thought is not about people's intentions and consciousness but it is considered as the normalised ways of thinking about schooling, students, teaching and learning mathematics. Postfoundational theories along with Foucauldian tradition interrogate the limits of rationality, place the current regimes of truth in doubt and open up possibilities to create alternative understandings with contingent foundations. Our efforts to reconceptualize opportunities to learn mathematics are concerned with questions and critique of normal and taken-for-granted in mathematics education settings. Nonetheless, postfoundational inquiries initiate a shift to creation than merely deconstruction and generates the unthought, with its contingency embedded in social, cultural and institutional contexts (Jackson & Mazzei, 2024).

In mathematics education, research from a postfoundational perspective is few in number, but advancing (Stinson & Walshaw, 2017). Particularly, studies drawing on Foucault's work focus on the cultural and historical processes of subjectivation through mathematics education as well as they make visible how differences are fabricated (Diaz, 2017; Yolcu & Popkewitz, 2019). These studies collectively argue that mathematics does not stay as it is in the spaces of schooling, rather the subject is transmuted with pedagogical tools and techniques, instructional aids and materials. Pedagogical tools and techniques are not merely enabling a better access and opportunity to learn mathematics but also embodying a comparative thought that inscribes differentiations, normalizations and hierarchies among students. In this sense, opportunities to learn mathematics is reconceptualized through the relationality of systems of thought and pedagogical practices that potentially can address mathematics teaching and learning in a broader context instead of focusing on individuals' own efforts.

This paper presents preliminary findings of a larger postfoundational ethnography (Jackson & Mazzei, 2024). This on-going project consists of two phases (first is interviews with 12 mathematics teachers, second is a semester-long observation of 3 teachers from three different schools) and aims to develop a cultural and situated understanding of opportunities to learn mathematics in relation to fabrication of differences in Turkey. We are in the first phase of the project. During the interviews, we ask teachers about purposes of teaching and learning mathematics, and also typical pedagogical strategies for providing access for all. Particularly, our questions focused on the possible classification and ordering of children and the pedagogical interventions for those groups of students.

Rather than capturing individual's beliefs, intentions and capacities of providing learning opportunities, the analytical focus is on the how these opportunities are organised by the practices and tools deemed necessary to provide access and equity in mathematics education. We deliberately seek to understand what pedagogical tools, strategies are reported as effective to provide access for all students for learning mathematics and under what circumstances. Decentring social actors and their intentions (Popkewitz & Brennan, 1997), the analytical focus is on the interactions between ways of thinking and pedagogical tools and practices. The relationality between these two is sought through the data to make visible the normalised statements for children and also the assumptions about teaching and learning mathematics.

Consistent with our theoretical approach, the analysis has started with open-ended questions: What kind of a child and society is envisioned by teaching mathematics in schools? What are the systems of thought that govern the type of mathematics incorporated in teaching and learning situations? How pedagogical practices are assembled with the making of children and their differences? What kind of pedagogical practices are designated for effective mathematics teaching and for whom? These questions enable our research team to conduct an inductive coding that captures participants' statements regarding mathematics, child, society and teaching and learning. In the analytical process, we continuously problematize the self-evident claims made by teachers and consider their multiplicity, partialness and contingency of the statements that govern the possibilities for learning opportunities. For example, when teachers talk about using real-life context to mathematics accessible, we consider what kind of mathematics is becoming accessible for whom and in what purpose the contextualization is serving. This kind of inquiry help us to make interactions between systems of thought and pedagogical practices visible. We consider the data and the relationalities emerged from the data in relation to self and society. That is, when we notice statements, such as "learning mathematics is for happiness or hardworking" as productive of kind of citizens and their differences. We are still in the process of refining and producing these themes that focus on the relationalities. In this paper, we present the preliminary findings emerging from one of the participant teachers. We chose Yıldız, because her data seems intensive of providing relationalities that assist to reconceptualize opportunities to learn mathematics from a postfoundational approach.

Relationalities between Systems of Thought and Pedagogical Practices

Organizing School Mathematics and Cultural Inscription of the Child

The analysis of Yıldız's statements continually reveals differential categories of mathematics that are organised in relation to contexts such as daily life and occupation. One of the prevalent purposes of school mathematics is to maintain the daily life, from shopping to measuring the objects at home:

> In daily life, for example, if they are going to buy a curtain or a tablecloth, they should know the length measurements or… They should know the litres at home and their conversions, for example, know how many litres of fuel a vehicle will take, they should know how to pay for shopping in instalments, we need to teach them enough to know the basics, at least they should learn these.

How mathematics permeates daily life of individuals is normalised not only through shopping situations but also calculating the amount of gas for driving a car or a sense of measurement for random household items. Knowing mathematics is considered as indispensable to pursue an adult life. Here, basic mathematics is deemed as a prerequisite and a baseline for all individuals in society.

Further, mathematics is divided based on the type of professions that require and do not require higher education. In Turkey, students are selected in higher education after taking centralised exams in which mathematics is part of it. Mathematics for passing high stakes exams or the advanced mathematics for a STEM related career are elevated in relation to the mathematics needed in skill-based professions such cook, mechanic or for agricultural work:

> We have children who will study advanced mathematics, and become engineers. It is beneficial for them to know [mathematics] in order to be good at their jobs in the future. [...] Also, according

> to today's needs, […] we tell them, 'If we want to move forward, if we want to get a certain education, if we want to use these in our daily lives, even if we don't study, you will all do jobs in certain places, for example, you will be a cook and you will use mathematics or you will be a mechanic and you will use it. Knowing something never hurts, if you know it and you add it to your daily life, you will do your job better' When we talk like this, it becomes more convincing. [...] So, I think [mathematics] is necessary in many areas.

Above quotes from Yıldız demonstrates how the occupations and so the mathematics needed for those occupations are ordered on a hierarchy. While calculating practices for cooking work is positioned at the lowest, the mathematics needed for engineering careers are referred to as "advance level." Here, the type of mathematics differentiates the kind of students in relation to their future vocational possibilities in the efforts of being responsive to students' interest or needs.

Mathematics is not only organised for occupational or daily life needs, but also different types of mathematics are ordered in relation to the career trajectories of students. Future possibilities are arranged along a hierarchy of the type of mathematics ranging from daily life needs towards STEM based career requirements. Nonetheless, the organisation of mathematics is not merely about career trajectories but also highly associated with cultural rules and norms of the society where for example Yıldız says "There is never any harm in knowing something, if you know it and incorporate it into your daily life, you will do your job better […] be honest people, be happy people. So, do your job well." Specifically, she mentions children "who are more hardworking, more planned and more disciplined" learning mathematics "more clearly." Here, mathematics goes beyond differential career requirements but also it is accompanied with cultural norms and values regarding what kind of people are desired in this culture. Learning mathematics is associated with personal qualities such as hardworking, planned and disciplined. As we explained next, this has crucial implications on how opportunities to learn are enacted with pedagogical practices.

Organising School Mathematics and Pedagogical Inscription of Child

Organisation of opportunities to learn mathematics is found to be associated with how teachers organise the types of mathematics, how they perceive the kinds of children and their future possibilities in relation to that type of mathematics. As discussed above, different contexts of mathematics are associated with the cultural inscription of the child. Second relationality we want to discuss is about the pedagogical inscription of a child. The way teachers consider school mathematics is not merely concerned with teaching and learning mathematics better, but also embedded with how categories of children are perceived and corresponded with particular pedagogical practices. For example, below quote from Yıldız is exemplar of how learning opportunities are arranged with exam-mathematics focusing on speed of test taking for students who are conscious about high stakes centralised exams are gatekeeping for future professions:

> Yes, as I said, from those student groups, the conscious students are like 'let me solve the problem directly, and let me move on to another problem', in other words, 'the more questions I solve, the better for me', you know, generally those who know a lot are not interested in the story part, they are like 'let me solve the problem and be done with it'. There is no such thing like asking a question, responding, explaining the solution or defending opinion. You know, they are like 'I

> solved it one by one, if I learn this, I will do it in the exam in the future, this is important for me, the rest is not important'. You know, there are those who are in a hurry…

Rather than contextualising the problems, spending time with discussion of questions or explaining the solutions, the instructional emphasis is put on the ability to gain competency to test taking those "conscious" students. On the other hand, Yıldız mentions students in the "lowest" group who do not want to participate in those activities. Opportunities to learn for those students are organised through notebook keeping and control, using daily life examples for basic mathematics rather than solving questions that might appear in the centralised exams:

> The students in the lowest group, as I said, do not want to participate at all. At most, they are on the notebook keeping part of it. You know, they don't participate in the lesson. I check the notebook with a little bit of force [when they need to keep] notebooks… or in very simple parts, they can give examples from daily life, depending on the content. But other than that, they are not involved in the parts where they [are expected to] solve questions, find solutions, generate ideas. So, they only are involved in the parts where they listen and keep the notebook.

Here, notebook keeping, a practice that needs time, is allocated with the students in the lowest group compared to 'conscious' others in the classroom. These students are subject to 'at least' keeping their notebooks properly, using daily life examples for basic mathematics instead of preparation for centralised exams that are perceived as gatekeeping for their future lives. Our position here is not to overemphasise the preparation for the exams than the notebook keeping, rather, through the analysis employed in this paper, we want to make visible how these two pedagogical practices are productive of constructing children in two distinct and unequal categories of being. That is, preparation for the exams or notebook keeping have less to do with teaching and learning mathematics effectively or increasing mathematical participation of students in the classrooms. Rather, these practices produce two distinct and hierarchical spaces of preparing "conscious" students for the next level in future life and restraining "lowest level" students with simple activities. Here, opportunities to learn mathematics are produced through the kind of pedagogical practice and the constructed categories of mathematics, which are also generative of differences and inequalities.

Conclusion

This paper aims at reconceptualizing opportunities to learn mathematics through postfoundational theories. We deliberately seek for relationalities between systems of thought and pedagogical practices of teaching and learning mathematics as organising learning opportunities. Grounded on interview data yet decentring teachers and their intentions, the analytics unpacks the normalised practices that govern the possibilities for mathematics, children and also teaching and learning. This has been helpful to disentangle the for granted knowledge and practices that deemed effective.

In our cultural and institutional context, particularly, we have observed an emphasis on mathematics that are necessary for the competitive centralised examinations. Yet these priorities are not merely considered for children's future career options but also, they are coming together with cultural norms and values such as being good at work, planned or hardworking. Here, particular norms and values are desired than the others. Systems of thought regarding the type of mathematics assemble with the

cultural inscriptions of child and in effect, these processes create hierarchies and inequities between students. The pedagogical practices are embedded in the broader cultural and institutional context and the systems of thought for the subjects: mathematics and child. Particularly, preparation for the centralised exams and notebook keeping appeared as pedagogical techniques that inscribe students in two distinct categories of being and acting, which simultaneously differentiate them on a hierarchy. Rather than arguing one is better than the other, our aim is understanding how these are generative of inequalities by subjecting students to limited opportunities despite the inclusive aspirations.

We, further, aim to find more relationalities through our data collected from mathematics teachers and more refined associations between the types of mathematics, groups for children and families and the pedagogical practices and strategies. According to the preliminary findings, opportunities to learn mathematics consist of multiplicity of pedagogical practices organised with the systems of thought about mathematics, children and society. Our continual questioning to detect the relationalities and to make visible the presumed categories of mathematics, students and pedagogical practices. Through pointing to the contingency of foundations, this reconceptualization extends the possibilities of action both in practical and research settings in mathematics education.

Research mixology: Blending mathematics education & digital sociology for a hybrid approach to experimental design

Giulia Bini[1], Sara Gagliani Caputo[1], Pietro Saccomanno[1] and Diego Ceccobelli[1]

[1]University of Milan, Italy; giuliagiovanna.bini@unimi.it

Keywords: Mathematical memes, class cohesion, cultural capital, hybrid research design

Introduction and rationale: When memes meet maths

This work presents the early stages of the MeMa project, led by the first author, connecting research in Mathematics Education (ME, the first and second author) and Digital Sociology (DS, the third and fourth author) to explore the role of mathematical memes (i.e., Internet memes with a mathematical content) to foster learning and cohesion in the classroom. Mathematical memes are a complex phenomenon, operating at the intersection of various communities, including teachers and students as in Bini (2022), and disciplines like ME and DS. To address this complexity, rather than networking theories within a specific research perspective (such as ME, as in Prediger et al., 2008), we adopt a novel hybrid approach to preserve each research perspective's distinctiveness while nurturing their interaction for complementary understandings. We illustrate this through the *mixology* metaphor, drawing on the art of *blending* elements enhancing the peculiarities of each component. Here, *blending* refers to aligning insights from ME and DS to create a cohesive yet multidimensional analysis of how mathematical memes function as educational cultural artifacts: ME examines the potential of memes to enhance learning opportunities, while DS offers a lens on their social impact.

Research mixology: Blending theoretical frameworks and methods

Theoretically, we blend Bourdieu's capital (1986) with Carron and colleagues' multidimensional model of cohesion (1985). Bourdieu defines capital as the set of skills, knowledge, cultural and social experiences providing individual advantages. Archer and colleagues (2015) extend this concept defining *science* capital as the resources and dispositions related to science that shape an individual's learning opportunities. Building on this, students' *mathematics* capital (MC) can influence how they perceive their mathematical abilities, shape their aspirations, and affect their likelihood of succeeding in mathematics. Carron and colleagues' model distinguishes between task cohesion (collaboration on academic goals) and social cohesion (interpersonal bonds), both of which are key to examining how memes affect classroom dynamics and perceived class cohesion (PCC). Blending these perspectives, the study explores the role of mathematical memes in education guided by the research hypothesis that memes can enhance students' PCC and engage students with low MC. Specifically, we ask: How does the creation, sharing, and discussion of mathematical memes interact with students' MC and PCC? Methodologically, the hybrid experimental design blends methods to produce meaningful data for both ME and DS researchers (Table 1). Given the one-year project duration, design choices reflect time constraints for experiments and data analyses. Experiments will occur from Dec 2024 to Feb 2025 in an Italian secondary school, exploring two dimensions: vertically, across grades 9, 11, and 13, to observe if students' maturity affects results; horizontally with three grade 11 classes, one participating in the full experiment, one in problem-solving activities only, and a control class.

Table 1: The hybrid experimental design

Schedule	Experimental design	Hybrid elements	Underlying Rationale
Nov 24	MCC questionnaire	Individual MCC and PCC questionnaires based on literature (Archer et al., 2015; Leo et al., 2002). Completed at home for free responses (DS) and non-anonymous for mutual (DS + ME) and classroom interventions correlation (ME)	MCC (ME) measured quantitatively before the activities, with qualitative observations during activities to assess engagement at different MCC levels. PCC (DS), expected to vary, is measured quantitatively pre- and post-activity. Cross-analysis (DS + ME) will examine correlations between MCC and PCC
Week 1 at home	PCC questionnaire pre-activity		
Week 1 at school	1h group meme creation activity; topic and groups chosen by teachers 2-hour class discussion	Student groups create mathematical memes on a previously covered topic (ME) Memes are shared on Padlet with non-anonymous comments (DS + ME) Memetic & mathematical discussion (DS + ME)	
Week 2 at school	1-hour group problem-solving activity; same topic, spontaneous groups 1-hour class discussion	DS focuses on spontaneous group dynamics, ME examines if students reference memes or earlier discussion during problem-solving, and observes the following mathematical discussion (ME)	
Week 2 at home	PCC questionnaire post-activity	PCC questionnaire post-activity is the same as pre-activity (DS)	

Following our first objective to establish a hybrid research approach to investigate memes, we look ahead to sharing insights that deepen our understanding of digital culture's role in education.

TWG 18: Mathematics Teacher Education and Professional Development

Subjects and objects of research and theories of learning in the education and professional development of mathematics teachers

Marita Friesen[1], Tracy Helliwell[2], Fanni Biró[3], Raffaele Casi[4], Andreas Ebbelind[5], Janne Fauskanger[6], Pere Ivars[7], Libuše Samková[8] and Gil Schwarts[9]

This group report focuses on two key aspects of research on teacher learning in TWG18: (1) what is being studied—the main topics of interest, that is, the subjects and objects of research; and (2) how these topics are investigated—particularly in relation to various theories of learning. Our goal is to map the contributions to CERME14 through these two lenses, offering both a descriptive overview of the current landscape and a critical perspective on our research community. Such a perspective is essential for identifying blind spots, questioning taken-for-granted assumptions, and pushing our collective work forward.

Keywords: Mathematics teacher education, professional development, learning theories.

The scope of TWG18

Research on teacher education (TE) and professional development (PD) centres on what and how mathematics teachers learn throughout their careers. Research from TWG18 explores the preparation of pre-service teachers (PSTs) and ongoing development of in-service teachers (ISTs), emphasising frameworks, methods, and tools that shape their professional learning across a variety of mathematical topics and classroom settings. As a group, we welcome research that explores and conceptualises mathematics teachers' growth and the development of their professional competences, knowledge, attitudes, and identities. We encourage studies firmly grounded in theories of teacher learning that enhance teachers' professional growth and development at all stages of the profession. The research presented in TWG18 took place in diverse contexts across the world. These included university courses, field practice, online platforms, school-based PD and spanned TE institutions, museums, and professional learning communities in both formal and informal settings. Participants comprised prospective and practising teachers across various international contexts. Group sizes ranged widely, from single case studies to cohorts exceeding 170 participants.

The subjects and objects of research into teacher learning (the *what* of TWG18)

The question of *what* PSTs should learn in university programmes to master their professional tasks and how they can be supported in their professional learning is of major interest to teacher educators and related research. A similar question arises for ISTs: What knowledge, attitudes, professional competences and practices should be addressed in PD programmes to promote students' learning of

mathematics? And how can ISTs be supported in analysing and reflecting their daily practice? A recent systematic review on PST education (Matsumoto-Royo & Ramírez-Montoya, 2021) revealed that many TE programmes are based on practice-based approaches, however with very different inventories of what is considered as most essential, different content-specific substantiations, and heterogeneous conceptualizations of practices in different grain sizes (from atomistic moves to holistic complex combinations of actions and theoretically grounded decision-making). A current review on research related to PD programmes for ISTs (Shure et al., 2025) showed a growing emphasis in PD research on tasks of teaching and corresponding teaching practices focusing on promoting conceptual understanding, using and connecting different representations and revealing and initiating student thinking. There has also been a call to further investigate the connection between the role of teacher collaboration and changes in teaching practices. Accordingly, we were interested in *what* was researched in our TWG in relation to the professional learning of prospective and practising mathematics teachers. Analysing the 35 papers and 10 posters of our group, we identified seven key topics that will be explained in the following.

Professional learning related to teachers' identity, knowledge and instructional practices

Veldhuis et al. investigated PSTs' awareness of their developmental trajectories in TE. Focusing on practicing teachers, *Izzi-Prato and Cordero* aimed at providing empirical evidence on how the ISTs develop their disciplinary identity as they engage in a PD experience. Examining the development of ISTs' professional identity during a PD programme, *Eraky* integrated eye-tracking technology with reflective practices. *Søyland and Jakobsen* examined whether Norwegian PSTs' foundational mathematical knowledge at the beginning of their teacher training could predict their academic performance in university courses. *Grünig and Vogel* explored the extent to which a German preparatory service fosters the development of technological pedagogical content knowledge (TPACK) among PSTs, identifying key factors that significantly contributed to variations in TPACK acquisition. *Avgeri et al.* reported on the initial phase of a topic-specific intervention aimed at enhancing PSTs' knowledge of fraction multiplication and division. Their study focused on developing learning arrangements to help PSTs construct meaningful and transferable understanding. *Hein et al.* conducted a case study on a PD module designed to enhance teachers' use of representations combining open-ended activities with structured multiple-choice tasks that introduced new concepts and provided immediate feedback. They examined how these complementary strategies influenced teaching practices. *Parasha* investigated the areas of growth and dimensions of change in the trajectories of secondary ISTs. The PD aimed at fostering argumentative dialogue in the classroom and the related study identified the programme components contributing most to these developments. *Lit et al.* reported on a design study exploring how PSTs can develop effective teaching strategies for problem-solving instruction. *Digel and Roth* explored how technology can support student learning when benefits are used to increase teaching quality. They developed large a PD programme on the concept of derivative and investigated mathematical understanding on student level.

Growth in teachers' knowledge and identity in connection to other disciplines

Čech and Samková conceptualised ITSs' ability to notice mathematical concepts in chemistry tasks as an integral part of mathematics teachers' conceptual knowledge. They investigated how secondary

teachers educated in both subjects solved ratio application tasks in chemistry, what the teachers detected about corresponding strengths and weaknesses and how this was connected to their teaching practices. *Maugesten et al.* were interested how the integration of programming into the mathematics curriculum may influence PSTs' identities. The study compared PSTs' designated and actual identities as programmers in mathematics to reveal how these reflect knowledge and attitudes related to programming and computational thinking. *Fojcik et al.* investigated the development of competencies of PSTs enrolled in a programming-based mathematics course. They explored the initial development of a PST's schemes when reflecting about her own learning experiences.

Professional learning of teaching practices: planning lessons, analysing textbooks

Lesson planning was examined as an instrument in TE, but also as a process. *Yilmaz Aslan and Ozmantar* researched how elementary school PSTs structured their lesson plans and described the challenges PSTs encountered throughout the process, while *Knaudt et al.* investigated how the design of a planning phase facilitated ISTs' planning actions. *Jones*, in relation to lesson planning, analysed learning objectives from all mathematical pedagogy courses in Sweden. Textbook analysis papers focused on critical thinking: *Østby* studied how ISTs would reflect on textbooks after using a corresponding theoretical framework, and *Ortiz-Laso et al.* investigated whether and how PSTs were able to analyse tasks from geometry textbooks to recognise their limitations, emphasising three different analytical perspectives: attributes, geometric processes, and modes of representation.

Professional learning through approximations and representations of practice

We found a large collection of various design formats: educational vignettes that were text-based *(Geldermann)*, cartoon-based *(Kuntze et al.)* or video-based *(Morales-Reyes & Zakaryan)*, silent video tasks *(Galiç et al.)*, video-clubs *(Didis Kabar & Walkoe)*, simulations *(Shaughnessy & Boerst)*, role playing *(Ødegaard; Sidenvall)*, and scriptwriting *(Rotem & Eraky)*. These representations and approximations of practice were often intended to support teachers in developing noticing (e.g., *Didis Kabar & Walkoe*; *Galiç et al.*; *Morales-Reyes & Zakaryan*; *Wirth et al., Schaap et al.*) or diagnosing student misconceptions (*Rieu et al.*) but also to help teachers learn to provoke meaningful classroom discussion (*Ødegaard*), elicit and respond to student thinking (*Shaughnessy & Boerst*), or lead students through productive struggle (*Rotem & Eraky*).

Mathematics teachers' professional learning within collaborative settings

Skott investigated the reflection phase of lesson study in two schools, examining how teacher groups adapted lesson study goals and tools to fit their local contexts. Similarly, *Redder Honoré and Falkenberg*, also working within a Danish context, reported on a continuing PD project aimed at implementing inquiry-based mathematics teaching (IBMT). They explored how a PD programme structured around a three-phase IBMT model supported implementation and identified the challenges and successes teachers experienced in each phase. *Casi and Sabena* explored a PD programme that fostered collaboration between teachers and museums. By amplifying Italian teachers' voices and reflective practices, they examined informal mathematics education in non-scientific museum contexts, with a focus on teachers' perceptions of emergent learning. *Bjørnebye et al.* investigated how the large-format ratio triangle could enhance PSTs' collaborative reasoning in missing-value

problems. By integrating full-body movement, speech, and symbolic representation, they explored how various semiotic resources supported collective proportional reasoning.

Professional learning through interaction between teachers and their environment

Ebbelind and Helliwell, through a meta-analysis of prior TWG18 papers, drew attention to the ways in which teachers' individuality is portrayed in relation to their institutional and social environments, suggesting a need to better account for this embeddedness when studying professional growth. Another group of contributions focused on the beliefs and values that teachers bring to their practice. These studies (e.g., *Bjuland et al.; Serrazina et al.*) explored how such beliefs—regarding the nature of mathematics, teaching, and learning—interact with the opportunities offered in both PST and IST settings, and how they shape teachers' professional trajectories. How teachers engage with instructional practices in various learning environments was explored in another set of studies: The papers by *Pozhegu-Ermeni et al., Wirth et al., and Maksym'yak* examined how teachers approach activities such as problem posing, interpreting student thinking, and negotiating the role of social and epistemic considerations in mathematics education. These practices were situated within structured learning experiences and were analysed as opportunities for reflection and development.

Exploring design aspects of PD programmes

Carlsson examined various PD designs and their impact on teachers' instructional practices. In contrast, *Schwarts and Friesen* investigated the shift from in-person to online PD environments. Their study explored how key design principles for effective PD—such as centering mathematical content, incorporating representations of practice, fostering collaboration, and adapting to participants' needs—can be translated into asynchronous online mathematics PD programs. They also identified the challenges and opportunities associated with designing such online formats.

Conclusion I: The subjects and objects of research into teacher learning in TWG18

Investigating professional growth related to teachers' knowledge, identity and practices is at the centre of TWG18. Reflecting current trends in mathematics TE research, about half of the studies addressed practice-based approaches. The connection to other STEM subjects, the use of technology and the use of various approximations of practice in research or to foster teacher and student learning were other key topics. There appears to be a growing interest in collaborative PD settings, the interaction between teachers and their environments and research questions related to design aspects of effective TE and PD programmes, e.g., related to scaffolding, online learning and opportunities for reflection. Although many key topics are represented in our TWG, we see that impacts of PD programmes on student learning are rarely addressed and that the mathematical content delivered in courses and programmes is often neglected when learning goals, contents and contexts are reported. Since this seems to be an ongoing and therefore alerting trend (cf. Friesen et al., 2023), we take our findings as opportunity to encourage studies relating teacher learning to student learning and centring the mathematics in mathematics education research.

Theories of teacher learning, growth and development (the *how* of TWG18)

In this section, we examine *how* research on mathematics teacher learning is framed through theoretical perspectives. Our premise is that articulating the underlying theoretical commitments—

even briefly—is essential for situating contributions within broader scholarly conversations and for making visible the assumptions that inform design and analysis. In what follows, we identify how theories are taken up across the papers in our group (whether explicitly named or implicitly guiding) and consider the implications of these patterns for the field. The theoretical perspective is the chosen viewpoint used to comprehend and enhance the research process, suggesting that it directs the reasoning in research as a fundamental criterion for the research endeavour. Theoretical perspectives include predefined structures, such as concepts and assumptions that guide ideas and the research design. Eisenhart (1991) refers to these structures as frameworks. We select from various frameworks, including theoretical, practical, and conceptual frameworks. According to Eisenhart (1991), a theoretical framework employs a formal theory to establish explanations about a phenomenon. A practical framework is informed by identifying what works in practice. Furthermore, one can view a conceptual framework as a scaffold that justifies the study in relation to its aim – a set of assumptions about reality that underpins the research. Eisenhart (1991) emphasises that the research interest itself does not determine the theoretical direction of the study. The researcher needs to choose an explicit conceptual framework. The selection of a framework is crucial for how the research process is conducted and what findings the researcher ultimately presents. Once a theoretical perspective is chosen, researchers must consider how to transform empirical material into meaningful data aligned with that perspective.

At its core, TWG18 focuses on the learning, growth, and development of mathematics teachers at all stages of the profession. Theoretical perspectives, in this context, help us to make sense of developmental processes. We maintain that articulating a clear theory of teacher learning is essential for designing effective TE and PD environments. For this reason, we are particularly interested in how researchers in TWG18 draw on and apply such theories in their work. Our review of the TWG18 contributions revealed that most papers were explicitly or implicitly informed by sociocultural theories of learning, or by theoretical hybrids that included sociocultural components alongside other frameworks of sorts. Sociocultural theories of learning, grounded in the work of Lev Vygotsky and others, have become foundational in mathematics education, particularly for understanding how learning is mediated through social interaction, language, tools, and cultural practices. These theories are especially influential in TE and PD, where learning is seen as participation in social and cultural practices. Rather than occurring in isolation, knowledge develops through participation in shared practices and dialogue with others, particularly those with greater expertise. Key constructs such as Vygotsky's Zone of Proximal Development (ZPD) and scaffolding underscore how learners grow through guided support that enables them to move beyond their current capabilities. Several key frameworks in education and in TE—such as situated learning (e.g., Brown et al., 1989), communities of practice (Wenger, 1998), and pedagogies of practice (Grossman et al., 2009) —are grounded in sociocultural theory. These frameworks build on the idea that knowledge is constructed through participation in social practices and that learning is embedded in the cultural and relational contexts in which it occurs. Other frameworks are less explicit in naming their sociocultural foundations, yet they are deeply informed by this perspective through their emphasis on participation, mediation and contextualized activity. A similar trend can be observed in papers submitted to TWG18: while many appear to be grounded in sociocultural theory or its derivatives, this theoretical lens often remains

implicit. In the following, we describe different ways in which sociocultural perspectives were used in our group.

Social practice theory, identity development

Eraky, *Maugesten et al*., and *Skott* investigate mathematics teacher identity and professional development through different theoretical lenses, all of which are connected to the concept of identity. *Eraky* combines cognitive science with a situated view of identity, using Looney et al.'s (2017) five-component model of teacher identity. *Maugesten et al*. draw on Sfard and Prusak's (2005) narrative identity theory and Beijaard et al.'s (2004) categorisation of teacher roles, while *C*. *Skott* uses Holland et al.'s (1998) concepts of figured worlds to analyse how teachers adapt lesson study practices, combined with J. Skott's (2013) Patterns of Participation framework. All three studies view identity as a dynamic and developmental concept. *Eraky* emphasises cognitive-affective and reflective dimensions, *Maugesten et al*. focus on narrative and role-based constructions, and Skott foregrounds socially situated practices. Through the use of theory, *Eraky* shows how technology can externalise cognitive processes and support reflective identity development. *Maugesten et al*. reveal how PSTs navigate the gap between current competence and future aspirations. *Skott* highlights the importance of cultural and institutional contexts in shaping PD practices.

Values

In 1988, Alan Bishop introduced the mathematics education community to the idea of values, arguing that mathematics is a deeply value-laden cultural activity, shaped by and embedded within the norms and practices of the societies in which it is developed and taught. Since then, the role of values has become increasingly recognised as central to a sociocultural perspective on mathematics education, particularly in the fields of TE and PD, as scholars have recognised that teachers' values influence their pedagogical decisions, classroom interactions, and the kinds of mathematical knowledge they prioritise, ultimately shaping students' learning experiences and mathematical identities. *Serrazina et al*. draw on Bishop's work, presenting an exploratory study to identify and discuss what first-year undergraduate students in Education value in the teaching and learning of mathematics. These authors argue that the process of valuing is inherently sociocultural since it is shaped by experiences, backgrounds, and social interactions over time as members of particular cultural communities. *Izzi-Prato and Cordero* theorise a PD proposal for mathematics teachers that is grounded in the development of their disciplinary identity. They draw on Cantoral's (2016) Socio-epistemological Theory of Mathematics Education (STME), which aligns with sociocultural perspectives by examining how values shape the social construction and institutionalisation of mathematical knowledge. STME is a deeply value-laden theory that challenges dominant, decontextualised views of mathematical knowledge and emphasises the inclusion of diverse cultural and social practices, reflecting a commitment to epistemic justice.

Anthropological Theory of the Didactic, and Instrumental Genesis

Several papers draw on theoretical frameworks that, while distinct in origin, share key assumptions with sociocultural theories —particularly the emphasis on context, mediation, and practice. For example, Anthropological Theory of the Didactic (see *Maksym'yak's* and *Jones'* papers) focuses on

the institutional organization of knowledge and didactic transposition. Instrumental genesis as a perspective examines how learners shape and are shaped by engaging with artefacts (in *Fojcik's* paper, with programming). These frameworks, though not sociocultural in foundation, offer complementary perspectives on learning as shaped by cultural and material contexts.

Noticing

While early research on noticing was grounded in a cognitivist perspective, recent work increasingly draws on sociocultural perspectives, framing noticing as a socially situated, culturally mediated process. This lens emphasizes that what teachers notice—and how they interpret it—is shaped by broader cultural, institutional, and relational contexts. Five papers (*Galiç et al.*; *Kabar & Walkoe*; *Kuntze et al.*; *Morales-Reyes & Zakaryan*; *Ortiz-Laso et al.)* and one poster (*Sumeyye*) explored teacher learning through the lens of noticing. While all draw on the core components of attending, interpreting, and responding (Jacobs et al., 2010), they vary in focus: *Sumeyye* considers noticing before teaching; *Galiç et al*. and *Kabar & Walkoe* examine student thinking; *Morales-Reyes & Zakaryan* analyze classroom videos using Sherin et al.'s (2011) framework; *Kuntze et al.* introduce multicriterion noticing, including how students use representations, and students motivation; and *Ortiz-Laso et al*. study curricular noticing (Dietiker et al., 2018) in relation to textbook tasks. Taken together, these contributions suggest that noticing frameworks are increasingly being applied beyond the analysis of student thinking, expanding the range of phenomena studied through this perspective.

Conclusion II: Theories of teacher learning, growth and development in TWG18

While sociocultural perspectives are widely represented in this year's TWG18 contributions, we observe limited engagement with other important theoretical lenses for understanding teacher learning—such as commognitive theory, socio-political and socio-ecological perspectives, or embodied cognition. These approaches could offer richer accounts of how, for example, language, power, and political contexts shape teaching practice and professional development. Their relative absence suggests an opportunity for the group to further diversify its theoretical repertoire and attend to dimensions of learning that remain underexplored. We encourage continued expansion of theoretical approaches to support research on emerging and understudied phenomena.

Teaching fraction multiplication and fraction division to prospective teachers: A design research study

Theodora Avgeri, Maria Bempeni, Konstantinos Tatsis and Xenia Vamvakoussi

University of Ioannina, Greece; t.avgeri@uoi.gr

We present findings from the first cycle of an ongoing topic-specific design research study focused on fraction multiplication and division. We designed a course unit addressed to prospective teachers to support them in building productive meanings for multiplication and division that are transferable to rational number contexts. Thirty-four prospective teachers participated in the first enactment of the course unit. They were pre- and post-tested via a paper-and-pencil test comprising 11 tasks, examining various aspects of knowledge in this area that are necessary for teaching. The results showed that their performance improved significantly after the intervention, but substantial conceptual difficulties were identified at both test moments.

Keywords*: Fraction multiplication, fraction division, conceptual change, teacher education.*

Introduction

Multiplication and division of fractions present teachers with many challenges (Copur-Gencturk, 2021; Izsák, 2008; Ma, 1999). Typically, teachers are able to perform computations, but face difficulties in problem solving, problem posing as well as in representing and interpreting the two operations and their algorithms (Ma, 1999; Olanoff et al., 2014). In terms of the theoretical framework of Ball and colleagues (e.g., Ball et al., 2008), such evidence indicates that teachers lack in content knowledge necessary for teaching mathematics, either Common Content Knowledge (i.e., mathematical knowledge necessary for problem solving in various contexts, including teaching; hereafter CCK); or Specialized Content Knowledge (i.e., knowledge that is used specifically in the context of teaching and allows, for example, for explaining, exemplifying, and representing mathematical content for students; hereafter SCK). Such limitations are bound to have adverse effects on the quality of teaching and, consequently, on students' learning.

In this paper we present findings from the first cycle of a topic-specific design research study (Gravemeijer & Prediger, 2019) aimed at developing materials and teaching-learning arrangements to enhance pre- and in-service teachers CCK and SCK on fraction multiplication and division.

Theoretical Framework

A major source of conceptual difficulties with fraction multiplication and division is the changes in meaning required in the transition from natural to rational numbers. The dominant meanings of these operations within natural numbers—namely "repeated addition" and "fair sharing"—do not generalize for fractions (Fischbein et al., 1985; Tirosh, 2000). In addition, the relationship between multiplication and division (as inverse operations) is reframed via the introduction of reciprocals, allowing for division to be replaced by multiplication by the reciprocal of the divisor. This reframing is crucial as it underpins the fraction division algorithm commonly known as "invert and multiply".

It is widely known that these changes are a source of difficulty for students as well as for pre-and in service teachers (Ma, 1999; Olanoff & Tobias, 2014; Tirosh, 2000). This phenomenon can be

theoretically approached by conceptual change perspectives on learning that is focused on problems faced by learners when their prior knowledge in an area is incompatible with the new content to be learned; we thus draw systematically on principles for instruction stemming from conceptual change approaches to mathematics learning, in particular rational number learning (Vamvakoussi, 2017) to inform our design. More specifically, in the phase of prospective analysis (Gravemeijer & Prediger, 2019) of our study, we looked for productive meanings for multiplication and division that are transferrable from natural to rational numbers (see also Simon et al., 2018). To this end, we invested in a relational approach to multiplication, interpreting an expression of the form a x b=c as depicting a relationship between three physical and/or numerical quantities (Polotskaia & Savard, 2021). For example, the expression 3x5 =15 is typically interpreted as "3 times 5 is 15"; from a relational perspective, it could be interpreted as "the triple of 5 is 15" and, simultaneously, "5 is one-third of 15". This is the same multiplicative relationship viewed from two perspectives, that allows for assigning a similar role to the natural and fractional number as multiplicative operators. The multiplicative relation between similar quantities can be established through measurement, a notion crucial also for the operation of division, since this meaning is transferable to rational numbers. A meaning for multiplication that is also transferable to rational numbers draws on the "rectangular area" model (Iszák, 2008), where the factors are represented as the lengths of the sides of a rectangle and the product as its area. The inverse problem situation, where the length of one side is the unknown quantity, affords a viable meaning for fraction division as well (Yim, 2010).

To foster the intended meanings for multiplication and division, we designed a course unit targeting prospective elementary teachers, consisting of short lectures, in-class activities, and self-study tasks. Consistent with our theoretical lenses (Vamvakoussi, 2017), the key ideas underlying the design of all components of the course unit were the following: a) explicitly problematizing the meaning of multiplication and division already in the context of natural numbers; b) systematic cross-domain mapping (i.e., an analogy between dissimilar domains) between the domain of physical quantities, specifically length and area, and the domain of number, established through measurement and implemented in terms of the representations as well as the problem situations employed; c) highlighting (deep) similarities and differences between natural and rational number contexts by systematically varying the types of numbers in the same problem situations (see also Sun, 2017). All instructional tasks for students were framed as classroom scenarios (Biza et al., 2007), with a view to making the tasks relevant to their professional interests. Students were asked to evaluate problems and problem solutions provided by hypothetical students, compare different representations, provide feedback, solve as well pose problems related to fraction multiplication and division; and to evaluate and modify instructional tasks. The course unit was enacted with prospective teachers. In this paper, we only present findings regarding students' performance in fraction multiplication and division tasks before and after the intervention. Data collected during the intervention are currently under analysis and will inform the retrospective analysis of the first implementation.

Method

The participants were 34 prospective teachers (hereafter, PTs) from a Department of Primary Education in Western Greece (26 female). According to their Study Program (8 semesters in total), the PTs completed two compulsory courses related to elementary mathematics and mathematics

education in the primary years (Grades 1 to 6). The participants attended a 7th semester elective course on mathematics education, within which the unit was embedded. They gave their informed consent for their research data to be used anonymously for research purposes.

We designed a test consisting of 11 tasks (T1 - T11) focusing on fraction multiplication and division. Except for 3 of the tasks (T1, T10, T11), all were framed as classroom scenarios (Biza et al., 2007). The PTs were presented with hypothetical students' responses to mathematical tasks in the form of solutions, representations, or statements, and were asked to evaluate them in terms of mathematical accuracy; to explain students' thinking; and to provide feedback, if necessary. In this paper, we will refer only to PTs' evaluations which reflect their CCK (T1, T2, T5, T6, T7) or SCK (T3, T4, T8, T9, T10, T11; Ball et al., 2008). Specifically, the first group of tasks examine whether the PTs can themselves perform fraction multiplication and division; recognize the appropriate operation for solving a problem; and can exchange dividing by n with multiplying by 1/n (CCK). The latter group of tasks examine whether PTs can correctly evaluate alternative solution processes, verbalize a rule accurately, and exemplify fraction multiplication and division via word problems or non-symbolic representations, which are actions that are particular to teaching (SCK).

In tasks T1 and T2, the PTs were asked to calculate the results of the operations 2/5×7/3 and 2/5: 7/3, respectively, writing down the calculation process in detail. In T3, the PTs were asked to evaluate the following calculation process: 3/4×5/2 = 3/4×10/4 = 30/16. If a PT acknowledged that the calculation process is correct despite the fact that converting to equivalent fractions is unnecessary, the response was deemed correct. In T4, the PTs were asked to evaluate the statement, "When I want to divide two fractions, I invert one and multiply". If a PT acknowledged that it matters which of the two fractions is inverted, the response was deemed correct. In T5, the PTs were asked whether the problem "5 kilograms of cherries cost 10 euros. How much does half a kilogram cost?" reflects the operation 5:1/2. Similarly, in T6, they were asked to judge whether the problem "A carpenter measures the length of a plank with a stick and finds it to be 18 sticks long. What would he find if he measured the length of the plank with two-thirds of this stick?" can be solved via the operation 2/3x18.

In T7, a circular diagram (Figure 1) was presented as a task given to students to fill in the missing number, and the PTs had to evaluate a statement claiming that this diagram is incorrect. This task examines whether PTs could substitute division with multiplication by the reciprocal of the divisor. Responses stating the diagram is correct and/or mentioning the missing number were deemed correct. In T8, the PTs were asked whether the representation in Figure 2 is a valid representation of the operation 2/3×3/4. This representation is, according to Iszak (2008), a powerful representation for fraction multiplication. In T9, the PTs were asked to create their representation for this operation.

Finally, in tasks T10 and T11, the PTs had to pose a problem matching the operations 3/4×2/5 and 4: 2/3, respectively. In these tasks, we examined which types of problems were created and whether they were appropriate (i.e., they matched the operation in question and used the given numbers).

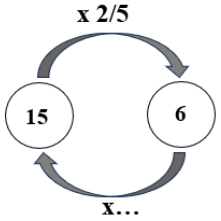

Figure 1: Circular diagram (T7)

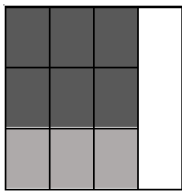

Figure 2: Fraction multiplication representation (T8)

The PTs completed the test before the intervention. The course unit was enacted in 6 sessions, approximately 2 hours each. The PTs worked on the in-class activities in groups of 3-5 members. Three research team members (first, third, and last author) were present to support student work and document their difficulties. The last author provided feedback in the form of short interactive lectures. After the intervention, the pretest sheets were returned to the participants who had the opportunity to review their initial responses and revise them if they judged it necessary. An identical empty sheet was provided to fill in the revised responses. Posttest responses included the unrevised and the revised responses.

Results

Responses were coded as correct/incorrect and scored by 0 and 1, respectively. The total score was calculated as the sum of correct responses across tasks. The Shapiro-Wilk test (sample size<50) showed that the data tested were normally distributed (p=>.05). The paired sample t-test showed a statistically significant difference between the pre- and post-test scores, $t(33) = -6.849$, $p = .000$. Specifically, there was a significant increase in the mean scores from pretest (M=4.76, SD =1.759) to posttest (M=7.35, SD=1.454). Table 1 presents the percentages of correct responses per task in the pre- and post-test. In all tasks, an increase in the percentage of correct answers is observed at post-test, with tasks T7, T8, T9, and T10 showing the most substantial improvement.

Table 1: Percentage of correct answers per task, in the pre- and post-test

	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11
Pre-test	85,3%	82,4%	35,3%	64,7%	82,4%	41,2%	44,1%	17,6%	0	11,8%	11,8%
Post-test	97,1%	94,1%	44,1%	73,5%	88,2%	61,8%	85,3%	61,8%	52,9%	35,3%	35,3%

Table 1 shows that the PTs reached their highest scores in T1 and T2 (i.e., in the calculation tasks), at both test moments. However, evaluating a calculation process for fraction multiplication (T3) as well as an inaccurate expression of the "invert and multiply" rule (T4) proved more challenging. Further, it appears that at pretest the majority of PTs recognized that the given operation did not match the given problem in the case of division (T5), but not in the case of multiplication (T6). At posttest, there were still about 40% incorrect responses in T6.

T7 elicited a substantial number of incorrect responses at pretest. The PTs stated that the second operation in the diagram should be division, or that the second operand should be the same as the first; or they explicitly claimed that it is impossible to find a number that, when multiplied by 6,

results in 25. Despite the large increase in correct responses at posttest, there were still about 40% incorrect ones in this task. In Task 8, a small number of correct evaluations were made at pretest that increased substantially at posttest. T9 elicited only incorrect responses at pretest; about half of the responses were correct at posttest. In most of the responses deemed incorrect (23 and 12 at pre- and post-test, respectively), the PTs calculated and represented the product (1/2), indicating that they misinterpreted the task. Two PTs represented the given fractions separately and put the multiplication sign in between. Appropriate representations were either grounded on the "part of a part" meaning of multiplication, or the rectangular area model, similarly to T8.

T10 and T11 proved challenging at both test moments. Fifteen PTs at pre-, and 6 PTs at pos-test did not pose any problem for T10 (and were scored by 0). The number of inappropriate problems at pretest was 15 and 3 of them were meaningless or unsolvable. The remaining 8 problems had a common feature: The given fractions were identified as parts of a quantity but were not combined multiplicatively, resulting either in addition problems (e.g., *Paul bought 3/4 of a kilogram of coffee, and Maria gave him another 2/5 of a kilogram. How many kilograms of coffee does Paul have in total?*); or fraction comparison problems (e.g., *John ate 3/4 of a pizza, and Helen ate 2/5. Who ate more*?). At posttest, there were 9 such problems in a total of 15 inappropriate ones. On the other hand, the number of appropriate problems increased from 4 to 13 after the intervention. Two problems at pretest and 5 at posttest were grounded on the rectangular area model of fraction multiplication (e.g., *The length of a rectangle is 3/4 m, and its width is 2/5 m. How much is its area?)*. The remaining were grounded on the "part of a part" meaning (e.g., *Konstantina bought 3/4 of a kilogram of apples and gave 2/5 of that to her friend Maria. How many kilograms did Maria get?*).

In T11, 16 PTs at pretest, and 3 PTs at posttest did not pose any problem. The number of inappropriate problems increased from 14 to 19 after the intervention. In many of these problems (6 at pretest, 12 at posttest), the given fraction (2/3) functioned as a multiplier of a quantity. Some of these problems (4 at pretest, 10 at posttest), were multiplication problems (e.g., *A kilogram of cherries costs 4€. How much do 2/3 of a kilogram of cherries cost?*). In the remaining such problems, arbitrary data were introduced to pose problems that did not correspond either to multiplication or to division with the given numbers, or they were unsolvable; however, 2/3 still functioned as a multiplier of a quantity (e.g., *4 kilograms of potatoes cost €5. How much do 2/3 of a kilogram cost*?). In one problem (at pretest), the roles of 4 and 2/3 were reversed, with 2/3 functioning as the dividend (*4 crackers cover 2/3 of a small baking tray's surface. How many centimeters does 1 cracker cover?*). The remaining inappropriate problems were mostly meaningless or unsolvable; corresponded to other operations, particularly subtraction; or a combination of the above (e.g., *I have 4 liters of milk, and I want to distribute them into 2/3 of a cup. How many liters of milk will I have left?*).

On the other hand, the number of appropriate problems increased from 4 to 12 after the intervention. Most of them were grounded on the measurement meaning of division (e.g., *A baker distributes 4 kilograms of dough into containers with a capacity of one kilogram, but he uses only 2/3 of the capacity. How many containers will he need?*). Only one problem at posttest was grounded on the rectangular area model (*I have a rectangle with an area of 4 square meters. If its length is 2/3 meters, what is its width?*). Additionally, 2 participants posed problems of the type "known part, unknown whole" at pretest, and retained them at posttest (e.g., *If 2/3kg of lemons costs €1, find the cost of 4kg*).

We cross-tabulated the individual total scores (max 11) at pretest with the corresponding ones at posttest (Table 2). Each cell of Table 2 represents the number of participants reaching the particular scores at pretest and posttest. The individual scores range from 1 to 9 at pretest; and from 4 to 11 at posttest, pointing to inter-individual differences with respect to performance at both test moments.

Table 2: Cross-tabulating the individual total scores at pre- and post-test

	Individual total score -Posttest												
Individual total score-Pretest	0	1	2	3	4	5	6	7	8	9	10	11	Total
0							1						1
1							2		1				3
2													
3						1		1	4				6
4							1	2					3
5					1	2	1	3		2	1		10
6							1	1		2		1	5
7							1	1	2				4
8									1				1
9											1		1
10													
11													
Total					1	3	7	8	8	4	2	1	34

Most participants (27/34) improved their score at posttest. The score of 14 of them increased by 1 to 3 points; the score of the other 13 increased by 4 to 6 points. Five participants retained the same score; two did not revise any of their initial responses; the others revised incorrect as well as correct responses. Finally, 2 participants received a lower score at posttest. Further, there were two participants who had a relatively high score already at pretest (8 and 9); one of them was among the ones who retained the same score, and the other increased the score by 1 at posttest. Finally, only one participant reached the maximum score (11), with an initial score of 6.

Conclusions - Discussion

We presented findings from the first cycle of a topic-specific design research study (Gravemeijer & Prediger, 2019) focused on fraction multiplication and division. We designed a course unit addressed to pre-service teachers, aiming to enhance their CCK and SCK (Ball et al., 2008). We targeted the challenges that relate to the transition from natural to rational numbers, thus the design of the course unit as well as the intervention was based on principles from instruction stemming from conceptual change perspectives on learning (Vamvakoussi, 2017). The key idea was to foster productive meaning for multiplication and division already in the context of natural numbers which can be transferred to rational number contexts (see also Simon et al., 2018). In this paper we focused on results regarding the participants' performance before and after the intervention in related tasks.

Consistently with prior research, before the intervention, most participants were able to execute the algorithms of fraction multiplication and division but had very poor conceptual understanding of the two operations and their relationship (Ma, 1999; Olanoff et al., 2004; Tirosh, 2000). This is particularly evident in problem-solving and problem-posing tasks in which, similarly to students, the participants appeared to confuse fraction multiplication with fraction division, fraction multiplication with addition, and fraction division with subtraction. Evaluating and constructing representations pertaining to fraction multiplication and division also proved very challenging (Iszák, 2008). Further, the participants were mostly unaware of the possibility to replace multiplication with division by the reciprocal of the divisor (Ma, 1999), with some of them stating explicitly that it is not possible to multiply a number and get a smaller result (Fischbein et al., 1983, Tirosh, 2000). Finally, a correct, even if atypical, calculation process for multiplication as well as an inaccurate formulation of the "invert and multiply" rule was evaluated incorrectly to a large extent. These results depict limitations in various aspects of Common Content and Specialized Content Knowledge (Ball et al., 2008), and underly the need for substantial support to prospective teachers. After the intervention, the participants' performance increased significantly. However, this should not be taken to imply that they have mastered the intended content. Indeed, many of the difficulties identified by the pretest, persisted after the intervention. This is not uncommon in conceptual change research because revising prior knowledge and building new knowledge in a complex area such as fractions is a challenging and time-consuming endeavor.

Our findings also indicate that there were inter-individual differences with respect to the participants' performance before and after the intervention, as well as to the extent they benefited by the intervention. Analysis of the data collected during the intervention will shed more light on the conditions that favor or constraint learning and will be examined in the phase of retrospective analysis of the study (Gravemeijer & Prediger, 2019) to inform our design for future implementations.

Preservice teachers' collective proportional reasoning in large-format ratio triangles

Morten Bjørnebye[1], Bjarte Rom[1], Henrik Løvik Njølstad[1] and Jonas Oskarsson[1]

[1]Inland Norway University of Applied Sciences, Norway; bjarte.rom@inn.no

A goal in teacher education is to help preservice teachers (PSTs) develop skills in using multiple representations to foster mathematical reasoning with their future students. However, there is limited understanding of how different semiotic resources can support students' collective reasoning about proportions. To explore this, the paper presents two excerpts from a design study involving PSTs working collaboratively on proportional reasoning within a large-format ratio triangle (LFRT). The semiotic analysis demonstrates that LFRTs can facilitate the integration of movement, gestures, speech, and symbols, enabling them to build on each other's ideas while reasoning through missing-value problems. The study also reveals that the level of participation in the collective reasoning process among PSTs within the LFRT can vary, ranging from active integration of semiotic resources to a more non-verbal role, where they translate verbal reasoning of peers into physical reasoning.

Keywords: Design research, teacher education, proportional reasoning, semiotic bundle

Introduction and research question

The ability to reason about proportional situations is fundamental to students' mathematical competence; however, it is a topic that many students find difficult to grasp and teachers find challenging to teach (Lobato et al., 2010). These challenges stem from superficial teaching methods focusing on procedures, and a lack of relevant context and visual aids, which hinder students' understanding of proportion concepts. Research shows that collaborative discussions help students understand and apply mathematical reasoning more effectively by encouraging them to articulate and justify their thinking (Hansen, 2022). In teacher education in Norway, a key objective is to equip the preservice teachers (PSTs) with the skills necessary to facilitate creative and mathematically grounded reasoning among their future students. A part of this goal is helping PSTs develop the ability to use multiple representations (concrete, embodied, visual, symbolic) to foster collective proportional reasoning. This approach not only enhances their pedagogical techniques but also ensures that they can teach these critical concepts, enabling their students to understand and apply proportional reasoning in diverse and meaningful ways. Some research has shown how multiple representations in proportional tasks, such as double number lines, ratio tables, and strip diagrams, can influence students' reasoning (Arican, 2018; Beckmann & Kulow, 2018; Orrill & Brown, 2012). However, Prahmana and Nusantara (2024) systematic review on ratio and proportion learning design revealed a limited exploration of modeling tools beyond ratio tables, resulting in a lack of variety in approaches to modeling ratios and proportions. Particularly, a gap remains in understanding how tasks involving full-body movement can foster collective proportional reasoning.

A ratio triangle features a V-shaped design, where each axis lies within a common measurement space, and proportional relationships are represented by corresponding sides maintaining consistent ratios, as seen in similar triangles. This visualization of proportional relationships is less clear when using a double number line or a table of proportional values. Based on a larger design study in teacher education, this paper addresses the following question: How does the use of various semiotic

resources in a large-format ratio triangle (LFRT) support PSTs collective proportional reasoning? The research seeks to gain deeper insights into how the LFRT, as an artifact, can enhance PSTs' collaborative reasoning in missing-value problems by integrating full-body movement, speech, and symbols.

Theoretical background

Mathematical reasoning can be defined in various ways, encompassing both individual and collective processes and products (e.g., Lithner, 2008; Niss & Højgaard, 2019). Collective mathematical reasoning is defined as lines of connected arguments emerging from collaborative efforts (Sumpter, 2016), which can be mediated through various semiotic signs (e.g., speech, movement, symbols, drawings, use of tools). Within a semiotic lens, Arzarello et al. (2009) introduce the concept of a semiotic bundle, which refers to a dynamic system of signs generated by one or more interacting individuals over time. This system typically includes the signs produced by a student or a group of students while solving a problem or discussing a mathematical question. The signs included in a bundle may evolve, and the relationships among these signs can also vary as the students or the interacting students produce them. As noted by Arzarello et al. (2009), collaboration enables students to share semiotic bundles, facilitating the transformation of informal and formal mathematics. Based on the view of learning as a semiotically mediated process (Presmeg et al., 2016), we use semiotic bundle to explore PSTs collective mathematical proportional reasoning in a LFRT.

Proportional reasoning involves a complex set of skills that intersects with various concepts in rational numbers and algebra, such as ratios, rates, fractions, and functions (Lamon, 2007). For PSTs, it is essential to understand what constitutes robust proportional reasoning, identify strategies used in proportional reasoning, and learn how to effectively support their future students in developing proportional skills (Weiland et al., 2021). A proportion is defined as a statement asserting the equality of two ratios, symbolically expressed as a/b=c/d. According to Lamon (2007), proportional reasoning involves providing justification for claims about the structural relationships among the four quantities of a proportion within a context that involves both the covariance of quantities and the invariance of ratios or products. This entails recognizing a multiplicative relationship between two quantities and extending that relationship to other pairs of quantities. Proportional reasoning is usually assessed using comparison or missing-value problems. In comparison problems, all four values of the proportion are provided, and the task is to find equivalent ratios. In missing-value problems, three of the four values are given, and the challenge is to identify the missing value to complete the proportion. For example, consider a situation where 4 coffee mugs cost $20, and you want to determine the cost of 6 coffee mugs. In this context, there are two measurement spaces: one involves the quantities of coffee mugs, and the other involves the corresponding monetary values. The within-measures strategy compares quantities within the same measurement space, forming ratios like 4/6 for the mugs and 20/x for the cost. In contrast, the between-measures strategy compares values across the different spaces, forming ratios such as 4/20 for mugs to money and 6/x for the missing value. Solutions to proportional problems can be achieved using both formal and informal strategies. Formal methods include cross-multiplication, while semi-formal methods encompass the rule of three or using a fixed factor for multiplication between ratios. Informal, flexible scalar strategies involve reasoning up and down within ratios. For instance, we can reason down by first determining the cost of 1 mug, which

would be $5 (20/4). Then, reasoning up to 6 mugs, we multiply the cost per mug by 6, arriving at $30 ($5 \cdot 6$).

According to Weiland et al. (2021), a robust understanding of proportional reasoning for PSTs involves using various representations to support reasoning, including ratio tables or triangles, double number lines, and strip diagrams. Ratio tables represent elements within proportional situations in a symbolic form and support thinking strategies for solutions by encouraging the use of multiplicative strategies such as halving, doubling, and multiplying by 10 (Dole, 2008). The double number line (DNL) is a visual tool that coordinates quantities in a proportion by using two parallel lines. For instance, if 2 kilograms of fruit cost 1.5 Euros, the DNL shows that doubling the amount of fruit to 4 kilograms would correspondingly double the cost to 3 Euros. The ratio triangle is designed to help visualize and solve problems involving proportional relationships through a triangular arrangement of numbers. Specifically, the ratio triangle can be used to solve missing-value problems by either identifying the scalar ratio as a within-measures strategy or identifying the functional rate as a between-measures strategy (Kazunga & Bansilal, 2016). Unlike the double number line, which uses parallel lines, the ratio triangle features a V-shaped design where each axis is within the same measurement space. In this research, we will explore how the large-format ratio triangle (LFRT; Figure 1) can support the integration of semiotic resources for students positioned along each measurement space, enhancing their collaborative proportional reasoning.

Arican et al. (2023) examined the strategy repertoire of 91 PSTs in solving missing-value word problems, finding that cross-multiplication was most used. Additionally, they discovered that PSTs who employed less common strategies in proportional problem-solving had a significantly larger strategy repertoire compared to those who favoured more common strategies. In another study, Arican (2018) showed that providing practical contexts for missing-value problems helped PSTs recognize proportional relationships in their solutions, thereby reducing the reliance on error-prone strategies like cross-multiplication. Copur-Gencturk et al. (2023) explored 238 teachers proportional reasoning on the non-routine task “which rectangle most closely resembles a square”: (a) 1 foot by 4 feet, (b) 17 feet by 20 feet, (c) 7 feet by 10 feet, or (d) 27 feet by 30 feet. They identified four categories of reasoning: incorrect (28%), additive (11%), relative (17%), and proportional (45%). Based on their findings, Copur-Gencturk et al. (2023) suggest that similar tasks can help teacher educators guide teachers in identifying covarying quantities and transitioning from additive to proportional reasoning. Orrill and Brown (2012) investigated teachers participating in a professional development course focused on proportional reasoning using DNL, a representation that was new to them. The participants demonstrated a stronger ability to reason about relationships within a single measurement space (e.g., comparing the number of kilograms in different scenarios) than to coordinate values across two different measurement spaces (e.g., comparing kilograms to Euros). The findings indicate that teachers require extensive support and guidance to effectively apply their proportional knowledge to DNL-related tasks. Berk et al. (2009) investigated 148 preservice elementary teachers' flexibility in proportional reasoning before formal instruction and the impact of two intervention versions. The study found that participants initially exhibited limited flexibility in proportional reasoning, and that the intervention significantly improved strategy flexibility, with gains retained six months later.

Method

This paper is part of a larger design project conducted in a mathematics didactics course attended by fourth-year students in five-year teacher education programs qualifying them to teach mathematics for grades 1-7 and 5-10 in Norway. The project involved four researchers (the authors) and 25 PSTs participating voluntarily. The design principles guiding this research included the integration of movement with (proportional reasoning as) mathematical content (Skulmowski & Rey, 2018), flexible strategy usage through the creation of original solutions (Lithner, 2017), collective reasoning (Sumpter, 2018), and supporting abstraction through the use of symbols. Prior to the group activities, an introductory lecture on the use of the LFRT was held. In this paper, we examine how a group of five PSTs utilized various semiotic resources within the LFRT to enhance collective proportional reasoning and explore different solutions in two tasks: a) Calculating 27% of 480 NOK, and b) Designing and solving their own proportional reasoning problem. The excerpts have been chosen to emphasize contrasting elements of collective reasoning using the LFRT, rather than the complexity of the mathematical tasks.

One PST presented the tasks, and one PST was positioned on each axis of the LFRT (i.e., the task's measurement spaces; Figure 1). Any group member was welcome to contribute when working on the tasks. The presentation and the solution of the tasks were videotaped by one of the group members. The videos were transcribed verbatim, and non-verbal actions were enclosed in brackets. The transcripts were translated from Norwegian to English. To capture how the PSTs' semiotic-mediated arguments build on each other in the excerpts examined, we employ synchronic and diachronic analysis of the semiotic bundle (Radford et al., 2017). The synchronic analysis captures how various semiotic signs are bundled together in brief moments of a particular PST's action, while the diachronic analysis examines how these semiotic bundles interconnect to form a coherent line of collective arguments.

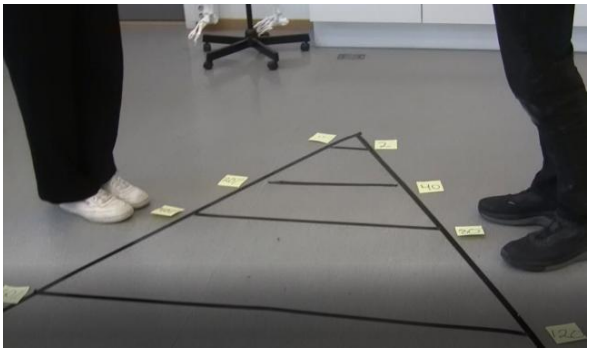

Figure 1: The LFRT is taped on the floor

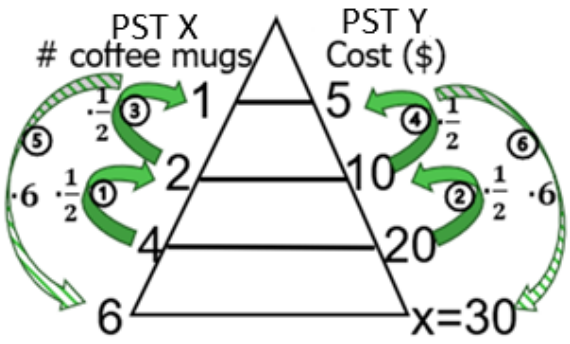

Figure 2: Example of coding

The transcripts were supplemented with coded illustrations, reflecting the PSTs use of semiotic resources in the reasoning process (Figure 2). These illustrations show numbers along the axes that correspond to values written on Post-it notes (or verbally stated if not symbolized), with the multiplicative structure of the movement-based verbal reasoning represented along curved arrows (Figure 2). Striped curved arrows indicate multiplicative reasoning without physical movement. To support the diachronic analysis, the reasoning steps within the ratio triangle are sequentially numbered in circles. Referring to the earlier example where 4 coffee mugs cost $20, and you want to

determine how much 6 coffee mugs cost, Figure 2 illustrates the positions of PSTs X and Y on the left and right axes of the LFRT, respectively, with the scaling process shown through six ordered movements. For instance, PST X's initial movement from the note labelled "4" to "2" (accompanied by the statement, "half of four coffee mugs is two coffee mugs") is represented by an arrow connecting these numbers, demonstrating multiplicative reasoning (i.e., ·1/2).

Results and analysis

We present and analyse two excerpts from the collaborative problem-solving activities carried out by the PSTs, focusing on their proportional reasoning within the semiotic framework. The excerpts were selected to highlight contrasting aspects of collective reasoning when using a LFRT. The selected group of PSTs had set up the LFRT using Post-it notes, placing percentages on the left side and corresponding numbers on the right to outline their steps in proportional reasoning (cf. Figure 1). Both excerpts present the groups third solution of the two missing-value problems examined.

Excerpt 1 begins with PST A presenting the task while PSTs B and C stand at positions representing 27% and x, respectively, and PSTs D and E observe.

A: We need to find 27% of 480 [B and C move to 100% and 480, respectively].
A: We first choose to find 50% [① and ②], which is?
C: 240.
A: Then we go down to find 25% [③ and ④].
C: Which is 120.
A: Yes, we took the half of 50% since 25% is half of 50%.
A: And then we needed 2% more to reach 27%, so we first find 1 percent which is 4.8 [⑤ and ⑥].
A: Then we multiply it by 2, which is 9.6 [⑦ and ⑧].
A: Adding it to 25% gives us 27% [B and C move to 27% and x, respectively], which is 129.6.

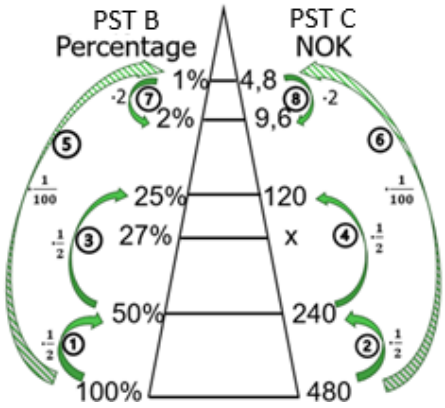

Figure 3: Coding of excerpt 1

Excerpt 2 addresses the task of finding 80% when 60% equals 120 NOK. The scene begins with PSTs A and D positioned to represent 60% and 120 NOK, respectively, while PST C introduces the solution, and PST E observes.

C: Now to solution 3 [A and D at 60% and 120, respectively].
A: We have 60%. We divide by 3 to get 20 [①].
D: And 120 divided by 3 is 40 [②].
A: Then we double 20% to get 40% [③].
D: And doubling 40 is 80 [④].
A: Then we multiply by 2 to find, or double to find 80% [⑤].
D: And 80 doubled is 160 [⑥].

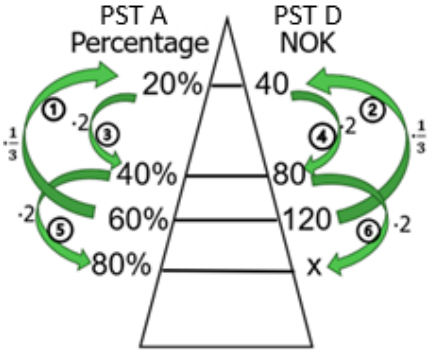

Figure 4: Coding of excerpt 2

In both excerpts, the PSTs collaboratively solve missing-value problems using the LFRT as an artefact while integrating various semiotic signs such as movement, symbols, speech. The reasoning

primarily follows a within-measures strategy, scaling up and down within the same measurement space, such as calculating 50% and then halving it to determine 25% (240/480 and 120/480, respectively), as seen in Excerpt 1. The PSTs' reasoning is both synchronic, connecting different semiotic resources in real-time, and diachronic, building on previous steps to form a coherent line of argument. For instance, in Excerpt 2, PST A's division of 60% by 3 to get 20% is followed by PST B's division of 120 NOK by 3 to get 40 NOK. The sequence of the six movement-based scaling steps ①-⑥ in Excerpt 2 illustrates how the PSTs' semiotic-mediated arguments accumulate to form a coherent line of reasoning (Figure 4).

In Excerpt 1, PSTs B and C positioned within the LFRT adopt a more passive verbal role, primarily translating PST A's verbal reasoning into physical reasoning. Excerpt 1 also demonstrates that not all reasoning steps need to be aligned with movement (the steps ⑤ and ⑥ in Figure 3). In contrast, Excerpt 2 presents a more balanced interaction, with both PSTs A and D, positioned in the task's measurement spaces, actively contributing to the reasoning process by building on each other's arguments and closely integrating movement into the scaling up and down the percentages and NOK, respectively. Consequently, the two excerpts differ in the level of PST participation and the semiotic resources employed in their collective proportional reasoning.

Discussion and concluding remarks

We analysed video recordings of PSTs group work to explore how various semiotic resources, particularly movement within the LFRT, support collective proportional reasoning. The research reveals two major insights. First, the LFRT facilitates the exchange of arguments through multiple semiotic resources, fostering the development of collective proportional reasoning. Second, the roles taken by PSTs during collective reasoning in the LFRT, as well as the extent to which movement is integrated into the reasoning process, can vary. Consequently, this research contributes to the understanding of collective reasoning (Sumpter, 2016), particularly in how it develops within proportional tasks using the within-measures strategy (Kazunga & Bansilal, 2016). The use of the LFRT in the PSTs reasoning processes mirrors the application of tools like the double number line in teaching proportional reasoning, as discussed by Orrill and Brown (2012). Both tools help visualize proportional relationships, making abstract concepts more concrete. However, our analysis shows that the PSTs are not merely using the LFRT to perform rote calculations; they are collectively engaging with it to construct and validate their reasoning processes. This reflects Orrill and Brown's (2012) finding that teachers need guidance in effectively using such tools to bridge their proportional knowledge with the task at hand. The collaborative nature of the problem-solving process, as seen in the two excerpts, aligns with the findings of Copur-Gencturk et al. (2023), who emphasize the importance of guiding teachers in recognizing covarying quantities to transition from additive to proportional reasoning. In the excerpts, PSTs work together to build on each other's ideas, moving from simple to more complex reasoning. This process of collective reasoning in practical contexts is crucial for reinforcing proportional thinking and moving beyond cross-multiplication and additive strategies, which are often error-prone (Arican, 2018; Arican et al., 2023; Copur-Gencturk et al., 2023). In line with Berk et al. (2009), who found that PSTs often struggle with proportional reasoning but can benefit from targeted interventions to improve strategy flexibility, our research highlights the value of the LFRT. This tool supports PSTs in understanding and working with ratios and proportional relationships both visually and physically, while fostering collective reasoning and the

use of various semiotic resources. This work contributes to the existing knowledge on task design aimed at improving collective proportional reasoning in teacher education, highlighting the value of incorporating semiotic resources like movement into the learning process.

Tensions emerging when discussing tasks for problem-solving lessons

As provoking tensions, talking about tensions, and managing tensions are found to be effective ways to promote teachers' professional development (PD), identifying tensions in PD initiatives is important. This study explores tensions that emerge in the 'task-centric' PD and research initiative Partners in Practice. Data from one small-group discussion, involving three teachers (Grade 8) and one teacher educator is explored. A main tension in the work of leading small-group discussions was the contrasting force between a safe practice where students solve routine tasks (tradition) versus a practice where they solve problem-solving tasks (innovation). A second set of tensions were found at the teacher-researcher level, within the research-practice partnership. A third set was at the teacher-teacher level or related to the teachers' work of teaching. This set might be illustrated by contrasting forces like using non-curriculum tasks versus curriculum tasks.

Keywords: Professional development, tasks, tensions, problem solving, mathematics teaching.

Introduction

Twelve lower secondary mathematics teachers and three teacher educators are involved in *Partners in Practice*, a professional development (PD) initiative with a problem-solving approach to mathematics teaching. In the beginning of the fifth PD session (six months into the project), one of the teacher educators shares a concern that we (as PD providers) have not succeeded in selecting tasks that are relevant for the teachers' practice. One teacher confirms that the teachers and the teacher educators have various inputs to the sessions, expressing that the tasks discussed are not relevant to the mathematical topic they focus on "just now". Another teacher expresses: "I feel we are in two different worlds, our daily work is from minute to minute, it is hectic, and the exam [Grade 10] is approaching, and suddenly we get a task from you at a session that we should try out [with our students]." After this discussion, the teachers and the teacher educators agree to discuss and try out tasks suggested by the teachers in the coming sessions.

Tasks have a fundamental role in mathematics teaching (e.g., Hiebert et al., 2003), in attempts to understand teaching and student thinking and learning in research on mathematics classroom practices (e.g., Tekkumru-Kisa et al., 2020), as well as in teachers' PD (e.g., Boston & Smith, 2011; Johnson et al., 2016). *Partners in Practice* is a 'task-centric' initiative where we seek to establish a collaborative space for continuous development of mathematics teaching practice. The vignette above illustrates how tensions might emerge, and understanding tensions is important for PD providers (e.g., Johnson et al., 2016). The present study aims at exploring these tensions.

Background

Tensions are often described as dilemmas where no ultimate solution can be found (Katz & Raths, 1992), and dilemmas have been extensively discussed in the research literature. As an example,

Lampert (1985) defines teacher dilemmas as problems to be managed, and she does not consider it a weakness that some dilemmas of teaching are not resolvable. Berry (2007) builds on Lampert's (1985) work and considers tensions as dichotomous forces acting on a teacher (educator). In a self-study on improving her own teacher education practice, Berry used the notion of tensions to capture the feelings of being pulled in different directions by competing pedagogical demands. The self-study identified twelve tensions, or dichotomous forces. One of these tensions, *Telling and growth*, is embedded in teacher educators' learning "how to balance their desire to tell prospective teachers about teaching and providing opportunities for prospective teachers to learn about teaching for themselves" (Berry, 2007, p. 120). Building on Berry's (2007) understanding of tensions as dichotomous forces acting on a teacher, others have identified comparable pairs of forces within the lived experiences of mathematics teachers. For instance, Andrà et al. (2019, p. 3) describe tensions as "pairs of contrasting forces that pull a teacher in two different directions." An example of a pair of contrasting forces might be a safe practice where students solve routine tasks (tradition) versus a practice where they solve problem-solving tasks (innovation) (Liljedahl et al., 2015). Unlike prior research on tensions, Liljedahl et al. (2015) found that "teachers do not simply manage these opposing forces, but also work at, and seek help in, resolving them" (p. 193). They argue that their extension of how tensions are understood (i.e., by including affective aspects) has implications for the work of providing PD for mathematics teachers and suggest that an emphasis on tensions is important "since provoking tensions, talking about tensions and managing tensions are effective ways to promote teachers' professional development" (Andrà et al., 2019, p. 5). In a more recent study aiming to better understand the way tensions might contribute to teachers' beliefs, decisions, and actions, how teachers live with tensions and how they resolve them, Liljedahl et al. (2023) understand the source of forces at play in tensions as personal/internal, meaning that tensions are strongly connected to past experiences and values arising from inside a teacher. The source of forces at play in tensions are also contextual/external, meaning that they arise from "norms, education and stakeholders" (Liljedahl et al., 2023, p. 1666). The present study defines tensions as contrasting forces (Andrà et al., 2019; Berry, 2007), and we aim at answering the following research question: What tensions emerge when teachers discuss tasks used in a problem-solving lesson?

Methods

This study is part of an ongoing project that aims at developing a problem-based approach to mathematics teaching, and it involves twelve Norwegian lower secondary teachers and three teacher educators (the first three authors of this paper). The PD sessions involve discussing key concepts related to problem solving, getting firsthand experience with solving mathematical problem-solving tasks and inviting teachers to try out problem-solving tasks with their own students. The discussions in the PD sessions range from how problem solving is defined in the Norwegian national curriculum from 2020, to tasks as presented in the textbooks used. When trying out problem-solving tasks, the focus this far has been on presenting tasks and facilitating group and whole-class discussions when students solve problem-solving tasks. In between sessions, the teachers are challenged to do some work like observing their own students' mathematical thinking when solving tasks. Tasks have not been designed in the PD sessions. However, characteristics of tasks to be used in the teachers' own

classes have been discussed, both tasks brought to the sessions by the teacher educators and by the teachers themselves. All sessions are recorded by audio and video, and transcribed verbatim.

The teachers participated in twelve two hours PD sessions over a period of 18 months. In this paper, data from a small-group discussion at the sixth session—involving three teachers (Grade 8) and one of the teacher educators—is explored. Based on the discussion from the previous PD session exemplified in the introduction's vignette, the teachers had selected a task related to the ongoing mathematical topic and tried it out in their classes. In this small-group discussion, the teachers reflect on their experiences from using the task with their students. The mathematical focus of the task is algebraic calculations with parentheses, and the students are going to find the area of a rectangle with a given length and width or a square with a given side. The task consists of a string of exercises where students are supposed to find the area of rectangles where the side lengths become increasingly more complex, from simple areas like 8×10 to more complex situations where the area can be expressed as $(5x + 4)(4x + 3)$. For instance, one of the teachers suggests: "Say that it says *10* on one side and *5x* plus *3* on the other side. What I thought they were going to do, that they just do like that, and then you get *50x* plus *3*. That it will be that order of calculations. That they forget to take it in parentheses."

The analysis of the discussion (15 minutes) started by identifying the parts of the transcription where tensions, or pairs of contrasting forces that might pull the teachers in different directions (Andrà et al., 2019), emerged when the task was discussed. This was followed by inductive coding of all utterances in the teachers' exchanges. In addition, memos were written. After one researcher inductively coded the whole transcription, two other researchers double-checked the coding, deleted and added codes and wrote memos where they disagreed. All three then discussed and agreed about the final coding before the coding was analyzed with the purpose of identifying patterns of tensions in the teachers' talk. As a supplement to this analysis, the transcript of the small-group discussion was divided into 14 episodes by one of the authors.

Findings

In addition to the main tension where students solve routine tasks (tradition) versus a practice where they solve problem-solving tasks (innovation), we found three levels of tensions in the teachers' talk: researcher-teacher, teacher-teacher and teacher-student. When dividing the transcript into episodes, the analysis revealed that sub-categories of contrasting forces within these overall patterns were interwoven, but we focus on the first two levels here due to space restrictions. Tensions related to the research-practice partnership were particularly prominent in two episodes while sub-categories of tensions related to the teachers' work of teaching were interwoven in all episodes.

The first episode is presented below to illustrate the complex pattern of tensions. Prior to the small-group discussion, one of the teacher educators has introduced a list of talk moves (Kazemi & Hintz, 2014) that might facilitate teacher-student dialogues in classrooms. As a starting point for reflecting on "what you've done" (1), the teacher educator (Raymond) challenges one of the teachers (Nina) to reflect on how this task could be used or revised to elicit student participation. Raymond seems to have noticed a possible tension emerging in Nina, between a wish for student dialogue and the student dialogue observed:

1	Raymond:	You talked about how you thought there was little dialogue, I heard you say. With this task, how could you have invited them into more of a student dialogue? Now that you have done something, based on the talk move, are there other steps you could have taken? Is there anything about the task that you could do something about? So, it's a good starting point for reflecting on what you've done. I noticed what you said about missing that there was a bit more student-dialogue.
2	Nina:	I would have had it later, but I thought we had to do it before today. So, I would've had it later in the chapter, where they had…
3	Kai:	So, you want to learn the rule first, and then the proof afterwards?
4	Nina:	Not necessarily, but…
5	Kai:	Because I want to.
6	Nina:	I want to have worked at least with parentheses. And then afterwards to have had that aha experience, oh, that's how it all goes together.
7	Kai:	Yes, but then you must have done it many times first. Okay, now you know the rule, but don't quite know why it gives an answer, and then you see, oh yeah, that's why you do it like that.

Nina's response (2) illustrates how different levels of tensions are interwoven. She seems to experience a tension between when to use tasks (especially tasks provided by the PD providers) and her teaching plan. Participating in the problem-solving session "today" forced her to use the task with her students before it was suitable concerning her teaching plan, indicating that there was a wish from the teacher educators to bring her classroom experience to the session. At one level, we identify two contrasting forces, teacher practice versus participating in PD sessions, within a research-practice partnership (Johnson et al., 2016). Related to the same level, there also seems to be a tension which relates to Berry's (2007) *Telling versus growth*: between the PD providers informing and creating opportunities to reflect and self-direct or between acknowledging teachers' needs and concerns and challenging them to grow. We also identify signs of Berry's tension *Safety versus challenge*: between providing teachers with a constructive learning experience and an uncomfortable learning experience.

We also identify a tension related to her work of teaching. For Nina this specific task seems to fit later, when the students have worked on more mathematical content from a particular textbook chapter, also indicating her view of teaching, she wants students to know the content they need to solve the task. We can illustrate this tension with the two contrasting forces: know content before working on a task versus learn content while working on a task.

In utterances 3–6, Kai and Nina seem to agree that their students must know some content before working on tasks like the one discussed. However, while Kai would like his students to "know the rules" before proving (3), Nina highlights some content the students would need for her students to have an "aha experience" while solving the task (6). Kai (7) seems to think that practicing routine tasks is important. After practicing "many times", you learn the rule, but not necessarily the reason why the rule works. The utterances indicate tensions between these teachers' views of teaching.

At the end of the group session (Episode 14), Nina's talk also made the tension of research–practice partnership (Johnson et al., 2016) visible when she expresses:

143	Nina:	But I would like to think that the tasks that are also presented here (in the sessions), and likely the ones that we have used, are perhaps given more for a grade four and up. So, it makes it difficult for the weak (students) to join. How will you manage to keep up if you barely know that…

144 Kai: You can't explore until you…
145 Nina: Yes, you must have some prior knowledge to do it. So, I think you aim too high with these tasks.

Here Nina challenges the PD providers for presenting tasks in the PD that could not be used for all students (143). Nina's last sentence "I think you aim too high with these tasks" might also be seen as a tension between the PD providers ideas about these tasks and the reality of the classroom. Kai challenges the idea of exploration in mathematics teaching (144) and Nina concretizes by highlighting the need for students to "have some prior knowledge" before exploring (145). These exchanges indicate the tensions, tradition (prior knowledge before exploring problems) versus innovation, and routine tasks (for all students) versus problem-solving tasks (for some students).

Tensions at a teacher-teacher level were identified in all episodes. In episode 6, Nina expresses that she would have liked to have "an hour or two" focusing on parentheses before working on the task where use of parentheses was of importance. She also thinks the students need repetition of "how it is when we multiply x by x". After this "hour or two" she would start introducing the task by only showing "the figure with four squares" and saying/asking "$5x$ and 3 and $2x$ and 5, and simply said, find the area! What should I do? How many ways can you find the area?" So, if Nina had the opportunity to let the students work on parentheses beforehand, she would make the introduction to the task short. Nina summarizes by stating that "the task is not open enough. It's an overtly teacher-directed task." Per agrees, but he expresses that "you have to go through some of the non-open tasks as well." Here the tension seems to include not only routine tasks versus problem-solving tasks, but which type of task comes first. It seems like they agree that "non-open tasks" (routine tasks) might be important to do before more open tasks (problem-solving tasks). In episode 7, these tensions are strengthened when the teachers agree that there are mathematical themes the students must master before working on more open tasks. Later in the group discussion (episode 8), Kai also says that he feels that the number of mathematical themes in the curriculum limits the time for exploration, indicating a tension related to mathematical themes versus lack of time for explorations. The issue of time is also emphasized (episode 9) when Nina finds it easier to invite students into dialogues by using non-curriculum tasks (or tasks not relevant to the mathematical topic they focus on "just now", see vignette in the introduction), but she finds it challenging to have time to work on such tasks: "That's when we have a dialogue, not when we start with the syllabus and work on it. Then it won't be that way, because you feel a bit… Yes, the time that isn't enough either."

To summarize, we have identified the contrasting forces, to solve routine tasks (tradition) versus a practice where they solve problem-solving tasks (innovation) (Liljedahl et al., 2015) as superior to other tensions. Patterns of tensions related to research-practice partnership can be divided into three sub-categories: a) teacher practice versus participating in PD sessions, b) *Telling versus growth* (Berry, 2007), and c) *Safety versus challenge* (Berry, 2007). Patterns of tension related to the overall category teachers' work of teaching are related to the sub-categories: a) student dialogue versus missing dialogue, b) know content before working on a task versus learn content while working on a task, c) know rules for managing a task versus learn rules while working on a task, d) non-curriculum (open) tasks versus curriculum (open) tasks, e) mathematical themes versus lack of time for explorations, and f) non curriculum tasks (and time to work on such tasks) versus curriculum tasks.

Concluding discussion

Selecting, discussing and trying out tasks for problem-solving lessons is vital to a PD initiative like *Partners in Practice*. Building on Andrà et al.'s (2019) finding that provoking, talking about and managing tensions are effective in promoting teachers' PD, we explored tensions in this PD initiative by identifying pairs of contrasting forces that might pull teachers in different directions (Andrà et al., 2019; Berry, 2007; Liljedahl et al., 2015, 2023). We identified complex collections of contrasting forces related to both the selection and enactment of tasks, and we found some overall patterns of tensions in the teachers' talk. First and most prominent was the tension between a practice where students solve routine tasks (tradition) versus a practice where they solve problem-solving tasks (innovation). A tension between tradition and innovation is previously discussed by Liljedahl et al. (2015), but whereas these researchers identified a tension between the traditional wishes of a teacher's practicum and her desire to be more innovative and the teacher's wish to enact her own teaching program and following the school's workbooks more generally, our findings relate more specifically to tasks (e.g., routine tasks vs. problem-solving tasks). Since tasks are fundamental in mathematics teaching (e.g., Hiebert et al., 2003), and in understanding teaching and student thinking and learning (e.g., Tekkumru-Kisa et al., 2020), this tension is important for PD providers to be aware of and discuss with teachers in PD sessions (e.g., Boston & Smith, 2011; Johnson et al., 2016). PD providers must be aware that (problem-solving) tasks might produce tensions.

In relation to the main tension between tradition and innovation, we found two other overall patterns of tensions. We identified tensions between 1) what the PD providers brought to the sessions and teachers' ideas, and between 2) the teachers, both having interwoven sub-categories of contrasting forces. The first one relates to Johnson et al.'s (2016) tensions within research-practice partnership and can be situated at the teacher-researcher level. Like Berry (2007, p. 133), we acknowledge that tensions "are not necessary *per se*, but they offer a useful way of conceptualizing and communicating practice." Berry (2007) also suggests that even though it is not expected that a series of tensions could provide guidance in all situations, tensions offer a way of understanding and improving practice. At a teacher-researcher level, we emphasize the importance of being aware that different participants bring different experiences and purposes when participating in PD sessions. More specifically, our analysis has illustrated how teachers and PD providers have different approaches when selecting tasks for use in PD. While the teachers want their students to work on tasks related to the syllabus or curriculum that are relevant to the mathematical topic they focus on "just now" (see 'Teachers' in Table 1), we as PD providers have suggested problem-solving tasks which are not necessarily related to the mathematical curriculum the teachers teach the exact time we meet for a PD session (see 'PD providers' in Table 1).

Table 1: Matrix for categorizing tasks for use in PD

Tasks	Non-Curriculum	Curriculum
Routine tasks - Tradition		Teachers ↓
Problem-solving tasks (open) - Innovation	PD providers →	Goal

The shaded cell in the 2 by 2 matrix in Table 1 suggests that PD providers might bring problem-solving tasks into the sessions which can also be related to the mathematical curriculum the teachers

teach at the time for the PD (curriculum tasks). We could consider this as a compromise between teachers and PD providers, bringing different perspectives to the PD sessions. The goal for future PDs might be to discuss problem-solving tasks more directly connected to curricula. On the other hand, Liljedahl's (2021) research based on empirical data from many classrooms revealed that the use of non-curriculum (open) problem-solving tasks in classrooms invited more students to think, and they were more engaged in the problem-solving activity compared to when students were introduced to curriculum tasks. We suggest that when PD providers bring problem-solving tasks (or non-curricular/open tasks) to the PD sessions, categorizing the task within the matrix in Table 1 might be an idea for further discussions in PD to highlight the challenge of selecting appropriate tasks for use in classrooms.

The other overall pattern of tensions was at the teacher-teacher level and was related to the teachers' work of teaching in which we identified six subcategories (see finding section). These tensions (e.g., know rules for managing a task versus learn rules while working on a task) illustrate the importance of identifying and unpacking the special mathematical work of teaching (Ball, 2017) in PD and consider the work of teaching to be "the core tasks that teachers must execute to help pupils learn" (Ball & Forzani, 2009, p. 497).

We acknowledge that our study is limited by the data we have analyzed from just one small-group discussion, and the small sample size is a limitation. However, we believe that our unpacking of this specific group discussion, highlighting tensions arising from teacher talk in a PD context might be useful for further studies and for understanding and improving PD practice. One promising direction for further research could be to delve into tensions that arise at a teacher-student level, bringing ideas from PD sessions into the teachers' practice in classrooms in which data also involves student voices.

On making mathematics flourish for students to grasp it: Teachers designing informal mathematics education workshops in museums

Raffaele Casi[1] and Cristina Sabena[1]

[1]Department of Philosophy and Education Sciences, University of Turin; raffaele.casi@unito.it

This paper presents findings from the InformalMath program, which aims to integrate Informal Mathematics Education Workshops (IMEWs) into teacher education through collaboration with non-scientific museums. Through a three-phase structure, teachers engaged in collaborative IMEW design, addressing challenges, and enhancing their understanding of integrating mathematics into informal contexts. Interviews with participating teachers revealed significant learning experiences, including group collaboration skills and the importance of hands-on activities. Moreover, teachers reported integrating elements of InformalMath, such as teaching through artifacts and emphasizing experiential learning, into their classroom practices. Overall, the program demonstrated the potential to transform mathematics education by fostering creativity, exploration, and meaningful engagement with mathematics beyond traditional classroom boundaries.

Keywords: Informal mathematics education, emergent learning, professional development, museums.

Introduction and theoretical background

Out-of-school settings may host educational activities intentionally designed to support mathematical learnings, within the perspective of the Informal Mathematics Education (IME). IME activities differ from most mathematics classroom activities because they offer learners greater freedom to pursue their interests, blur the boundaries between disciplines, and lack of traditional forms of academic assessment (Nemirovsky et al., 2017). The type of learning generated by IME experiences has been described by Nemirovsky (2018) as "emergent learning". Emergent learning, in contrast to teleological learning, focuses on the spontaneous and often unpredictable nature of gaining knowledge. Teleological learning is goal-oriented, structured around achieving predefined objectives, such as passing specific tests or accomplishing set targets. One limitation ascribed to the teleological learning approach is that it often limits learners by confining them to specific outcomes and disregarding the natural, organic process of learning. On the contrary, emergent learning approach allows for a richer educational experience by acknowledging and integrating the memories, sensations, and emotions of learners. By doing so, it fosters a deeper connection to the material, making learning a personal and impactful experience that can adapt and evolve in response to the learners' motivations and contextual interactions. This makes learning more engaging and ensures that it is more aligned with the individual's cognitive and emotional development.

We believe that teachers can serve as IMEducators, and we agree with Nemirovsky and colleagues (2017) that the education of IMEducators requires different approaches from those prevailing methods in mathematics teacher education (TE). This suggests the need for designing and implementing TE programs in IME, as well as investigating them from a research perspective.

To address this research gap, we explored IME in the context of non-scientific museums and designed a TE program named InformalMath. Seeking an approach that diverges from the prevailing paradigms

in TE and aligns with the perspective of emergent learning characteristic of IME, we identified Korthagen's (2017) framework as a valuable reference. Korthagen offers a critical analysis of traditional models, specifically those they term Professional Development (PD) 1.0 and 2.0. PD 1.0 primarily emphasizes theoretical knowledge dissemination, often leaving a disconnect between conceptual understanding and practical application. PD 2.0 shifts focus to practice-oriented training but still struggles to bridge the gap between the technical and personal dimensions of teaching.

In contrast, Korthagen's PD 3.0 marks a transformative shift by integrating professional skill development with personal growth. This model acknowledges that effective teacher learning involves not only cognitive processes but also emotional and motivational dimensions. Furthermore, PD 3.0 incorporates principles of socio-constructivism, recognizing the critical role of social interactions and collaborative practices in the learning process. Teachers are not seen as isolated learners but as participants in a dynamic, interactive community where shared experiences and reflections deepen understanding. This perspective aligns with Vygotsky's (1978) emphasis on the social context of learning, where collaboration with peers and mentors fosters the co-construction of knowledge.

Within the InformalMath program, the socio-constructivist elements of PD 3.0 are particularly relevant. The collaborative and inquiry-based nature of IME environments benefits from this framework, as it encourages teachers to engage in reflective dialogues that integrate theory with practice and to co-develop adaptive teaching strategies. By delving into the personal aspects of teaching, PD 3.0 supports teachers in navigating the complexities of informal learning environments, such as those encountered in non-scientific museums. This approach also resonates with Schön's (1987) concept of the reflective practitioner, wherein ongoing reflection bridges theory and practice, cultivating a richer, more responsive pedagogy. Ultimately, this synthesis of professional and personal growth equips teachers to create meaningful, learner-centered experiences that are adaptable to diverse educational settings.

In this paper, we give voice to the teachers and highlight their reflective practices at the conclusion of the InformalMath program, focusing particularly on their perceived emergent learning.

InformalMath teacher education program

The InformalMath program, which ran from December 2021 to June 2024, was structured into three distinct phases with the goal of providing in-service training for primary and middle school mathematics teachers on the unique context of non-scientific museums. The core of the program is to collaboratively design IME Workshops (IMEW, Casi, 2024) within a team of teachers, mathematics education experts, and museum education specialists.

The training program is structured into three distinct phases through which teachers acquire progressive autonomy, according to a cognitive apprenticeship model (Collins et al., 1989). In the first phase (Discovery Phase) teachers explore various IMEWs to gain understanding and inspiration. In the second phase (Guided Co-design Phase) teachers are guided by teacher educators in designing new IMEWs within museums proposed by the educators. Again, in the third phase (Scaffolded Co-design Phase) teachers designed an IMEW in a museum, but in this case they also chose the museum itself. This design is then shared with the museum so that it can be offered to schools interested in

providing this unique educational experience to their students. In Phases 2 and 3 teachers collaborate in small groups. In our presentation at CERME13, we shared the initial findings from research carried out on the Guided Co-design Phase (Casi & Sabena, 2023). In the current paper, we focus on the Scaffolded Co-design Phase, which corresponds to Phase 3 of InformalMath.

Among the twenty-two teachers participating in the second phase, seven opted to continue into the third one. We explored the reasons provided by the fifteen teachers who decided to exit the program to determine if there were specific issues with the course that influenced their decision. The feedback from these teachers revealed that their departure was influenced by changes in their personal lives (such as pregnancy or relocating outside the region) or professional circumstances (like a career shift, increased responsibilities in school administration, or changing schools).

Phase 3 started in March 2023. The teachers were divided into two groups: Group P composed by four primary school teachers, and Group M composed by three middle school teachers. Group P chose to explore and design at the Royal Castle of Moncalieri (castellodimoncalieri.it/), one of the UNESCO World Heritage castles located close to Turin. Group M's choice was the Museum of the Soundscape (museopaesaggiosonoro.org/), a small museum in Riva presso Chieri, about 20 km from Turin.

The co-design method was the same as that already used Phase 2. It involved, in different roles and at different times, teachers (T), teacher educators (TEd) and museum educators (MEd). Unlike the previous phase, however, agency in the choices was devolved more to the teachers, drawing on the principles of cognitive apprenticeship (Collins et al., 1989). Each group decided the modalities of co-working, for instance time and space for their meeting. At certain moments each group discussed the design with T, TEd, and MEd. Table 1 details the actions of this phase.

Table 1: Actions composing the Scaffolded Co-design Phase

Actions	Participants
1. Group formation and Museum choice	T; TEd
2. Museum visit and sharing of first ideas	T; TEd; MEd
3. Design: first draft	T
4. Scaffolding activity	T; TEd
5. Design: second draft	T
6. "*Dress Rehearsal*": T presented the IMEW to TE and ME	T; TEd; MEd
7. Design: finalising	T
8. Whole group presentation	T; TEd

As a result of the work of the two groups, two IMEWs were designed. Due to the limited space available in this paper, we simply give a brief suggestion of the topics covered in the two IMEWs, deferring their description to the project website www.informalmath.unito.it.

Group P designed 'Eye... A Game at the Castle' ('Occhio... Un gioco al Castello', in Italian) for the Royal Castle of Moncalieri. The IMEW is structured as a treasure hunt in the rooms of the castle, where the object of the search are geometric shapes and geometric properties.

Group M designed 'A Matter of Ratio' (‘Una questione di rapporti’, in Italian) to guide students to investigate the relationships between sound and mathematics while visiting the impressive Museum of the Soundscape. This small and original museum collects and make memories of sounds, noises and melodies that have characterized the local landscape, from rural culture to contemporary times.

Research questions and methods

We acknowledge that designing IMEWs is a demanding endeavor for teachers. We are also convinced that through engaging in this process, teachers can learn a lot. Furthermore, while the IMEWs, along with the entire InformalMath project, are conducted outside the school context, we believe that teachers' participation in such endeavors may also yield benefits for their everyday practice. Based on these considerations, we formulate three research questions:

RQ-1. What critical issues and difficulties did the teachers perceive, related to the third phase of the program?
RQ-2. What learning did the teacher report as a result of participating in the program?
RQ-3. What aspects related to IME did the teachers perceive as being filtered into their classroom practice?

RQ-1 specifically focuses on the design processes during the third phase of the program (for results regarding Phase 2, see Casi & Sabena 2023). Since Phase 3 is the final phase of the program, RQ-2 explores the teachers’ emergent learning throughout the entirety of the program. Lastly, RQ-3 connects the learning experiences within IME to the classroom context.

To answer the research questions, we collected the voices of participating teachers through individual semi-structured interviews. The interviews took place between Actions 7 and 8 (see Table 1) in March 2023. Interview questions were shared with teachers five days before the interview date. The interviews were conducted via online calls by the first author of the paper. Below is the English translation of the six questions that shaped the interview:

Q-1. What difficulties did you face in the third phase of the program? How did you overcome them?
Q-2. What do you think you learned in this phase?
Q-3. Considering your experience in InformalMath, what do you think about IMEWs in museums?
Q-4. Are there aspects of InformalMath that you think you have brought into the classroom in your daily teaching? If yes, which ones? If no, why?
Q-5. What do you feel you have learned from active participation in InformalMath program?
Q-6. As teacher educators, should we have done anything differently? Can you give us any suggestions for repeating the experience with other teachers?

Q-1 and Q-2 address challenges and insights from the third phase of the program, repeating questions posed in focus groups at the end of the second phase (Casi & Sabena, 2023). Q-3 solicits teachers' views on IMEWs after being involved in InformalMath for more than two years. Q-4 and Q-5 prompt teachers to reflect on the entire TE program. These questions aim to capture teachers' perspectives at a more advanced stage of their autonomy within the project. Lastly, Q-6 seeks to identify critical issues that we as teacher educators can address in future iterations of InformalMath.

The interviews were recorded and fully transcribed. However, one interview deviated from the planned setting: a teacher chose to include a colleague who was not involved in the InformalMath project. Due to this methodological bias, this interview was therefore excluded from the analysis. The transcriptions underwent qualitative content analysis, with entire sentences as units of analysis. Categories were developed inductively, and each sentence was assigned a label summarizing the intended expression of the teacher. These labels were then grouped according to their content, resulting in the final list of categories.

Results

Tables 2, 3 and 4 report the categories identified as described in the previous section and indicate in which interview were detected. All teachers' names are pseudonyms.

Table 2 reports the categories related to difficulties, responding to RQ-1.

Table 2: Categories of difficulties perceived by teachers

Difficulties perceived reported by teachers	Ada	Anna	Bianca	Dario	Lea	Lina
D1. Working in groups	✓	✓		✓		✓
D2. Accepting that the math in the IMEW is too basic	✓		✓	✓		✓
D3. Designing required extensive study	✓		✓			
D4. Choosing a meaningful museum for doing mathematics					✓	✓

D1 refers to the experience of working in groups; this was also found in second phase of the project (Casi & Sabena, 2023). D3 concerns the study needed to design an IMEW. The teachers described this need related to the peculiar themes of the chosen museum. D2 and D4 refer to the mathematics present in the IMEW, highlighting a tension between the simplicity of the topics and the significance of the relationship between mathematical topics and museum content.

The response to RQ-2 is reported in Table 3, which shows the categories related to the learning described by teachers.

Table 3: Categories of learning identified by teachers

Learnings reported by teachers	Ada	Anna	Bianca	Dario	Lea	Lina
L1. Group working when there is not full agreement		✓	✓		✓	✓
L2. How to design an IMEW, from the beginning to the end		✓	✓	✓		✓
L3. How to make mathematics flourish in a context where it does not seem to be present			✓	✓		
L4. In mathematics it is important the doing, possibly by hands	✓					✓

L1 can be directly traced back to D1, indicating how a perceived difficulty was exploited for learning. L2 and L4 highlight different nuances of learning in mathematics education, such as the importance of hands-on activities in the mathematics laboratory and how to design an IMEW. L3, which we named after one teacher (Bianca)'s words, underscores the significance of recognizing and leveraging the mathematics already present in informal contexts, specifically in the two chosen museums, rather than merely adding mathematical content to these contexts.

Table 4 allows us to answer RQ-3, showing the elements of InformalMath that teachers claim to have let filter in their teaching practice in the classroom.

Table 4: Categories of elements filtered in the classroom teaching practice reported by teachers

Elements filtered in the classroom teaching practice	Ada	Anna	Bianca	Dario	Lea	Lina
E1. Teaching mathematics through artifacts	✓		✓	✓		✓
E2. Emphasis on informal activities and outdoor education		✓		✓	✓	
E3. Practice first, then theory. Experiencing precedes formalizing				✓	✓	✓
E4. Creation of interdisciplinary teaching paths from science to mathematics through formalization				✓		✓
E5. Activities designed were taught to students in the classroom		✓	✓			

E1 is closely linked to L4 and represents a key element of InformalMath and IMEWs nature, drawing from the established research in Italian mathematics education, particularly regarding the mathematics laboratory and the semiotic mediation of artifacts (see Casi, 2024). E2 reflects teachers' effort to move some lessons outside the classroom (e.g., garden, gymnasium, schoolyard), integrating typical IME spaces into formal classroom practice. E3 and E4 both refer to mathematical formalization, which must take place after the experience, both with respect to laboratory activities and interdisciplinarity with science. Here, the emphasis is on the modalities of the IME rather than its spaces. E5 concerns the direct use of activities constituting IMEWs at school, facilitated by teachers for implementation in the classroom context.

As highlighted in the comments of the tables, the categories emerging as answers to the RQs are intertwined. This is evident also in the teachers' words form the interviews, which were carried out by the first author. We report here some excerpts from Bianca and Dario. Both teachers referred in explicit way to what they had expressed during focus groups or personal essays in the previous phases.

In answering Q-5, Bianca says

> Bianca: I've learned how to make mathematics flourish, so to speak, in every place. That means looking with a different eye, in this case the mathematical eye, at the things around us. Then ensuring that the students, when they visit the castle, can see them too. So that the students understand when they look at the carpet, and they see the birds put in symmetrical positions, they understand that there has been weaving, but it's not just weaving: plus, there are mathematical properties that the person who wove the carpet put in! Our job as teachers is to make sure that students see and grasp these things, I really understood that in this course.
>
> Interviewer: Tell me more about this.
>
> Bianca: It had happened before: you see an object, that time it was the *Metrocubo di Infinito* [pièce by M. Pistoletto] in the museum in Rivoli [in Phase 2], you understand it mathematically, and you want your students to get that experience. It's a sudden and beautiful thing; we had talked about it before.

Bianca initially refers to her learning, linked directly to her IME experience, describing how she learned to observe the reality around her with mathematical eyes. Later, she shifts the focus of the talk to the role of the teacher, and how it is important to her to make sure that students can have the same learning. When asked to elaborate on this concept, she refers to an episode that happened during Phase 2 of the program (discussed in Casi & Sabena, 2023, p. 3357). In that episode, Bianca referred

to the process of discovering mathematics in the museum from the students' perspective as the most difficult aspect encountered in designing an IMEW. Now, one year later, after having co-designed the IMEW in the Castle of Moncalieri, she appears to have overcome such a difficulty, as she says that she learnt how to make mathematics flourish in every place. Moreover, she recognizes this feature as central in her teacher role (Our job as a teacher is…)

The following is an excerpt from the interview with Dario, in response to Q-3:

Dario:	[This program] has stimulated me a lot to conceive for my students more and more interdisciplinary paths, because once you unlock this mechanism [seeing mathematics in the museum] it is easy to see mathematics in other contexts as well, such as the sciences. As I said earlier, I am not trained as a mathematician, and it has always been difficult to think about how to teach it [math] well.
Interviewer:	And how do you manage this?
Dario:	I always did this thing of trying to connect math to science. But now I've noticed that I always start in lessons from the sciences, and then get to the math. I'll give you an example: to work on ratios, I start from speed experiments, without explaining the formal part first. I start from that, then do the formalization. So, this inversion perhaps was given to me by this very program: no longer explaining and then making experiments, but the other way around: making people discover and then going to formalize later. This has definitely increased a lot in my work.

Dario expresses his views about IMEWs in museums by relating his experience back to his work in the classroom context, and how the opportunity to see mathematics in museums allowed him to learn a way of working (unlocking a mechanism) that led him to seek connections with mathematics in other contexts. As a result, he says he began to design interdisciplinary classes for his students, which enabled him to overcome difficulties related to his lack of initial training in mathematics. When Dario mentions his previous discussion about his non-mathematics background, he is referring to a conversation that took place during the focus groups at the end of Phase 2 (Casi & Sabena, 2023, p. 3358). In that discussion Dario expressed difficulty in finding a teaching approach that do not overlook fundamental aspects of mathematics. However, in the interview above, it appears that he has found a method that suits him well, leveraging his education (Dario has a MS degree in Geology), to support students in meaningful mathematics experiences. This change in Dario's perspective appears to have been strongly influences by his experience in Phase 3 and by subsequent reflection on those experiences.

Conclusions

The structure of the InformalMath program proved to be effective in guiding teachers through the process of designing IMEWs collaboratively. By allowing teachers greater autonomy and agency in the design, particularly in the Scaffolded Co-design Phase, they were able to overcome obstacles and develop a deeper understanding of how to integrate mathematics into informal contexts. The results of our research revealed that participating teachers reported significant learning experiences throughout the program. From gaining practical skills in group collaboration and IMEW design to recognizing the importance of hands-on activities and interdisciplinary connections, teachers expressed a newfound appreciation for teaching mathematics in diverse contexts.

Furthermore, the interviews conducted with participating teachers provided valuable insights into the impact of the InformalMath program on their teaching practices. Teachers described how they had

integrated elements of InformalMath, such as teaching mathematics through artifacts, emphasizing informal activities and outdoor education, and prioritizing experiential learning over formalization, into their classroom teaching. These findings highlight the transferability of skills and concepts learned through the program to the broader educational context.

However, it is important to acknowledge that the limited number of teachers who participated in the third phase of the research constrains the statistical robustness of the findings. Nonetheless, it was never our intent to conduct a nomothetic study; rather, we aimed to explore the potential of IME elements for teacher education. In this sense, we believe that this work provides a promising foundation for future investigations in the field, offering preliminary insights and actionable frameworks for developing innovative approaches to mathematics education.

Overall, the InformalMath program has demonstrated its potential to transform mathematics education by equipping teachers with the knowledge, skills, and confidence to engage students in meaningful mathematical experiences both inside and outside the classroom. As we move forward, further research and exploration into the implementation of IMEWs and their impact on student learning will be essential for continuing to enhance mathematics education practices.

Investigating how secondary school teachers perceive mathematical concepts in application contexts: The case of ratio and chemistry tasks

Adam Čech[1] and Libuše Samková[1]

[1]University of South Bohemia in České Budějovice, Faculty of Education, České Budějovice, Czech Republic; cechad00@pf.jcu.cz

This paper presents a qualitative empirical study investigating how secondary school mathematics teachers perceive the concept of ratio in application contexts given by lower secondary school chemistry tasks on stoichiometry. Considering the ability to notice mathematical concepts in application contexts as an integral part of conceptual knowledge of mathematics teachers, especially those who specialise both in mathematics and the school subject covering the application context, the aim of the study is to analyse various ways of how such specialised teachers solve the application tasks, detect potential strengths and weaknesses in their ability to notice mathematical concepts in the tasks and connect the ways of solving to their current teaching practices. As a consequence of the study, we discuss its implications for initial teacher education and professional development courses that educate all mathematics teachers together regardless of their other specialisation.

Keywords: Mathematics teachers, conceptual knowledge, mathematics teacher's specialised knowledge, application tasks, ratio.

Introduction

With this contribution, we follow up on our previous investigations (Čech & Samková, 2024) that concerned lower secondary school students solving tasks with both mathematics and chemistry content, namely the topics of ratio and stoichiometry. Since stoichiometry is defined as "the determination of the proportions in which elements or compounds react with one another" (Encyclopaedia Britannica, 2024), the concept of ratio is in the background of all stoichiometry tasks, including lower secondary school tasks on molar mass and the law of mass conservation. The respondents of the previous study were ninth graders who had already completed the topic of ratio (in the seventh grade) as well as the topics of molar mass and the law of mass conservation (in the eighth grade). The study revealed that the students were mainly unable to notice the concept of ratio in stoichiometry tasks and that their solution procedures were usually based only on purely chemical algorithms. To better understand the circumstances, we redirected our focus to teachers, namely, to teacher knowledge and practices that come into play when dealing with similar tasks. Therefore, the qualitative study presented in this paper involves five teachers whose students were respondents of the previous study and, to get a broader picture, one more teacher with similar background (specialisation, teacher training). As the neglected topic was the mathematical concept of ratio, we address the issue from the perspective of didactics of mathematics and construe stoichiometry tasks as applications of this concept. The research question is: *How do secondary school teachers specialising in both mathematics and chemistry perceive the concept of ratio in application contexts given by lower secondary school chemistry tasks on stoichiometry*? This question consists of two sub-questions. *Which procedures can the teachers use to solve the problems,* and *how do the teachers relate the procedures to their own teaching practice?* Our goal is to obtain feedback relevant not only

to participating teachers, but also to teacher educators. In this way, our contribution addresses two of the TWG18 key themes identified at CERME13 (Friesen et al., 2023): crossing the boundaries between different school subjects during initial teacher education and mapping the relationship between what takes place during initial teacher education and what happens in classrooms. The relationship goes both ways, and we take them both into consideration by discussing implications for classroom practice as well as initial teacher education.

The study takes place in the Czech Republic, where the initial teacher education of secondary school teachers takes the form of a five-year master's degree programme. Before entering the programme, each applicant chooses two school subjects in which to specialise. During the studies, content courses and didactic courses of the two school subjects are run separately. For mathematics, the offer of the other subject is usually open so that mathematics can be combined with any other secondary school subject (chemistry, biology, various languages, arts, etc.). Courses on mathematics content and didactics then educate all prospective mathematics teachers regardless of their other specialisation. The first author of this paper is a young researcher who is a secondary school teacher specialising in mathematics and chemistry. The second author is a researcher and mathematics teacher educator.

Ratio in lower secondary school stoichiometry tasks

In this paper, we discuss lower secondary school stoichiometry tasks that deal with molar mass and the law of mass conservation. These tasks typically include the process of balancing chemical equations by adding stoichiometric coefficients to them, calculating the molar mass of compounds, or calculating missing quantities of reactants and/or products in problems where quantities are given in terms of mole or mass. According to the categorisation of proportional stoichiometry tasks made by Ramful and Narod (2014), such tasks belong to the two lowest categories. Each of these tasks can be solved in different ways, using not only procedures learnt during chemistry lessons, but also mathematical procedures based on the concept of ratio. For instance, in the task presented at the top of Table 1, the solver can base the solution on a purely chemistry algorithm for oxidation-reduction (see the left side of Table 1) or proceed from the fact that chemical equations inform us in a special way about ratios of individual elements present in the compounds. In the latter case, no oxidation numbers are needed to solve the problem, only equivalent ratios (see the right side of Table 1).

Table 1: A sample of a stoichiometry task (top), a chemistry procedure using oxidation-reduction (left) and a mathematical procedure using ratios (right).

<table>
<tr><td colspan="2">Add the stoichiometric coefficients to the chemical equation: $Al + SiO_2 \longrightarrow Al_2O_3 + Si$</td></tr>
<tr><td>$Al^0 \rightarrow Al^{III}$ 3 4
$Si^{IV} \rightarrow Si^0$ 4 3
$4\ Al + 3\ SiO_2 \longrightarrow 2\ Al_2O_3 + 3\ Si$</td><td>$Si : O = 1 : 2 = 3 : 6$
$Al : O = 2 : 3 = 4 : 6$
$Si : Al = 3 : 4 \Rightarrow 3\ Si, 4\ Al$
$\Rightarrow 3\ SiO_2$
$\Rightarrow 2\ Al_2O_3$</td></tr>
</table>

Empirical research focusing on the mathematical side of lower secondary school stoichiometry tasks is rather scarce. In addition to Ramful and Narod (2014) mentioned above, this issue of mathematics and stoichiometry was also addressed in detail by Gabel et al. (1984); however, both papers follow the perspective of didactics of chemistry and at higher levels of schooling. Ramful and Narod (2014) studied solutions provided by prospective chemistry teachers and found that it was not easy for them to transfer their knowledge of ratios from mathematics to chemistry. Gabel et al. (1984) showed that high school chemistry students preferred chemistry algorithms to mathematically based procedures and, at the same time, displayed weak knowledge of included chemistry concepts.

Teacher knowledge

Teacher knowledge is a complex matter that can be construed from different perspectives, all of them reflecting in its own way how and why content knowledge is or is not passed out to students. As most useful for the presented study, we found the perspectives of conceptual knowledge in mathematics (Hiebert & Lefevre, 1986) and mathematics teacher's specialised knowledge (Carrillo-Yañez et al., 2018). Conceptual knowledge is defined as "knowledge that is rich in relationships" (Hiebert & Lefevre, 1986, p. 3) and as such can generalise to other situations. Also, when procedures are learnt conceptually, they can be applied in new contexts. In our case, when mathematical knowledge of the topic of ratio is conceptual, the concept of ratio can be noticed in stoichiometry tasks and so procedures known from mathematics can be applied in such tasks. Mathematics teachers' specialised knowledge (Carrillo-Yañez et al., 2018) is divided into (i) mathematical knowledge consisting of knowledge of topics, knowledge of the structure of mathematics, and knowledge of practices in mathematics; and (ii) pedagogical content knowledge consisting of knowledge of mathematics teaching, knowledge of features of learning mathematics, and knowledge of mathematics learning standards. *Knowledge of topics* includes not only definitions, properties, models, representations, and procedures, but also different associated contexts, awareness of applications, and connections to content from other disciplines. *Knowledge of mathematics teaching* includes knowledge of different ways of representing content and also knowledge of resources, teaching materials, textbooks, tools, etc., their potential and limits; *knowledge of mathematics learning standards* includes sequencing of the topics, that is, ways of connecting prior, current, and future knowledge. In our case, *knowledge of the topic* is relevant for knowing the context of stoichiometry tasks as associated with the topic of ratio, *knowledge of mathematics teaching* for knowing different ways of representing ratio within the context of stoichiometry tasks, and *knowledge of mathematics learning standards* for connecting the seventh-grade topic of ratio with its eight-grade application in stoichiometry.

Materials and methods

We conducted a qualitative study (Holton, 2007) with six in-service secondary school teachers of mathematics and chemistry as participants; we labelled them R1 to R6. Four of them have a shorter teaching experience (up to 6 years; R1, R2, R3, R5), and the other two have a long one (more than 20 years; R4, R6). All except R4 studied the teacher education programme at our university. All except R5 were mathematics or chemistry teachers of students from the previous study (Čech & Samková, 2024), but none of them taught both subjects to them. Having a different teacher for mathematics and chemistry is a common practice in secondary schools in our country.

To collect data, we assigned the participants a paper and pencil worksheet containing a mixture of application tasks related to ratios, all suitable for the lower secondary school level. Some of the tasks were located in usual everyday practical contexts used in our country during mathematics lessons (e.g. mixing muesli ingredients in a given ratio), and others in scholarly contexts from chemistry lessons. The tasks were ordered by complexity. The five less complex tasks at the beginning of the worksheet served as a warm-up, and the participants could solve them in any way they were comfortable with. The two most complex tasks at the end of the worksheet (Table 2) formed the main data collection instrument. To obtain detailed information on conceptual and specialised knowledge, we employed comparisons of multiple solution strategies (Durkin et al., 2017) and asked the participants to solve each of the tasks in three different ways and then relate the procedures to their own teaching practice.

Table 2: The assignment of the two most complex task

T6	Add the stoichiometric coefficients to the chemical equation. Find the ratio of the mass of the elements in the CaO compound. How many grammes of calcium and how many grammes of oxygen are produced from 490 grammes of CaO? element | g/mol O | 16 Ca | 40 $CaO \longrightarrow Ca + O_2$
T7	Using the chemical equation, find how many g of Al and SiO_2 were used to prepare 408 g of Al_2O_3. First, add the stoichiometric coefficients to the chemical equation. element | g/mol O | 16 Al | 27 Si | 28 $Al + SiO_2 \longrightarrow Al_2O_3 + Si$

During data analysis, we first open-coded all data materials related to T6 and T7. When coding procedures, we divided them into individual steps and monitored instances where an explicit mathematical or chemistry approach was used. We also highlighted all the places that seemed interesting from the perspective of conceptual knowledge. Then, we compared the codes across all procedures provided by individual participants and across all participants. Afterwards, we went through the texts relating the procedures to teaching practice and monitored instances relevant to teacher knowledge. Finally, we compared the procedure codes with the teaching practice codes and sought relations and patterns to create code categories. At the end of the process, we applied theoretical coding with respect to the two knowledge frameworks (Carrillo-Yañez et al., 2018; Hiebert & Lefevre, 1986). In the Results section, we focus on data related to T6, as this task had higher data density.

The two authors cooperated during the coding process: first, we worked separately, then we discussed and compared our codes and categories and reflected on the comparisons. This process also included several semi-structured interviews conducted by the second author, in which the first author (who has the same specialisation and graduated from the same university as most of the participants) explained and clarified some aspects and circumstances related to the course of initial teacher education at our

university, to textbooks, and to common teaching practice. This additional perspective allowed for a more accurate interpretation of collected data. We took written records of the interviews.

Results

As shown in Table 3, the six participants presented solution procedures of various quantities and backgrounds. Particular samples for task T6 are presented below.

Table 3: Types of solution procedures provided by participants for tasks T6 and T7; shaded are procedures declared as "I would use it in my own practice"

	T6			T7		
	procedure 1	**procedure 2**	**procedure 3**	**procedure 1**	**procedure 2**	**procedure 3**
R1	ratios	molar mass & rule of three		molar mass & rule of three		
R2	molar mass	ratios	rule of three	molar mass	molar mass	
R3	molar mass	rule of three	ratios	molar mass	rule of three	ratios
R4	molar mass	rule of three		rule of three		
R5	ratios	ratios	molar mass	ratios	rule of three	molar mass
R6	rule of three	ratios		rule of three	ratios	

For T6, the participants altogether provided four different types of solution procedures: based on a chemistry approach with molar mass (for a sample, see Figure 1), on the rule of three (a mathematical algorithm commonly used in our country to solve tasks on proportionality; Figure 2), on ratios (Figure 3 left), and on a combination of chemistry and mathematical approaches (Figure 3 right).

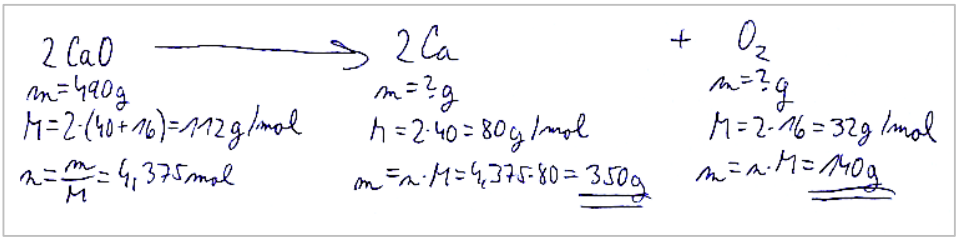

Figure 1: A chemistry-based procedure with molar mass provided by R3 for the task T6

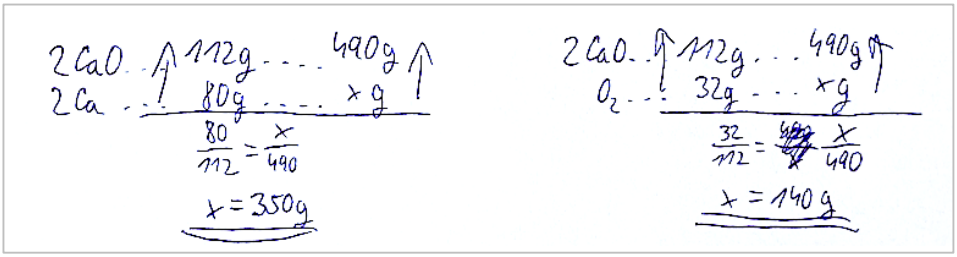

Figure 2: A mathematically-based procedure with the rule of three provided by R3 for the task T6

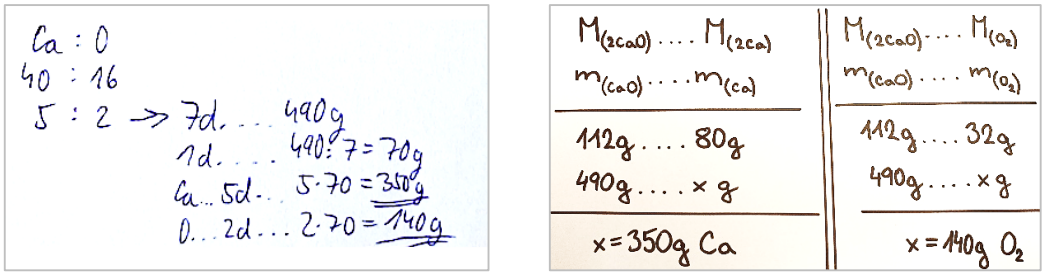

Figure 3: A mathematically-based procedure with ratios provided by R3 for the task T6, "d" is a Czech abbreviation for the word that has the same meaning as "part" or "parts" in English (left); a mixed-type procedure with molar mass and the rule of three provided by R1 for the task T6 (right)

Responses relating the procedures to participants' own teaching practice varied a lot. We found three patterns in them, represented by participants R3, R6, and R2. Participants R3 and R2 provided similar solution procedures but with opposing opinions on those that were based on ratios:

R3/molar mass: I use this procedure in my teaching because students know the formula 

R3/rule of three: I use this procedure in my teaching because some students prefer the rule of three to the formula.

R3/ratios: I do not use this procedure in my teaching because students see only mathematics in it. Chemistry is removed from this procedure.

R2/all: I use all these procedures and decide between them individually according to the needs of the student.

R6 presented just mathematically-based procedures and wrote:

R6/rule of three: I use it because it is easy. Students know the rule of three.

R6/ratios: I use it because it uses ratios that students work with in mathematics.

According to the findings mentioned above, the interview between the second and the first author focused on aspects that could impact the awareness of the procedure based on the ratios and its active use in the classroom. A detailed discussion on the content of the courses on didactics of mathematics at our university revealed a possible key moment. During the courses, individual mathematical topics were discussed, prospective teachers gave presentations about them, and, among others, sought and showed various textbook tasks related to the topics. These textbook tasks usually served as the outline of the presentation. Since the textbooks include only applications to other disciplines already familiar to students (e.g. a map scale at the time when ratio is taught), the seventh-grade mathematics textbook with the topic of ratio does not include the application to the eighth-grade chemistry topic of stoichiometry. In addition, eighth or ninth grade mathematics textbooks do not return to the ratio topic. Therefore, from the perspective of mathematics, such future applications remain unaddressed in the textbooks and remained unaddressed during the courses on didactics of mathematics.

Discussion

As an answer to our research question *How do secondary school teachers specialising in both mathematics and chemistry perceive the concept of ratio in application contexts given by lower secondary school chemistry tasks on stoichiometry?* we may state that the teachers participating in our study are mostly aware of the possibility to apply the concept of ratio in the context of chemistry

stoichiometry tasks (so, the relationship between ratio and stoichiometry is fully perceived) and so that they learnt the topic of ratio conceptually (Hiebert & Lefevre, 1986). This is in contradiction with the findings of Gabel et al. (1984) as the teachers in our study are able to transfer their knowledge of ratios from mathematics to chemistry. However, some of the teachers do not consider such applications suitable for their own teaching practice (e.g. R3/ratios) or implement them in a way that would result in students noticing the concept of ratio in stoichiometry tasks (Čech & Samková, 2024).

From the perspective of *mathematics teacher's specialised knowledge* (Carrillo-Yañez et al., 2018), the teachers in our study know different contexts associated with the concept of ratio and are aware of its applications. That is, their *knowledge of topics* is sufficient. For themselves, they can connect mathematics to other disciplines, namely chemistry. However, our findings indicate that, at least for some of the teachers, there are weaknesses in *knowledge of mathematics teaching*: the teachers know different ways of representing content and various textbooks, but they may not be aware of their limits. In this particular case, applications to other disciplines appearing in available textbooks address current and prior knowledge only, but not future knowledge. In that sense, the lack of awareness of such limits also relates to weak *knowledge of mathematics learning standards*. During the interview in our study, it turned out that the courses on didactics of mathematics at our university could also have such weaknesses. These revelations bring the following implication for initial teacher education courses: To fix the weaknesses found, the theme of possible future applications of individual mathematics topics should be explicitly added to the content of the courses on didactics of mathematics. Ideally, it can be done together with the instruction for prospective teachers to look for materials and resources outside the textbooks, cover lower secondary school textbooks for higher grades and other school subjects, and create new materials that would reflect various possible future applications of the topic. Another implication concerns the timing perspective, both for the initial teacher education and for classroom practice. It remains to be explicitly acknowledged that future applications of the sixth to eighth grade mathematics topics can be addressed during the ninth grade, where a final repetition of all lower secondary school topics takes place. As a part of the repetition, a new perspective on various lower secondary school topics can be introduced to students, for instance, in a format using comparisons of multiple solution strategies (Durkin et al., 2017). In particular, the ratio-based procedures to eighth-grade stoichiometry tasks can be discussed and contrasted with other applications of the concept of ratio already known to students from seventh-grade mathematics.

Having the tasks in our data collection materials related to chemistry, we also have to consider the perspective of didactics of chemistry. We do not suggest forgetting the chemistry procedures that are important for future and more complicated upper secondary chemistry tasks (e.g. for the higher-level tasks in Ramful & Narod, 2014). However, we suggest enriching them by including also the mathematical procedures, that is, by including the perspective of didactics of mathematics. In this way, conceptual knowledge in both mathematics and chemistry can be enhanced by acknowledging connections between concepts in different disciplines (Hiebert & Lefevre, 1986).

As educators of mathematics teachers, we cannot influence what happens in chemistry classes and courses on didactics of chemistry, but we can still include chemistry applications in mathematics teaching and courses on didactics of mathematics. If these applications are lower secondary school applications, they have been completed by all prospective secondary school mathematics teachers

(regardless of their other specialisation), because they all had attended lower secondary school. Thus, chemistry applications can be included in initial education courses for mathematics teachers, even if most of the attendees of these courses do not have chemistry as their other specialisation.

Pre-service mathematics teachers' conceptualizations and noticing of algebraic thinking

Makbule Gözde Didiş-Kabar[1] and Janet Walkoe[2]

[1]Tokat Gaziosmanpasa University, Faculty of Education, Tokat, Türkiye; gozde.didis@gop.edu.tr

[2]University of Maryland, College Park, USA

This study investigated how an intervention based on video clubs designed using a novel perspective on algebraic thinking supported middle school pre-service mathematics teachers' (PSTs) noticing of students' algebraic thinking. This research was conducted as part of a mathematics methods course that integrated the intervention in the course context. At the end of the intervention, post-interviews were conducted with five PSTs. The findings indicated that the intervention had supported PSTs in interpreting students' algebraic thinking from a broad perspective, including both students' early nascent algebraic reasoning and their more advanced conceptual algebraic ideas.

Keywords: *Algebraic thinking, seeds of algebraic thinking, noticing, pre-service mathematics teachers, video clubs.*

Introduction

The National Council of Teachers of Mathematics [NCTM] (2000) underscores the importance of algebraic thinking, stating that all students should learn algebra, as algebraic competence crucial in post-secondary education and in the workforce. Therefore, algebra plays a critical role in school mathematics. NCTM (2000) emphasizes that algebra includes more than symbol manipulation by displaying the four fundamental ideas of algebra: "Students' understanding of patterns, relations, and functions; students' representing and analyzing mathematical situations and structures using algebraic symbols; students' using mathematical models to represent and understand quantitative relationships and students' analyzing change in various context" (p. 37). Furthermore, Kieran (2004) points out that early algebraic thinking focuses on activities such as proportional thinking, problem solving, noticing structure, and analyzing relationships among quantities. Different characterizations of algebra and algebraic thinking offered in the literature (e.g., Kaput, 2008; Kieran, 2004; NCTM, 2000) provide a broad perspective on the scope of algebraic thinking, and algebra is approached as a way of thinking in a dynamic structure.

Students can display various algebraic reasoning while engaging in mathematical tasks. Driscoll and Moyer (2001) stress that when teachers have insight into students' algebraic thinking, they can design their courses to enhance and further their learning. So, it is essential that teachers can notice and reason about students' emergent algebraic thinking during classroom instruction. A teacher's capacity to recognize and interpret student's ideas thinking and make decisions based on student thinking has been referred to as "teacher noticing" (Jacobs et al., 2010). Teacher noticing has been identified as an essential teaching skill. Jacobs et al. (2010) define professional noticing of children's mathematical thinking as involving three interrelated skills: "attending to children's strategies, interpreting children's understandings, and deciding how to respond on the basis of children's understandings" (p. 172). Teacher noticing has been a topic of interest in mathematics

teacher education research; however, more research is needed, focusing on specific content domains. Walkoe (2015) examined the development of pre-service teachers' noticing of algebraic thinking rather than on particular algebraic concepts during a methods course that engaged PSTs in a video club. Seven pre-service teachers watched and discussed videos from algebra classes using an online video tagging tool. The findings displayed those PSTs tended to be more evaluative and descriptive while discussing students' algebraic thinking in early sessions; however, their discussions about student thinking were more substantive in the later sessions.

Pre-service teachers' noticing skills, particularly in a specific mathematical domain, should be supported through different interventions or professional development activities designed to support developing their noticing skills. As Walkoe (2015) stated, when teachers' noticing in algebra is developed, teachers could be better supported to engage with students' algebraic thinking in classroom. Therefore, investigating teachers' noticing of student thinking in algebra is crucial. This study aims to investigate how a video club intervention supports middle school pre-service mathematics teachers' (PSTs) noticing of students' algebraic thinking. The intervention focused on pre-service teachers' attention to children's formal and pre-formal algebraic thinking by incorporating a "Seeds of Algebraic Thinking" framework that allowed teachers to reason about students' nascent algebraic reasoning (see Walkoe and Levin, 2020). PSTs' noticing was enhanced and tracked using a video annotation tool (www.anotemos.org). This study extends prior research on teacher noticing of student algebraic thinking in a video club context. The following research questions guided this study: *To what extent does an video-based intervention designed using Seeds of AT perspective support PSTs' noticing of students' algebraic thinking?; What is the level of PSTs' noticing of students' algebraic thinking as they participated in an video-based intervention that leverages the Seeds of AT perspective?; What is the level of PSTs' noticing of students' algebraic thinking who did not participate in the video-based intervention?*

The Seeds of Algebraic Thinking

The Seeds of AT perspective, a theoretical perspective introduced by Walkoe and Levin (2020), highlight sub-conceptual cognitive resources that stem from children's early, pre-instructional experiences. This perspective suggests that larger concepts in algebra are constructed from sub-conceptual pieces, with the roots of these pieces originating from a child's lived experiences. These seeds, as pre-instructional resources, are not inherently related to algebraic concepts. Walkoe and Levin (2020) highlighted the crucial role of children's pre-instructional experiences in their later mathematics learning. "Balance", "in-betweeness", and "closing-in" are three examples of seeds of algebraic thinking the authors discuss (Levin & Walkoe, 2022; Walkoe & Levin, 2020). For instance, balance is a resource children gain early in life as they learn to walk or balance on a teeter totter. Later, in formal algebra, balance serves as a productive resource for relational understanding, a concept that can be confusing early on for algebra students (Walkoe & Levin, 2020).

Methods

This study utilized a case study research design. Two different cases—the noticing levels of PSTs who participated in the intervention, those who did not—were investigated.

Research Context and Participants

This research was conducted as part of a mathematics methods course offered to middle school mathematics teachers in their third year in the 2023–2024 academic year at a large Mid-Atlantic, public university in the US. The course had various general and specific goals. One of the particular goals of this course was to explore the impact of a Seeds of AT framework (Walkoe & Levin, 2020) on the video club (VC) intervention. This study involved five pre-service middle school mathematics teachers. Three volunteer PSTs who attended the intervention were chosen for interviews (PST1, PST2, and PST3). Additionally, to explore the impact of the intervention, two volunteer PSTs, who did not enroll in this methods course, were also selected for the interviews (PST4 and PST5). PST4 and PST5 were in their fourth years in the same program. These PSTs had enrolled in the methods course in previous year; however, they did not participate in the intervention discussed in this study, while taking the methods course. As this interview was conducted, PST3, PST4 and PST5 had taken the mathematics course "Algebra for Pre-service Middle School Teachers".

Intervention

The PSTs participated in a series of six VCs (see Figure 1). Before each VC session, as part of the VC professional development, PSTs worked on a mathematical task (e.g., Rat-a-Tat Cat, Flag Area,) that they would see students engaged in in the video. During the VC sessions, PSTs individually watched short video clips (4–10 minutes), which included students/kids' discussions or classroom excerpts while they were engaging in these mathematical tasks. These videos were selected by the second author based on her video library. PSTs watched the videos on an online platform where they could observe students' algebraic thinking. Then, they tagged and commented on moments when they noticed students thinking algebraically. The tags and annotations were logged in the system and the facilitator had access to PSTs' tags and comments.

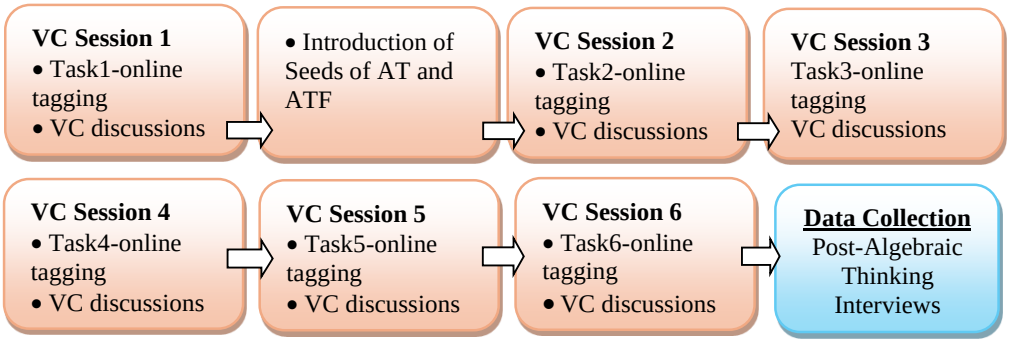

Figure 1: The design of VC professional development and data collection

Furthermore, as seen in Figure 1, PSTs were introduced to the Seeds of AT perspective and an Algebraic Thinking Framework (ATF) (Walkoe, 2015) before attending the second VC session and a class meeting was held to discuss these frameworks. The two instructors of the course facilitated the VC sessions. Finally, when PSTs finished annotating the videos, the PSTs and the facilitators discussed the nature of the students' algebraic thinking and the seeds they observed in the video clips. During the VC discussions, the facilitator pointed out PSTs' tags and invited them to share their thoughts. The facilitators pushed PSTs to articulate what they noticed and why they found that

particular moment interesting using prompts such as, "What about this video is possibly algebraic? What about the balance is algebraic for you?".

Data Collection Process

After the VC sessions concluded, to investigate PSTs' noticing of students' algebraic thinking, the post-interviews were conducted with five volunteer PSTs. In the post-interviews, PSTs were asked to examine five mathematics questions (e.g., see Figure 2 and 3) selected from previous research studies or adapted from the online resources along with possible student solutions of these questions. PSTs were asked the following questions to focus more on the PSTs' noticing of students' algebraic thinking. These questions were: Describe in detail, "Where do you notice students' thinking algebraically? How can you interpret this student's response? What did you learn about this student's understanding?". The data for this study were PSTs' post-interviews.

Data Analysis

We used content analysis to analyze the data obtained through post-interviews. To determine each PST's attending and interpreting levels, we coded for the depth of PSTs' explanations, where they described and interpreted students' algebraic thinking on the student solutions to five mathematics questions. We used the codes described in Table 1, which were informed by teacher noticing research, particularly Jacobs et al. (2010), Walkoe (2015) and Sherin and van Es (2009). We traced how PSTs' explanations connected with students' algebraic thinking.

Table 1: Noticing students' algebraic thinking coding scheme

<table>
<tr><th>Attending</th><th>Interpreting</th></tr>
<tr><td>Level 0: No evidence. Participants do not provide details of students' algebraic thinking.</td><td>Level 0: No evidence. Participants interpret students' strategies/thinking ways in a general sense without attending to students' AT; not connected with student's algebraic thinking. They talk about general teaching and learning issues.</td></tr>
<tr><td>Level 1: Participants provide some evidence of attention to students' algebraic strategies/ways of thinking by either describing or evaluating.</td><td>Level 1: Limited evidence. Participants superficially interpret students' strategies/thinking ways; connected with students' AT (formal algebra, procedural), providing less evidence and narrow level (one idea).</td></tr>
<tr><td rowspan="2">Level 2: Participants provide much evidence of attention to students' algebraic strategies/ways of thinking.</td><td>Level 2: Limited evidence. Participants interpret students' strategies/thinking ways using some evidence; connected with students' AT (procedural or conceptual), not so wide (at most two ideas).</td></tr>
<tr><td>Level 3: Robust evidence. Participants interpret many details of student strategies/thinking using much evidence, connected with students' AT in terms of formal algebra and early algebraic ideas (e.g., seeds); Mainly conceptual, broad level (more than two ideas).</td></tr>
</table>

Results

The analysis of the interview data showed that PSTs, who participated in VC intervention, could provide evidence of attention to students' algebraic thinking strategies. However, even though one PST (PST1) was able to provide evidence of attention to students' algebraic strategies, she interpreted students' algebraic ways of thinking superficially and provided less algebraic evidence. Therefore, PST1's noticing student algebraic thinking level was at Level 2 (L2) in terms of attending and mostly at Level 1 in terms of interpreting. She generally interpreted students' algebraic ideas at narrow and procedural levels by focusing only on algebraic ideas. On the other hand, two PSTs (PST2 and PST3) noticed the level of student algebraic thinking in terms of attending and interpreting were at the top levels (see Table 2).

Table 2: PSTs' noticing level of student algebraic thinking

	Attending					Interpreting				
Questions	PST1	PST2	PST3	PST4	PST5	PST1	PST2	PST3	PST4	PST5
Q1	L2	L2	L2	L2	L2	L1	L3	L3	L2	L2
Q2/S1*	L2	L2	L2	L1	L2	L2	L3	L3	L2	L1
Q2/S2	L2	L2	L2	L1	L2	L2	L3	L3	L1	L1
Q3	L1	L2	L2	L2	L2	L1	L3	L3	L2	L1
Q4/S1	L2	L2	L2	L2	L2	L1	L3	L3	L2	L2
Q4/S2	L2	L2	L2	L1	L2	L1	L3	L3	L1	L2
Q5	L1	L2	L2	L2	L2	L2	L3	L2	L2	L1

* Q2 and Q4 include two students' solutions (S1 and S2). Q1, Q3 and Q5 include only one student solution.

On the other hand, the analysis of the interview data showed that like other PSTs, the PST4 and PST5 who did not participate in VC intervention could provide ample evidence of attention to students' algebraic thinking strategies. Particularly, PST5's attending level was consistently at Level 2. However, unlike the PST2 and PST3, who participated in VC intervention, these PSTs interpreted students' strategies/thinking at a limited level. As seen in Table 2, their interpreting levels were either at Level 1 or Level 2. That means these PSTs mostly did not interpret the details of students' algebraic strategies using evidence and they did not attend to conceptual aspects of students' strategies.

Q1: What number goes in the __? $37 + 54 = __ + 55$ (Stephens, 2008).
Student's solution: "36 goes in the box. 55 is one more than 54, so the number in the box has to be one less than 37, so it's 36".

Figure 2: Solution (S) for Question 1 (Q1)

When PST2 examined the student's solution in Figure 2, she noticed how the student's understanding of algebraic thinking was evident in their solution. The student's thought process, "36 goes in the box; because 55 was more than 54, the number in the box must be less than 37" was a demonstration of relational understanding. According to PST2, the student's focus on the relationship between numbers demonstrates this understanding. Furthermore, PST2 provided the conceptual underpinnings of algebraic thinking by mentioning the balancing idea behind the student's solution. The excerpt of PST2 for this solution was as follows.

> PST2: …What the student did is they focused really on the balancing portion, and they really focused on just seeing the numbers as individual things they needed to compare them to, umm, I feel like this works with this equation…What I can tell from the students' solution is that they might not be used to missing variable equations, so because balancing is something that is an algebraic seeds that kids learn from a young age through many different forms…

Like PST2, PST3 noticed the algebraic idea behind the student's solution and interpreted the student's idea conceptually. PST3 pointed out the student's use of relational understanding of the equal sign. PST3 interpreted this as an early form of algebraic thinking, referencing the student's use of "the balance idea" in the solution. This interpretation by PST3 not only acknowledged the student's progress but also focused on the early algebraic ideas at a broad level. On the other hand, PST4 could recognize student's relational understanding of equal sign and interpret student solution by pointing out student's understanding, too; however, PST4 did not focus on the balance idea and interpreted student's thinking at a less broad level than PST2 and PST3, as shown in the following excerpt.

> PST4: I can learn that they have a good understanding of what the equal sign means here. And an understanding of what we must do to keep those numbers equivalent, meaning keeping 37 plus 54, equivalent to blank plus 55. And they understood that, if we added one somewhere, we take it away to keep it at the one.

When PST1 examined the student's solution, as shown in Figure 3, she just described it by comparing her thinking. While interpreting, PST1 connected with the student's algebraic thinking by pointing out why the student might have constructed algebraic expressions rather than equations. However, PST1's interpretation was narrow, ambiguous and did not include much more understanding of the student's algebraic thinking details. PST1's attending and interpreting level for this question was Level 1.

Q3: Classify all numbers that leave a remainder of 3 when divided by 5 and a remainder of 1 when divided by 3.
Student's solution: Students writes $5x+3$ and $3x+1$ on her paper and stops there.

Figure 3: Student solution (S) for Question 3 (Q3)

Similarly, PST5's interpreting level was at Level 1. As presented below, PST5 pointed out the student's formulation of an equation by using a variable and focused on the student's good understanding of algebra. Even though she connected with algebra, her interpretation was general and procedural without providing more detail about the student's strategy.

> PST5: I think they show a pretty good understanding of algebra and how to use algebra, to kind of set up things to then be able to solve. So, I think a lot of the times we work problems like this, the hardest part for students...I think that students did the hard part, which is making an equation out of these words, and putting a variable in there.

> Although they didn't solve for x, or anything, I think it shows pretty good algebraic understanding.

On the other hand, PST3 viewed the students' solution from a broader perspective, recognizing the potential of their abstract thinking: "I think they're definitely thinking algebraically in terms of thinking a little bit more abstractly…" and "use of working backwards idea", "... I think maybe they're trying to use algebra and the idea of working backwards, and that's where the $5x$ plus 3 and the $3x$ plus 1 comes from".

Discussion and Conclusions

The findings showed that although the attending levels of all PSTs who participated and non-participated in the intervention were nearly the same, their interpreting levels differed. All PSTs could notice and provide some evidence of attention to students' algebraic strategies in their solutions; however, not all could provide robust evidence by connecting with students' conceptual algebraic thinking while interpreting students' solutions. We found that the intervention supported two PSTs (PST2 and PST3) in interpreting students' algebraic thinking from a broad perspective, and their interpretation of students' solutions algebraically included both students' early algebraic perspective and conceptual algebraic ideas used in their solutions. For instance, in the solution of the open box (Q1) question, they could notice and interpret students' use of balance, which is a productive resource that comes into play when thinking about the relational understanding of the equal sign (Walkoe & Levin, 2020, p.30). In the solution to the Q3, they could notice students' working backwards idea to set up an equation from a word problem. Teachers' noticing of students'early algebraic ideas not only helps them understand where these ideas may originate based on students' experiences but also supports students' formal algebraic thinking in later stages (Levin & Walkoe, 2022). One of the reasons why the intervention might have supported two PSTs' interpreting is related to their rich class discussions on PSTs' noticing of students' use of small-grained algebraic ideas. Through online tagging tools, PSTs attended to students' algebraic thinking. In the VC discussions, PSTs deeply interpreted students' algebraic thinking in terms of not only fully formed conceptions, but also nascent ideas. In addition, they discussed various seeds, such as balance, replacement and greater or less in algebraic or non-algebraic contexts, which they observed and tagged in the videos. So, all these factors may impact on two PSTs' high-level interpretation.

On the other hand, we did not observe any prominent impact of the intervention on PST1's interpreting level. The data displayed that the attendance and interpretation of PST1s were nearly the same as that of PST4 and PST5. PST1 could interpret students' solutions by connecting with the algebra; however, she mainly provided limited evidence of students' algebraic thinking from a narrower perspective than PST2 and PST3. There may be various reasons why the intervention did not have a distinctive impact on PST1's interpreting level. PST1 might have displayed less effort in attending to students' algebraic thinking while watching the videos or discussing their noticing, or the intervention time may not be enough to make sense of the Seeds of AT perspective. This study suggests that the video-based intervention designed using the Seeds of AT perspective has potential to support PSTs' noticing students' early and nascent/developing algebraic thinking. However, the findings of this study were limited only to post-interview data, and the analysis of individual video

tags and class discussions will provide more robust evidence to understand the support of intervention.

Teaching with technology to foster conceptual understanding: Student level evaluation of a professional development programme

Susanne Digel[1] and Jürgen Roth[1]

[1]RPTU University of Kaiserslautern-Landau, Mathematics Education, Landau, Germany; s.digel@rptu.de

The digital transformation of schools is imminent, yet numerous obstacles persist that hinder the effective integration of technology-enhanced teaching (TET). As pointed out in the PISA framework, technology can support student learning when benefits are exploited for teaching quality. Teachers themselves report a lack of skills for technology integration to foster understanding and learning, and call for professional development programmes on technology-enhanced teaching. This paper outlines the concept and evaluation of the professional development programme MaTeGnu for upper secondary schools fostering understanding through TET with a focus on basic mental models. In the evaluation of student learning as the most remote level of PD success, students from classes of MaTeGnu teachers demonstrated higher understanding of the concept of derivative than their peers. Consequently, a focus on basic mental models appears to be promising for PD in this context.

Keywords: Technology-enhanced teaching, professional development programme, evaluation, conceptual understanding, digital tools.

Technology-enhanced teaching

The International Computer and Information Literacy Studies 2018 and 2023 show that schools in Germany have adopted technology-enhanced teaching (TET) only at a low level (Fraillon et al., 2020). Even when using TET, teachers often do not fully exploit the potential of technology but use it as substitute in traditional teaching processes (e.g., for presentation or as textbook; Backfisch et al., 2021). At the same time, teachers report a lack of agreed TET principles for beneficial learning and corresponding quality teaching material, as well as a high demand of PD programmes (Mußmann et al., 2021). Since research in mathematics education has carved out and validated several findings on how technology enhances student learning (e.g., Digel et al., 2023; for an overview see Hillmayr et al., 2020), a major leverage to foster TET is to implement effective teacher professional development programmes for teaching with technology, enriched with adequate teaching material.

MaTeGnu – a professional development programme on TET focusing on basic mental models

A relevant shortfall of upper secondary school mathematics teaching is the focus on formalisms, which is often not accessible to students. This is often justified as a preparation to higher levels of abstraction at universities, but Rach and Ufer (2020) have shown that procedural knowledge without a conceptual basis is not sufficient for academic success while at the same time formal representations are dispensable. A conceptual foundation needs basic mental models that guide the teaching and learning process (Greefrath et al., 2023). The professional development programme MaTeGnu (Teaching mathematics with technology effectively focusing on basic mental models) aims at fostering understanding in upper secondary school through TET with a focus on basic mental models. The PDP is outlined as a three-year course, accompanying teachers with their math course through a

complete cycle from the beginning of upper secondary school to the A-levels. Each module is dedicated to the understanding of one concept (derivative, integral, vectors and matrices, hypothetic-prognostic probability, exponential growth) using TET to learn the respective basic mental models.

The concept of derivative

This study evaluates the module on derivatives. Greefrath et al. (2023) describe four basic mental models (BMMs) characterizing the concept of derivative: (RC) local rate of change, (TS) tangent slope, (LA) linear approximation, and (AF) amplification factor. RC uses the understanding of the mean rate of change, but unlike that it is not a quotient, but the limit of quotients. TS uses the idea of a tangent as a clinging straight line to the graph. LA can be described with a "function microscope": when zooming in on the graph it appears as a straight line and the relationship represented by the graph can be described locally by a linear relationship. AF views the derivative as a proportionality factor, indicating how (small) changes in the independent variable affect the dependent variable.

Teachers' professional knowledge on technology-enhance teaching (TET)

As previously indicated, the integration of technology does not automatically enhance the quality of teaching. The teaching quality itself can be operationalized with the four aspects cognitive activation, individual learning support, classroom management and cognitive support (Kleickmann et al., 2020). To exploit the benefits of technology for teaching quality, teachers need to build professional knowledge on TET as described in the TPACK model (Mishra & Koehler, 2006). First, teachers need technological knowledge (TK) to handle digital educational tools, like for example the dynamic mathematics software GeoGebra which is widely used in mathematics classes. Teachers also need technological content knowledge (TCK) to use these tools, for example to calculate derivatives or integrals. They also need technological pedagogical knowledge (TPK) to organise students' interaction and documentation of their work with a digital tool. Finally, the facet TPCK describes teachers' crucial technological pedagogical content knowledge, necessary to use features of a digital tool deliberately to foster the learning process of their students (e.g., the use of multiple representations and systematic variations in GeoGebra to foster students' representational flexibility and their basic mental models of functions (Digel et al., 2023). TPCK thus enables teachers to exploit the potential of technology to enhance teaching quality.

Changing teaching practice in a professional development programme

Participating in a TET professional development programme can significantly enhance teaching practice, mediated by collaboration (Konstantinidou & Scherer, 2022). In their research synthesis on effective professional development programmes related to TET, Lipowsky and Rzejak (2021) developed an offer-and-use model describing influential factors of teacher PD (see Figure 1).

Changes in teaching practice do not happen instantaneous but undergo a transfer process (Fütterer et al., 2024). This process forms the centre of the offer-and-use model. At first teachers review their lesson design regarding how technology serves the learning objectives (unfreezing). From there teachers iteratively try to reconceptualise their planning, revise the practical implementation in the context and, if convinced of the utility, implement it in the classroom (changing). As soon as they are convinced of the practical results, they consolidate their concept (freezing). This transfer process can

be fostered by a PDP, if a collaborative network is established, to accompany and support the transfer. Each module in the MaTeGnu PD consists of one-to-two-day-workshops on how to foster basis mental models with TET for one mathematical concept (e.g., derivative). The workshop combines professional knowledge on TET and basic mental models (BMMs) with evaluated teaching material and initiates the unfreezing phase. It is followed by meetings in a professional learning community (PLC), formed by 16-20 participating teachers and coached by two teacher educators. These meetings accompany the changing phase through guidance and exchange on reconceptualization and planning as well as reflection on implementation and collective revision, leading to individual freezing phases.

Evaluation of MaTeGnu

Lipowsky and Rzejak (2021) incorporate the four levels to evaluate training programs by Kirkpatrick and Kirkpatrick (2016) in their offer-and-use-model (Figure 1).

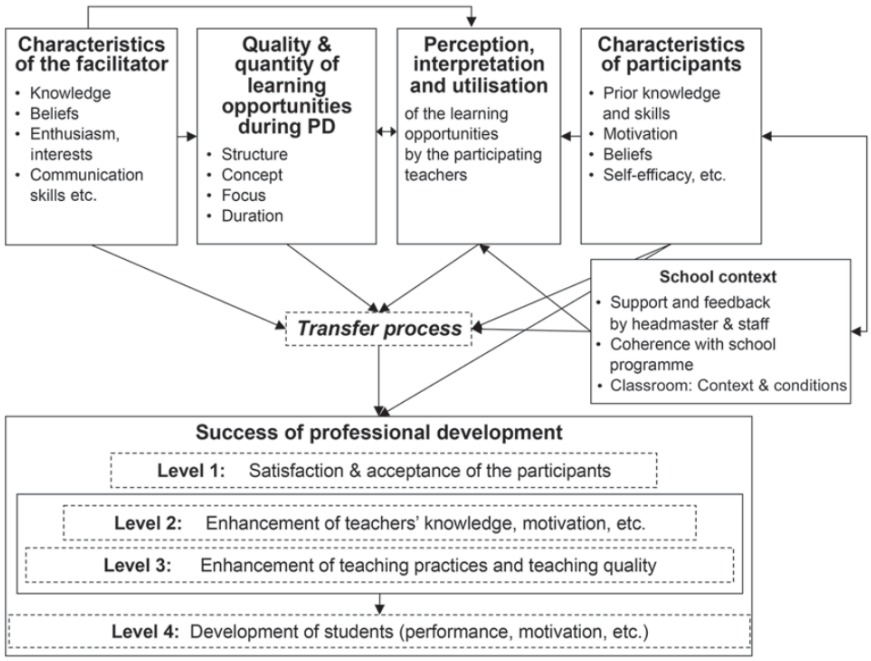

Figure 1: Offer-and-use-model on influential factors of teacher PDPs (Lipowsky & Rzejak, 2021)

The evaluation component of MaTeGnu presented in this study is located on level four: results, i.e., the development of students. Since MaTeGnu has the goal to foster understanding through TET with a focus on basic mental models, two main research questions guide this evaluation study:

RQ1: Do students in MaTeGnu math classes show different preferences for explanations of derivative with basic mental models or formal expression than students in regular math courses?

RQ2: Does the understanding of the concept of derivative of students in MaTeGnu math classes differ from that of students in regular math classes?

Level four is the most remote in the effect chain of the PD and considering the complex transfer process and the manyfold influences on the process as outlined in the offer-use-model (Figure 1), hence rather low effects are to be assumed. Nonetheless, it is a central objective of MaTeGnu with

the three-year perspective as well as intensive peer interaction and coaching network to initiate, accompany and foster the transfer process.

Method

Greefrath et al. (2023) provide a test on basic mental models of derivatives with eight questions and explanations from the perspective of each basic mental model (GV-A). We added another formal-symbolic explanation (FS) to each question and asked the students to rate the suitability of each explanation for their own explanation to a classmate on a unipolar four-point Likert-scale (see Figure 2 for sample item). Additionally, a test on conceptual understanding of derivatives (FALKE, Klinger, 2021) was used. The combined test (GV-A, FALKE) is outlined in a multi-matrix design, with a total of 58 items, distributed in six different booklets with 14 anchor items. The test time was 45 minutes.

Figure 2: Sample item: Test on basic mental models of derivatives (Greefrath et al., 2023)

The derivative f' of a function f at point x can be explained differently.					
Please rate the suitability of the following explanations for use when explaining it to a classmate.		very suitable	suitable	less suitable	not suitable
RC	The derivative indicates the local rate of change at the point x.				
TS	The derivative indicates the slope of the tangent at a point on the graph of f.				
LA	The graph can be approximated well by a straight line in the vicinity of x. The derivative indicates the gradient of this straight line.				
AF	If you move a small distance Δx from x to the right or left, the value of the function changes by $\Delta y \approx f'(x) \cdot \Delta x$.				
FS	The derivative at point x is the limit of the difference quotient $\frac{f(x+h)-f(x)}{h}$ for $h \to 0$.				

Sample of the study

To answer our research questions an experimental-vs.-control-group design has been used. The teaching material, workshop content and PLC concept have been piloted with a group of 18 expert teachers during their qualification as MaTeGnu teacher educators. The qualification has been outlined in the same way as the MaTeGnu PDP and the experts have also implemented the teaching material of the modules in their math classes. The students of these classes participated in the combined test mentioned above (GV-A, FALKE) after completing the MaTeGnu lesson series on derivative, forming the experimental group (EG). This sample consists of *n=151* students *(76* female*, 75* male*, 0* diverse) with an average age of *M=18.9* and tests were performed from June to December 2024. Before the MaTeGnu qualification of teacher educators started, each school of the teacher educators participated in the combined test with mathematics classes that had just completed the subject

derivative. This sample formed the control group (CG), since the teachers have not participated (yet) in the MaTeGnu PDP. The sample of the control group consists of *n=571* students (*256* female, *260* male, *0* diverse) with an average age of *M=17.1*. Tests were performed from June to November 2023.

Results

The reliability of both tests (GV-A, FALKE) was analysed using IRT. The GV-A Likert-scale was aggregated (suitable/not suitable) for dichotomous coding to answer RQ2. The two-dimensional Rasch model with the aggregated GV-A on the first dimension and the concept test FALKE on the second showed acceptable reliabilities (Wilson, 2005) (rel_{WLE} *= 0.64 / 0.72* (CG); rel_{WLE} *= 0.68 / 0.74* (EG)). The one-dimensional generalised partial credit model (GPCM) of the four-point Likert-scale GV-A (to answer RQ1) showed good reliabilities (ibid.) (rel_{WLE} *= 0.88* (CG) and rel_{WLE} *= 0.78* (EG)).

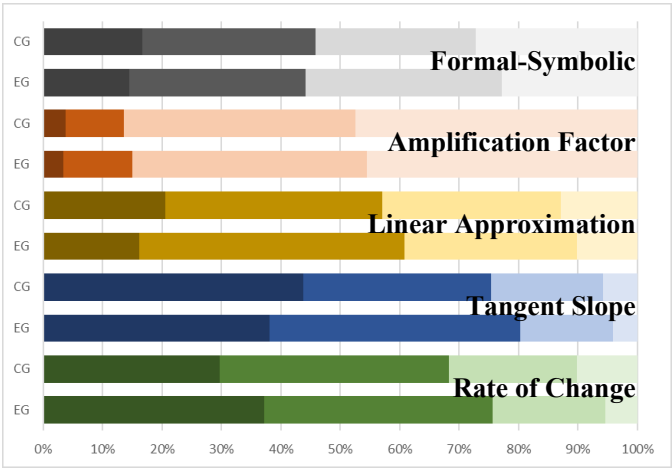

Figure 3: Likert-scale suitability ratings of the presented sample item in CG (top) and EG (bottom)

Figure 3 compares the ratings for the suitability of each explanation presented to explain the derivative to a classmate. in the control group (top) and experimental group (bottom) of the sample item. Darker colours represent higher suitability (very suitable, suitable, less suitable, not suitable).

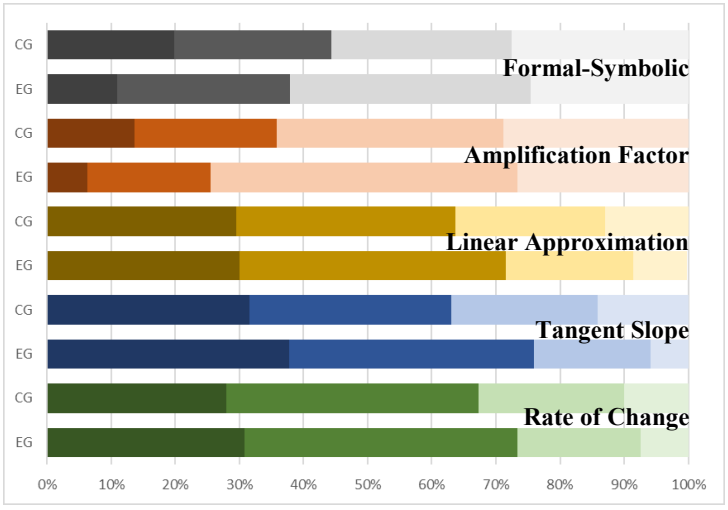

Figure 4: Aggregated ratings of all items in control group (top) and experimental group (bottom)

Figure 4 shows the aggregated ratings of all items for the suitability of each explanation presented to explain the derivative to a classmate. The ranking is similar in both groups with the highest suitability given to tangent slope (TS), followed by local rate of change (RC), linear approximation (LA) and formal-symbolic (FS), while amplification factor (AF) is rated a much lower suitability in the sample item. Comparing the ratings between control and experimental group, we identify higher ratings for tangent slope and rate of change in the experimental group. This distance is even bigger in contextualised items, where lower ratings for the formal-symbolic explanations with a considerable distance between CG and EG can be observed as well.

The overall solution rates for the FALKE test on conceptual understanding of the derivative are lower in CG (*M=0.54*) than in EG (*M=0.58*). The solution rates of individual items vary considerably but show a similar pattern in both groups (Table 1). Looking at the content of items with low solution rates (marked in Table 1) there are two clusters: 1) Graph of f given, interpret f' (Z8PC, X4TP, S3AB): e.g. graph of a function f is given, decide which of the following three properties ($f'(0)>0$; $f'(1)<0$; $f'(x)<0$ for all x) does f' possess; 2) Determine the slope in context (JSE, Y2VKc): e.g. the graph of f has to be drawn for a cone-shaped vessel that fills up with water. Items with high solution rates either 3) present a graph for f' (U3TP, W7CKa, V3RKa) or 4) use a linear relationship in context (Y2VKab, N1FR, D6LGa).

Table 1: Solution rates for FALKE test items in control and experimental group

	Z8PCa	Z8PCc	Z8PCd	Z8PCe	X4TP	S3AB	JSE	Y2VKc	U3PT	W7CKa	V3RKa	Y2VKa	Y2VKb	N1FR	D6LGa	Z8PCb	V3RKb	V3RKc
	Cluster 1)						2)		3)				4)			others		
CG	.27	.37	.25	.36	.36	.33	.46	.34	.75	.76	.78	.71	.68	.83	.84	.50	.51	.51
EG	.41	.62	.34	.44	.43	.40	.53	.35	.71	.87	.82	.73	.76	.78	.82	.49	.47	.48

Discussion

Explanations employing basic mental models (tangent slop, linear approximation and local rate of change) elicit noticeably higher suitability ratings than formal symbolic explanations in both the experimental and control group. While the presence of tangent slope in numerous schoolbooks and of local linear approximation in several German A-level tasks might explain these findings, local rate of change is not a common approach for teaching derivatives. One explanation is that the item stem have captured the accessibility of the explanation rather than reflecting the familiarity with the explanations from their math classes. In this context, the findings of this study demonstrate the significant explanatory value of basic mental models for students, thereby substantiating the comprehensive strategy of MaTeGnu to combine TET with a focus on basic mental models. There is an increase in tangent slope, rate of change and linear approximation in the experimental group, despite the high level already evident in the control group. Furthermore, the ratings for formal-symbolic explanations in the experimental group are even lower than the mediocre ratings in the control group. Regarding our fist research question, we can infer that MaTeGnu students exhibit a higher preference for explanations with basic mental models. It appears that MaTeGnu facilitates a

transition in focus from formal-symbolic to basic mental models. Furthermore, the emphasis on the rate of change in MaTeGnu renders all three basic mental models more accessible to students.

The concept test results expose two levels of difficulty across experimental and control group: while easy items present the graph of *f'*, difficult items ask for properties of *f'* without a graph. This finding suggests a strong correlation between conceptual understanding of derivatives and graphical representation. The interpretation of a given graph of the derivative is therefore considered part of their conceptual competence. To determine the derivative only from the function or situation (as in difficult items) is considerably less developed. The experimental group demonstrates higher solution rates particularly in these items. Regarding research question two we can state that MaTeGnu students demonstrate higher conceptual understanding, particularly in more intricate aspects.

Conclusion

The findings of this study suggest that MaTeGnu supports teachers in transitioning the emphasis from formal-symbolic to basic mental models in the learning process of the concept of derivatives. Emphasising the basic mental model *rate of change*, as outlined in MaTeGnu, appears to facilitate the integration of all three basic mental models in the teaching and learning. Furthermore, our results demonstrate that fostering basic mental models broadens and deepens students' conceptual understanding.

The high explanatory value of basic mental models for students supports the approach of MaTeGnu to use technology-enhanced teaching to set a focus on understanding with basic mental models. This focus could serve as an effective strategy to exploit technology benefits for learning and overcome (beliefs of) mindless working when teaching with technology (Thurm & Barzel, 2022). The approach has proved itself even in the more formal setting of upper secondary school mathematics. Furthermore, the experimental group's lead in difficult items of the concept test indicates that the MaTeGnu approach appears to be most beneficial for complex conceptual competencies.

Our distinct findings at the most remote level of PDP success (i.e., student learning) demonstrate the impact of the MaTeGnu PDP concept. The combination of a topic-focused workshop, concatenated with evaluated teaching material, a professional learning community and the just-in-time procedure accompanying teachers in one of their math classes over a long period, seems to foster the complex transfer process in teaching practice considerably.

Exploring the notion of individuality in research on mathematics teacher education and professional development

Andreas Ebbelind[1] and Tracy Helliwell[2]

[1]Linnaeus University, Faculty of Technology, Växjö, Sweden; andreas.ebbelind@lnu.se

[2]University of Bristol, School of Education, Bristol, UK

In this paper, we present findings from our initial analysis of TWG18 papers published in the CERME13 post-conference proceedings. In response to the call by Jeppe Skott to re-centre the individual in research on and with mathematics teachers in his plenary address during CERME12, we look into the notion of individuality and the individual-context relationship in research on mathematics teacher education and professional development. We present our results having analysed the abstracts of 40 papers to explore how the interaction between teachers and their environment are portrayed.

Keywords: Teacher education, professional development, individuality, situatedness, context.

Introduction

During CERME12, Jeppe Skott delivered a plenary lecture entitled: *Conceptualizing individual-context relationships in teaching: Developments in research on teachers' knowledge, beliefs and identity* (Skott, 2022). In that plenary, Skott traced the evolution of research concerning teachers' knowledge, teachers' beliefs, and teachers' professional identities over recent decades, asking "how and to what extent aspects of 'the social' have been taken into account" (p. 35) in each of these fields of research, with particular concern for how relationships between individuals (i.e., teachers) and their contexts are conceptualised. Skott claims that while studies concerning teachers' knowledge and beliefs have predominantly drawn on constructivist underpinnings and are primarily cognitive in their approach, contextuality has "gradually been taken into account in both fields" (p. 47). However, the context is mostly framed regarding external constraints (p. 52). On the other hand, studies concerning teachers' professional identities have been rooted in more profound social perspectives on human functioning, emphasising the situated and structural aspects which can influence or even constitute, professional identities (p. 47). Having acknowledged the positive outcomes from each field, Skott observes the lack of personal variability in research on teachers. He argues for interactionist approaches as a complement to what he calls 'variable oriented approaches' (that prioritise agency or structure and ignore the significance of local practices) and 'community/social oriented approaches' (that prioritise situation or structure and overlook the individual), contending that interactionist approaches "re-centre the individual, while maintaining [a] participatory stance" (p. 51). According to Skott, interactionist approaches focus on how meaning emerges in local contexts (e.g., classrooms, schools, professional development programmes) through interactions between groups of individuals and how teachers adjust their actions accordingly in relation to these situations.

Lutovac and Kaasila (2018) have made similar accounts elsewhere. Having prioritised the social aspects of identity, these authors suggest more studies are needed that re-focus on the individual element that the notion of identity was set out to illuminate in the first place. In other words, the focus

on the social constitution of identity has led to a need to re-emphasise how individuals react to and engage with the multiple challenges and commitments they face on a daily basis in their localised situations. One aspect of teachers' multiple challenges and commitments is what we call everyday work-life. Skott (2022) stresses the need to understand the complexity of mathematics teachers' everyday encounters, especially since most individuals cannot access sustained subject-specific professional development (PD). For mathematics teacher education (TE) and PD to be effective and impactful on teachers' practices, researchers need to consider the tensions, challenges and successes that teachers face within their individual contexts to usefully inform the design and implementation of future TE programmes and PD initiatives in new and potentially unpredictable ways. This might be especially valuable in the light of sustainable careers.

We (Andreas and Tracy) were group leaders and co-leaders of Thematic Working Group 18 (*TWG18: Mathematics Teacher Education and Professional Development*) at the last two CERME conferences (CERME12 and CERME13). We have read, reviewed and edited many papers and posters in these roles and organised and facilitated several group discussions. These experiences have made us curious about how studies presented in TWG18 are situated concerning the call made by Skott (2022). We therefore ask *in what ways do researchers conceptualise the individual-context relationship in studies presented in TWG18*? By asking this, we are also asking *whether (and in what ways) individual teachers feature as part of the unit of analysis in the research on mathematics TE and PD presented at CERME, and what other relationships exist*? In this paper, we report specifically on our analysis of TWG18 papers from the CERME13 post-conference proceedings in light of these overarching questions.

Learning: acquisition or participation

Research on how mathematics teachers learn can be grounded in two main metaphors: learning-as-acquisition and learning-as-participation (Sfard, 1998; 2009). Learning-as-acquisition, often linked to certain constructivist theories (e.g., Piaget's model of cognitive development), emphasises the individual process of *acquiring* and *possessing* knowledge, beliefs, or skills such as noticing. The focus here is on mental processes, positioning learning as occurring within the head of the learner. According to Skott (2022), learning-as-acquisition is the basis of a range of frameworks relating to mathematics' teacher knowledge, including some aspects of the 'Knowledge Quartet' (Rowland, 2013) and 'Mathematical Knowledge for Teaching' (Ball et al., 2008). These frameworks emphasise content acquisition, mental schemas, and knowledge transmission (Stetsenko, 2008).

In contrast, the metaphor of learning-as-participation centres around a social community or becoming a practice member. Here, learning is seen as a process of engagement in social practices, where the individual and the community shape one another. Learning-as-participation, aligned with situated learning theories, involves key concepts such as emergence, apprenticeship, cultural embeddedness, and cooperation (Stetsenko, 2008). It highlights the social nature of learning, situating it within a broader socio-cultural and historical context (Wenger, 1998). As Skott (2022) noticed, learning-as-participation is beginning to receive more attention in research on mathematics teachers. While learning-as-acquisition focuses on internal cognitive processes, learning-as-participation emphasises the social, relational, and dynamic nature of learning. However, the dichotomy between these

perspectives is often criticised for overlooking their similarities (Sfard, 1998). For example, some aspects of the Knowledge Quartet can be interpreted through a situated lens, particularly contingency, which involves adaptive teaching decisions in real-time situations (Ebbelind, 2020).

The rise of identity as a focus in mathematics education reflects a shift towards participation, described by Lerman (2000) as 'the social turn' in mathematics education. Identity is increasingly seen as a dynamic, participatory process, consistent with a sociological paradigm (Darragh, 2016) rather than a static attribute corresponding to a psychological paradigm (Darragh, 2016). The psychological perspective views identity as an internal construct (i.e., learning-as-acquisition). At the same time, the sociological frame sees identity as shaped by social interactions and the individual's actions within specific contexts (i.e., learning-as-participation). This sociological approach is often linked to symbolic interactionism, in which identity is constructed and reconstructed through participation in social practices (Skott, 2022). While Skott (2022) advocates for re-centring the individual by ensuring their part within the unit of analysis in research on and with mathematics teachers, discursive research and research that draws on social practice theories, for example, have tended to turn their gaze away from the individual toward dominant discourses and, for example, 'Communities of Practice' (Wenger, 1998) as opposed to the individuals who participate within them (Ebbelind, 2020).

In our post-conference report on TWG18 at CERME13 (Friesen et al., 2023), we noted that even though teacher learning is now widely acknowledged as situated, i.e., "a product of the activity, context, and culture in which it is developed and used" (Brown et al., 1989, p. 32), the way this situatedness is conceptualised can differ:

> From some perspectives, the learner is viewed as being situated *within* a particular environment or context, for others, the learner is considered *part of* the environment or context. How this relationship is conceptualised informs researchers' methodological decision making. During TWG18 discussions, participants grappled with the consequences of their own methodological decisions (Friesen et al., 2023, p. 3173, emphasis original)

The motivation for writing this paper thus lies partly in the call made by Skott (2022) and in our desire to explore the ways in which individuals and contexts are related in research on and with mathematics teachers. In doing so, we hope to identify whether dominant discourses seem to exist within research presented at TWG18, and to share these findings with TWG18 participants at CERME14 as a way of prompting further reflection and discussion.

Methodology

The study of TE and PD has been a major focus of research in mathematics education over recent decades. Various research activities on this topic have been presented and discussed at previous CERME conferences. Of the thematic working groups that focus on mathematics teachers, TWG18 has concentrated on research into the preparation of prospective mathematics teachers and the PD of in-service mathematics teachers from any phase of education. Discussions within TWG18 cover models and programmes of TE and, including their contents, methods, tools, and impacts. TWG18 provides a communicative, collegial, and critical forum for discussing these and related issues,

embracing diverse perspectives and theoretical approaches, and contributing to our development as researchers, educators, and practitioners.

To develop insights relating to the questions set out in the introduction (summarised here as: *in what ways do researchers conceptualise individual-context relationships?* and *in what ways do individual teachers feature as part of the unit of analysis?*), we retrieved all TWG18 papers from the CERME13 post-conference proceedings which consisted of 40 papers in total and began with an analysis of the abstracts from each paper. In our joint reading of the set of abstracts, we noticed that each one referred to the basis of research. By 'basis of research', we mean the motivation or starting point that the study is based upon and/or that justifies the need for the study. We identified four broad categories for the basis of research (each category is explained in the results section): 1) an assumption; 2) a lack of something; 3) exploring a phenomenon; 4) developing something.

Having established the broad research basis of each study, we then looked in the abstracts to identify the unit of analysis when describing the results. Here, we identified three broad categories (again, the categories are explained in the results section): 1) group(s) of teachers, 2) individual teachers, and 3) objects. Since our focus is on the notion of individuality, we then looked more closely at those studies where we categorised the unit of analysis as 'individual teachers' by going into the full papers. With these studies, we looked at how the individual-context relationship is conceptualised. We appreciate the limitations of performing an initial analysis based on the content of a set of abstracts and use this approach primarily to identify papers considering individual variability in their findings. Having said that, we believe the results from this initial stage of analysis are illuminating in terms of providing a broad categorisation of TWG18 research that can usefully provoke reflection and discussion amongst TWG18 participants.

Results

In this section, we present the findings from our analysis. After presenting an overview, we explain the seven broad categories introduced in the previous section, exemplifying them with examples from selected TWG18 abstracts before presenting more nuanced findings in relation to those papers identified as recognising the individual variability of participating mathematics teachers. Table 1 presents our broad categorisation of TWG18 research from the CERME13. For example, there were six studies based on 'an assumption' where the unit of analysis was 'group(s) of teachers'. There were three studies that used the basis of 'developing something', where the unit of analysis was an 'object'. Altogether, we found that based on our broad categorisation, there were 10 different types of study (denoted by the shaded cells within Table 1).

In terms of the basis of research, there were seven papers where the abstract begins with *an assumption*. For example, Frey and Sproesser (2023) state, "Functional thinking plays a key role in mathematics education and beyond" (p. 3195). An assumption like this, often justified with references to earlier work done by other researchers, is used to justify doing the research. Most papers that start with an assumption report on pilot studies or are framed as initial stages of more extensive studies or doctoral projects.

Table 1: Summary of TWG18 papers (CERME13) by research basis and unit of analysis

		Unit of analysis			
		Group(s) of teachers	**Individual teachers**	**Object**	
Basis of research	**An assumption**	6	1	-	**7**
	A lack of something	7	4	-	**11**
	Exploring a phenomenon	7	2	2	**11**
	Developing something	7	1	3	**11**
		27	**8**	**5**	**40**

Eleven papers start by articulating a need for something that is lacking (i.e., a deficit), such as knowledge, variability in research, noticing skills or particular beliefs. Examples include Ebbelind et al. (2023), who state, "there remains an undocumented variability in how teachers change that identity studies try to document" (p. 3187), and Crisan (2023), who states, "an explicit model of subject-specific mentoring is needed" (p. 3371). Many of the papers that present *a lack of something* specifically concern a lack of teacher knowledge in relation to desired knowledge, putting the teacher in a deficit position. We have written elsewhere about the deficit view of mathematics teachers and teaching in research (Ebbelind & Helliwell, 2024; Helliwell & Ebbelind, 2024). 11 papers begin by stating their intention as to explore something such as teachers' noticing skills, teachers' knowledge, teachers' beliefs, teachers' identity, discourses, content or tools. This *exploring a phenomenon* group includes Mizoguchi et al. (2023), who explore "the conditions and constraints [...] from the perspective of the didactic tools proposed to teacher-students for the design of teaching and learning sequences" (p. 3251). Papers within TWG18 that set out to explore a phenomenon tend to go in diverse directions. Finally, 10 papers emphasise the development of a tool, intervention or design. For example, Casi and Sabena (2023) "design informal mathematics workshops, with the support of teacher educators and museum experts" (p. 3175). The category of *developing something* includes various things: developing learning opportunities or potential, developing learning spaces, developing design principles to use when planning PD programmes, and developing tools.

Concerning the unit of analysis reported in the results of the TWG18 studies, 27 papers reported their results in relation to a *group(s) of teachers*. These studies can be considered as having a 'variable oriented' approach (Skott, 2022) since they are not particularly concerned with the way in which different individuals respond in relation to the local context. In reporting on findings in relation to a group of teachers, results tend to be presented in more generalised terms. In research on a group of teachers, the issue of context can be dealt with by increasing the sample size (i.e., with the effect of averaging out the effect of the local contexts) or by paying attention to the details of a particular context (Wiliam & Lester, 2006). Five papers report results in relation to *objects* such as tools, resources or instructions for supporting TE and PD including role-play as a tool for developing

teaching. Finally, and most significantly in terms of our questions, eight papers report on *individual teachers*, describing individuals' commonalities and differences. However, from this initial analysis, it is not yet clear how the individual-context relation is conceptualised (i.e., how individuals attend to and adjust their actions in relation to local situations and social practices). For these eight studies, we looked closer into the full papers, asking how the individual-context relationship is dealt with and/or conceptualised.

In doing so, we focused on the relationship between the individual subjects and the context of the situation to understand how papers position the individual and whether a participatory stance is taken, classifying each paper in relation to the 'learning-as' metaphors used by Sfard (2009) and Stetsenko (2008). We found four of the eight papers rooted in the learning-as-acquisition metaphor. These studies seem to be concerned with the knowledge needed to foster the mathematical knowledge considered as being essential for success, teachers' explicit knowledge for teaching, and teachers' noticing skills. Although these four studies focus on individual subjects, we consider them to be framed by a 'variable-oriented approach' (Skott, 2022) since individuality is not considered in relation to the local social contexts. The remaining four papers were found to be rooted in the learning-as-participation metaphor. They are concerned with how participation in a development project influences the identity of teachers; how the stories influence individuals told of experiences gained in social practices; how the perception of being a part of mathematics courses influences descriptions of the subject of mathematics, and how moments of dissonance arising from participation in teaching and TE guides teachers' narratives.

Concluding thoughts

A close relation to TWG18 is Thematic Working Group 20 (*TWG20 Mathematics Teacher Knowledge, Beliefs and Identity*). Given the nature of the research in TWG20, we speculated whether this may be the forum where individuality is most prevalent in research on and with teachers. This remains a question for us, yet we read in the CERME13 report on TWG20 that:

> Despite the increasing number of research studies in the educational literature that investigate preservice and in-service teacher identity development and the factors affecting that process, there were few presentations at CERME13 that focused on this topic, which tends to be approached from a narrative perspective. Instead, many of the studies presented focused on beliefs [...] (Martignone et al., 2023, p. 3677)

From this we conclude that the participatory perspective is underrepresented in both thematic working groups. Through the process of analysis we have new questions for the TWG18 community to consider. For instance, how might we support one another in questioning the underlying assumptions behind our research on mathematics TE and PD and how might be develop different framings and approaches that open up new possibilities. We close by acknowledging that in setting out to analyse part of a field of research, we have tried to avoid reporting on another 'lack of' in research on mathematics TE and PD, and yet are aware of the challenges in doing this.

Preservice teachers' professional instrumental genesis for integrating programming in the math classroom: the beginning

Martyna K. Fojcik[1], Marie-Frédérick St-Cyr[2], Chantal Buteau[3], Eric Muller[3] and Joyce Mgombelo[3]

[1]Volda University College, Norway; martyna.fojcik@hivolda.no,

[2]Université du Québec à Montréal, Canada; [3]Brock University, Canada

We investigate the development of professional competencies of preservice teachers enrolled in a programming-based math investigation course designed for future teachers. We discuss a case study of a student's experience in this course. Grounded in the instrumental approach, the analysis of the student's scheme elements suggests her initial professional instrumental genesis, including for example her early development of a scheme of preparing a programming-based math task aiming at students to complete it mindfully.

Keywords: Programming, preservice teachers, professional instrumental genesis, schemes.

Introduction and context

In recent years several countries and jurisdictions have integrated programming as a part of mandatory math curricula (Broley et al., 2023), which in turn creates the need to develop pedagogical programming competencies for math teachers. Some recent studies of inservice (Grimeland et al., 2022) and preservice teachers (Maugesten et al., 2023) argue that even after some initial introduction to programming-based math activities, teachers still report having limited teaching competencies in that area. In fact, inservice teachers' "lack of knowledge about programming is clearly an obstacle for developing good teaching plans that would enhance pupil knowledge" (Grimeland et al., 2022, p. 3129). Similarly, Maugesten et al. (2023) have concluded that preservice math teachers highlighted programming as a tool for motivation "rather than developing students' math competence" (p. 7). This points to the need to understand more about pre- and inservice mathematics teachers' development of professional knowledge and beliefs in the context of exploring math through programming.

This study contributes to this need by focusing on preservice teachers' initial professional development in a math content course integrating computer programming, that is targeted for future teachers (MICA III*, Mathematics Integrated with Computers and Applications III*). MICA is a sequence of three math project-based courses (I-II-III/III*) in which math majors and all preservice secondary math teachers conduct pure and applied math investigations supported by programming (Buteau et al., 2015). For example, MICA I students investigate, numerically and graphically, the behavior of the discrete dynamical system based on a two-parameter cubic; and MICA III* students solve, through creating simulations in Python, a probability problem with seemingly multiple answers ('Bertrand paradox'), of a random chord being longer than a side of the inscribed triangle (for MICA III* project guidelines, see Brock University, n.d.).

In 2021, the MICA III* course was revised in response to the recent integration of "coding" in school mathematics curricula in Ontario (Canada). In this course, future teachers complete the math investigation projects, regular reflection tasks, and a final didactical project in collaboration with local schoolteachers through which pre- and inservice teachers co-learn and develop some professional competences in this area. This study explores the development of preservice math teachers'

professional competencies by focusing on a case of a MICA III* student, Nadia (pseudonym). By framing this research in the double instrumental genesis (Haspekian, 2017), we examine the initial development of elements of Nadia's schemes of integrating programming in the math classroom.

Theoretical framework

Our research is grounded in the instrumental approach as articulated in mathematics education (e.g., Trouche, 2004), especially the double instrumental genesis that brings together personal and professional geneses (Haspekian, 2017). The instrumental approach allows us to study the user's appropriation of an artefact as an instrument to reach a goal through a specific activity. The user's appropriation of an artefact happens through instrumental genesis, a dialectical combination of two processes: instrumentation (from the artefact to the learner) and instrumentalization (from the learner to the artefact) (Trouche, 2004) where the learner is transformed by the artefact and the artefact is transformed by the learner. Thus, an instrument is composed of an artefact and schemes. A scheme is defined by Vergnaud (1998) as a stable organization of the subject's activity for a given goal, with four components: goal of the activity (goal, purpose); rules of action (RoA, information gathering, strategies); operational invariants (OI, concepts, propositions considered true, beliefs, justifications); and possible inferences (inferences, new structures and patterns).

To look more closely into the user's appropriation of an artefact (in our case programming) for professional use, we frame our work on the double instrumental genesis (Haspekian, 2017). This framework considers personal and professional instrumental genesis and links them together (Figure 1). In the context of math teachers, the personal instrumental genesis (IGpe) involves the development of schemes by the teacher when they interact with the artefact for their own learning (personal goal, personal instrument). The professional instrumental genesis (IGpro) entails the development of schemes by the teacher when they interact with the artefact for their teaching (professional goal, professional instrument; e.g., to guide students to develop their own personal genesis). As part of IGpro, Haspekian (2017) considers the teacher's instrumental orchestration, which Drijvers et al. (2010) describe as the "intentional and systematic organization and use of the various artefacts available … in order to guide students' instrumental genesis" (pp. 214–215). This instrumental orchestration consists of three components (Drijvers et al., 2010):

- Didactical configuration – e.g., selecting artefact, classroom format
- Exploitation mode – teachers' decision on how to use artefacts chosen, e.g., preparing activities
- Didactical performance – ad hoc decisions when teaching

The components are not considered linear but rather intertwined and connected, where didactical configurations influence and are a part of exploitation mode, and both of those components are again intertwined in didactical performance.

Previously, Haspekian (2017) used this framework by looking at experienced math teachers who have started to introduce a new artefact (e.g., programming) in their math teaching. In this study, we use this framework, specifically IGpro, in a case study of a preservice teacher who has experience in programming for math but has limited pedagogical knowledge and teaching experience. Therefore, we are not looking for stable schemes for IGpro, but rather at the initial development of elements of such potential schemes that a MICA III* student starts developing. By "potential" schemes, we mean

schemes in construction with tentative stability. Finally, we view the initial development of professional competences through our framework as the initial development of potential schemes for IGpro.

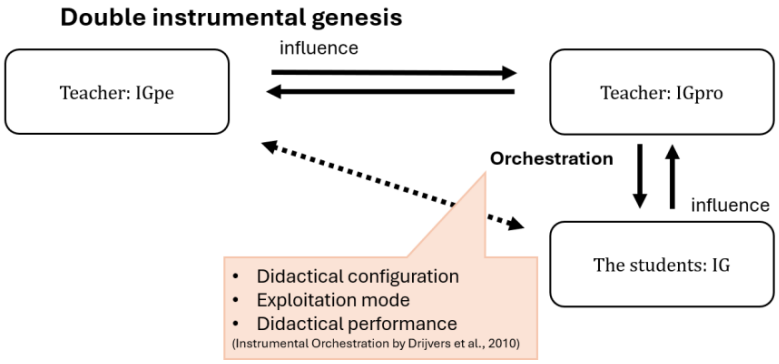

Figure 1: Double instrumental genesis, based on Haspekian (2017, p. 25)

In our work, we explore the framework of double instrumental genesis, in the case of programming-based math investigations (Buteau et al., 2024; St-Cyr et al., 2025). In this study, we focus on preservice teachers' development of professional competencies, exploring and deepening our understanding of future teachers' professional genesis, namely: *What elements of schemes of integrating programming in the school math classroom are developed by preservice teachers as they reflect about their own learning experiences in programming-based math investigations course?*

Method

This study focuses on exploring the case of Nadia, a preservice teacher enrolled in a MICA III* course. In this course, students write reflection tasks that involve guiding questions, integrating selected didactical literature, to think about the way they worked on the investigation projects, with the purpose of building their awareness about learning processes for them and for others. The final project in this course involves a collaboration with local schoolteachers during which the students in pairs prepare and teach a programming-based math lesson in the teachers' Grade 3–9 class. For a majority of students, this is their first experience of teaching math in school.

Nadia was selected, among other volunteer participants, due to her deep reflections on her professional experiences. The data was collected as a part of a larger naturalistic, mix-methodology and iterative design research study focusing on university teaching and learning of programming as a meaningful tool for mathematics (e.g., as done in MICA courses). Data for this study consist of: Nadia's responses to pre- and post-course questionnaires that included some questions related to students' future teaching career; semi-structured post-course interviews that sought elaboration on selected questionnaire responses and inquired about her overall MICA experience; and five written reflections tasks that she wrote during the course. An example of a reflection task is: "Describe one key moment where you received or gave help: What was the issue, what was the strategy used by the 'helper,' and in what ways did it help the person who needed help (in terms of cognitive, interpersonal, and/or intrapersonal domains)?" (Brock University, n.d., Part B – The Reflection section, Item ii).

Data is coded by identifying elements of Nadia's IGpro schemes when she "explicitly makes a connection between their or others' learning experience in relation to the teaching or the learning environment, or when they explicitly comment about their future teaching role" (Buteau et al., 2024, p. 4); that is, their future instrumental orchestration. The first two authors identified individually

excerpts that highlight Nadia's reflections or views that mentioned or were connected to teaching and learning. The authors then compared the individually marked excerpts they had selected and kept only the ones they both identified and coded these excerpts. The coded excerpts were thereafter discussed with the rest of the team, to come to a joint understanding of elements of Nadia's potential schemes for IGpro. This stage required many iterations. In the last stage, when all authors agreed on the elements of potential schemes, we analyzed further the identified schemes and their elements and categorized them by their relation to the instrumental orchestration components.

Findings

In this section, we present Nadia's early development of IGpro where, through completing the MICA III* course, she starts to see herself as a math teacher capable of integrating programming in a math classroom. We first investigate Nadia's initial development of programming as a professional instrument, and we then delve into details of this instrument by highlighting some of Nadia's potential professional schemes. We do so by selecting three illustrative examples associated with each of the three components of instrumental orchestration.

Nadia's initial development of programming as a professional instrument during the course

In the pre-course questionnaire, Nadia was asked to indicate her level of confidence "to teach a math activity with programming in a Grade 6–12 class", for which she answered "not confident", stating:

> I do not feel as of right now I am equipped to teach any programming for Grades 6–12 as I am not aware of the many softwares out there and would not know how to make a lesson out of it/teach it to young students. (S1)

She reported her lack of knowledge and pointed to the competencies (i.e., schemes) she thought she would need for such a professional activity, namely (i) to choose an appropriate programming language, and (ii) to make/teach a programming-based math lesson. However, by the end of the MICA III* course, Nadia answered "very confident" to the same question in the post-course questionnaire. During the interview, Nadia grounded her response with her experiences in the final project whereby she had the opportunity to teach six classes, and she now felt more equipped for her future teacher role. We interpret that Nadia acknowledges having developed her professional instrument to a certain extent for integrating programming in school math classrooms. Next, we investigate Nadia's professional instrument by presenting potential schemes related to her IGpro, and associated to the three components of instrumental orchestration. These schemes actually address Nadia's lack of competencies she mentioned at the start of the course.

Nadia's potential scheme, associated with her didactical configuration

An example related to selecting resources, as part of didactical configuration, was mentioned by Nadia in the interview when she reflected on the programming languages she could use in the future. After having used VB.net in MICA I-II, Nadia was introduced in MICA III* to Scratch (one assignment), and Python (three assignments). In her final project, she chose to make a programming-based math activity in Scratch, explaining that it fits well with geometrical shapes and angles that the students can easily modify, which were the concepts for her planned math lesson. When Nadia was asked in the interview if she would use Python to teach math in high school, she stated:

> Yeah, absolutely. ... I don't think that it's something that's too advanced. It depends on, kind of, [students'] experience with programming from before. (S5)

We interpret from this excerpt that Nadia is starting to develop her scheme of "Choosing a programming language (to teach selected math concepts)" (Goal), with a RoA "I assess the experience of the students I work with", and grounded on an OI of "What programming software is useful depends on students' previous knowledge" (see Table 1). This illustrates how Nadia considers students' previous experiences and thereby willing to adapt her choice of the artefact based on the goal of the activity. Furthermore, Nadia's explanation about her choice of artefact in the final project suggests another RoA "I select a language that provides a math representation (in code, in output) aligned with my didactical aim", grounded on an implicit OI "Different programming languages afford different representations of math concepts (in code, in output) at 'different effort cost'".

Table 1: Nadia's elements of a potential scheme, associated with her didactical configuration

Goal	Choosing a programming language (to teach selected math concepts)
RoA	(i) I assess the experience of the students I work with; (ii) I select a language that provides a math representation (in code, in output) aligned with my didactical aim
OI	(i) What programming software is useful depends on students' previous knowledge; (ii) (Implicit) Different programming languages afford different representations of math concepts (in code, in output) at "different effort cost"

Nadia's potential scheme, associated with her exploitation mode

Once the programming language and a math topic are selected, the teacher then needs to prepare (or select) a task. Reflecting on experiences of collaborating with peers explaining math to each other, Nadia commented during the interview on why when teaching a programming-based math activity it is important for her to guide the learner. She explained how she prepared for this in the final project:

> So, now [some students] have the answer. But I just asked them why? But I didn't necessarily even need to do that because in our activity there was questions afterwards that ask what does the turn angle do? What does this do? What does this do? And so, they actually kind of had to demonstrate, um, their, their learning. (S40)

We interpret Nadia's excerpt as elements of her potential schemes for IGpro, of "Preparing a math-programming task that aims at encouraging the students to do the activity mindfully" (Goal) with a RoA "I prepare a worksheet with questions for students to complete to demonstrate their learning", and grounded on the OI "Teacher should ask 'why is it working?' (a) to encourage students to understand what they do, (b) to have the opportunity to see if the student understands the connection between the code and the math" (see Table 2). We interpreted further two implicit OIs: "Programming in math is about exploring math concepts, learning them, not just calculating or programming the answer" and "One can code the right answer by tinkering (without understanding)." This illustrates how Nadia is building her IGpro on the reflections about her own learning of math, where she plans to prompt students to investigate the math in the programming-based task by guiding students both during her preparation of the task (task guidelines) and during implementation when she plans to walk around and ask students when looking at their work.

Table 2: Nadia's elements of a potential scheme, associated with her exploitation mode

Goal	Preparing a math-programming task that aims at encouraging the students to do the activity mindfully
RoA	I prepare a worksheet with questions for students to complete to demonstrate their learning
OI	(i) Teacher should ask "why is it working?": (a) to encourage students to understand what they do, (b) to have the opportunity to see if the student understands the connection between the code and the math; (ii) (implicit) Programming in math is about exploring math concepts, learning them, not just calculating or programming the answer; (iii) (implicit) One can code the right answer by tinkering (without understanding)

Nadia's potential scheme, associated with her didactical performance

Nadia did not have classroom teaching experiences prior to the participation in the MICA III* course. Yet, during the interview, she reported the following conversation when preparing with her peer partner and her two associate schoolteachers for the classroom implementation (final project):

> So, like, we kind of explained to [the schoolteachers]: "please, when going around the classroom, don't try to tell students to change their block. Ask [students] what parts they think are wrong. Ask them." And so, that's kind of the way where we were almost teaching [the schoolteachers], how to teach coding within the [math] classroom. (S17)

We interpret this as Nadia's potential professional scheme of "Intervening with an individual student to address an error with their math program" (Goal), with two RoAs: "I ask the students what part they think is wrong" and "I do not tell students what to change", grounded on the OI "To teach math-programming, teachers do not have to tell the answer to the students, but should ask the students what part is wrong" (see Table 3) and an implicit OI "It is more helpful for the students if I help them identify the issue and guide them to find a solution, rather than directly tell them what to fix."

Table 3: Nadia's elements of a potential scheme, associated with her didactical performance

Goal	Intervening with an individual student to address an error with their math program
RoA	(i) I ask the students what part they think is wrong; (ii) I do not tell students what to change
OI	(i) To teach math-programming, teachers do not have to tell the answer to the students, but should ask the students what part is wrong; (ii) (implicit) It is more helpful for the students if I help them identify the issue and guide them to find a solution, rather than directly tell them what to fix

Discussion and concluding remarks

In this paper, we presented the case of a preservice teacher's (Nadia's) initial professional development in a math content course (MICA III*) focused on programming-based math investigations, that is targeted for future teachers. The research question guiding this study is: *What elements of schemes of integrating programming in the school math classroom are developed by preservice teachers as they reflect about their own learning experiences in programming-based math investigations course?*

Our case study shows that this kind of course can contribute to the development of schemes of integrating programming in the math classroom; that is, to the initial development of professional competencies in programming-based math investigations course for future teachers. Our analysis showed that, at the start of the course and despite her previous two MICA courses, Nadia was aware of her lack of competence for integrating programming in a school math classroom. She specifically identified two missing competences: knowing a programming language and the kind of math activity appropriate for the school classroom. Additionally, our analysis showed that, throughout the course, Nadia has started developing those competences to the extent that she reports, at the end of the course, feeling "very confident" to integrate programming in a school math classroom. More specifically, we identified elements of professional schemes related to the above two competences, that Nadia developed in the course, and that are part of the three instrumental orchestration components.

By highlighting a preservice teacher initial development of IGpro for integrating programming in a math classroom, our study contributes to the research about preservice teachers' competencies development through a programming-based math investigations course approach. It also contributes to the literature on the double instrumental approach (Haspekian, 2017) by focusing on preservice teachers' IGpro where programming is the artefact and by detailing their schemes in connection with their associated components of instrumental orchestration. In fact, we argue that the instrumental orchestration organizes the teacher's overall activity of integrating programming in a math classroom.

A limitation of this study is that the data was taken from a larger research project and not gathered with this study in mind, so questions were not specifically targeted to seek insights into participants' IGpro; in particular, we do not directly look at participants' activity, but rather at their reflections on the activity. This study utilized a case study research design and focused on a math content course integrating computer programming that is targeted for future teachers. The implications of the study should not be read in terms of generalizability, but of transferability to other cases (Creswell, 2008).

Our results align with other studies (e.g., Maugesten et al., 2023) that argue there is still more to learn about the development of preservice teachers' competencies for implementing programming-based math activities in their future classrooms. Our study offers one way of understanding the development of such preservice teachers' competencies through the double instrumental genesis. Our ongoing work (e.g. St-Cyr et al., 2025) seeks to deepen our understanding of ways by which preservice teachers' development of programming-based mathematical competencies (i.e., personal instrumental genesis) can support, and is enhanced by, their development of professional competencies in this area (i.e., professional instrumental genesis).

Teacher noticing refers to the ability of teachers to attend to, interpret, and make instructional decisions based on students' mathematical understanding. This paper examines the role of silent video tasks in supporting teacher noticing in mathematics education. A silent video task is a short, dynamic mathematical task presented without audio, text, dialogue, or explanations, designed to highlight a specific mathematical concept. The study is a preliminary part of an ongoing project focused on designing teacher noticing professional development (TNPD). In this study, five in-service mathematics teachers participated in TNPD using silent video tasks focused on the concept of slope. The results show improvement in teachers' ability to attend to students' strategies and interpret their understanding, although making instructional decisions based on this noticing remains a challenge.

Keywords: Teacher noticing, silent video task, professional development, mathematics education.

Introduction

Teacher noticing (TN) has recently been highlighted as a crucial element in the understanding of professional competence (König et al., 2022). Jacobs and her colleagues (2010) defined teacher noticing as an ongoing ability to attend to the students' strategies, interpret their understanding, and decide how to respond based on their cognitive processes. TN improves teaching practice by enabling decision-making on where and how to focus attention to address classroom complexities (Blömeke et al., 2022), yet despite its critical role, much work remains in its enhancement and assessment (Sherin et al., 2011). This emphasizes the necessity for innovative approaches in teacher education and professional development that prioritize the improvement of TN skills (Amador et al., 2021). Therefore, we propose using of silent video task (SVT), comprising brief, dynamic mathematical animations devoid of audio, text, or dialogue, as a means of facilitating teacher noticing and addressing the need for an innovative method. SVT enables teachers to concentrate on a specific mathematical concept, facilitating focused engagement with students' cognitive processes and reasoning. It also encourages students to articulate, explain, and justify their ideas using mathematical language (Kristinsdóttir, 2023), thereby enabling teachers to comprehend students' mathematical reasoning. Professional development for teacher noticing provides teachers with opportunities to notice key aspects of student thinking and classroom dynamics (Jacobs et al., 2010). This study is part of a long-term ongoing project aiming to design a professional development program aimed at enhancing TN in mathematics education through the use of SVT. This paper aims to explore the impact of using silent video task on teacher noticing professional development (TNPD) in mathematics education to identify benefits, challenges and needs for improvement for designing TNPD.

State-of-the-art and theoretical framework

Teacher noticing is the process through which teachers become aware of the complexities in mathematics classrooms, including students' thinking and responses, and interpret these events within a pedagogical framework (Mason, 2021; van Es & Sherin, 2002). Rather than addressing all classroom interactions, Jacobs et al. (2010) examined teacher noticing specifically in terms of students' mathematical thinking from a cognitive-psychological perspective. The authors focused on students' mathematical thinking and expanded its conceptualization beyond attending and interpreting by incorporating instructional decision-making as a key component. Accordingly, teacher noticing consists of three interrelated dimensions: attending to students' strategies, interpreting their understanding, and deciding how to respond (Jacobs et al., 2010). Attending involves focusing on details in students' work, which provides insights into their strategies. Interpreting requires teachers to analyse students' understanding based on these observations. Finally, deciding entails making pedagogical decisions. It is important to highlight that there is no single best way to make these decisions (Jacobs et al., 2010). Jacobs et al.'s (2010) framework serves as a basis for our study.

Silent video tasks are innovative tools for capturing and analysing students' mathematical reasoning. These short, text-free animations illustrate mathematical concepts, prompting students to collaboratively generate voice-over explanations (Kristinsdóttir, 2023). SVT promotes critical thinking and deeper engagement but also presents challenges such as technological literacy requirements and classroom management. Despite these challenges, SVT provides valuable insights into students' reasoning, making it a promising tool for enhancing teacher noticing (Galiç et al., 2024). By focusing on how students think and justify mathematical ideas, teachers can better understand reasoning processes and identify misconceptions (Kristinsdóttir, 2023). The combination of video-based interventions and written responses supports teacher noticing of students' thinking.

Although research on SVT in teacher noticing is still emerging, studies suggest its potential for assessing and improving teacher noticing (Galiç et al., 2024). In this study, SVT was used into a TNPD program to enhance teacher noticing in mathematics education. Our aim is to enhance teacher noticing through the use of silent video task for in-service mathematics teachers in a professional development program. In this respect, we aimed to answer the following research questions: To what extent do in-service mathematics teachers improve teacher noticing of students' mathematical thinking in the context of slope through the use of silent video task in teacher noticing professional development program?

Method

This study employs a Design-Based Research (DBR) methodology, following Gravemeijer and Cobb (2006). DBR is an iterative process consisting of three phases: (1) preparing for the experiment, (2) experimenting in the classroom, and (3) conducting retrospective analyses. This study represents the first experimentation of the TNPD based on the literature, with subsequent retrospective analysis guiding its revision. The design of the TNPD is based on the theoretical framework of teacher noticing as proposed by Jacobs et al. (2010). Teacher noticing is a domain-specific skill that requires both pedagogical and content knowledge to enable teachers to notice students' mathematical thinking and

interpret the students' understanding behind their strategies within a specific learning domain area (Ivars et al., 2020). This study focuses on slope due to its role in mathematics curricula and its connections to advanced topics like derivatives, ratios, rates of change, and real-world applications (Stump, 1999). Given the challenges in teaching slope, including its multifaceted conceptualizations and potential for misconceptions, professional development programs are essential for enhancing teachers' ability to notice (Styers et al., 2020).

We designed silent video tasks utilizing GeoGebra, a dynamic geometry software, to enhance the understanding of mathematical concepts considered a basis for understanding slope conceptualization by Nagle and her colleagues (2019). The procedure for designing silent video tasks is outlined in the study by Galiç et al. (2024). We shared the silent video tasks with lower secondary students (8^{th} grade, age 14 students), requiring them to provide a voice-over for the videos in order to define the mathematical aspects of the video. We named students' voice over of silent video tasks as students' videos in this study.

Before and after the TNPD process, mathematics teachers were asked to implement researcher-designed silent video tasks in their classrooms and collect video recordings of their students. Each teacher collected two students' videos from their classroom. The teachers then analysed these videos by using a reflection paper including the following questions:

(i) Attending – Please describe in detail what you think each child did in their voice-over of the given silent video task.
(ii) Interpreting – Please explain what you learned about students' understanding of the slope concept in their voice-over of the given silent video task.
(iii) Deciding – Pretend that you are the teacher of these students. Explain what problem or problems you might pose next on the basis of students' understanding in their voice-over of the given silent video task.

During TNPD, mathematics teachers were asked to individually make a voice-over for the researcher-designed silent video task. Next, they were provided with two students' videos featuring unfamiliar students and were asked to analyse these videos using a reflection paper. After completing their analysis, the teachers were required to re-make voice-over the same videos to refine their analysis. This process was repeated weekly for four weeks, ensuring a structured and iterative approach to enhancing teacher noticing. TNPD is guided by four conceptualizations of slope: geometric ratio, algebraic ratio, functional properties and calculus. Each conceptualization was determined each week.

Silent video tasks were developed using GeoGebra to represent the four slope conceptualizations (see Galiç et al., 2024) based on design principles of silent video task by Kristinsdóttir (2021). The videos were created after reviewing curricula, designing prototypes, and refining them based on expert feedback. The final videos were transcribed, analyzed, and filtered for mathematical reasoning and technical quality, essential for teacher noticing. Videos of unfamiliar students were selected to offer an authentic, unbiased opportunity for teachers to analyze student thinking. The selection process emphasized diverse student approaches and reasoning. The participants in this study were five in-service mathematics teachers with diverse teaching experiences, selected based on their varying levels of experience and backgrounds in mathematics education to ensure a rich sample.

In this paper, we analyzed their reflection on students' videos before and after TNPD in order to explore the impact of using silent video task on enhancing teacher noticing. We have found it helpful to adopt the same framework for both the design of the TNPD and analyzing data, namely Professional Noticing of Children's Mathematical Thinking by Jacobs et al. (2010). This framework has two categorizations of attending to students' strategies in silent video task. However, in our case, the third emerged as limited evidence and was added. Therefore, we analyzed the data under three classifications for each dimension of teacher noticing, namely lack of evidence, limited evidence and robust evidence. For attending to students' strategies, we coded as lack of evidence when teachers did not describe students' strategies. On the other hand, teachers' explanations that included descriptions of students' strategies without details were classified as limited evidence. When teachers presented all the mathematical concepts and details of students' strategies and correctly identified the strategy, we coded it as robust evidence. In terms of interpreting students' thinking, teachers who showed robust evidence of interpretation were able to explain the key concepts of slope in detail, using appropriate mathematical language. In contrast, teachers' interpretations that showed a lack of evidence included no or incorrect interpretations using general statements without using the conceptualization of the slope concept. When teachers correctly interpreted students' understanding of the context slope in less detail, we classified it as limited evidence. With similar categorizations of attending and interpreting, we classified deciding from general to specific pedagogical decisions. When teachers decide to respond to students with general statements without using students' thinking, we code it as lack of evidence. Attempts to ask general questions, explain students' videos to students, and ask the same question using different numbers were classified as limited evidence. If the teacher's decisions included further elaboration with rationale, asking students some questions to make them think mathematically or extending students' thinking, we coded it as robust evidence.

Results

We present the comparison of the three dimensions of teacher noticing of five in-service mathematics teachers before and after TNPD. We provide an overall summary of the results in Figure 1.

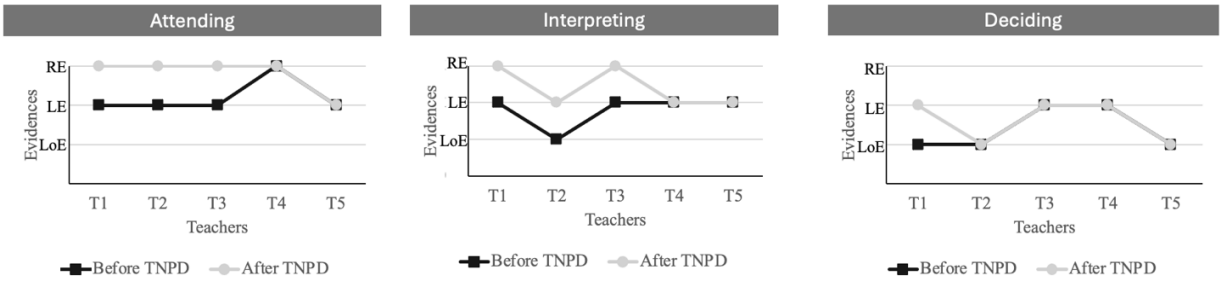

Figure 1: Teacher noticing of five in-service mathematics teachers before and after TNPD

As Figure 1 illustrates, teachers mostly demonstrated a lack of evidence or limited evidence before TNPD. However, it is encouraging to note that mathematics teachers improved their level of evidence in noticing skills at least one level. Three mathematics teachers have been demonstrating a growing ability to attend to students' strategies in the given silent video task after TNPD. In terms of interpreting students' understanding, we can see two distinct outcomes. We observed an improvement

for three mathematics teachers. On the other hand, two teachers did not show any improvement in this skill. Surprisingly, we did not observe any changing in decisions to develop students' thinking on the basis of their understanding at a robust evidence level.

We present T1's statements as an example for each dimension of teacher noticing. Table 1 illustrates T1's improvement for attending to students' strategies from limited evidence to robust evidence.

Table 1: Improvement of T1 in attending to students' strategies

Before TNPD	The students successfully related the falling speeds of the balls to the differences in slope. However, they were unable to precisely articulate the point at which the triangles overlap.
After TNPD	The students stated that the task involved a scenario related to the concept of slope. They pointed out that climbing a steeper mountain is more challenging. Although their use of mathematical terminology was not entirely accurate, their interpretations and approaches were appropriate. However, they did not thoroughly examine the details. In particular, they did not analyze the changes in slope during the ascent and descent on the ramp. Specifically, the part of the scenario in which the slope increases to a certain point, then decreases and approaches zero, was not addressed.

As can be seen in Table 1, T1 first described the students' strategies by providing limited and general evidence related to the students' explanation, such as word errors, and wrong expressions. However, she ignored the use of slope conceptualization. After TNPD, she described the students' strategies with specific evidence from the students' videos. Table 2 illustrates T1's improvement for interpreting students' understanding from limited evidence to robust evidence.

Table 2: Improvement of T1 in interpreting students' understanding

Before TNPD	The students did not relate its velocity to the steepness of the slope.
After TNPD	Although the students correctly stated that slope is the ratio of vertical change to horizontal change, they did not mention when and why the slope is positive or negative. They did not address the relationship between the right triangle and the concept of slope. This lack of understanding may stem from the real-life examples of slope commonly used in our national curriculum.

Before TNPD, T1 could not interpret the students' understanding. She could not make any claims about students' understanding or students' thinking. On the other hand, T1 interpreted students' understanding of slope with details after TNPD. For instance, she mentioned that students' understanding of the geometric ratio of slope and the characteristic of slope as positive or negative. Table 3 illustrates T1's improvement for interpreting students' understanding from lack of evidence to limited evidence.

Table 3: Improvement of T1 in deciding how to respond

Before TNPD	I realized that more concrete examples are needed for a meaningful understanding of this topic.
After TNPD	The student did not provide a detailed explanation and offered only a partial understanding of the concept. I am capable of teaching the notions of positive and negative slope.

As evidenced in Table 3, T1 was unable to determine an appropriate response to enhance students' thinking about slope, based on their existing understanding, before the implementation of the TNPD. She merely reminded the students of the missing point in the video, which did not facilitate further student thinking. When we examined T1's decision after TNPD, it is evident that she attempted to make a decision based on the students' understanding. In the earlier dimension, interpreting, she identified the students' lack of understanding of negative and positive slope. Consequently, she decided to teach it to the students. Despite her decision being based on the students' explanation, it did not it did not provide adequate support for students' thinking.

Discussion and Conclusions

The study yielded significant insights into teachers' attending, interpreting, and deciding skills. While some participants demonstrated growth in attending skills (e.g., T1, T2, T3), others, such as T4, maintained consistently high initial levels. Interpreting skills improved for certain teachers (e.g., T1 advancing from limited evidence to robust evidence, and T2 progressing from lack of evidence to limited evidence). However, deciding skills exhibited minimal change overall, except for T1. Teachers frequently struggled to distinguish among the dimensions of teacher noticing. Consistent with prior studies (e.g., Santagata & Yeh, 2016), this research highlighted the challenge of separating attending and interpreting, as these dimensions often overlap. In some cases, teachers interpreted students' understanding within the deciding dimension of noticing. To address these challenges, professional development programs should explicitly define the dimensions of noticing, offering clear guidance on what to attend to, how to interpret mathematical thinking, and how to make informed instructional decisions. Researchers might also consider examining teacher noticing through a holistic lens to allow for comparative insights and a broader understanding of the phenomenon.

Teachers need to articulate the mathematically significant aspects of students' solutions in order to assess their understanding (Jacobs et al., 2010). Although all teachers were able to focus on students' strategies, some teachers in this study found it difficult to interpret students' understanding. The findings indicated that attending to students' strategies is not enough to interpret their understanding (Jacobs et al., 2010). The ability to interpret mathematical ideas accurately may require an understanding of the subject matter (Fernandez et al., 2013). We also observed that teachers had difficulty interpreting students' understanding, particularly concerning calculus conceptualization. As a next step, we plan to interview mathematics teachers to further explore these difficulties. Additionally, we will delve into their awareness of their own noticing improvement during these interviews.

The findings suggest that while silent video tasks are effective for assessing noticing (Galiç et al., 2024), they alone are insufficient for enhancing teacher noticing without additional support. Teachers

showed some improvement in their decision-making skills during the TNPD, but this was not strongly supported by robust evidence. The "deciding" dimension seemed to be less developed compared to "attending" and "interpreting". This finding aligns with the findings of previous studies (König et al., 2022). This may be because making informed instructional decisions is more complex and requires more support and practice. In the next phase, interviews will be conducted with teachers to gather their feedback and perspectives, and updates will be made to improve the decision-making component of the TNPD. Overall, working with student videos had a greater impact on teacher noticing development than the production of voice-overs. The videos provided authentic opportunities for teachers to analyse and interpret student thinking, fostering a deeper understanding of student reasoning and refining their noticing skills.

As Amador et al. (2021) pointed out, methodological concerns may have arisen when researching teacher noticing. The framework used for analysis faced challenges in classifying responses due to a lack of evidence or clarity in teacher explanations, especially in interpreting students' mathematical understanding. This issue highlights the need for a clear definition of mathematical thinking to guide teachers in the processes of noticing for future studies, as pointed out by Ivars et al. (2020). Nevertheless, we suggest in focusing on what to notice instead of the level of evidence for teacher noticing in the future studies. In the next cycle of DBR (Gravemeijer & Cobb, 2006), we will first determine students' mathematical thinking and go deeper into what mathematics teachers notice to improve TNPD.

Acknowledgment

We would like to express our sincere gratitude to all the mathematics teachers who volunteered to participate in this study. We also would like to extend our thanks to the reviewers, group leaders, and all participants in the CERME14 TWG18b group helped improve our work.

Development of self-reported technological pedagogical content knowledge (TPACK) during the preparatory service of prospective mathematics teachers in Germany

Fabian Grünig[1] and Markus Vogel[2]

[1]St.Gallen University of Teacher Education, Institute of Educational Psychology, St.Gallen, Switzerland; fabian.gruenig@phsg.ch

[2]Heidelberg University of Education, Institute of Mathematics and Computer Science, Heidelberg, Germany

In this study the self-assessed technological pedagogical content knowledge (TPACK) growth of 91 prospective mathematics teachers during the 2017-2018 preparatory service in Baden-Württemberg, Germany, was surveyed. In addition, data about hypothetically beneficial factors of the preparatory service were collected and their influence on knowledge acquisition was analysed using multiple regression analysis. Over the study period, a small to medium effect was found for the increase in knowledge. Multiple regression analysis revealed that the number of seminar sessions about technology integration in the mathematics classroom during the preparatory service and the extent of digital media use in teaching as significant factors influencing the TPACK acquisition of the prospective teachers.

Keywords: Teacher competencies, technological pedagogical content knowledge, teacher induction, workplace learning.

Theoretical background and research questions

The integration of digital technologies into mathematics education presents a significant challenge for prospective mathematics teachers. Technological pedagogical content knowledge (TPACK; Mishra & Koehler, 2006) is considered essential for effective classroom technology implementation, encompassing knowledge about effectively teaching with technology in ways that are appropriate for specific subject matter and pedagogical approaches.

In Germany, the "Vorbereitungsdienst" (preparatory service) bridges theoretical knowledge learned at university and teaching practice (Kultusministerium Baden-Württemberg, 2014b). This 18–24-month induction program follows university education. During the preparatory service, prospective teachers are supported in two main ways: through mentors at training schools and by trainers in state seminars for teacher education. At schools, they progress from observation to supervised and independent teaching. Mentors provide feedback and guidance. Simultaneously, at the state seminars they attend seminar sessions on pedagogy and didactics.

Research on the development of (not necessarily technology-related) professional knowledge during this phase has shown mixed results. Some studies suggest the preparatory service is effective in enhancing professional competence (e.g., van Driel et al., 2002), while others report little to no improvement (e.g., Kirschner et al., 2017). Alongside evaluation studies, large-scale surveys underscore the importance of the preparatory service in developing technology-related teaching skills.

The Bund-Länder-Indikator 2016, a series of studies assessing digital education across Germany's federal states, reported that over 80% of in-service secondary school teachers felt that the preparatory service should include better training on using digital media in teaching (Eickelmann et al., 2016). This highlights a perceived gap in technology-related preparation during this phase of teacher education. Similarly, the International Computer and Information Literacy Study (ICILS) 2018 study emphasized preparatory service's role in fostering prospective teachers' digital competencies. Younger teachers (aged up to 39) were more likely to acknowledge that the preparatory service had encouraged them to think about how digital media influences their teaching methods (Drossel et al., 2019). This suggests that recent changes in the implementation of the preparatory service may positively impact TPACK development.

However, questions remain about which specific aspects of the preparatory service support TPACK acquisition. To understand how technology integration in mathematics education is addressed, various curricular documents must be examined. In the German context relevant resources include: Reference frameworks for media education, such as the European Framework for the Digital Competence of Educators (Redecker, 2017) and the strategy paper of the Conference of the Ministers of Education and Cultural Affairs for education in a digital world (Kultusministerkonferenz, 2016); training standards for teachers, either federal or state-specific (e.g., Kultusministerium Baden-Württemberg, 2014b, 2016; Kultusministerkonferenz, 2012); and media education plans or seminar curricula (e.g., Kultusministerium Baden-Württemberg, 2014a, 2018).

An analysis conducted by the authors on preparatory service curricula uncovered a substantial gap in fostering technology-related teaching competencies for mathematics education. No explicit curricular components addressing subject-specific technology integration. The media education plans and seminar curricula examined contain only vague literature references about media use in mathematics classrooms, offering minimal practical guidance. Due to space limitations, the analysis cannot be presented in detail here.

On a broader scope, research on TPACK has identified several factors that are beneficial for professional development. Based on prior studies, the following learning opportunities (Lohse-Bossenz & Vogel, 2021) are considered relevant for fostering TPACK during teacher education

- Discussion of mathematics-specific digital tools and media in formal seminar sessions (Ning et al., 2022; Wang et al., 2018)
- Practical use of digital tools and gaining firsthand experience by incorporating them into one's own teaching (Li et al., 2022; Mueller et al., 2008; Tondeur et al., 2017)
- Mentor-guided discussions about technology use in mathematics instruction, allowing mentees to share experiences and receive targeted feedback (Ning et al., 2022; Tondeur et al., 2017; Zhang & Tang, 2021)
- Collaborative reflection on teaching with digital media, enabling teachers to critically assess and improve their practices (Harris, 2016; Zhang & Tang, 2021)
- Basic technological knowledge (TK) at the start of training, which serves as a foundation for developing TPACK, though the extent of its influence remains debated when other TPACK components are considered (Li & Li, 2024; Li et al., 2022; Schmidt et al., 2009)

Given the current state of research and the lack of explicit curricular elements targeting subject-specific technology integration within the German teacher induction system, this study makes a unique contribution by conducting a detailed, longitudinal assessment of TPACK growth during the preparatory service and by systematically examining the relative impact of various learning opportunities on technology-related knowledge development during the critical preparatory service phase. The research questions guiding this investigation are:

RQ1: Does the preparatory service of prospective mathematics teachers lead to knowledge acquisition in the technological pedagogical content knowledge (TPACK)?

RQ2: Which factors within the preparatory service significantly contributes to explaining the variance in the knowledge acquisition?

Methods

The study utilized a longitudinal design with two measurement points over the course of the 2017-2018 preparatory service in the state of Baden-Württemberg, Germany. The sample included 91 prospective mathematics teachers preparing for the (non-gymnasium) secondary school track. During their preparatory service, participants completed a self-assessment questionnaire at both measurement points to evaluate their TPACK. The questionnaire contained subscales for technological knowledge (TK) based on Schmidt et al. (2009), and technological pedagogical content knowledge (TPACK) based on Handal et al. (2012). Both instruments were adapted for the German language by the authors.

The TK subscale consists of seven items that assess general technological skills knowledge rather than specific technologies. They cover aspects such as the ability to solve technical problems, the ease of learning new technologies or past opportunities to work with different technologies. Responses are rated on a 5-point Likert scale, ranging from “Strongly Disagree” to “Strongly Agree”.

The TPACK subscale for mathematics teachers includes seven items adapted from Handal et al. (2012). They are also rated on a 5-point Likert scale, ranging from “Strongly Disagree” to “Strongly Agree”. Topics focus on the integration of technology, pedagogy, and mathematics content knowledge and cover aspects such as using technology to assist students in developing math problem-solving skills, representing math problems linking symbolic, numerical, and graphical data or incorporating authentic tasks into math lessons.

At the second time point, participants additionally reported on factors hypothesized to influence TPACK development. These factors aimed to explore the potential mechanisms and opportunities contributing to the acquisition of TPACK throughout the preparatory service:

- *Seminar sessions on technology integration:* Participants reported the number of seminar sessions that addressed the use of various digital tools in mathematics teaching, including computer algebra systems, dynamic geometry software, graphing calculators, and general computer/tablet use. Response options ranged from “None/Never” to “5 or more” sessions.
- *Collaborative case analysis:* Participants indicated whether they engaged in analysis of their own concrete teaching examples during seminar sessions.

- *Mentor discussions:* Participants reported the frequency of discussions with their mentors about using digital media in mathematics lessons. This was assessed for different types of technology, with response options ranging from “None/Never” to “5 or more” discussions.
- *Teaching experience with digital media*: Participants estimated the typical duration of technology use in their own teaching, reported in minutes for a standard 180-minute teaching unit. This was collected for various types of digital tools and software. This item was taken from the MiU project (Ostermann et al., 2019) and adapted for this study.
- *Initial technological knowledge:* The TK subscale from the first measurement point was used to assess participants' general technological knowledge at the start of the induction year.

To evaluate the influence of hypothesized factors on TPACK growth, a score was aggregated for each factor. The frequency of both seminar sessions and mentor discussions related to digital tools was coded on a scale from 0 to 5. A sum score was then calculated for different types of digital tools discussed. The occurrence of collaborative case analysis was coded dichotomously (0 = no occurrence, 1 = occurrence) based on whether participants engaged in collaborative analysis of cases involving technology use. To acquire a score for the teaching experience with digital media per participant, the specific technology was identified which was used the most. The duration of media use was quantified as the proportion of its use within a 180-minute unit. For the TK score as well as the TPACK scores at both measurement points a mean score was calculated across all items.

Multiple linear regression analyses were conducted to determine the impact of these factors on TPACK growth while controlling for baseline TPACK scores. The initial regression model included the TPACK score at the first measurement point as a baseline predictor along with all five hypothesised factors. A backward selection approach was used to identify relevant factors. Predictors were removed step-by-step based on statistical significance. At each step, model comparisons ensured that removing a predictor did not significantly reduce the model’s explanatory power. To address missing data, analyses were conducted across 100 imputed datasets. The pooled results from these datasets were used for both model selection and reporting.

The following analysis reveals the outcomes of these methodological approaches, providing insights into TPACK development among prospective mathematics teachers during their preparatory service.

Results

This study involved $n = 91$ prospective teachers from six state seminars, with between 1 and 31 participants responding to the questionnaire at each seminar. Addressing RQ1, the analysis of the self-assessed TPACK scores showed a statistically significant increase from $M = 2.88$ ($SD = 0.80$, $\alpha = .90$) at the first measurement point to $M = 3.20$ ($SD = 0.77$, $\alpha = .90$) one year later, $t(77.096) = 3.765$, $p < .001$. This represents a small to medium effect size (Cohen's $d = 0.45$).

Participants reported attending a median of 2 seminar sessions ($M = 2.38$, $SD = 2.75$) on technology integration in the mathematics classroom. They also reported having a median of 2 discussions ($M = 3.10$, $SD = 3.99$) with their mentors on the same topic. The most frequently mentioned technology in seminar sessions was dynamic geometry software (DGS), reported by 52 participants. In contrast, graphical calculators and scientific calculators were the least mentioned, with only 6 and

22 participants, respectively, noting sessions involving these technologies. However, scientific calculators were the most frequently discussed technology in mentor discussions, with 50 participants reporting at least one discussion on the topic. In their own classrooms, the prospective teachers reported using digital media for an average of 36.20 minutes per session (SD = 35.99 minutes).

Addressing RQ2, the baseline model, which included only the TPACK score at the first measurement point, explained $R^2 = 24.93$ % of the variance. At the beginning of the backwards selection process a model with all predictors was computed. It explained an additional $\Delta R^2 = 18.80$ % of the variance beyond baseline prediction. During the selection process, predictors that did not significantly contribute to the model were removed one by one. First, the frequency of mentor discussions was excluded ($\beta = -0.008$, $p = 0.730$). Next, the collaborative case analysis variable was removed ($\beta = 0.149$, $p = 0.431$), followed by the initial TK score ($\beta = 0.106$, $p = 0.304$). At each step, comparisons confirmed that removing these variables did not significantly reduce the model's ability to explain variance ($p > 0.282$ for all comparisons).

The final model incorporated the initial TPACK score ($\alpha = 0.426$, $p < 0.001$) and two significant predictors: seminar session frequency ($\beta = 0.082$, $p = 0.001$) and digital media teaching experience ($\beta = 1.032$, $p = 0.004$). The model explained 39.70% of variance in TPACK, with additional predictors contributing 14.77 percentage points beyond the baseline score.

Discussion

The findings of this study provide insights into the development of TPACK among prospective mathematics teachers during their preparatory service. The small to medium effect observed in self-reported TPACK growth suggests that the preparatory service does contribute to the development of technology-related competencies, albeit to a modest degree. A detailed survey measured various aspects of the induction experience, such as formal learning sessions, informal discussions, and hands-on teaching practice, to understand their influence on TPACK development.

Using a backward selection approach, the study identified two key factors that significantly affected TPACK growth: the frequency of technology-focused sessions in seminars and the extent of digital media use in the prospective teachers' own teaching These findings emphasize the importance of combining theoretical training with practical application to foster TPACK acquisition.

The impact of technology-focused seminar sessions highlights the value of structured learning opportunities in teacher training. This suggests that the preparatory service should allocate time and resources specifically to teaching how to integrate technology into the mathematics classroom. Additionally, the positive impact of prospective teachers using digital tools in their own teaching demonstrates the importance of learning through reflective practice. Offering supervised opportunities for technology use in real classrooms is essential for developing TPACK.

Interestingly, factors such as collaborative case analysis, mentor discussions, and initial technological knowledge did not significantly predict TPACK development when controlling for other factors. This unexpected result suggests a need to reevaluate how these elements are implemented in the preparatory service or how they were measured in this study. For instance, the assessment of case analysis did not focus explicitly on technology-related reflections, which may have limited its

relevance to TPACK development. General case work might not be specific enough to explain TPACK outcomes. Although TK scores are often identified as relevant factors in other studies, they did not show significant effects here. Further analysis revealed no extreme low or high scores (floor or ceiling effects) and no significant influence on TPACK growth when TK was the sole predictor. Recent studies also questioned the relevance of TK in TPACK development (Li & Li, 2024; Li et al., 2022). Mentor discussions, while theoretically valuable, may not have stood out due to variability in mentoring quality and appears to be masked by other factors. In many schools, mentor selection is often delegated to school leadership, who may prioritize factors such as general teaching experience or workload considerations over specific qualifications for (technology-related) mentoring.

The small sample of 91 participants from a single German state limits generalizability. Additionally, since the participants were drawn from different state seminars, variations between these groups could have influenced the findings. Variations between state seminar groups couldn't be properly assessed due to sample size. This implies a need for caution when applying these findings to broader contexts. The study relied on self-reported indicators for TPACK, which, while well-established as predictors of teaching practice, do not correlate perfectly with objective measures of knowledge. This limitation suggests that the study might not have captured the full spectrum of TPACK development, particularly with respect to objective and demonstrable competencies.

The study highlights the need to balance theoretical training with practical opportunities in teacher preparation programs. However, the limited variance explained by the model suggests that other factors, not examined here, may also influence TPACK growth. Future research should explore additional variables that might influence TPACK growth. Longitudinal studies extending beyond the induction year could give further inside which factors support TPACK acquisition in the long run.

From "anyway using many representations" to targeted practices: A teacher's professional learning in an asynchronous online PD

Kerstin Hein[1], Anne Tester[1], Lena Böing[1] and Susanne Prediger[1,2]

[1]TU Dortmund University, Dortmund, Germany; kerstin.hein@math.tu-dortmund.de

Asynchronous online teacher professional development (PD) courses have a long tradition. However, only a few studies have investigated the content-related learning pathways that such courses can initiate. We present a case study from the larger PD design research project Mastering Math, which follows a teacher's professional learning pathway initiated within a PD module. The content of the PD module connects representations to deepen students' understanding of subtraction; with the case study, we can show that professional learning of representations is also possible based on focused asynchronous PD activities.

Keywords: *Online professional development, multiple representations, professional learning*

Introduction

Although multiple representations are widely used in many mathematics classrooms, teachers' practices in dealing with them have been shown not to be always sufficiently targeted to profoundly enhance students' conceptual understanding of concepts and operations (Dreher & Kuntze, 2015; Prediger & Wischgoll, 2023). Therefore, there is a need for scaled professional development.

Asynchronous online teacher professional development (oTPD) courses have been developed and promoted for two decades in order to scale up PD offers and to make them more flexible, for example, in rural areas (Bragg et al., 2021; Dede et al., 2009). However, there is still a lack of research that captures the content-specific professional learning pathways that have been initiated, particularly for oTPD in mathematics education (Friesen et al., 2023). In this paper, we present a PD design research study of an oTPD module that addresses multiple representations, which aims to answer the following design research question: *What professional learning pathway can be initiated by an oTPD module designed to promote teachers' practice with multiple representations?*

Theoretical background

Research gap on teachers' content-specific professional learning in oTPD

Within the last 20 years, research on oTPD designs has primarily focused on reducing dropout and enhancing teachers' cognitive and communicative engagement in content-independent research perspectives. For example, studies have demonstrated the potential of combining inputs with PD activities using interactive features in closed or open formats (reviewed by Bragg et al., 2021). While many studies have shown the overall effectiveness of oTPD, the authors of the review call for disentangling the conditions and effects of using particular design elements differently and tracing the professional learning pathways in more detail (Bragg et al., 2021; Seago & Knotts, 2021). Dede et al. (2009) and Friesen et al. (2023) also call for more content-specific research into the different PD contents and the content-specific professional learning pathways of individual teachers.

Teachers' content-specific learning pathways can be investigated with respect to changes in teachers' simulated practices in carefully designed PD activities, with vignettes designed to simulate particular content-specific instructional demands (Dreher & Kuntze, 2015). Simulated practices can be captured by teachers' suggestions about what they perceive and how they would react to the situational demands simulated in the vignette. As the extensive research on teacher noticing has shown, what teachers perceive and how they react is shaped by their overall orientations (e.g., the more graphic representations are used, the better) and by the categories that they implicitly or explicitly apply to their noticing and decision making (Sherin, 2014). For the practices in view of our PD project, the unpacking of learning goals into sub-goals serves as an important diagnostic category. Teachers who clearly articulate learning sub-goals tend to address enhancement practices that are more specifically targeted at carefully chosen sub-goals (Prediger et al., 2023).

Teachers' practices for dealing with multiple representations

For enhancing students' conceptual understanding of mathematical concepts and operations (such as subtraction), the use of multiple representations (manipulatives, graphical, verbal, and symbolic) is widely promoted (Lesh, 1979). However, the use of multiple representations does not always lead to deeper conceptual understanding, only when the representations are explicitly connected, with an explanation of where to find the relevant elements and structures that represent the operation (ibid.). In our German context, almost all teachers appreciate the work with multiple representations but have heterogeneous practices in its implementation: Dreher and Kuntze (2015) investigated teachers' underlying views and noticed in dealing with multiple representations and found evidence that many German teachers are unaware of typical challenges in dealing with multiple representations. For the case of multiplication, Prediger & Wischgoll (2023) showed that many teachers do not know the underlying structures and rarely use the diagnostic category of surface translations (that not only the two numbers need to be found in both representations) for their noticing, more concise learning goals were not addressed as topic-specific diagnostic categories. In order to enact enhancement practices that leverage students' ability to explicate the underlying structures and to connect representations, teachers' categories for unpacked learning sub-goals should also include the typical *models for the operation*, such as counting in units for multiplication (Prediger & Wischgoll, 2023). For subtraction, the two crucial models are *taking away* and *determining the distance* (van den Heuvel-Panhuizen & Treffers, 2009). In summary, the relevant categories for enhancing students' understanding by dealing with multiple representations include whether the student translates only the involved numbers or also the underlying structure modelled by the operation and the particular models for the content in view of this paper, for subtraction *taking away* and *determining the distance*.

Design of the overall PD program and the oTPD module in view of this paper

Research context of the Mastering Math program

Since 2010, formative assessments, teaching materials and PD materials have been developed for the program Mastering Math so that teachers can foster their at-risk students' conceptual understanding of basic arithmetic concepts such as place value understanding, the meaning of addition/subtraction, multiplication/division, etc. in conceptually focused foundation lessons (Prediger et al., 2023). In a two-year PD program, teachers experiment with the materials and work in twelve PD modules,

consistently targeting practices for three situational demands, *specifying learning contents/goals*, *monitoring/noticing students' learning progress* and *enhancing students' understanding* (of basic concepts). In the third PD, in view of this paper, the three demands are addressed in terms of dealing with multiple representations for subtraction, which has already been addressed in the previous modules, but for the basic concepts of understanding place value understanding and the number line. As the Mastering Math program (with face-to-face PD modules conducted by facilitators) has shown overall effectiveness for students' mathematical learning and teachers' professional learning (Prediger et al., 2023), we can now investigate more focused aspects for the scaling-up process with oTPD.

Design of the oTPD module on work with multiple representations for subtraction

As there are too few facilitators available to conduct face-to-face PD modules, we have started to develop asynchronous oTPD modules for scaling up (Tester et al., 2024; so far, four modules). Participating volunteer teachers can work through the oTPD modules and experiment with the teaching materials in between. Each three-hour PD module consists of a number of thematic blocks, each of which addresses one or two of the situational. Figure 1 documents the design of Blocks 1 and 4 (out of 12) of the oTPD that the teacher in our case study worked on, with the content and formats. Inputs (with video sequences or slides) and PD activities are combined with different formats. Module 3 deals with typical challenges and specifying learning goals for representations of subtraction. PD activities use closed formats (such as multiple choice or drag-and-drop) and open formats (such as reflection questions, e.g., the teachers have to identify typical challenges or suggest enhancement practices), partly based on written vignettes or classroom videos (Seago & Knotts, 2021). Figure 2 shows further activities and inputs of later blocks.

Methods of the case study

The overarching design research project: Given the dual aims of developing an oTPD and investigating professional learning processes, the overarching project adopted a design research approach to teacher PD, in which designs and the qualitative investigation of their outcomes are iteratively refined, so far in three cycles of design experiments (Bragg et al., 2021; Prediger, 2019). In the empirical section of this paper, we present a qualitative case study of one teacher's professional learning pathways, as outlined in the design presented above. Similar intended learning pathways have been described for teachers in face-to-face teacher professional development programs (Prediger et al., 2023), but rarely for asynchronous teacher professional development programs (Tester et al., 2024). The case is from Cycle 2, in which 20 teachers participated.

Methods of data collection for the case study in this paper: As recommended by Dede et al. (2009), our methods of data collection "make use of the data streams collected in technology-mediated interactions… [when and] to what ... they respond, in what order they solve problems, and their trajectory of learning" (Dede et al., 2009, p. 15). The data were collected in the Moodle learning management system, where the oTPD modules of the Mastering Math program (Prediger et al., 2023) are implemented. In addition to teachers' responses and self-corrections, Moodle tracks the chronology of work with timestamps. The teachers' professional learning gains are assessed by capturing their simulated practices in parallel open-ended diagnostic vignettes in situated ways (Friesen et al., 2023), here with Block 1 a) from Figure 1 and a parallel vignette in Block 12. For this paper, we chose the case of the pseudonym Helen, a secondary school teacher in North Rhine-Westphalia, who attended a synchronous kick-off meeting with her colleague at her school to receive a general presentation of the Mastering Math program. Helen's example illustrates how the oTPD can enhance professional learning.

Methods for qualitative data analysis: *Teachers' responses* within the oTPD activities were qualitatively analysed regarding teachers' simulated practices and the underlying content-specific categories for perceiving and thinking (methodologically based on the framework for content-related teacher expertise; Prediger, 2019). These categories include, for example, goal categories such as meaning-related language in "Which number is the whole? Which number we seek?" and appropriate representations. For productive enhancement practices, categories for reaching deep connections might include, for example, seeing the mathematical structures in the materials. To analyse the process over time, the time stamps were analysed in relation to the content of the blocks and accomplished activities. By comparing the categories and processes over time, we intend to investigate the teacher’s professional growth within the oTPD.

Empirical insights into Helen′s professional learning pathway

Time structure and chronology of Helen's work: After the kick-off meeting (October, 20) of the PD program, Helen worked within Module 2 on number lines (November, 1, 2.01-2.42 pm; November, 7, 9.28-9.29 pm) and looked at the beginning of Module 3 (meanings of addition and subtraction: December, 14, 9.55 pm). Helen worked within Module 3 while skipping the activities marked as complimentary (January, 4, at 9.24-10.26 pm). Helen completed the open-ended questions when they were relevant to the certificate (vignettes) and the activities saved for the school practice

(here, stimuli and learning goals). Helen looked again at Block 3 on models for addition/subtraction (January, 18, 10.26-10.27 pm), where she had skipped the activity, and then at Block 1 with the pre-vignette. In summary, Helen first previewed the introduction, later worked through the module linearly without the complimentary activities and later looked back at the overviews of the models and the pre-vignette.

The starting point of Helen′s professional learning pathway in Block 1: At the beginning of Block 1, Helen was asked to analyse Finn′s translation of the symbolic expression 35– 19 into a graphic representation with two unconnected amounts of money, 35 € and 19 € (see Figure 1). Finn′s drawing exemplifies a typical student challenge, as it represents both numbers (subtrahend and minuend) separately, without explication of a subtractive structure, neither *taking away* nor *determining the distance*. Teachers are invited to identify this challenge when analysing Finn′s work and to suggest a targeted approach to overcoming it, for example by starting a conversation about what it means to represent an operation graphically. Helen's answer to the pre-vignette was as follows:

> Helen (Block 1a): "I would ask him to represent the subtraction also with (drawn) base-10 blocks, with ten rods and unit cubes. So, we could talk again about the total quantity. Subsequently, I would make him draw the total quantity on the number line so that he can conduct the calculation on the number line."

Helen did not make explicit the main challenges that she saw in Finn′s drawing, so we have to infer her diagnostic categories from the suggested enhancement practice. The main strategy of her enhancement practice was to change the representations: She proposed two more different representations, base-10 blocks and the number line. On the number line, she intended to solve arithmetic problems, which might refer to a perceived challenge of decomposing a ten into 35 before removing 19 from 35. Helen may have planned the base ten blocks to address this decomposition problem but without articulating it explicitly. Instead, she wrote about her intention to talk about the "total quantity" ("Grundmenge" in the original German), a technical term for interpreting the minuend in sets. While she did not address the main challenge of representing the subtrahend with its own money drawing, she may have alluded to the implicit idea that Finn needed to learn to represent a subtraction by explicating the taking away structures: the minuend should represent the whole (the "total quantity") and the minuend a subset that is taken away, but she did not articulate these plans explicitly. These observations are consistent with the teacher practices identified for multiplication (Prediger & Wischgoll, 2023): Many teachers had some key ideas of the model in mind but rarely explained that students should explicitly articulate how the mathematical structure that is modelled by the symbolic expression is represented graphically. Rather than planning for these deeper learning opportunities, teachers suggested changing the representation (again, without an explicit plan for targeted enhancement practices with this new representation).

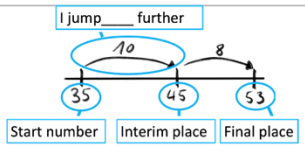
Advanced point of Helen′s professional learning pathway in Block 12: Post-vignette: The post-vignette in Block 12 was designed to run in parallel with the pre-vignette, with a more explicit invitation to formulate prompts that may be useful later in the class (which are automatically integrated into the teacher′s personalised planning document). Helen′s answers to the post-vignette:

> Helen (Block 12: "I would ask him what we have to do in general (taking away vs. add). Then I would ask him from which number we have to take away something, and, I would say, that it is not possible to find everything that he drew in the second

> wallet in the first. In this way, he would have to 'decompose' the notes by himself. Subsequently, I would ask him, how he can draw that we can take something away. Maybe we can cross out/circle better?"

Helen′s suggested prompt: "Mark in the left wallet, what you have to take away!" The analysis shows that after working through the oTPD module, Helen explicated the need to talk about the taking away structure that is modelled by a subtraction. Instead of talking about total quantities in two further representations, she addressed the targeted ideas by leveraging Finn′s resources. While she still felt the need to address the calculation obstacle of decomposing tens for the subtraction with carry, her main attention went to the key idea: When representing an operation, the two numbers should not be addressed separately, but the action of taking away (modelling subtraction) should be represented. For this much more targeted learning goal, she provided graphical scaffolds (by suggesting a way of to draw the action) and conceptual scaffolds in her suggested prompt. In this way, her simulated practices became much more targeted to the student′s detailed learning needs. The targeted practice drew upon new categories explicated in her writing: the model taking away and the explicit requirements for drawings to represent not only the numbers separately, but also the structure.

Helen′s professional learning pathway between pre-vignette and post-vignette: Helen′s simulated practices changed considerably from pre- to the post-vignette in terms of making implicit ideas and targeted learning sub-goals explicit. What happened in between? Already the activity that followed the pre-vignette in Block 1b (printed in Figure 1) provided a learning opportunity as multiple choices of interpretations provided categories for articulating interpretations more concisely. Helen chose the correct one. In the drag-and-drop activity in Block 4, Helen wanted to express the complementary relationship to addition which is important, yet not in the simulated situation. Figure 2 depicts some of the further professional learning opportunities in Blocks 6 to 9 that focus on monitoring and enhancing students′ ability to explain how representations are connected.



Relevant steps in the trajectory of the oTPD Module 3 on dealing with representations for subtraction (key slides or questions)	**Formats of oTPD elements in these blocks (each block combines activities and inputs)**
Monitor students' learning progress / enhance students' understanding	***(Sequence of inductive-deductive blocks)***
Block 6/7: Discussing conditions for the match of representations **b)** Which representations do not match to the story? (Subtraction) ... **e)** Analyse how the teacher works with the students. **f)** Plan your next prompt to make the students aware that the two numbers cannot be represented independently. 	**a)** Introduction to the task and challenge in the video case ("Why does this representation fit? How can the minus be represented within the representations?") **b)** Drag-and-drop activity to monitor incorrect representations **c)** Text input about representations that match **d)** Text input about learning needs in conditions for matching of representations (exemplified for representing 305-30 with base-10 blocks) **e)** Video of an enhancement teacher and student dialogue **f)** Activity: Preparing oral prompts to support students
Block 8: Supporting the connection of representations a) What do students need to articulate for explaining why these representations match? How do you plan to support the students' explanation? 	**a)** Activity: Preparation of oral prompts to elicit students' explanations of connections between representations **b)** Text input on possible prompts with for explanations and underlying structures
Block 9: Language support for articulating meanings Extracts from a poster with language scaffolds 	**a)** Input by expert video about phrases needed to articulate meanings and connections **b)** Cloze text activities: "Which phrases can support the articulation of meanings?" **c)** Text input about language such as "What number is searched?"

Figure 2: Further professional learning opportunities in between connecting representations

In Block 6, Helen correctly identified the problematic representation of both numbers, indicating that the learning in Blocks 1b and 4 was having an effect. When asked to prepare oral prompts for the students in the video case (Block 7), Helen focused on decomposing the hundreds rather than the key ideas about connecting representations. In Block 8, she correctly identified the model of determining the distance and unfolded it for the students as in the videos and texts given earlier. In Block 9, she chose appropriate language scaffolds to support students′ articulation of meanings. In this way, she exploited the professional learning opportunities, even though there is still room for improvement their design for clarity.

Summary of Helen′s professional learning pathway and implications

The analysis of Helen's case shows that, although her work was fragmented over several sessions and took unexpected turns, she was following an interesting professional learning pathway. The practices she articulated in the pre-vignette were guided by superficial categories and not yet articulated with explicitly targeted sub-goals of conceptual understanding. In particular, general requirements for connecting representations or the concrete model of *taking away* were not addressed (similar to the findings of Prediger & Wischgoll, 2023). In her intermediate activities, she was distracted by additional ideas that were not core to the tasks (e.g., decomposing bundles of tens). First, she used "total quantity" in her formulations and also expressed it to the students as "amount that is still missing". In this way, she unconsciously jumped between models. In the post-vignette, she addressed the need to graphically represent also the structure of *taking away*, not just individual numbers. In a later oTPD activity, she also elicited explanations of connections from the students that were still missing in the post-vignette. Overall, we can see a professional learning pathway characterised by successive unpacking of learning goals and successive targeted prompts.

In this single case study, we see the first modest indications that the rich open-ended activities that ask teachers to articulate their initial ideas can be successfully combined with more focused multiple-choice formats that introduce new ideas or categories for learning goals in a cognitively activating way with immediate feedback (Seago & Knotts, 2021). Although Helen did not make immediate use of all the inputs and activities, she did pick up on goal categories offered (e.g., appropriate connecting representations). Helen took advantage of the opportunity to work time independently in the evening and returned to relevant input on the most important learning goals. However, there is also the obstacle of going to school in between to use the material for diagnostic judgements or to enhance students. While the case study of Helen′s pathway suggests that it is possible to trace professional learning pathways in a qualitative way and that it is fruitful to combine data on the content and the time to understand more about how teachers can learn with oTPD, a single case should not be over-interpreted in terms of generalizability. Further research is needed to investigate more cases and examine the design elements individually, as suggested by Bragg et al. (2021).

Acknowledgment

Mastering Math has been funded since 2010 by Telekom Foundation and several State Ministries of Education. The online PD is developed and investigated in SchuMaS, funded by the German Ministry of Education and Research (grant no. SMS2101L-01PR2101C to S. Prediger).

Development of the disciplinary identity of the mathematics teacher: A professional development proposal

Maximiliano Izzi-Prato and Francisco Cordero

Center for Research and Advanced Studies of the National Polytechnic Institute (Cinvestav), Mexico; maximiliano.izzi@cinvestav.mx

Socio-epistemological theory defines the notion of mathematical school discourse as a system of reasoning that governs the practices, actions, and decisions of the actors within the educational system. Teachers being immersed in this system of reasoning, accept certain established practices as predominant paths that are difficult to question. From the Soltsa socio-epistemological program, it has been pointed out that this is one of the reasons why a distance is established between school mathematics and the realities of both students and teachers. In this context, the program seeks to propose the development of the disciplinary identity of mathematics teachers by strengthening three aspects of their practice: resistance, legitimation, and project. The objective of this paper is to discuss a professional development proposal for mathematics teachers, which is grounded in the development of their disciplinary identity.

Keywords: Teacher professional development, socio-epistemology approach, functional Mathematics.

Research problems and some theoretical aspects

The report presented here describes an ongoing doctoral research project in the Department of Mathematics Education at Cinvestav, Mexico. The theoretical framework considered is the Socio-epistemological Theory of Mathematics Education (STME) (Cantoral, 2016; 2019). This scientific theory within the field of Mathematics Education falls under the sociocultural paradigm of the discipline and studies the processes of social construction of mathematical knowledge and its institutional diffusion. It considers that mathematical knowledge is constructed in diverse social contexts, whether in academic knowledge (scholarly), technical (professional), or popular (everyday life), as a socially produced entity with context and heritage. The theory suggests that incorporating the sociocultural dimension of mathematical knowledge into didactic interventions could be beneficial for mathematics education in schools.

Specifically, this research is immersed in the socio-epistemological program known as *forgotten subject and the transversality of knowledge* (Soltsa for acronym in Spanish) (Cordero et al., 2022; Cordero, 2023). This program aims to recognize the functional uses of mathematical knowledge within various communities by documenting their relationship with the peculiarities of their everyday lives. The goal is to acknowledge the plurality of mathematical knowledge, that is, to give epistemological validity to different ways of doing mathematics. In doing so, the objective is to influence institutionalized school mathematics and its teaching and learning practices.

Within the framework of the Socio-epistemological Theory of Mathematics Education (STME), the theoretical notion of *mathematical school discourse* (dME for acronym in Spanish) has been developed, characterizing it as a system of reasoning (Bourdieu, 1997 in Soto & Cantoral, 2014) that

governs the practices, actions, and decisions of individuals, as well as the regulations that shape the school system around the teaching and learning of mathematics. A system of reasoning shapes a social structure that sets boundaries on what is considered acceptable and what is not within that system. Bourdieu suggests that our actions and decisions are influenced by social and cultural dispositions we have acquired throughout our lives. These dispositions include ways of thinking, perceiving the world, and acting, which are socially constructed and often operate unconsciously. In the educational sphere, the system of reasoning can determine which knowledge is valued and how students' skills are assessed, thereby influencing their success or failure within that system.

In this sense, the dME hegemonically imposes certain meanings, procedures, and arguments associated with what is conceived as doing mathematics. One of the characteristics of dME is that it prioritizes the abstract, formal, and procedural treatment of pre-established concepts of the curricula.

The dME produces certain phenomena, one of which is *adhesion* (Cordero et al., 2015). This notion of *adhesion* refers to the process by which the normative nature of the dME leads to the internalization and reproduction of its traits as norms that are rarely questioned. This dynamic establishes a framework for the teaching and learning of mathematics, where teachers, operating within institutional and cultural constraints, adopt and replicate these practices as part of their professional role. In this way, the dME perpetuates itself, not through individual choice, but as a result of the broader structure in which educators and students are embedded. This results in certain knowledge being accepted as truth, certain procedures and arguments being favored over others, and the lack of recognition of mathematical knowledge constructed in other contexts than school (Cordero et al., 2015). Figure 1 presents a schematic representation of the structure of the dME, reconstructed based on Soto and Cantoral (2014).

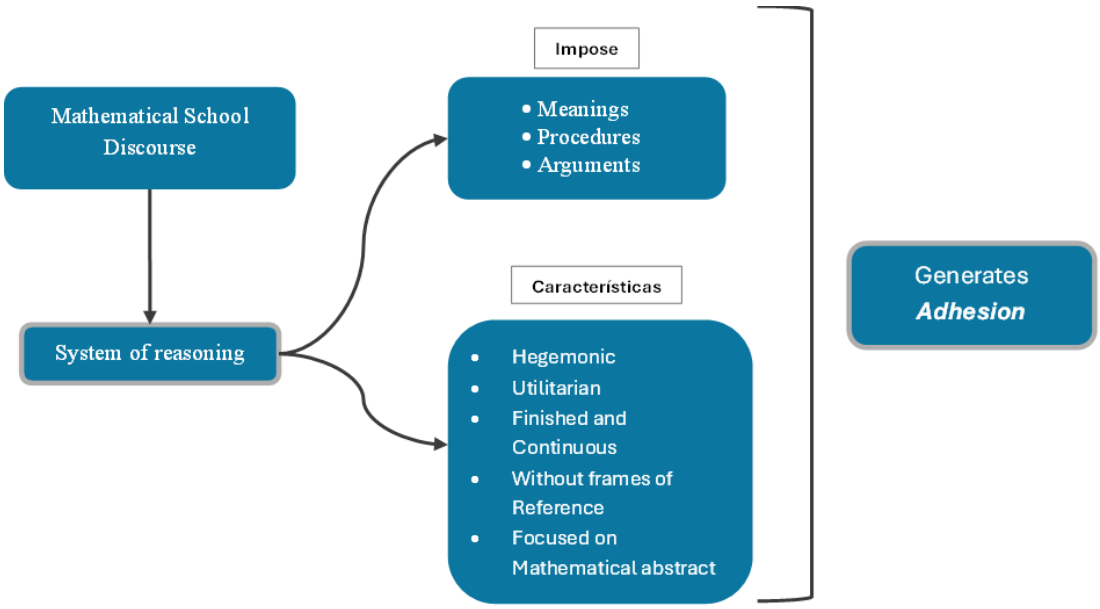

Figure 1: Mathematical School Discourse

This issue of *adhesion* is sought to be addressed through the theoretical construct of *disciplinary identity* of mathematics teacher's (Opazo-Arellano & Cordero, 2021; Opazo-Arellano et al., 2022). Cordero (2023) explains that the notion of *disciplinary identity* aims to describe the actions teachers take to "value the mathematical knowledge of people in order to influence the practice and teaching of mathematics" (p. 169). The model of *disciplinary identity* consists of three systematically interrelated components: *resistance, legitimation* and *project.*

Resistance involves a critical stance towards dME. This component is expressed by valuing epistemologies of mathematical knowledge that challenge the established norms of the dME, shifting the focus away from the mathematical abstract concepts without rejecting them. *Resistance* manifests in new perspectives and practices in mathematics teaching, questioning adherence to a dominant epistemology and promoting epistemological plurality.

Legitimation refers to the process through which the teacher recognizes and validates different types of knowledge, not just traditional school knowledge. This recognition leads to a reconsideration of mathematics teaching, valuing the plural use of mathematical knowledge, which can be reflected in the teacher's practices and the design of the school activities they implement.

The *Project* component represents the construction of new, autonomous proposals and arguments in the teaching of mathematics, which emerge from the teacher's creation of school activities. This component highlights the development of innovative uses of mathematical knowledge, reflecting the teacher's autonomy and creativity.

Within this framework, the objective of this research is to provide empirical evidence on how practicing mathematics teachers develop their *disciplinary identity* as they engage in a professional development experience. And, the objective of this paper is to discuss this professional development proposal.

The Experiment

We characterize this research project as an implementation (Artigue, 2021) of some results obtained from studies framed within the socio-epistemological Theory of Mathematics Education (STME) (Cordero et al., 2022). By implementation (Artigue, 2021), we refer to the type of application that involves translating theoretical results with an empirical basis into strategies, methodologies, or practical interventions that can be used for the benefit of society, or at least as applications to better understand possible pathways for innovative educational actions in practice. Artigue (2021) reflects on the inherent challenges of conducting this type of research. For instance, she mentions that applied studies are expected to serve as a bridge between basic research and its implementation in education in a rigorously scientific way. In this sense, applied research, while it can draw on findings from scientific studies conducted under controlled conditions (coming, a priori, from any study within the discipline), must seek, as part of its disciplinary nature, to face the challenge of amplifying the relevance of those results. In figure 2, we present a global outline of the experiment as we are currently conceiving it.

The experiment we are designing consists of three stages, as shown in figure 2. The first stage will involve an initial immersion with a community of in-service mathematics teachers. While we have

not yet defined the exact population, we do have certain candidate groups of mathematics teachers from different states in Mexico or Uruguay. The objective is to have an approach on their daily professional practice and register aspects of the dME.

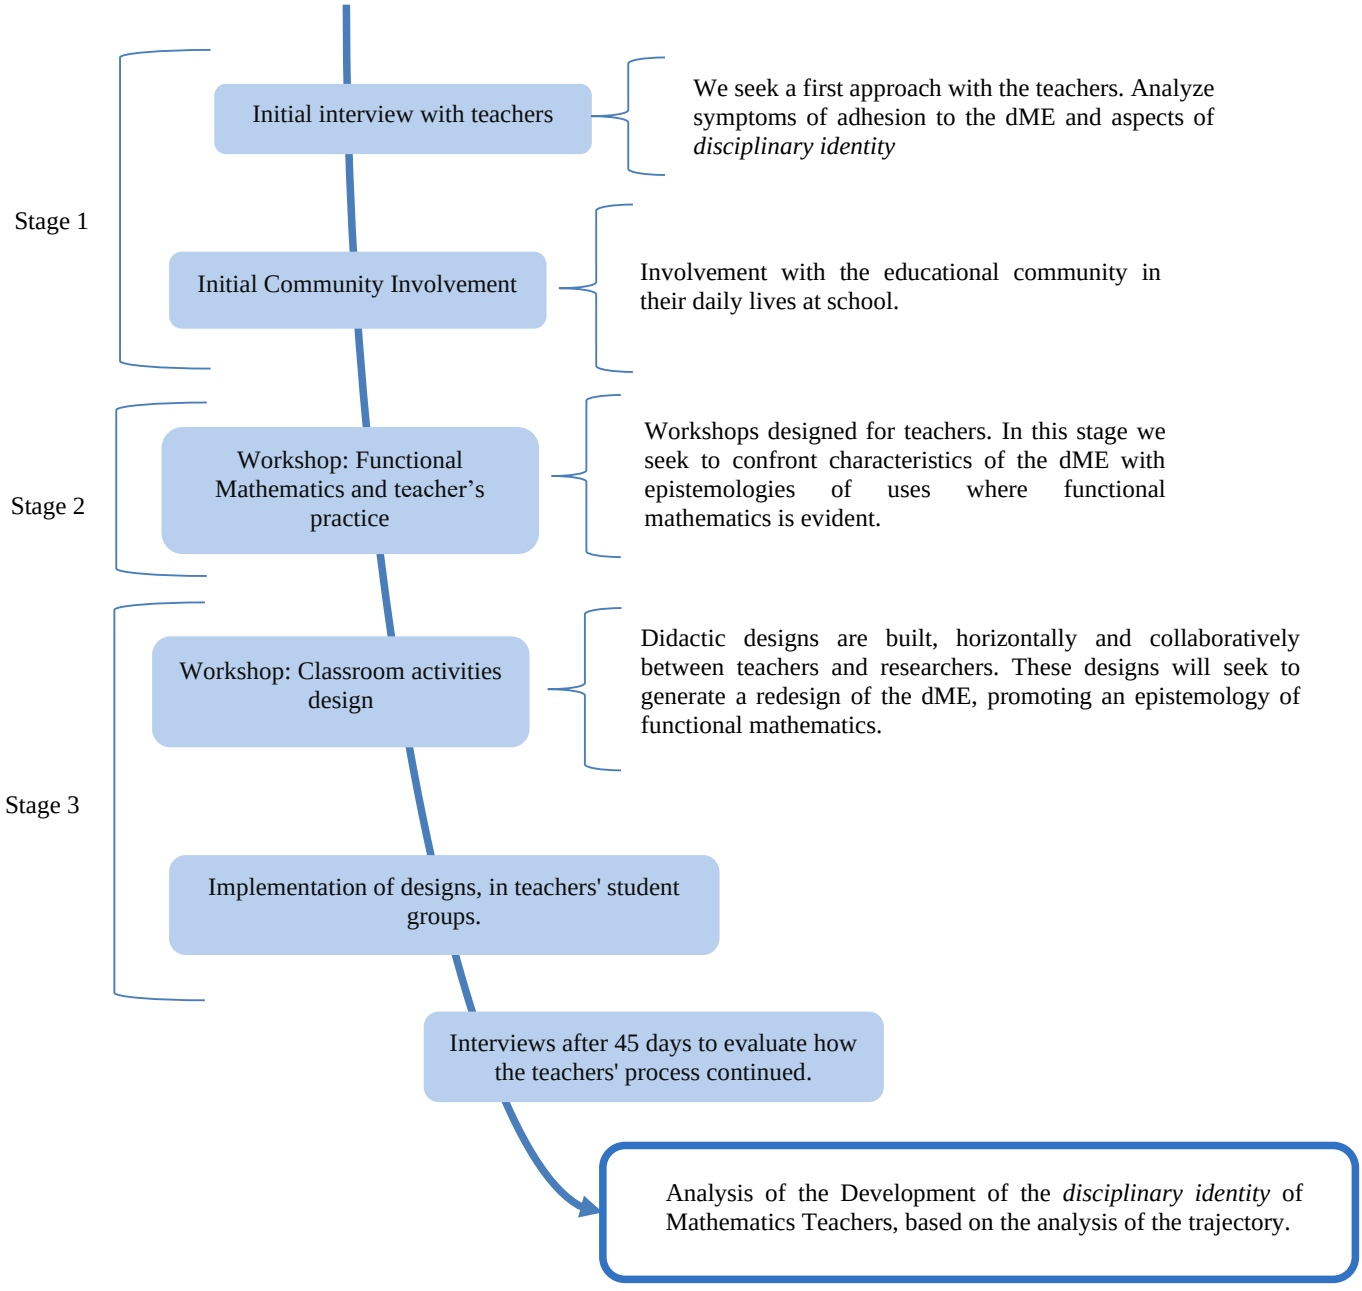

Figure 2: Overall structure of the experiment design

In the second stage, workshops will be conducted for the teachers. The goal of these workshops is to confront characteristics of dME and to facilitate this discussion, examples from the teachers' own

everyday professional practices, observed during the first stage of the research, will be brought into focus to problematize these theoretical aspects based on what is familiar to them. We consider that the success of this stage will be crucial to achieving the objectives of the final stage of the experiment.

In the last stage, based on the workshops in which the teachers participated, they will design didactic activities for their students with the aim of questioning certain established norms of dME.

Some theoretical foundations and methodological considerations for each of the stages

From the perspective of the Soltsa program, individuals generate knowledge by being immersed in and influenced by the communities they belong to. To better understand the teacher groups we will be working with, it will be necessary to become involved with the educational community in their everyday school environment. The methods considered for achieving this include interviews, classroom observations, and audio/video recordings (Rockwell, 2009; Guber, 2013). These considerations will guide the entire duration of the experiment, with a particular focus during the first stage.

In the first stage of the experiment, we aim to identify and record the dME in concrete situations that we can revisit to problematize during the workshops in the second stage. These characteristics can be observed, for example, in the opinions expressed by teachers, in how they organize their classes, in the tasks they assign, in how they validate or invalidate knowledge, and in how they value certain student contributions, among other aspects. During the last months of 2023, we had the opportunity to conduct an initial exploratory experience with practicing teachers in Uruguay. With them, we discussed and reflected on notions related to dME, and what we observed was promising. Teachers with certain orientations generally become aware of this phenomenon, because they recognize it from their practice, and achieving this awareness is a good starting point.

For the second stage, in the workshop design, we have considered two crucial theoretical methodological aspects for this project. The first is that the epistemological foundation of the workshop is based on the *category of modelling* proposed by the Soltsa program (Cordero et al., 2022; Cordero, 2023)

This *category of modeling* is proposed as a variety of the concept of mathematical modeling, as a theoretical way to characterize the uses of mathematical knowledge in specific situations. These situations occur within mathematical knowledge communities and are structured by sequential elements that build mathematical thought: meanings, procedures, and instruments, which lead to a situation-based argument (Cordero et al., 2022; Cordero, 2023). The core of the category does not lie in the mathematical model itself but rather in how the mathematical features of a specific situation can be meaningful and useful to a particular community. This perspective implies that the value of mathematics is not solely in its abstraction or formalization but in its ability to adapt to and address the needs, problems, or contexts relevant to the community that engages with it. This situation can be framed within two axes: institutionalization and the transversality of knowledge, where situations, domains, and alternations between settings occur, such as school-academia, work-profession, and city-everyday life (Cordero et al., 2022; Cordero et al., 2024). For example, Cordero et al. (2024)

shows how the category of *reproduction of behaviour* and its transversality can be interpreted across various domains and specific situations.

In second Stage, to apply this epistemological approach in the workshops for teachers, we consider the concept of *design of socialization school situation* (DSES, for acronym in Spanish), as proposed by the Soltsa program (Cordero et al., 2022). According to Cordero et al. (2022), the goal of these processes is to affect the dME by creating opportunities to emphasize the uses of mathematical knowledge within specific situations. This approach counters the phenomena induced by the dME while also enabling the analysis of teachers processes of developing of their *disciplinary identity* (Cordero, 2023).

The DSES concept is supported by two main aspects: an epistemological base rooted in the *category of modelling*, and a perspective that includes various factors contributing to the teaching and learning of mathematics depending on the intention, in this case it's the perspective of *disciplinary identity*. Rodríguez-Amador and Cordero (2023) provide an example of how this framework can be applied in a middle school context, focusing on the real-life situation of rainwater harvesting. This example highlights how mathematical knowledge can be used functionally, rather than simply acquiring abstract concepts. This design approach prioritizes the functionality of mathematics in context over the formalization of mathematical definitions or concepts. The idea of DSES is essential in the workshops because it shifts the focus from traditional, concept-driven teaching to a more contextual, use-oriented approach. This allows teachers to explore how mathematics can be relevant and practical in the everyday lives of students, promoting a more meaningful engagement with mathematical knowledge.

Gaete-Peralta et al. (2024) provide an epistemological foundation for developing the DSES intended for mathematics teachers in this research, which sets the second Stage. This work describes recent research from the Soltsa program, which focuses on the uses of quantification, through the analysis of how mathematical knowledge is used in specifics situations. It offers an alternative to the traditional dME in this topic, which is predominantly centered around formulas and primarily associated with the measurement of geometric figures. Additionally, the master's thesis by Izzi-Prato (2021), developed from a socio-epistemological perspective, recorded uses of measurement and quantification with epistemologies that also confront the traditional school concepts of measurement.

In the third stage of the experiment, the participating teachers will be invited to create their own designs. The aim is to observe the development of elements related to their *disciplinary identity*. We believe that in this stage, it will be possible to assess whether they have developed the ability to redesign aspects of dME and appreciate other mathematical epistemologies, as well as apply them in activities with their students. The methodological details of this stage are still in the design phase.

Conclusion

In this research, we explore a path to developing a *disciplinary identity* for mathematics teachers. We argue that it is crucial for teachers to develop a *resistance* to the norms of dME and to be knowledgeable about alternative approaches. However, approaches that have developed these mathematical epistemologies, as proposed by Soltsa, within the educational system, have not yet been

widely implemented. Throughout the paper, we highlight that this research aims to make an impact by implementing results derived from empirical studies, focusing on a professional development trajectory of teachers that is intended to be discussed in this paper.

In this regard, we believe that documenting the development of the *disciplinary identity* of mathematics teachers, as we propose here, could be beneficial to their professional practice. Teachers are consistently required to connect with the reality of their students or to work in interdisciplinary approaches, among other demands. However, the elements of the formal mathematics curriculum often make this task seem artificial and challenging. We believe that this approach, through collaborative work with practicing mathematics teachers, could help bridge the gap between reality and school mathematics, and counteract the hegemony of dME and some of the unfavorable phenomena it produces, such as *adhesion.*

Planning considerations stated in intended learning outcomes for primary teacher education in Sweden

Malin Jones

Dalarna University, Falun, Sweden; maje@du.se

Intended learning outcomes (ILOs) in mathematics pedagogy courses describe the competencies preservice teachers must demonstrate to pass the course. This study uses the notion of praxeology from the Anthropological Theory of Didactic (ATD) to analyse ILOs concerning "planning for mathematics teaching" in Swedish teacher education syllabi. The results showed that the tasks (T) of planning varied in what preservice teachers had to consider in their planning, with the national curriculum being most prevalent, followed by utilising theoretical perspectives, and considering the learners. Few ILOs clarified techniques (τ) to use for planning. Eleven out of 19 universities required preservice teachers to provide justification for their plans. Some ILOs put additional restrictions on the preservice teachers, such as using a particular teaching approach. The results suggest that mathematics teacher education courses operate with somewhat different praxeological equipment.

Keywords: Mathematics teacher education, planning, praxeologies, intended learning outcomes.

Introduction

Planning mathematics teaching is essential for high quality instruction (Corey et al., 2021; Stein et al., 2008) and can be described as the making of a detailed description of what to be taught, how, and for whom, perhaps by using a template guiding teachers on what to include. But planning can also be explained as a cognitive process in which the teacher makes choices and decisions related to the context in which they find themself (Grundén, 2020), which is how the concept will be defined in this paper. For teachers in Sweden, certain aspects are already decided in the national curriculum, such as what mathematical content is to be taught and what mathematical competencies students ought to acquire. However, there is nothing written about the extent to which the specific content is to be taught, and nothing regarding pedagogical methods or theoretical perspectives that should be adopted (Swedish National Agency of Education, 2022). So, in a world with a wide range of different mathematical teaching approaches and innovative tools of varying quality, it will thus be the task of teacher education to provide preservice teachers (PSTs) with praxeological equipment (knowledge, skills, and attitudes) to make decisions rooted in subject-specific and general pedagogical theories and research results that support their choices (Chevallard, 2022).

PSTs' practice of planning mathematics teaching has long since been considered an important element of teacher education by teacher educators at universities, by mentor teachers in field practicums, by researchers, and by the Swedish government (Kastberg et al., 2017; Rusznyak & Walton, 2011; Swedish Ministry of Education, 1993). This is in line with Swedish values for teacher education. This study found that planning competence is addressed in the syllabi of mathematics pedagogy courses at all Swedish primary teacher education programs for grades 4–6. Yet despite planning being a learning objective in PSTs' mathematical pedagogy courses and possibly even a practice to enhance PSTs' pedagogical content knowledge and teaching competence (Rusznyak & Walton, 2011), a majority of Swedish PSTs experience that they have not gained sufficient knowledge

about planning mathematics teaching – particularly in areas such as selecting appropriate teaching materials or adapting and modifying mathematical tasks (Christiansen & Erixon, 2021).

An on-going mapping review study (Jones et al., manuscript) suggests that there is limited research on how planning as a multi-faceted activity is addressed in mathematics teacher education, with more research addressing subdomains of planning, for example, designing and adjusting mathematical problems or predicting student responses. This observation led to an interest in examining how Swedish mathematics teacher education addresses planning practices in its mathematical pedagogy courses. It seemed reasonable to begin the investigation by analysing intended learning outcomes (ILOs) related to planning as stated in the syllabi because they are closely linked to the course content and what is assessed in PSTs' process of planning. Furthermore, from an anthropological perspective, ILOs also reflect what is foregrounded in teacher education practices in the institutions, and a comparison across institutions in a country can facilitate the understanding of conditions and constraints imposed nationally on the institutions (Chevallard & Bosch, 2020).

Swedish mathematics pedagogy courses and intended learning outcomes (ILO)

In Sweden, mathematics pedagogy courses are mandatory within primary teacher education programs for grades 4–6. The organisation and number of these courses taught within the four-year programs vary between universities, but all programs include a minimum of 30 mathematics credits, which equates to 800 study hours (see also Christiansen et al., 2021). The reason for the variations between universities has to do with whether practical components are included in these courses or kept as separate courses. In most cases, the mathematics pedagogy course content includes both mathematics and mathematics pedagogy. The syllabi for these courses are official documents and are available on the universities' websites. One of the purposes of the syllabi is to outline the intended learning outcomes, which includes specifying the knowledge and skills that PSTs need to demonstrate to pass the course – therefore also informing course assessment (Christiansen et al., 2021).

Notions within the anthropological theory of didactic

The anthropological theory of didactic (ATD) states that any human activity can be described in terms of praxeologies, where the activity in question comprises a *praxis* block and a *logos* block (see Figure 1). The praxis block relates to the practical aspects of the activity – the know how – and is further divided into two components: The type of *task* (*T*) which addresses the problem or problems the praxeology aims to solve, and *technique* (τ) which describes strategies used to carry out a specified task (*T*). The logos block relates to the knowledge about the praxis – the know why – and is also separated into two components, *technology* (θ) and *theory* (Θ), where the notion of technology (θ) describes and gives justification for the praxis, and theory (Θ) which is perceived as a higher level of justification, often invisible, taken for granted and part of a cultural context (Bosch et al., 2020). Analyses within the component of theory (Θ) are for this reason beyond the scope of this study and only the concept of technology (θ) will be used. Within ATD, any learning situation, no matter what

the level or kind, is explained as a *didactic system*[1] (*S(X, Y,* ♥). This system (*S)* includes learners (*X)*, study assistants (*Y*), and a didactic stake (♥) — "the thing [praxeology] that is to be learned" — (Boch & Gascón, 2014 p. 71).

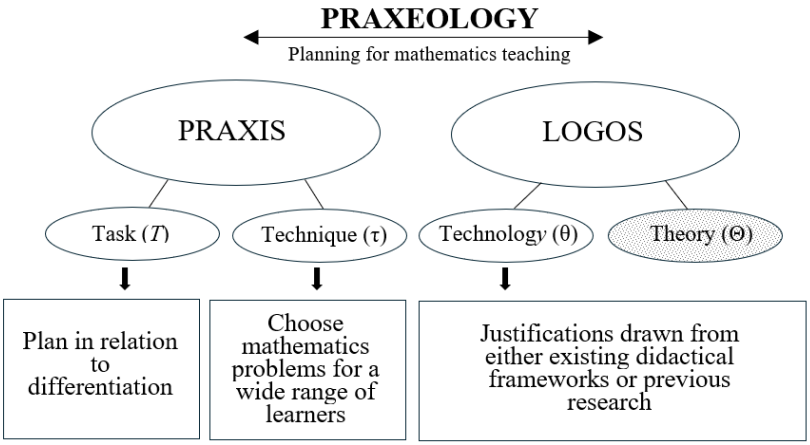

Figure 1: Didactic praxeology model

When teacher education is viewed as a didactic system (*S*), the learners (*X*) are pre-service teachers, the study assistants (*Y*) are teacher educators (including cooperating teachers), and the didactic stake (♥) consists of the teacher knowledge of praxeologies that PSTs are to acquire. **Figure 1** illustrates an example of a didactic praxeology model where the didactic stake (♥) involves *planning for mathematics teaching with a particular focus on inclusion*. A technique (τ) to plan for inclusion might involve deciding on the sequencing of the content, choosing activities for students, etc., or using known strategies for adjusting the difficulty level of an existing task. The technology (θ) used to justify the adjustments might relate to either existing didactical frameworks or previous research. PSTs can practice such a planning task in mathematics pedagogy courses through exercises that might say: *Plan a series of three 40-minute lessons where students work with proportionality expressed in decimals, fractions, and percentage representations. Vary between inquiry-based and traditional teaching and explain and justify how the activities and problems you choose are aligned with the competencies expressed in the national curriculum, as well as how an inclusive perspective is integrated* (fictive example).

A didactic analysis within ATD and the use of a praxeology model seeks to describe didactical systems (*S(X, Y,* ♥) present in any social situations at a given time and understand how these systems or their components evolve over time within broader contexts of institutions, societies, and cultures (Chevallard & Bosch, 2020). The notion of praxeology is a useful tool in didactic analysis, because it encompasses discourse on both knowledge and practice, "it provides a unitary vision of these different activities, without considering some of them as more 'intellectual', 'abstract', 'difficult' or

[1] In ATD, letters and symbols are used to clarify that a concept's meaning is specific to ATD's definition, which may differ from its general interpretation. For example, in ATD the word task (*T*) has a broader meaning and refers to a verb followed by an object, e.g., drinking water or writing a letter.

theoretically based than others, and thus without assuming the scale of values usually given to them" (Bosch & Gascón, 2014, p. 69).

This paper describes the praxeology—planning for mathematics teaching as reflected in ILOs in Swedish teacher education—for grades 4–6 through the lens of the praxeology model, which enables a comparative analysis of potential variations between universities. In so doing, I hope to further the discussion of using ATD's notion of praxeology to provide a more nuanced discourse on PSTs' practical and theoretical knowledge related to the planning process. The research questions guiding this study are: *What praxeological components, related to the didactic stake (♥) planning for mathematics teaching, can be identified in the intended learning outcomes (ILOs) stated in the syllabi for mathematics education within primary teacher education programs for grades 4–6, and are there variations between universities?*

Method

To identify praxeological components (T, τ, θ) related to the didactic stake (♥) *planning for mathematics teaching* as specified in the ILOs outlined in the syllabi for mathematical pedagogy courses in primary teacher education programs for grades 4–6, and to compare variations between universities, the study was conducted as follows.

From the websites of the 19 Swedish universities offering teacher education programs for grades 4–6, 53 obligatory mathematic pedagogy course syllabi were collected during the spring of 2024, including courses with a mathematics focus within field practicum. In the first phase of the analysis, all the syllabi were reviewed to identify ILOs that specified what PSTs should be able to do in relation to planning, designing, or structuring mathematics teaching and activities. While not all the collected syllabi addressed this praxeology in their ILOs, every university had at least one mathematical pedagogy course that did. ILOs from 37 syllabi were extracted for further analysis.

The second phase was to analyse ILOs in greater detail and categorise their content in relation to the components of the praxeology model. For example, one ILO stated, "After passing the course, the student should be able to plan, implement, and analyse teaching based on the national curriculum, as well as didactic and subject-specific theoretical aspects" (University A). In this example, the subtasks that are visible in relation to planning for mathematics teaching are (T_{pc}): Plan considering the "national curriculum" ($T_{pt)}$, and plan considering the "didactic subject-specific theoretical aspects". "Implement and analyse *teaching*" could also be interpreted as Tasks (T_i and T_a); however, these tasks (T) do not fall within the praxeology of planning for mathematics teaching in this study because they can be interpreted to fall within a praxeology of teaching. Techniques (τ) explaining strategies for how to incorporate the national curriculum are not visible in this IOL, and neither are the components of the logos block, because we cannot identify the specific theories that PSTs are expected to use that justify the techniques (τ). The tasks (T) identified in the ILOs were characterised according to the aspects that PSTs were expected to consider in their planning, which were grouped into three major categories to allow for easier comparison between universities.

An example of an ILO that included technique (τ)- and the technology (θ)- component stated: "After passing the course, the student should be able to, based on a didactic analysis, plan a teaching situation

and justify the choice of teaching materials, working methods and working approaches" (University K), "didactic analysis" is understood as a technique (τ) and "justify the choice of…." as technology (θ). Institutional constraints are also evident in this ILO because "plan a teaching situation" implies a specific, limited context that influences how the task (*T*) is carried out. In the first ILO example, the word "plan" was not linked to a limitation of either scope or teaching method.

Result

The results are presented in two tables. Table 1 summarises what was identified in the ILOs associated with the components of the praxeological model, but also institutional constraints on PSTs planning practices. The tasks (*T*) related to the didactic stake (♥) *planning for mathematics teaching* required PSTs to consider: 1) the national mathematics curriculum, 2) theoretical aspects, and 3) learners. Table 1 also displays subcategories observed within the tasks ($T_{pc,\ pt,\ pl}$). Only one technique (τ) was identified – the encouragement to use didactic analysis as a strategy for planning. In terms of the logos block and the technology (θ) component, some of the ILOs stated the need for PSTs to critically justify their planning. Institutional constraints are not part of the praxeological model, but they still warrant attention because such constraints will affect the PSTs' decisions in the planning process. Table 2 shows the distribution of the main categories (from Table 1) among the Swedish universities.

Table 1: Aspects of praxeologies identified in IOLs

Component of praxeology	**Types of** (*T*) (τ) (θ)	**Types, thematised into tasks** (*T*) **Technique** (τ) **Technology** (θ)	
Task (*T*): Planning considering …	National curriculum (T_{pc})	• Lgr22 • Mathematical abilities and grading criteria stated in Lgr22 • Supportive material from The Swedish National Agency for Education	
	Theoretical aspects (T_{pt})	• Didactic perspectives • Subject didactics • Current research • Literature	• Didactic and subject-theoretical aspects • Documented experience
	Learners (T_{pl})	• Inclusive perspective • Equity perspective • Students' diversity • Students' prerequisites	• Students' different interests and backgrounds • Accommodations • Additional support needs
		• Assessment of students • Progression	• Formative assessment • Reasoning competence
Technique (τ)	Didactic analysis		
Technology (θ)	Critical justifications	• Justify choices • Evaluate • Concretise	• Argue • Reflect • Explain
Institutional constraints on PSTs' planning practice	Teaching method	• Problem-based approach • Laboratory approach • Aesthetic learning process	• Formative student-oriented teaching • Various ways of working • Teaching materials
	Scope	• Mathematics activity • Full unit • Delimited section of unit	• Lesson series • Teaching situation

Table 2: Praxeology components of planning identified in different universities

University		A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	Sum
(*T*)	National curriculum	x	x	x	x		x	x	x	x	x		x	x	x	x		x	x	x	**16**
	Theoretical aspects	x	x	x		x	x	x	x	x				x	x	x	x		x	x	**14**
	Learners		x	x		x	x	x	x	x	x		x		x	x	x			x	**13**
(τ)	Planning strategies											x									**1**
(θ)	Critical justification		x	x			x	x	x			x	x			x	x		x	x	**11**
Institutional constraints	Teaching method		x	x	x	x	x		x					x	x		x			x	**10**
	Scope		x				x	x	x	x		x	x	x		x	x	x	x		**12**

Table 1 and Table 2 enable us to answer the questions: *What praxeological components, related to the didactic stake (♥) planning for mathematics teaching, can be identified in the intended learning outcomes (ILOs) stated in the syllabi for mathematics education within primary teacher education programs for grades 4–6, and are there variations between universities?*

The results show that the tasks (*T*) of planning mathematics teaching vary in what has to be considered in a Swedish teacher education context. National curriculum is the most prevalent (16 universities), followed by utilising theoretical perspectives (14), and considering the learners (13). Nine universities expected PSTs to take into consideration all three of these contextual aspects, one none of them, and two universities only one aspect. Few ILOs clarified techniques (τ) for planning that PSTs were expected to master, only didactic analysis was referred to, and one university explicitly mentioned this. Although there appears to be a general agreement among universities to consider the national curriculum in the planning process, less uniformity is seen in the ILOs concerning the inclusion of critical justification for the decisions PSTs make, where only 11 out of 19 universities make that explicit. All but two universities also put additional restrictions on PSTs, such as using a particular teaching approach or plan for a specific scope.

Discussion

The choice of ILOs as research data clearly did not provide a sufficiently robust foundation for making all the components of the praxeology model visible and thus may not have offered a fair reflection of either the intended learning or what may be covered within the pedagogy courses. To gain deeper insight into this, data such as examination tasks and interviews with teacher educators are needed. For instance, we identified only one ILO indicating that PSTs were encouraged to use a

specific technique (τ) to plan their teaching. Regarding the *logos* and the component of technology (θ), it was evident that most universities required PSTs to justify the choices made in the planning process, but the grounds for such justifications (e.g., frameworks or research evidence) were not specified in the ILOs. A possible reason for the general and ambiguous articulation of ILOs could be the pedagogical freedom that characterises the Swedish educational context at all levels which allows for a variety of techniques (τ) to be employed. This also facilitates future developments of the pedagogy course without requiring changes to official documents.

The anthropological perspective in research aims to describe rather than rate and evaluate what becomes visible in the data (Bosch & Gascón, 2014). However, descriptive studies can serve as a basis for discussions on consequences of different approaches. For instance, the result of this study indicates that in the Swedish teacher education context, three domains seem to receive particular emphasis in the planning process: the national curriculum, theoretical aspects, and learners. The prominent focus on the National Curriculum could be attributed to pedagogical freedom, as well as the fact that teaching resources are no longer reviewed by a governmental agency. Similarly, the emphasis on learners could be related to the goal within the Swedish education system to ensure all students' right to an inclusive and equal education, which highlights that "teaching shall be adapted to the circumstances and needs of each pupil" (Swedish National Agency for Education, 2022, p. 6). However, if certain areas receive greater attention within teacher education, it may imply that others are given less, and we need to consider the potential consequences of this distribution of focus. For example, none of the ILOs referred to considering lesson activities, and at this point, we do not know if there is a correlation between this and PSTs' experiences of lacking knowledge regarding selecting appropriate teaching materials or adapting and modifying mathematical tasks (Christiansen & Erixon, 2021). Table 2 suggests that Swedish teacher education programs emphasise different aspects for PSTs to consider when planning for mathematics teaching. This diversity may reflect institutional constraints but could also stem from insights developed within institutions regarding effective ways of supporting PSTs' learning. Cross-institutional discussions could positively influence the development of mathematics pedagogy courses (see Kastberg et al., 2017). However, this is the first stage in a more comprehensive analysis. Future stages will include detailed case studies and nuanced discussion.

Intertwining theory and practice: Design of planning phases in PD training to support effective teacher planning processes

Katharina Knaudt[1], Raja Herold-Blasius[1] and Christoph Selter[1]

[1]TU Dortmund University, Germany; katharina.knaudt@tu-dortmund.de

Professional development (PD) represents an opportunity to enhance teaching quality and transfer innovations throughout the school system. For this, PD must meet certain quality criteria, such as intertwining theory and practice. In this study, a practical phase lies between two PD training sessions, and a 30-minute planning phase is embedded within the PD training itself. This study aims to investigate how the design of the planning phase can facilitate teachers' planning actions. In an explorative study, 11 groups (N=28) of teachers were observed and videotaped. The interviews were transcribed and categorized by applying qualitative content analysis. First results indicate that substantial planning includes interlinked quality criteria of good (mathematics) teaching and an explanation of actions. Also, not every group of teachers seems to achieve complete and finalised planning due to several framework conditions. Thus, the design of the phase requires adaptation.

Keywords: Professional development, facilitators, planning phase, mathematics, primary school.

Introduction and Theoretical Background

Professional development (PD) in tertiary education is an important part of enhancing the quality of teaching. PD allows addressing the constant change and evolvement of schooling conditions (Fussangel et al., 2016). These changes are reflected in, for example, new curricula, digital media, and new didactic findings. To encounter these changes and design and plan effective lessons, both general didactic and specialized didactic quality criteria for good (mathematics) teaching were developed. General didactic criteria include mainly organizational and methodological aspects, which may be applied to every subject (Meyer, 2018). These include, among others, the proportion of learning time, clarity of content, competence orientation, variety of methods, and promotion of meaningful communication by proper tasks. In addition, subject-specific didactic content must also be included when planning good mathematics lessons. Prediger et al. (2022) have identified five quality criteria for this and point out that lessons should be designed with a *conceptual focus* and a *cognitive demand*, be planned considering *longitudinal coherence*, take into account students' heterogeneity, and, thus, allow *adaptivity* to the learners' level of knowledge, and enhance content-specific *communication* between the students.

Teachers should be constantly trained to meet these standards for high-quality mathematics teaching. PD is one way to do so. To ensure the effectiveness of PD training, several quality criteria have been developed based on various studies (Barzel & Selter, 2015; Desimone & Garet, 2015; Lipowsky, 2020). All researchers agree on the following four criteria of effective PD training (Knaudt et al., 2023), although naming them differently: (1) learning in professional learning communities and stimulation of cooperation, (2) intertwining of theory and practice, (3) experiencing the effect of one's actions, (4) case reference and participant orientation. Also, PD training should be designed for the long term and enable coaching and feedback, guide understanding of the profession, focus on students' competencies, and enable input (Darling-Hammond et al., 2017; Desimone & Garet, 2015).

It is important to note that when applying these criteria, they should be combined to provide effectiveness and not be understood as standalone measures (Sims & Fletcher-Wood, 2021). One way to address these different criteria and integrate them into PD training is to incorporate a practical phase between PD training sessions and embed a 30-minute planning phase within the PD training itself (Knaudt et al., 2023). Yet, in current research, it remains open how a planning phase should be structured and how concrete tasks should be designed for the effective planning of lessons.

A previous study analyzed the content of planning phases and its qualitative impact on the design of the phase. Knaudt et al. (2023) found that a planning phase was mainly used to review the material and then to focus on ‘what to teach’ rather than ‘how to teach’. It was also observed that during the planning phase, the teachers pursued different aims depending on the compositions of the teacher teams. For instance, the practical phase can be implemented directly in one's lessons if the teachers have their class or it must first be transferred to colleagues, if not. The authors recommended changes in the design of the planning phase. However, it remained open whether or not these changes led to effective or purposeful planning of mathematics lessons.

Research and Design Questions

This design-based study builds on these previous findings by addressing the new design of the planning phase and by investigating whether or not a certain structure or task leads to effective planning. It aims to investigate whether the design of the planning phase is conducive to the objective or whether other elements should be changed. This leads to the following questions:

- Research question: To what extent do teachers plan a practical phase purposefully with the tasks and material provided to them in the planning phase of the PD training?
- Design question: How should the design of the planning phase be adapted to best support teachers in planning and implementing the practical phase in the classroom?

Design of the Study

This study was conducted within the broader project ‘School makes strong’ ['Schule macht stark']. One aim of this project is to foster the basic mathematical competencies of primary school students by developing and carrying out various PD training modules. One module covers the basic numeracy skills of third- and fourth-graders. Each module consists of six training sessions, and in between are inserted a practical phase, transfer to the teaching staff, and digital self-study modules (Figure 1).

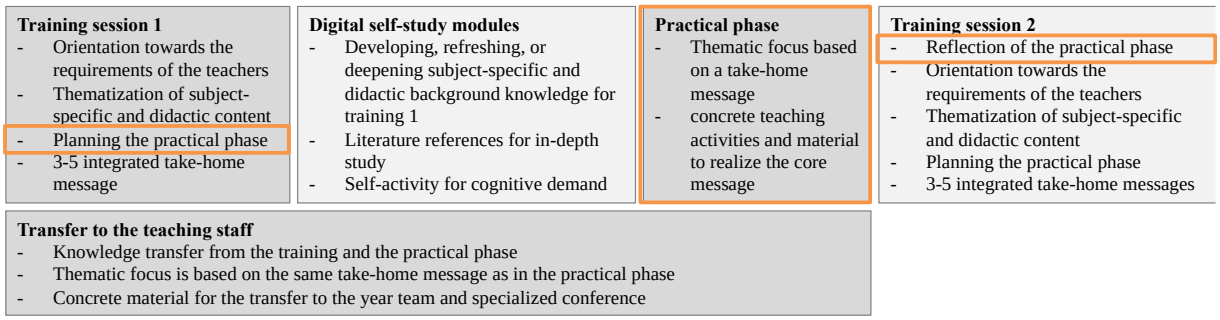

Figure 1: Professional development series and its elements

During the **planning phase**, the practical phase should be planned for implementation in the class. The practical phase includes an activity that can be integrated into any mathematics lesson. This ensures that the activity can still be implemented independently of the series of lessons, and the teachers are supported in their knowledge acquisition. Therefore, this phase fulfils certain features:

- Take-Home Message (THM, core content in one sentence): The practical phase relevant for this study deals with analogies of place values promoting the THM 'I promote a material-based understanding of analogies of place values through action-prompting activities'.
- Mathematical content: Analogies of place values mean that the simple task 3+4 also helps with supposedly difficult tasks such as 30+40 or 3000+4000.
- Mathematical activity: The activity includes a ritualized initial game in which students are required to solve a challenging task with the assistance of a relatively straightforward one. They may draw upon the analogy of place values in doing so. (Figure 2).
- Material package: All material relevant to the THM is bundled in a material package, which includes a mathematical activity, language support, further tasks, digital and haptic materials.

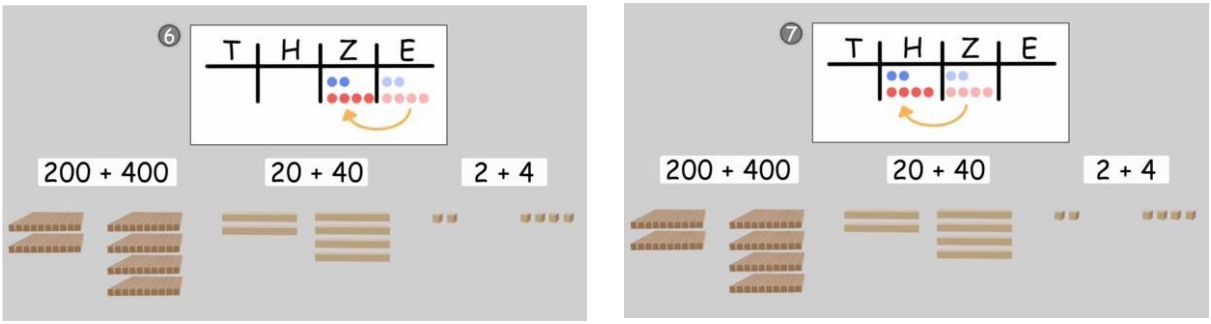

Figure 2: Approach with a place-value chart and the Dienes-material

The planning phase follows a certain **design structure**. It is 30 minutes long and embedded at the end of each training session. This phase aims to implement the practical phase in a lesson the next day without the need to start the planning process anew. The teachers may choose their objective: (1) plan the implementation of the activity from the practical phase for their class, or (2) plan the transfer of material to the teaching staff. It is necessary to address these different objectives in the planning phase due to the considerable heterogeneity of the participating teachers. Independent of their chosen objective, they can (1) gain an overview of the material package, (2) use a focused planning instruction to plan its implementation (e.g., 'If not all of the prerequisites (e.g. tenfold) have been met, how should this be addressed? What specific forms of support are provided during difficulties (stimuli, materials, etc.)? How is linguistic support provided to the children when using analogies?', and (3) clarify questions.

Data Collection

The data of this study was collected and analyzed in the second of two cycles. 11 planning phases with two to four teachers in a group (total of 28 teachers) were observed and videotaped (Figure 3). Each group consisted of teachers from one teaching staff; hence, they were not mixed. Each planning phase lasted between 20 and 30 minutes (a total of 280 minutes) and was fully transcribed.

Additionally, the facilitators (N=4) who led PD training sessions were interviewed guideline-based about the practical and the planning phases. Those interviews were videotaped and fully transcribed.

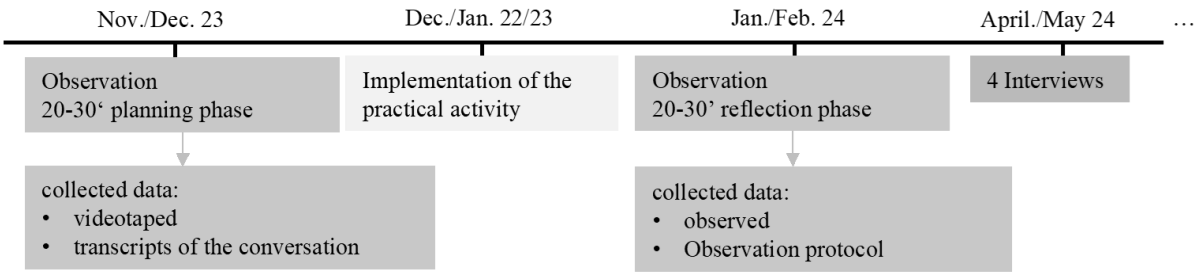

Figure 3: Timeline of the data collection in the second cycle

Data Analysis

All transcripts were analyzed using a coding system (Table 1) (Knaudt et al., 2023). This system is based on deductive codes of effective (mathematics) teaching (see C1 and C2) and inductive codes generated through the observation of the planning phases (see C0 and C3) (Kuckartz & Rädiker, 2020). Applying these categories and their subcategories to the provided data allows for categorizing and analyzing all teachers' statements. After that, all coding of each planning phase was illustrated within progress plans (Figure 4), which show in which order and at which point in the conversation the statements were coded. This way, those diagrams provide an overview of the data and allow investigations into the interconnectedness of the coded categories and their relative frequency to each other.

Table 1: Overview of categories

Category	Description	Example
C0: No planning	Statements that did not result in planning	‘I had forgotten again that someone was listening to us.’ (Teacher C, transcript 27)
C1: Planning good teaching	This includes all planning statements that were made on a general didactic level.	‘Or you make groups of four, that they do such a group work and then …' (Teacher B, transcript 40)
C2: Planning good mathematics teaching	Statements that refer specifically to the planning of mathematics lessons.	‘… Some children may see the balloons, some may see, well, everyone has a different focus.’ (Teacher A, transcript 25)
C3: Framing planning actions	Statements that framing the planning actions, like overview the material package.	‘Oh no, open the planning grid first.’ (Teacher B, transcript 4)

Results

A review of the data revealed three research findings that have a significant impact on the design.

Research Results

Figure 4 exemplifies four of the 11 progress plans and shows typical distributions of the categories. Some groups (Team I) planned in terms of general didactics (C1), subject didactics (C2), and framing (C3) during the planning phase. Others (Team III) concentrated on planning good (mathematics) teaching (C1 or C2), while others (Team II and IV) focused on framing planning actions (C3).

Figure 4: Progress plan of planning actions of four in-service mathematics teacher groups

Addressing the transfer to the teaching staff within the planning phase is used meaningfully. Following the results of the previous study, the transfer was included in the planning phase. It has now been confirmed that this design change is a beneficial addition. Analyzing the progression diagrams, frequent coding of framing planning activities (C3) is revealed. For example, Team II focused on transferring the material to the teaching staff. Due to unknown reasons, they cannot carry out the activity by themselves. Instead, they must pass on the content and consider how this is best realized (C3, light berry). Within the planning phase, discussions are then held on the content level (C2). For example, the teachers talk about specific actions and tasks for the children (line 72). Also, they included the organizational level (C1), talking about the presentation to their teaching staff (line 57) by distributing the take-home message and the corresponding material package.

57	Person 1:	Present the slides. Alternatively, print out individual ones [reads out]. But we can throw that on the wall. That would now be the first slide you throw on the wall, say: "The take-home message", So what's it about?
72	Person 1:	Exactly, then first, actually, with this visualization. The one becomes a ten, and the colleagues then also guess, 'Let the children lay it out, the small task and then the big task'

Planning good teaching (C1) and planning good mathematics teaching (C2) are mutually interlinked and result in a substantial planning phase. Comparing the four teams, the categories for effective teaching (C1) and those specific to mathematics teaching (C2) occur throughout the planning phase, indicating interlinked planning actions of the teachers. However, their frequency varies. Both categories alternate or can be double-coded. If a teacher's statement can be double-coded, the focus is on 'how to teach'. The double-coding provides a more detailed explanation of the implementation process. For example, in line 111 (Team II), the teacher's objective is to adopt a long-term perspective on understanding (C2) and, at the same time, to promote this through a structured activity (C1). In line 112, the conceptual focus ("building understanding") and longitudinal coherence ("regular practice") in good mathematical teaching are emphasized. Thus, the double coding continues. The categories for good teaching are interlinked with those for good mathematics teaching.

111 Person 2: Yes, and as I said, with the children, it is also more likely that you repeat this two to three times every day.

112 Person 1: A ritualised introduction, actually, nh? Building understanding is not about, I'm going to do this once anyway, but about regular practice. And then initially without bundling and unbundling, right? Because thirteen plus eight or something (Person 2: or eight plus five) is difficult.

In contrast, the following statement (line 30) is coded in only one category. The teacher considered the levels of knowledge (C2) based on the heterogeneity of the students. However, it remains unclear how the activity could be adapted to address this. The planning would be richer if the teacher interlinked the thought of adaptivity (C2).

30 Person 2: So, my fear now is that if I only do it [the activity] with tiles, the children won't understand it.

Statements that allow double-coding show more substantial planning actions than the ones that can only be coded with one category.

Prevailing circumstances determine the extent to which the planning phase can be completed in a meaningful and aim-oriented way. Due to several reasons, some teams do not consider the practical phase and the *corresponding* planning phase as meaningful. The progression diagram of Team IV reveals a high frequency of framing planning activities (C3, dark berry). Yet, their emphasis is different from Team II. They have already covered the content in class, do not see a need in the activity given, and instead use the planning phase to report on previous experiences. Thus, they focus on sharing experiences (Team IV, line 31) and not on planning the activity.

31 Person 2: I had the same thing today in my fourth year at school. There were tasks where the aim was to do clever maths, i.e. to use strategies. And then there were always tasks like plus 599, and the children then really had to calculate plus 600 and minus one. And then I took out the Dienes-material again to lay it out.

Furthermore, in interviews with the facilitators, they reported several factors that prevent teachers from engaging in those planning activities. For instance, only single teachers are present at the PD training session instead of the entire team. They also report on materials that are missing or not available for their class, e.g., mathematics textbooks. Further, they mention that the timing of school content does not always match the timing of our PD training sessions. If the content is covered too early or too late in the PD training, the activity cannot be planned properly. The current objective of

the planning phase is to plan an activity for one's lessons in 30 minutes to be implemented on the next day. The facilitators' interviews indicate that a planning phase can only be effective with a more flexible objective. Possibly, the effectiveness of the planning phase is higher when planning is initiated within a PD training but finished within a school team.

Design Result

The three research results prompted the redesign of the planning phase. First, based on the positive results of the transfer, the transfer to the teaching staff should be planned by all teams and not offered as an alternative objective. Hence, the planning phase is divided into two 15-minute slots to plan the transfer to the teaching staff and to plan the practical phase. Second, the focus of the planning phase should be on planning good (mathematics) teaching. Therefore, general didactic criteria for effective teaching and subject-specific didactic criteria for effective mathematics teaching should be directly addressed within the planning process. To achieve this, the task within the phase is formulated more precisely, and the focus is directed towards one of the five quality criteria of good mathematics teaching. Third, the high frequency of framing planning activities (C3) enriched with the facilitators' report resulted in a modification of the timeframe from 30 minutes to 15 minutes. The mathematical activity is integrated into an activation phase within the PD training session, which allows addressing initial questions promptly. This way, teachers may start content planning immediately. The planning phase itself is limited to 15 minutes, and the objectives of the planning phase are more flexible concerning the timing of when to carry out the practical phase or the transfer to the teaching staff. This way, the planning is not finalized within the PD training, but the implementation of the activity is initiated. In sum, with these design changes in the planning phase, teachers should be enabled to use the planning phase meaningfully and aim-oriented for themselves without perceiving it as unnecessary.

Discussion and Conclusion

Considering the generalizability of the findings in this study, two main limitations should be taken into account. The results are specific to the mathematical content and structure of the PD training in the broader project. Also, only a small number of teachers participated in this study. Nonetheless, the results of the current study hold implications for future research and teacher education.

The aim of this study was (1) to gain a profound understanding of planning actions undertaken by teachers during a planning phase integrated into a PD training program and (2) to ascertain how the structure of this phase can facilitate the planning process. Studies have already shown that the connection between theory and practice is important (Barzel & Selter, 2015; Desimone & Garet, 2015; Lipowsky, 2020), which can be confirmed by our results. The results of this study indicate that a high connection between planning good teaching (C1) and planning good mathematics teaching (C2) leads to rich planning actions. Yet, a simple existence of the planning phase to provide an opportunity to connect theory and practice (Darling-Hammond et al., 2017; Lipowsky, 2020) is not sufficient. Instead, the planning phase needs to be integrated into a regular activity within PD training. Also, the participants' needs concerning their school curriculum and other circumstances should be considered. A flexible but obligatory way of planning has to be found. Based on the research findings of this study, the design of the task, structure, and timeframe of the planning phase were modified.

Future research should ascertain whether these modifications lead to better planning actions. Additionally, it would be of interest to observe the implementation of the practice phase after planning to identify factors to support teachers during the planning phases. In this study, integrated planning phases of practical phases exemplify the implementation and purposefulness of the quality criterion 'intertwining theory and practice' of effective PD programmes by demonstrating qualitative insights. It remains open whether this leads to a transfer of PD content into the teacher's lessons and whether the results can be transferred to other PD concepts and content.

Noticing of students' thinking – Is it sufficient for teachers' analysis of interaction in the mathematics classroom? – A vignette-based study

Sebastian Kuntze[1], Sigal-Hava Rotem[2], Yael Nurick[1], Marita Friesen[3] and Jens Krummenauer[1]

The key role of teacher noticing regarding students' thinking has been emphasised in recent mathematics education research. Even if corresponding methodological approaches differ, it can be assumed that noticing aspects of the learner's thinking and reasoning affords access to teachers' learner-adapted reactions and help, among other. However, the articulation of a student's thinking is embedded in classroom situations and content-related interaction processes, thus there is a need to explore whether the noticing of students' thinking is sufficient for an adequate analysis of classroom situations and which analysis foci should complement this focus. Through a vignette-based explorative study, we address this research need: The findings indicate cases in which an additional focus on content-related interaction aspects, in particular on teacher reactions, is needed.

Keywords: Noticing, teacher noticing of student thinking, vignettes-based study, classroom cartoons, teachers' analysis of classroom interaction.

Introduction

Teachers' ability to notice relevant situation aspects of the mathematics classroom has received increased attention in mathematics education research (e.g., Fernández et al., 2018), above all for its relevance for responding adaptively to demands of the situation and providing help to learners (Kuntze et al., 2021; Sherin et al., 2011). In this context, under the label of *teachers' noticing of students' thinking*, various studies have pointed at the significance of the teachers' focus on aspects of the individual mathematical understanding of the learners. Focusing on students' thinking is associated with high learner orientation and assumed to enable teachers to react adaptively to the students' learning needs (e.g., Hardy et al., 2019). As noticing in the sense of knowledge-based reasoning is a knowledge-based process (Sherin et al., 2011), its foci can be based on various criteria (e.g., student's use of representations, student's motivation, …), which are connected to professional knowledge elements and can be assumed to be in a competing relationship (Kuntze et al., 2021). Under this perspective, there is a need for research into the interplay of noticing foci, such as exploring their potentially conflicting role when making sense of processes in a classroom situation. Consequently, finding out about teachers' noticing of aspects of students' thinking together with other noticing foci which can play an additional role for interpreting classroom situations is of high interest.

This study thus responds to this research need, by using a vignette-based design: Purposefully designed vignettes afford examining whether teachers attend to specific situation aspects which can be implemented in the corresponding vignette in relatively controlled ways (e.g., Skilling & Stylianides, 2020). Profiting from these methodological possibilities, we asked teachers to analyse a vignette in which specific analysis requirements were implemented. In the vignette, a vignette teacher reacted to a student in a way which was rather disconnected to the student's thinking. The research interest focused on whether an analysis of the student's thinking also led to a correspondingly critical

evaluation of the vignette teacher's reaction. The study further explored which other noticing foci may have inhibited the teachers from a corresponding analysis of the teacher's reaction, in case of successful analysis of the student's thinking.

Theoretical background

Approaches to mathematics teachers' *noticing* and related constructs such as *professional vision* are numerous (e.g., Amador et al., 2021; Berliner, 1991; Choy, 2014; Fernandez & Choy, 2020; Sherin et al., 2011; Vondrová & Žalská, 2013) – a common feature of the approaches is that observations in classroom situation contexts are made by teachers and connected with elements of professional knowledge. In particular, the notion of *knowledge-based reasoning* (Sherin et al., 2011) emphasises this core of teacher's noticing. In our research, we build on these advances in research into teacher expertise and often use the notion of teachers' *analysis* of classroom situations, emphasising that in noticing, teachers connect observations with specific professional knowledge elements (e.g., Kuntze & Friesen, 2018; Kuntze et al., 2021). The use of criterion knowledge relevant for such observations and hence for the teachers' analysis is facilitated by criterion-related *awareness* (Kuntze & Friesen, 2018), which facilitates teachers' access to the corresponding criterion-related knowledge. In case of several relevant criteria, so-called *multi-criterion noticing* denotes the corresponding requirement for teachers' analysis of classroom situations (Kuntze et al., 2021) – namely to include several different criteria in noticing processes. In prior research we have explained the supporting role of criterion-related awareness for noticing in more detail and explored the associated prerequisites for teachers' noticing empirically (e.g., Kuntze & Friesen, 2018; Kuntze et al., 2021). In the present paper, we connect this scope with approaches to noticing students' thinking (e.g. Fernandez et al., 2018; Jilk & Crespo, 2015; Scheiner, 2022). In the lens of our theoretical framework, noticing students' thinking requires awareness of how the students think mathematically, as well as corresponding content knowledge and pedagogical content knowledge (Shulman, 1986) which has to be connected with situation observations. However, further awareness criteria might be beneficial for a more comprehensive analysis of the respective classroom situations, including the quality of teacher reactions – in line with the research need introduced above.

Vignette-based methodologies offer a broad spectrum of possibilities in the context of exploring this research need. By the notion of *vignettes*, we understand *representations of practice* (Buchbinder & Kuntze, 2018), which by definition stand for classroom situation contexts and carry demands relevant for the profession of mathematics teachers. Vignettes can be taken from authentic contexts such as video recordings of classrooms or they can be designed so as to exemplify elements of mathematics education theory, enabling a normative approach for defining and coding analyses as "adequate" in case an analysis fulfils the corresponding built-in analysis requirement. Vignettes can combine analysis needs in complex settings (Kuntze et al., 2021) and be an opportunity for analysis and profession-related learning (Kuntze et al., 2022; Skilling & Stylianides, 2020). Design possibilities and characteristics for vignettes and their use are described in Kuntze et al. (2022) or Skilling and Stylianides (2020) in more detail.

Research interest and research questions

For exploring the role of aspects of noticing the students' thinking in relationship to noticing related to other potentially relevant analysis criteria, vignettes in which student thinking can be analysed and plays a role for the subsequent interaction are particularly suitable. The combination with a teacher reaction, which does not optimally connect to the student's thinking, is a vignette design feature which adds a further profession-relevant analysis requirement to the analysis of the student's thinking, which is however connected to this analysis step, as the teacher's reaction has to be analysed against the background of how the student thinks. Being able to evaluate the helpfulness of a teacher reaction is a profession-related requirement (e.g. Hardy et al., 2019; Rotem et al., 2019) which necessarily builds on noticing related to the student's thinking. Consequently, this mainly explorative study based on specifically designed vignettes focuses on the following research questions:

(1) Does an adequate analysis of students' thinking warrant also an adequate analysis whether teacher reactions to the learners' needs are appropriate?

(2) Which other analysis foci beyond aspects of students' thinking can be identified, which may strengthen teachers' analysis of classroom situations in this context?

The study aims in the first place at collecting proofs of existence for phenomena, namely (according to the first research question) cases, in which noticing of the students' thinking coincides with inappropriate analyses of the rather unhelpful vignette teacher reaction, and (as far as the second research question is concerned) insight into the potential role of other analysis foci. As noticing and analysis competences can be assumed to be still under development, a focus on pre-service teachers is particularly interesting for this study, as implications for vignette-based learning opportunities in mathematics teacher education might be drawn from potential findings.

Design and methods

The vignette set this study is based on has been designed by the second author and been further developed in collaboration with the first author of this paper, checked for validity under the scope of school culture aspects from the Israeli and German perspectives. The design features mentioned above have been implemented. This paper focuses on the vignette shown in Figure 1. In this vignette, the students reason in an example-based way and appear to have difficulties in translating their approach into a general, variable-based algebraic formula. The teacher's answer mainly takes up the student's "n+1" utterance like a formula conjecture and provides two falsification variants. The student probably interprets the teacher's answer as not having understood their approach and continues with a new attempt of his explanation. The vignette does not offer evidence that the teacher's conjecture-falsification approach is useful for the learners, in relationship to their mathematical thinking.

Together with the vignette presented in Figure 1, the pre-service teachers were asked (a) to explain what the student(s) meant mathematically by their statement and to justify by referring to their observations from the classroom dialogue. Further, they were asked (b) about their interpretation of the teacher's intention in her response, to judge (c) on the helpfulness of the teachers' reaction for

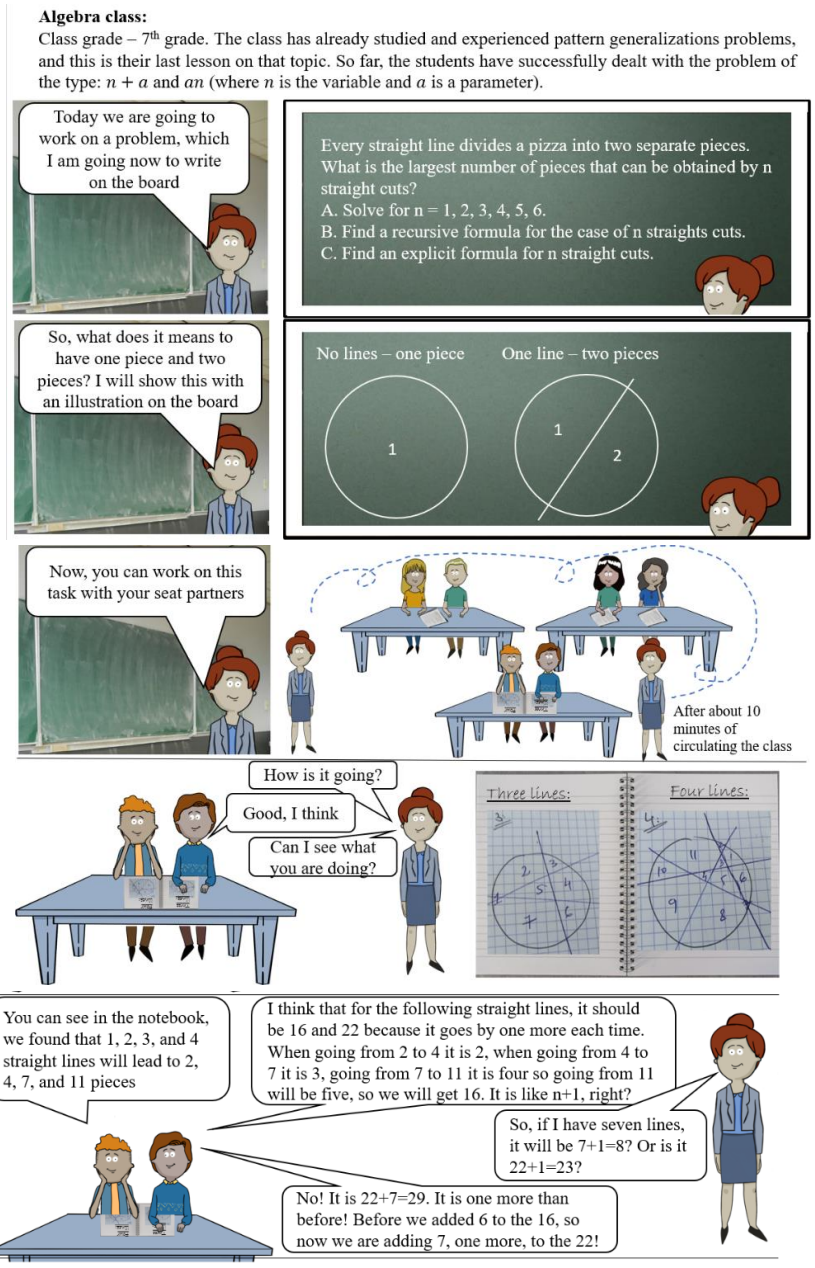

Figure 1: Vignette (inspired by Palatnik & Koichu, 2015) in English translation

the students' learning, and to describe (d) how they would have reacted in the classroom situation. Again in these sub-tasks, the pre-service teachers were explicitly encouraged to justify their answers with their observations.

The vignette was handed out to pre-service teachers in Israel and Germany. As a first step in the collaborative research process, this paper focuses on the data from a sample of 30 pre-service teachers from a South-German university of education, who were asked to answer the vignette questions in written form and hand them in through a *Moodle* environment associated to a seminar, in which no specific intervention related to the vignettes took place. According to a criteria-based interpretive

analysis (Mayring, 2015), a first coding procedure focused on whether the student's thinking had been analysed in a way that shows that the student's mathematical reasoning has been captured. On the basis of this selection of cases according to the adequate analysis of student's thinking, the cases were further examined with respect to the analysis of the teacher's reaction related to the student's thinking, using a bottom-up interpretive approach in accordance with the explorative research interest. As laid out in the previous section, this analysis led to the identification of cases that play the role of proofs of existence of phenomena according to this study's research aims.

Results

In line with research question (1) and the analysis presented in the previous section, cases of adequate analyses of the student's thinking were identified, in which, however, the teacher's reaction was evaluated positively. In order to illustrate the results of the analysis, we present the (complete) answer data of one of these cases. The following were the answers to the analysis tasks (a)-(d) introduced above:

> "(a) The student is able to explain well how he proceeds and thinks that it continues. At the end he says a wrong sentence, which the teacher takes as an opportunity to "feign ignorance", encouraging the student to explain it again. Mathematically, he means that each step between the number increases by one. One could represent it like this:
>
> $a_1 \overset{+1}{\rightarrow} a_2 \overset{+2}{\rightarrow} a_3 \overset{+3}{\rightarrow} a_4 \overset{+4}{\rightarrow} a_5$ ... with a_n as the elements of the sequence, $n \in N$. As the students explains quite precisely how he calculates, this formula can be deduced from his statements.
>
> (b) I think the teacher has the intention that the student explains his calculation and his chain of thought even more precisely. If he manages to express his thoughts more precisely, he can deduce the formula directly from that. As it is, it still appears to be a little confused, but I am almost sure the student knows what he does, just without being able to express it in a better way. The teacher gives him the chance by her comment to find the formula himself and to improve his language abilities.
>
> (c) I think the question was helpful in the sense that it will like this be easier for the student to set up the recursive formula, as they are already on the right way by reformulating it. I see this as very helpful, as formulae make life easier in general and in task b) on the blackboard, precisely this is asked.
>
> Moreover, the student learns to express himself in a more elaborated way and more precisely and to explain, which can bring him forward on the language level.
>
> (d) I like the approach and would not have done it differently. I would build on the better formulation and have it expressed in written form, respectively ask for the corresponding formula. Maybe something like: 'Can you write this also mathematically?' or 'Is there a formula with which you can write this down?'." [Sample answer from a pre-service teacher]

Given the length limits of this paper, we will in the following have to limit the presentation of results of the interpretive analysis to key aspects.

In particular the answer part in section (a) indicates that key aspects of the student's mathematical thinking have been analysed adequately: In the first sentence, an overall interpretation of the student's reasoning is given ("The student is able to explain well how he proceeds and thinks that it continues."). The pre-service teacher judges on the vignette student's question "It is like n+1, right?" in a somewhat questionable way ("At the end he says a wrong sentence"), as the vignette student might not see the formula requested in the task in the expression "n+1" included in his question. However, the third sentence shows a consistent mathematical interpretation of the student's thinking: "Mathematically, he means that each step between the number increases by one." This is formalised in the follow-up sentence: "One could represent it like this: …", this section of the answer even showing awareness of a difference between the vignette student's representation and the arrow-based representation chosen by the pre-service teacher. The pre-service teacher links the analysis back to the observations made in the vignette ("As the students explains quite precisely how he calculates, this formula can be deduced from his statements").

This analysis of the student's mathematical thinking is however not sufficient for a critical analysis of the helpfulness of the vignette teacher's reaction. The pre-service teacher completely agrees with the vignette teacher's reaction ("I like the approach and would not have done it differently") and justifies the helpfulness (e.g., "the student learns to express himself in a more elaborated way"). At the same time, the pre-service teacher's answers to (c) and (d) hardly connect to observations from the vignette.

A possible interpretation is that the pre-service teacher neglects an analysis of how mathematically distant the vignette student's thinking is from the solution required by the task and from the vignette teacher's response, as dealing with formal algebraic expressions and variables might still be a severe obstacle for the vignette student. An additional analysis focus on relating different "kinds" of mathematical reasoning of the participants in the classroom interaction and on the ways of representing mathematical thinking involved in the classroom interaction could have been helpful here (cf. research question (2)). In the case of this vignette, such a noticing focus could have led this pre-service teacher to perceive the potential gap between reasoning with specific numbers vs. reasoning with algebraic expressions including variables.

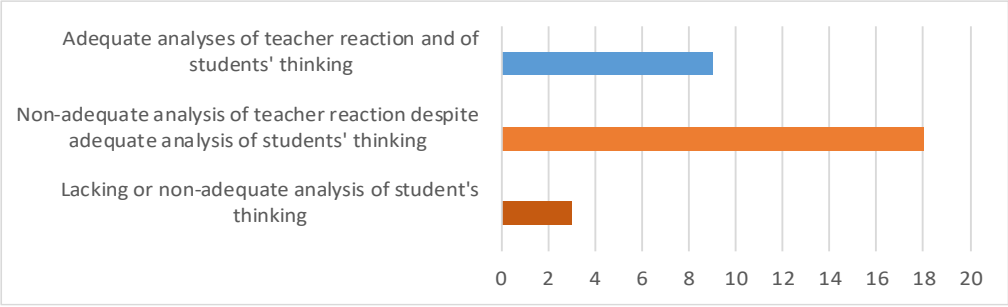

Figure 2: Frequencies of code combinations

Further examples of pre-service teachers' noticing in this sample support that an additional focus on aspects of the classroom interaction can play a key facilitating role for analysing the helpfulness of

the vignette teacher's reaction, and there are also examples of adequate analyses with evidence that such noticing had taken place. Figure 2 shows frequencies of code combinations, revealing that more than 50% of the pre-service teachers did not notice the non-helpfulness of the teachers' reaction despite an adequate noticing of the student's thinking.

Discussion and conclusions

Research question (1) focused on whether an adequate analysis of students' thinking warrants also an adequate analysis of the appropriateness of teacher reactions given the learners' needs. In the sense of a proof of existence, this research question can be answered by the case presented above, in which a pre-service teacher provided evidence of relatively deep noticing of the student's mathematical thinking in a written summary of her/his analysis of the vignette. However, the approval of the vignette teacher's reaction appears to be in contradiction to this analysis of student thinking. Analysing the helpfulness of the vignette teacher's reaction thus requires using further noticing criteria, such as a focus on comparing and relating different mathematical approaches of the participants in the classroom interaction or a focus on the quality of classroom interaction processes (cf. research question (2)). Such discourse-oriented foci of noticing and analysis should receive increased attention, both in teacher education/professional development and in empirical research into teacher noticing. When including several foci of noticing and classroom situation analysis, multi-criterion noticing (Kuntze et al., 2021) should be considered, both in the design of profession-related learning opportunities for teachers and in research into aspects of teacher expertise.

Discourses of diversity in mathematics teacher education research: An analytical framework for meta-didactic praxeologies

Natalya Maksym'yak

Stockholm University, Department of Teaching and Learning, Stockholm, Sweden;
natalya.maksymyak@su.se

Mathematics teacher education research engaging with discourses of diversity reflects visions of mathematics education with complex relations between pre-service teachers, students, and mathematics. This requires practices that cultivate these relations. Utilising the Anthropological Theory of the Didactic, this methodological paper proposes an analytical framework for meta-didactic praxeologies. This is done by identifying the relations informed by discourses of diversity envisioned within the field. Preliminary results indicate that the proposed framework makes it possible to identify meta-didactic praxeologies by pinpointing the envisioned relations aimed at generating them. This invites a dialogue within the field about praxeological variations produced through the discourses of diversity in mathematics teacher education.

Keywords: Anthropological theory of the didactic, discourses, diversity, mathematics teacher education, praxeologies.

Mathematics teacher education pedagogies and education models

The analysis presented in this paper is an attempt to develop an analytical framework for mathematics teacher education practices based on an analysis of recent research publications engaging discourses of diversity in mathematics education. Discourses of diversity echo across political agendas and in educational and research spheres. Through the conceptualisation of equity, inclusion, and social justice, these discourses inform institutional practices, teachers' dispositions, and students' positions in mathematics and mathematics education across diverse contexts (e.g., OECD, 2018). These discourses further reflect relations and practices within mathematics education, including mathematics teacher education (e.g., Skog & Valero, 2021). In relation to mathematics and mathematics education, discourses of diversity focus on expanding multiple cultural, linguistic, and contextual perspectives in mathematics teaching and learning. They aim to represent mathematical concepts as contextually relevant to diverse identity markers, address social justice issues, or position mathematics at the core of social justice concerns.

The mathematics teacher education research field, engaging in discourses of diversity, addresses various concerns and visions of current mathematics education in schools. Although the aim of improving teacher preparation is shared, what constitutes knowledge and effective teacher education pedagogies differ. By discussing teacher education models and positioning them as co-determined by both theory and practice, Brooks et al. (2023) provide a valuable addition to widely used teacher education models, focusing on pedagogical approaches used in teacher education and their possible theoretical justifications. Even though the analysed models are positioned within a specific teacher education context, they do not address the mathematical teacher education pedagogies driven by specific discourses, such as those of diversity. This paper seeks to address this area of concern by examining how discourses of diversity inform teacher education practices. Mathematics teacher

education practices informed by these discourses do not fall under a specific model, making it difficult to comprehensively understand their pedagogical structures using Brooks et al.'s (2023) approach. However, recognising how these discourses inform teacher education practices and reflect envisioned relations is crucial to addressing the equity-driven and inclusion-oriented challenges in mathematics teacher education.

The multifaceted discourses of diversity continuously inform mathematics teacher education pedagogies, diffusing equity-driven and inclusion-oriented knowledge, visions, practices, and relations. As these discourses gain prominence in educational research as a way to address equity and inclusion, mathematics teacher education institutionalises them, encountering various pedagogical challenges (e.g., Guðjónsdóttir & Óskarsdóttir, 2020). Engaging with research publications raises critical questions about what is produced by the research field and how the discourses of diversity envision knowledge and inform mathematics teacher education pedagogies. As equity-driven and inclusion-oriented discourses are central to mathematics teacher education research, understanding their role in shaping practices is essential. Hence, there is a need to develop a framework that allows systematic analysis of envisioned mathematics teacher education pedagogies.

Theoretical Framework

The Anthropological Theory of the Didactic (ATD) considers "doing, teaching, diffusing, creating, and transposing mathematics, as well as any other kind of knowledge, […] as human activities taking place in institutional settings" (Bosch & Gascón, 2014, p. 68), where each activity is defined as praxeology. The theoretical notion of praxeology can be considered within any institution, regardless of the grain size. A *praxeology* consists of the praxis and logos blocks, and the praxis block can be further understood by the type of tasks (T) it entails and the ways of doing them (techniques – τ). The logos block further consists of technology (θ) – a discourse for the techniques – and theory (Θ) that justifies the technological discourse grounded in theories, principles and/or assumptions (Bosch & Gascón, 2014). However, these justifications do not need to be explicit; they can also include conjectures and taken-for-granted ideas residing in belief and value systems articulated by discourses that are reproduced by praxis.

In the context of mathematics teacher education, *meta-didactic praxeologies* refer to the teaching practices enacted in teacher education, and the notion is used to distinguish the praxeologies teacher education engages in, considered "the practices and the theoretical reflections developed in teacher education activities" (Aldon et al., 2013, p. 101). As this paper is positioned in the field of mathematics teacher education, meta-didactic praxeologies (MDP) will be the theoretical notion of praxeologies referred to. Thus, the type of tasks and techniques described and discussed in the paper refers to the praxis involved in teaching pre-service teachers (PSTs) how to teach the desired knowledge as envisioned in mathematics teacher education. Similarly, the logos is discussed as a discursive justification of the proposed praxis.

As praxeologies are considered a human activity of knowledge dissemination, the theoretical notion of *didactic transposition* refers to transforming knowledge from its scholarly state into content suitable for teaching in educational settings (Figure 1).

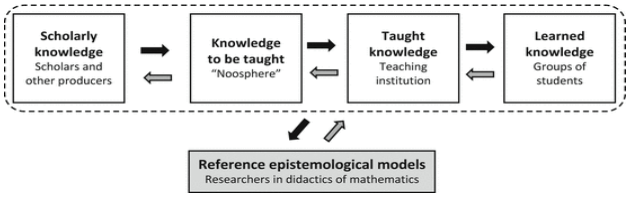

Figure 1: Didactic transposition (Bosch & Gascón, 2014, p. 71)

Produced scholarly knowledge is further addressed in the *noosphere* of the didactic transposition. The noosphere can be considered an institution or a field that deals with issues and concerns regarding all teaching processes concerning knowledge to be taught. A reference epistemological model, or knowledge reference model, acts as a heuristic and analytical tool to explore knowledge and its transposition within and across spheres and institutions (Gascón & Nicolas, 2022). Within the scope of this paper, the proposed analytical framework is positioned in the equity-driven and inclusion-oriented teacher education noosphere, and the aim is to describe the MDP as produced within the field. This is done by examining the relations connecting and linking PSTs' institutional position toward an object of primary inquiry, as well as the proposed praxis in empirical research.

It is essential to incorporate the theoretical notion of *relation* into the analytical framework as it models personal and institutional connections and links with various knowledge objects (Miyakawa, 2024). Thus, the notion allows us to identify and discuss the discourses that are the justifications on which the proposed praxis is grounded. The notation of relation is represented as $R(x, o)$, where x is a person, and o is an object – anything that exists for x. This can further be understood as "a set of links of any kind between x and o" (Bosch et al., 2020, p. xix). Similarly, from the institutional perspective, such a relation can be denoted as $R_I(p, o)$, where p is an institutional position (e.g., teachers) in the institution I (e.g., school). To exemplify, $R_I(p, o)$ models connections teachers (p) make to students' mathematical thinking (o), or critical awareness teachers (p) have towards mathematics teaching for equity (o).

Engaging with the envisioned relations that link PSTs' position to the desired objects allows for the analysis of diversity discourses within the given field. This process addresses the logos block of the praxeology driving the privileged praxis, as it, through discursive nuances, articulates the principles, assumptions and taken-for-granted ideas. In the context of this paper, the notion of relation can be elaborated as $R_{I'}(p', R_I(p, o))$ where $R_{I'}$ models links and connections that any position (p'), within the proposed noosphere knows, feels, or privileges towards the envisioned relation R_I that models what PSTs (p) should know or feel about some desired object (o). Thus, $R_{I'}(p', R_I(p, o))$, shaped by discourses of diversity, informs the praxis of MDP, which is then justified by $R_{I'}(p', R_I(p, o))$.

The aim and the research question

This methodological paper examines scholarly works in the mathematics teacher education research field that engage with discourses of diversity. The aim is to develop an analytical framework to describe meta-didactic praxeologies by elaborating on the relations and mathematics teacher education practices envisioned in the field. The guiding research question is as follows: *What meta-didactic praxeologies are produced in mathematics teacher education research engaging with discourses of diversity?*

Methodology

The analysis presented in this paper utilises a *researching research* approach, which enables the investigation of the conceptualisation of objects of inquiry and goes beyond simply summarising and mapping empirical findings insofar as it critically examines what is produced and envisioned by empirical work (e.g., Skog & Valero, 2021). The analysis identifies the nuances in diversity discourses through envisioned relations and privileged teacher education practices, although it does not constitute a comprehensive review of the literature in the field. From Skog and Valero's (2021) database (2006–2020), which focuses on equity, inclusion, and social justice in mathematics teacher education contexts, eight empirical articles (2008–2019) were selected for thorough reading and analysis, four of which are mentioned in this paper. Articles that did not have mathematics in explicit focus or did not explicitly address the relation between PSTs and a mathematics education object of inquiry were excluded. In other words, the articles focused on the knowledge of teaching mathematics for equity and inclusion envisioned for PSTs and how this knowledge is disseminated in mathematics teacher education programmes. No distinction was made between primary or secondary mathematics teacher education in the proposed analysis.

Analysis

The data processing and analysis operationalised theoretical notions of *relation* and *meta-didactic praxeologies*. The discourses captured through the notion of *relation* identified links PSTs were positioned to manifest and towards what *objects* of knowledge, as envisioned within the research field – $R_{I'}(p', R_I(p, o))$. Through the inclusion criteria for the empirical studies, institutions (I') and (I) and positions (p') and (p) were already pre-determined: (I') – mathematics teacher education noosphere; (I) – primary/secondary educational institutions; (p') – any position within the proposed noosphere; and (p) – mathematics PSTs (primary/secondary). Thus, the analysis aimed to identify the connections and links $R_I(p, o)$ emphasised in the empirical work $R_{I'}$ – implied or focused – between PSTs (p) and an object (o). To exemplify, a relation R_I (p, o) models the "connections" PSTs (p) make towards "students' multiple mathematical knowledge bases" (o). Thus, the relation between PSTs' position and "students' multiple mathematical knowledge bases" ("MMKB") is linked by "connections". Similarly, a relation R_I (p, o) models the "critical awareness" PSTs (p) develop towards "mathematics teaching for equity" (o). Consequently, the relation between PSTs and "mathematics teaching for equity" is linked by "critical awareness". Thus, through the operationalisation of the notion *relation*, the analysis of diversity discourses allows for the description of the *logos block* of MDP where the discursive justifications can be identified; it is through the precision and nuances of the produced discourses and a systematic approach to analysis that the logos block can be identified within these discourses. The examples below will further elaborate on the operationalisation of the notion in analysis.

To operationalise the theoretical concept of *meta-didactic praxeologies*, the analysis sought to identify the *praxis block* of the praxeologies as manifested in the empirical studies. This included the praxis directly addressed and those implied through broader context. Firstly, through content analysis, this entailed the *type of tasks* mathematics teacher educators engaged with to facilitate the establishment of the envisioned relation, where the desired object of knowledge was identified. In

other words, mathematics teacher educators' type of tasks was identified by the created conditions for PSTs to engage with the praxis at hand. Next, the *techniques* that were carried out to accomplish the mathematics teacher educators' tasks were determined. To exemplify, the mathematics teacher educators' type of task (T) is *to create conditions* for PSTs to develop and plan problem solving-based mathematics lessons that "connect" to students' "MMKB". Consequently, the means (τ) of accomplishing this type of task, as presented in the empirical data, is to facilitate PSTs' engagement in cultural communities and the analysis of mathematical lesson plans. To connect this example to the logos block, the justification presented by the relation modelling "connection" is grounded in social processes, establishing effective teaching of mathematics as "culturally relevant" through instructional implementations and practice-based pedagogies, for instance, "[…] teacher learning as a sociocultural activity wherein PSTs develop understandings and practices as they interact over time in multiple communities, such as mathematics methods courses […] and children's homes and communities." (Aguirre et al., 2012, p.180). In another example of MDP, the type of task (T) is *to create conditions* for PSTs to develop "critical awareness" of issues and concerns of "equitable and socially just mathematics teaching and learning", where the techniques (τ) utilised are facilitation of self-study narratives, discursive observations, emotional engagement and critical dialogue, as well as intervention and creative actions. As for the logos block, the justification lies in the relation modelling "critical awareness", where professional knowledge of mathematics teaching and learning is grounded in reflexive work, for instance, "[pedagogy of discomfort] in generating critical dialogue […] feelings of discomfort are crucial aspects of transformative learning about self and society." (de Freitas, 2008, p. 46). Together, the praxis captures the equipment utilised in mathematics teacher education to generate the envisioned relations. Positioning relations as the justification discourses of the praxis block provides an overview of the whole praxeology, praxis and logos of MDP. At this stage of the analysis, the logos block is discussed as a whole, omitting the elaboration of *technology* and *theory*.

Following content analysis and coding, two groups were established, guided by relational correlations (desired object of knowledge and relations modelling links) and the generated practices and justifications shaping these relations. This resulted in the identification of two primary praxeological approaches - *praxis-driven* and *logos-driven meta-didactic praxeologies*. Meta-didactic praxeologies are categorised as praxis-driven when they are grounded in mathematical activities and emphasise praxeologies aimed at addressing and enacting these activities within the given context. These are justified by context-specific discourses rooted in diversity and theoretical, conceptual, and instructional frameworks. In contrast, logos-driven meta-didactic praxeologies are categorised as such when they are grounded in theoretical and pedagogical principles, as reflected in the discourses of diversity and critical frameworks. They emphasise praxeologies of mathematics teaching and learning, focusing on context-specific key issues and concerns of the field. The two categories of meta-didactic praxeologies are further discussed below with supporting excerpts from the sample articles.

Results and discussion

In investigating MDP within mathematics teacher education research informed by diversity discourses, variations are observed across the empirical data examined. As a result of the analysis,

the analytical framework discussed here provides possibilities to identify and discuss the envisioned relations and desired object of knowledge that shape the discourses and justifications of the privileged practices of mathematics teacher education. Consequently, the analytical framework serves as a lens into the field engaged with discourses of diversity in mathematics education, providing an overview of meta-didactic praxeologies that are produced.

The praxis-driven MDP generate relations R_I that model didactic practices, choices, and decision-making towards (o) students' "mathematical thinking", "mathematical communication", and/or "multiple mathematical knowledge bases". Such relations model, for instance, "connections" towards children's "MMKB", as in: "[…] PSTs to explore the practice of making connections to children's MMKB" (Aguirre et al., 2012, p.188). Praxis-driven MDP moreover engage with the type of meta-didactic tasks (T) that are to create conditions for PSTs to effectively teach, develop understandings, practices, capabilities, and/or manage practices. The techniques (t) of carrying out the type of tasks vary accordingly and can be seen through, for example, facilitating situated learning and simulations "[t]o simulate teaching in diverse settings, we developed a middle school classroom in Second Life [software]" (Brown et al., 2011, p. 273). Consequently, the praxis-driven MDP are justified by practice-based pedagogies and co-construction of learning, such as community engagement that is seen in Aguirre et al. (2012):

> […] to engage PSTs with the local community and to increase their knowledge of students' out-of-school activities and practices, particularly those that might relate to mathematics instruction. (Aguirre et al., 2012, p. 181)

On the contrary, logos-driven MDP produce relations that model "critical awareness", conceptions", "becoming", "identity", and "relationships", for instance, "[…] to consider and reflect on classroom relationships and practices that can promote social justice in mathematics classrooms" (Boylan, 2009, p. 1). Logos-driven MDP also consider the type of tasks (T) that create conditions for PSTs to engage in issues and concerns of equity and social justice, for example, creating conditions that encourage PSTs to consider and reflect on social and personal ideologies, challenge beliefs and identity, develop critical perspectives, and engage in critical reflection of the self as well as social power structures. This includes providing opportunities to develop and deepen one's understanding of mathematics education, critically informed through various critical perspectives, for instance, "[…] to trouble or contest the dominant belief expressed by my PSTs […]" (de Freitas, 2008, p. 44). Corresponding to the tasks, the techniques (t) are troubling discourses and dispositions and eliciting perceptions to critically examine current beliefs and practices by interventions and critical dialogue engaging educational experiences and enactments. Such logos-driven MDP are therefore justified by transformative learning and pedagogies of discomfort.

Informed by discourses of diversity, the *relation* in the empirical studies examined is often explicitly elaborated and given a purpose and contribution within diverse contexts concerning all and/or a diverse body of students, mathematics and mathematics education, and communities/society. Driven by the discourses of diversity, the proposed MDP analytical framework could potentially be discussed using Brooks et al. (2023) categorisations, thus contributing to a more comprehensive understanding of pedagogical models. Logos-driven MDP often centre around relations that emphasise PSTs'

positions. These praxeologies address issues and concerns of diversity by fostering critical awareness and identity work and by challenging PSTs' traditional beliefs, practices, and dispositions. Thus, the examined studies deemed it necessary to situate these connections and links as part of the internal endeavour. In contrast, praxis-driven MDP tend to centre on PSTs' positions, which also emphasise improvement and change. However, the focus often lies on teaching methods, new didactical instructional strategies, and choices. Although incorporated, reflective work frequently does not engage with interpersonal aspects. Consequently, these studies situate connections and links envisioned for PSTs to establish as external knowledge to be acquired.

Engaging with the ATD and operationalising the notions of *relation* and *praxeologies* provides research strategies for understanding how equity-driven and inclusion-oriented mathematics education is informed and disseminated in mathematics teacher education, thus contributing to the production of knowledge in noosphere and the further development of a knowledge reference model of meta-didactic praxeologies driven by discourses of diversity. This analytical framework helps to grasp the nuances of praxeologies produced to engage with envisioned relations toward desired objects of knowledge. While mathematics teacher education addresses issues of equity and inclusion, these practices have yet to be systematically investigated. By engaging with the discourses of diversity, the analysis shows how these discourses inform mathematics teacher education praxeologies, resulting in logos- and praxis-driven meta-didactic praxeologies. In line with Brooks et al. (2023), this work further contributes to understanding how various models inform and shape mathematics teacher education pedagogies. Through the complex reciprocity of relations and praxeologies, the proposed analytical model opens discussions on the complexity of MDP, advancing equity-driven and inclusion-oriented mathematics teacher education. Furthermore, it can be utilised in mathematics education institutions to examine context-specific institutionalised practices and the relations that inform them.

The presented methodological paper attempts to develop an analytical framework of MDP by analysing a small sample of research. This factor might reduce reliability and validity. However, the aim is to discuss a perspective that addresses questions of diversity discourses that ATD has not yet addressed and offers pragmatic nuances that address the struggles of diversity discourses in mathematics teacher education, thus enabling the multifaceted practices of mathematics teacher education to be addressed systematically.

Preservice teachers' identity as programmers in mathematics

Marianne Maugesten[1], Odd Tore Kaufmann[1], Khaled Jemai[1], Toril E. Rangnes[1] and Shipra Sachdeva[1]

[1]Østfold University College, Norway; marianne.maugesten@hiof.no

In this study we investigate preservice teachers' actual and designated identities. Analyses of preservice teachers' reflection notes written to complete a compulsory task about programming reveal both similarities and differences between preservice teachers' actual and designated identities. Both identities reflect a positive attitude towards programming and the importance of computational thinking. However, actual identity highlights preservice teachers' knowledge of problem-solving and their perception of programming as challenging but rewarding. In contrast, designated identity emphasizes the importance of programming knowledge to enhance students' learning, and knowledge of different programming tools to develop the students' knowledge.

Keywords: *Preservice teachers (PT), actual and designated identity, programming, mathematics.*

Introduction

Programming and Computational thinking (CT) have received increasing focus and important role in schools. CT represents one of the "21st century" key skills (Bocconi et al., 2018). In Europe, most countries locate CT within the general subject information and communications technology, while some countries have integrated CT in other subjects and/or as cross curricular approach (Bocconi et al., 2018). In 2020, the Norwegian mathematics curriculum for grades 1–10 was revised, and programming was integrated in mathematics. Exploration and problem solving are related to CT in the curriculum (Ministry of Education and Research, 2020). Programming is related to computational thinking, and CT is described as the thought process involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent (Wing, 2006).

The introduction of programming in Norwegian mathematics curriculum poses an interesting implementation challenge. This introduction delegates the responsibility of including CT and programming in mathematics to mathematics teachers. There is a need to know more about how mathematics teachers and preservice teachers (PT) perceive programming as part of mathematics education in relation to their developing professional identities (Kaufmann et al., 2023; Nordby et al., 2024).

In their research studies, Nordby et al. (2024) found that primary teachers' lack of knowledge of CT affects their adoption of CT in mathematics teaching. Therefore, mathematics teachers need to learn more about how and when to include CT tools in mathematics. While Nordby et al. (2024) focus on primary teachers, other studies have focused on PT (Kaufmann et al., 2023; Maugesten et al., 2023). The findings of these studies reveal that the PT were motivated to teach programming, and they identify themselves as digital natives. Also, the findings revealed that not until their fifth year of teacher education, they realized that they need knowledge about both programming and experience. Kaufmann et al. (2023) found that PT had a positive attitude toward programming. Even though they

expressed a limited understanding of how programming can be integrated into their mathematics teaching, they consider themselves as digitally competent.

In this paper, we analyse PTs' reflection notes written to complete a compulsory task about programming and computational thinking. Reflective practice is essential to the Norwegian teacher education. PT are encouraged to continually reflect on their experiences, the teacher role and student perspective. We follow Lutovac and Kaasila (2018b) in understanding that narrative identity is a reflective and dynamic process involving individuals and their social context, i.e. teacher education. Therefore, social interaction and communication is essential to one's narrative identity. This reflective approach helps PT to critically evaluate and reshape their professional identities over time. The Norwegian context interacts to create a supportive and dynamic environment for PTs' identity formation. Our aim was to explore how PT in their fifth year of teacher education identify themselves as mathematics teachers using programming to solve mathematical problems. The research question addressed is: What characterizes PTs' actual and designated identity based on their written reflections in a compulsory task when solving a mathematical problem through programming?

Teachers' identity

Considering the new requirement to incorporate programming into mathematics education, we explore how this curriculum change may influence future teachers' identities as mathematics teachers teaching programming. Over twenty years ago, da Ponte et al. (2002) highlighted that "ICT may actually play an important role in teacher education, thus contributing to the professional and personal development of prospective teachers" (p. 97). However, the identities of PT are likely still evolving as they transition from being PT to becoming teachers (Beijaard et al., 2004). These identities will be influenced when they encounter new challenges, such as integrating programming, a subject they did not experience in their own schooling (Arslan & Haser, 2024).

In recent decades, educational research has increasingly focused on teachers' professional identity, recognizing its crucial impact on their performance (Philipp, 2007). Lutovac and Kaasila (2018a) define mathematics teacher identity as teachers' understanding of themselves regarding mathematics and its teaching. Teacher identity is the essence of the teaching profession, as it helps teachers formulate their own notions about "how to be," "how to act," and "how to understand" their roles and responsibilities in society (Sachs, 2005). Beijaard et al. (2004) assert that teacher identity greatly affects the decisions teachers make about their instructional strategies, subject matter, and interactions with students. Understanding teacher identity in mathematics education and teacher education programmes has an important role in developing teacher identity in line with contemporary understandings of mathematics teaching and learning (Arslan & Haser, 2024).

Following Darragh and Radovic (2020) and Sfard and Prusak (2005), we consider teachers' professional identity to be the narratives that individuals use to justify, explain, and understand themselves in relation to their work as teachers. These narratives are constructed from social discourses and provide insights into how those individuals currently view their identities (Lutovac & Kaasila, 2018a; Sfard & Prusak, 2005).

In this paper, our understanding of identity is guided by the work of Sfard and Prusak's (2005) narrative identity framework. According to Sfard and Prusak (2005), actual identity consists of narratives about the actual state of affairs and these narratives are usually told in present form. A statement such as "I am quite good at programming in mathematics," is an example of actual identity. Designated identities are narratives that have the potential to become a part of one's future actual identity. Such identity can be recognized by the use of future form or words that express wish, commitment or obligation. A statement such as "I must learn programming because one day I will teach my students about programming in mathematics" is an example of designated identity. According to Arslan and Haser (2024), closing the gap between actual and designated identity is described as a learning process, and failing to close the gap between these two identities negatively affects identity development. Therefore, exploring PTs' identity is important to understand how they identify as a mathematics teacher teaching programming.

Method

The data material is a compulsory written task for PT in their fifth year of teacher education. The topic was to develop and solve a problem-based task in mathematics related to computational thinking and programming suitable for future students in primary and lower secondary school. The PT chose their own mathematical problem to solve based on the criteria given by the teacher. PT had some experience with programming in previous workshops, but this is their first written task.

The 31 respondents (15 from 2022 and 16 from 2023) were PT studying to teach grades 1–7 (8 respondents) and grades 5–10 (23 respondents). The group of PT included both males and females aged between 23 and 30 years old. The PT gave their consent for data collection and were informed about the possibility of withdrawing from the study whenever they wanted. The project was also reported to SIKT (Norwegian Agency for Shared Services in Education and Research).

PTs' identities were explored by using Sfard and Prusak's (2005) concepts of actual and designated identity. These identities were further analysed by using the categorisation of Beijaard et al. (2004). They developed three relevant categories to describe teachers' identities: The teacher as subject matter expert (SME), as pedagogical expert (PE), and as didactical expert (DE). SME teachers have profound knowledge on the subject matter. PE concerns teachers' engagement with students and supporting the growth of students. DE teachers possesses the necessary expertise and deliberate intent to design and deliver lessons related to curriculum that facilitate students' deep comprehension of the subject matter. We have not had the opportunity to conduct a longitudinal study on changes in identity, such as the one by Arslan and Haser (2024).

The first author divided and placed narratives relating to actual identity in one category and narratives relating to designated identity in another category. The narratives belonging to actual identity often started with the words "I can" or "I am," while the narratives in designated identity started with "I will do ... in the future". The first and second authors (who do not teach the PT) discussed narratives in each category and placed them in the subcategories SME, DE and PE as described both by Beijard et al. (2004) and in Arslan and Haser (2024). Narratives categorized as SME are related to PTs' written reflection focusing on their own and future students problem-solving and programming skills. Narratives within DE are written reflections about teaching and learning mathematics and

programming. Narratives related PE are written reflections about students' growth and their own role as a teacher. The difference between DE and PE is that DE is related to mathematics and programming, while PE is more general without being connected to specific subject. However, it was not always easy to distinguish between PE and DE in the analysis process. In cases with uncertainty between PE and DE, these were discussed by the first and second author until agreement was reached. Each narrative was assigned with the year, the program 1–7 (B) or 5–10 (U) and a number (e.g., 23B1 was a PT from the batch of 2023, grades 1–7 and number one).

Findings

The table below presents a brief overview of the findings.

Table 1: A summary of the findings

Category/Subcategory	Actual identity	Designated identity	Total
Subject matter expert SME	11	7	18
Didactics expert DE	0	7	7
Pedagogical expert PE	8	13	21
Total	19	27	

From the table, we see that, except for Actual identity, DE, all subcategories are represented, and the total number of narratives identified varies from 0 to 13. According to the main categories, Actual identity and Designated identity, more narratives are identified as designated identity (27) than actual identity (19). This finding may indicate that the PT have chosen tasks with content that can be linked to their future profession because they are so aware that they are going to become teachers.

The identification of the subcategories Subject Matter Expert (SME) and Pedagogical Expert (PE) were 18 and 21, respectively. This can be explained by the fact that most PT knew little about programming in mathematics beforehand and therefore described the academic challenges they encountered in their problem-solving process (SME). Teacher education in Norway is not a subject-specific education in mathematics, which may be why the narratives are more general and apply to multiple subjects (PE). In the following sections, we present some illustrative narratives from the data and their categorization into the subcategories presented in Table 1.

Subject Matter Expert, SME

Regarding PTs' SME, many of their narratives focus on their own problem-solving skills (actual identity) and how they should as a becoming teacher focus on the relationship between programming and problem-solving (designated identity). The excerpt below is a narrative that illustrates PTs' SME and actual identity:

> 23U6: This is a task that has made me a better problem-solver, through patience and debugging, and which will help me further when it comes to programming.

The PT had little experience with programming during their study, and therefore it seems important for them to develop knowledge about computational thinking when they are programming.

The PTs' designated identity reveals a focus on their future students:

22U6: For students to develop computational thinking, it is required that they identify a problem and find algorithms to solve this problem using digital tools.

Another important part of their designated identity is the importance of an in-depth knowledge of various computational thinking tools/programs. This PT emphasises Scratch as a suitable program for grades 1–7.

23B6: Given that I am specializing in grades 1 to 7, I think Scratch will be the best-suited program and I will gain more knowledge and competence in it.

The PTs' narratives are seldom about mathematical content knowledge. They want to develop skills in programming and see that problem solving can be useful for that.

Didactical Expert, DE

The narratives of DE were all designated identities. In the narratives in this subcategory, the PT emphasize diverse teaching methods and how CT could be related to the curriculum.

22B2: This also fits both after grade 4 and grade 5 to achieve the competence goals of 'creating (and programming) algorithms and expressing them using variables, conditions, and loops'.

This PT emphasizes that the task she has chosen is meaningful. It is relevant for future planning and content in lessons. Students need different learning styles, and variation is important.

22U8: Another advantage is working with different methods. It introduces a type of variation in teaching, where students can engage with mathematics in a different way.

According to the narratives categorised as DE, it seems that didactic competence is important as becoming teachers in their students' learning processes in programming.

Pedagogical Expert, PE

Supporting the growth of future students and themselves is a hallmark of the narratives in the subcategory PE. Narratives categorized as actual identity are for instance connected to perseverance.

23B5: I have also gained insight into my own ability to handle challenges and to have perseverance in working to find solutions and to use programming tools to solve a mathematical problem by practicing with different algorithms until I found the solution I wanted.

Another PT linked the challenges to course literature.

23U1: I found it quite challenging to work with programming as I repeatedly discovered errors, had to fix the problems, and then continue the process until I got it right. This can be related to Herheim and Johnsen-Høines' (2021) research on productive struggling, even though I had no one to spar with. I thought a lot to myself and used the internet to find good solutions on how I could solve the problem along the way.

With respect to their future profession, PT refer to both students and their role as teachers. With a focus on students, the PT refer to motivation, creativity, interest, and ownership that support personal growth as this narrative shows:

23U5: I believe one advantage of programming is that there may be students who do not excel in mathematics usually but have an interest in this. I also believe this type of

work can give students the feeling that they can be creative and create something of their own. They gain ownership of the task/problem.

The role of the teacher and future teaching becomes apparent in this PTs' reflection:

23B5: I have chosen this language because it has great relevance for future teaching. The algorithmic way of thinking involves a systematic approach to problem-solving and decision-making. The key concepts and methodologies that characterize this approach play a central role in tackling challenges in a structured and efficient way. The algorithmic way of thinking is a valuable approach to developing problem-solving skills and promoting efficiency in various areas of life.

A summary of the findings shows that through their work with the self-chosen task, PT reflect on their identity as learners both in terms of academic, pedagogical, and didactical aspects in their narratives. We identified that most instances which were categorised as actual identity included narratives of PTs' knowledge about problem-solving and their development as problem solvers by using programming as a tool. The PTs' designated identity gets revealed in the narratives with both knowledge and reflection around students, the teacher role, and the need for knowledge. We did not identify any differences between the two programs, may be because they are coordinated.

Discussion and conclusion

The current curriculum in Norway (Ministry of Education and Research, 2020) requires the integration of programming into mathematics education. To prevent programming from becoming a tool that teachers struggle to incorporate or reject (e.g., Kaufmann & Stenseth, 2021), it is important to understand how the identities of prospective teachers influence their perceived capabilities as mathematics instructors using programming. Our research question was: What characterizes PTs' actual and designated identity based on their written reflections in a compulsory task when solving a mathematical problem through programming? Having a clear and decisive designated identity is critical in shaping actual identity, because designated identity serves as a roadmap in the identity development process (Arslan & Haser, 2024). Our research offers additional and valuable insights into the limited studies on PTs perspectives regarding the integration of programming into mathematics education, particularly by examining how this introduction may influence their actual and designated identities. The results might have been different if the reflections were oral.

Our findings indicate that PTs' identity as SME, the actual and designated identities is sometimes consistent, and other times different. The consistency is due to their narratives about SME presented in a positive way both in the actual and the designated identity. Knowledge in computational thinking is important in both SMEs, their own CT in actual identity and the students' CT in designated identity. We identified that most instances which were categorised as actual identity included narratives of PTs' knowledge about problem-solving and their development as problem solvers. However, in the instances categorised as designated identity focused on knowing programs to develop the students' knowledge. The instances of PTs' actual identity are characterized by a general impression that programming is difficult. It requires hard work to learn programming, which can sometimes be frustrating. Despite finding it challenging, they remain positive about working with programming. Our results are in accordance with Kaufmann et al. (2023) and Nordby et al. (2024). In Kaufmann et al. (2023) PT maintained a positive attitude towards programming. None of them opposed its

inclusion in mathematics education, likely because they felt the requirement of integrating it into their teaching due to curricular mandates. According to Nordby et al. (2024) despite teachers encountering some resistance, and their struggle to embed programming in their mathematics teaching, they were positive to include programming in mathematics education.

Our findings indicate that PT who used DE narratives focused on their role to support the learning of their students. This is in accordance with Arslan and Haser (2024), who found that PT whose metaphors were classified as DE emphasized the significance of employing diverse methods and being mindful of students' needs based on their varying knowledge levels. They highlighted their aspiration to be mathematics teachers capable of effectively utilizing different approaches to support their students' mathematical learning in a meaningful manner.

Our findings indicate a difference between PTs' actual and designated identities with respect to how they identify as PE. Their actual identity is characterized by the emphasis on perseverance and highlighting productive struggle as an important trait when working with programming. When it comes to designated identity, they prioritize motivating students in programming, sparking their interest and creativity, and recognizing that programming can support diverse teaching methods. This is consistent with Kaufmann et al. (2023) and Nordby et al. (2024) who also found that the PT and teachers emphasize the teacher's motivational role.

Our results contrast with Arslan and Haser's (2024) findings. According to their research, the PTs did not feel ready as mathematics teachers. They stressed their lack of experience. Their negative emotions as a teacher emphasised the need for professional development, and they had feelings of fear and anxiety due to this lack of professional development. We do not find any of this in our data. Although the PTs emphasise that they have little knowledge and experience with programming, none of them underscore frustration. Nevertheless, for teacher education we suggest more knowledge about programming in mathematics before the written task. Considering that the inclusion of programming in the Norwegian mathematics curriculum is still in its infancy and that our participants are just beginning their journey, it seems based on their narratives that they are accepting the inclusion of programming in mathematics education. Our analysis identifies an inspiration and a willingness to embrace new ideas and activities with programming. Focusing on and nurturing these efforts could lead to PT becoming facilitators who welcome programming into mathematics education.

Exploring mathematics teachers' informal use of an online self-learning platform while planning a digital learning environment

Sophie Mense[1]

[1]University of Muenster, Institute of Fundamental and Inclusive Mathematics Education, Germany; sophie.mense@uni-muenster.de

This case study explores primary school mathematics teachers' informal self-directed online learning experiences in the context of lesson planning for digital combinatorics learning environments. The study provides first insights into how teachers interact with online meta-resources supporting their informal professional development (PD), addressing the gap in understanding teachers' actual usage of online resources and the lack of foundational knowledge for user- and needs-oriented development of online platforms. Three teacher teams were recorded during their lesson planning sessions while using an online self-learning platform. Their topics of communication and digital actions were qualitatively analysed, revealing patterns in platform usage and topics of communication. These findings offer first insights into teachers' informal PD with online resources that might be useful for the design of user scenarios for future online self-learning platforms for teacher PD.

Keywords: Informal professionalization, online professional development, self-directed learning.

Introduction

The design of learning environments using mathematical action technologies, aimed at fostering a deep understanding of mathematical content, presents a significant challenge for teachers as it requires Technological Pedagogical Content Knowledge (TPACK) (Mishra & Koehler, 2006). In terms of teacher professionalization in this area, the approach 'Learning technology by design' (Koehler & Mishra, 2005) has been proven to be successful, providing teachers with materials driven by their immediate requirements while solving pedagogical challenges. However, the demand for support typically arises when teachers plan lessons for their own classrooms, rather than during formal professional development (PD) programs or workshops. In today's digital age, the abundance of online resources allows teachers to direct their professional growth according to their specific needs (Beach, 2017). Meta-resources (MR) specifically designed to assist mathematics teachers in planning teaching and learning activities, can fulfil a dual purpose: supporting lesson planning while simultaneously promoting teacher PD (Gueudet et al., 2023). Teachers' actual usage and related challenges while using online MR are not well understood yet. This results in a lack of foundational knowledge for user- and needs-oriented development of online platforms, despite the growing importance of this form of PD. Therefore, there is a desire for research that observes and analyses teachers' actual use of digital platforms in their work (Gueudet et al., 2023). These insights inspired the author and co-developer of the *Kombi* app[1] to create an online learning platform providing MR for all facets of TPACK required for teaching combinatorics in primary schools using the *Kombi* app, which teachers can access for informal PD while planning their lessons. The teachers' use of this platform will be in the focus of this study. After providing a brief overview on the theoretical

[1] The German version of the free iOS app for iPads is available at https://apps.apple.com/de/app/kombi/id1626071081.

background of informal PD, the use of MR during lesson planning and online self-directed learning, as well as introducing the self-learning platform for teaching combinatorics with the *Kombi* app, this paper addresses the research question: What usage patterns can be observed among teachers using an online self-learning platform with meta-resources while planning a digital learning environment for teaching combinatorics?

This question will be addressed through a qualitative analysis of the teacher teams' actions and discussions throughout their video-recorded lesson planning process. The goal is to identify usage patterns that can inform the design of user scenarios for future online self-learning platforms for teacher PD and guide the evaluation of design decisions for the *Kombi* platform used in this study.

Theoretical background

Informal PD is conceptualized as self-directed and self-initiated learning activities, primarily driven by intrinsic motivation with the goal of professional growth or improvement, occurring outside of organized learning events. Therefore, these informal learning activities are not planned or curriculum-based, but intentional, open, practice- and action-oriented, with a focus on reflective experiential processing (Röhl et al., 2023). Evers et al.'s (2016) five categories of teachers' informal learning activities can be applied to classify these activities: (1) *keeping up-to-date* (e.g., reading relevant literature and online resources), (2) *experimenting* (e.g. trying out new teaching methods, materials or technologies), (3) *reflecting and asking for feedback* (by themselves, with colleagues or students), (4) *collaborating with colleagues with the aim of improving lessons* (e.g., peer-planning, discussing of lessons), and (5) *collaborating with colleagues with the aim of improving school development* (e.g., discussing ideas about improvement and innovation on a school level). The role of digital technologies is emphasized in each category.

One opportunity for teacher informal PD and the ongoing improvement of teaching practices is during lesson planning (Gueudet et al., 2023), which is an important part of the everyday teacher job. The collaborative design of lessons by teacher teams can be particularly effective for professional learning, especially when they anticipate students' solution strategies and responses and engage in discussions about the lesson plans (Wake et al., 2016). Even though lesson planning is a routine aspect of teachers' work, it can be demanding due to the cognitive effort required before they engage in teaching and interact with students. Following the Documentational Approach to Didactics (Trouche et al., 2020) (digital) MR can support teachers in selecting appropriate materials and open up new possibilities for both individual and collaborative lesson planning (Gueudet et al., 2023). PD is particularly needed in combinatorics: While determining the number of elements in a set is crucial for both probability and calculations (Höveler, 2018), teachers often struggle with this topic, facing challenges in both content knowledge and didactics (Matitaputty et al., 2024).

While planning MR to support teachers' lesson planning, it needs to be considered that teachers do not follow prescriptive frameworks or normative guidelines when planning lessons and the typical linear steps—such as defining objectives, selecting activities, organizing, and evaluating lessons—do not reflect how teachers actually think (König et al., 2021). This suggests the presentation of MR in a nonlinear form. However, when digital MR are not presented in a sequenced order, only available on different websites or not always available on trustworthy websites regarding their quality, it

requires teachers' self-directed online learning (SDOL, Beach, 2017) to independently seek out and acquire knowledge according to their own needs, taking responsibility for their own learning. Since teachers do not typically follow linear steps, it is crucial to understand how they approach SDOL. Beach (2017) developed a model for teachers' SDOL, describing the central phenomenon 'Navigating a PD Website' with categories like, amongst others, *Focusing on Student Needs and Instructional Goals*, *Evaluating Information*, *Encoding Information for Future Retrieval*, *Reflecting on Learning* or *Intentions for Practice* that will inform this paper's analysis. This understanding can help tailor self-learning platforms to teachers' needs and thereby optimize teacher informal PD.

Context, content and design of the online self-learning platform

Teachers' use of MR in lesson planning is explored via an online self-learning platform that integrates MR to enhance combinatorics lessons with the *Kombi* app. Developed within a topic-specific design research project (see e.g., Mense et al., 2023), *Kombi* supports interactive problem-solving, strategy recognition, and structured solutions. It also includes a tool for creating digital task series.[2] Since its December 2022 release, *Kombi* has surpassed 350,000 downloads, increasing demand for teaching resources. In response, the author developed a platform integrating online MR to support *Kombi*-based lesson planning as part of her PhD project (see Figure 1, right), aligning with claims that mathematics teachers need MR to support their individual and collective design work with digital resources. The resources designed using the 'Learning technology by design' approach (Koehler & Mishra, 2005), cover essential TPACK facets with text, videos, and publications.

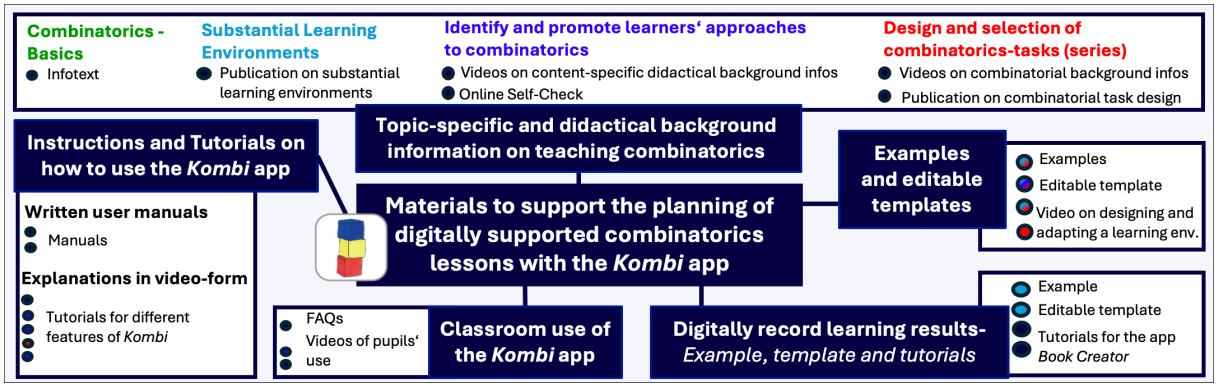

Figure 1: Brief overview of the content and design of the self-learning platform (translated)[2]

On a CK and PCK level the platform provides teachers with information on learners' possible individual approaches to combinatorics and how to promote systematic approaches to combinatorial listing and counting strategies, as well as information on important factors for sets of problems and the consequences of task design on the set of outcomes (cf. English, 1991; Höveler, 2018). On a TK level it provides manuals and tutorials for the app *Kombi*, and on a TPK level insights into how children use *Kombi* and its digital potentials, as well as which operational difficulties should be anticipated. On a TPACK level it provides an exemplary learning environment with the app *Kombi* and didactic explanations on how to digitally adapt it. All MR except the publications were designed

[2] Detailed insights into the self-learning platform and the app can be found under https://tinyurl.com/FiguresCERME14

by the author specifically for this platform and reviewed by colleagues and her supervisor. They are saved within a learning management system (LMS) course, and a document provides an organized overview with links to each resource. This approach was deliberately chosen to provide teachers with both flexibility and guidance, allowing them to navigate the LMS course without adhering to a linear sequence. Greater flexibility can better align individual needs with the content of online programs, thereby accommodating the diverse backgrounds and preferences of participants within the same course (Dille & Røkenes, 2021). However, not much is known about how teachers use this flexibility and their needs for support, leading to this study's research focus. Currently, access is limited to study participants, with plans for public release after finalized data collection for the PhD-project.

Methods

Setting and participants

The study examines collaborative lesson planning and informal PD of teacher pairs using an online self-learning platform. From a PD perspective, this approach aims to support professional learning through collaborative work. Methodologically, it has the added benefit of allowing thinking and planning processes to be verbalised and analysed within an authentic setting. In March 2024, teacher pairs designed combinatorics learning environments using the *Kombi* app, with full access to online MR. They set learning objectives, determined *Kombi*'s integration, and decided when to use MR, ensuring an authentic usage context. The sample of the three teacher pairs examined in this case study from the seven teams surveyed so far was selected to illustrate varying usage patterns. It includes three pairs of primary school mathematics teachers (aged 28 to 49, with 5 to 19 years of teaching experience) from four schools in western Germany. These teachers volunteered to participate after contacting the author for additional resources, making them representative of the intended audience for the online self-learning platform and informal PD. Team A consisted of Year 4 parallel class teachers, Team B of Year 2 parallel class teachers, and Team C of teacher friends from different schools who teach Year 2 and Year 3. All participants have previously explored the *Kombi* app, but none have yet used it in their classrooms.

Data collection and analysis

The teacher pairs met in person after school to plan their learning environments, while the author joined their meetings online via Zoom. The teachers used two devices: one computer for accessing the self-learning platform and making planning notes, and an iPad to use the *Kombi* app and other apps if needed. Both screens were shared via Zoom. After a brief introduction, the researcher muted her microphone and turned off her camera to quietly observe the planning process and record both the conversations and the two shared screens (cf. Beach & Willows, 2014).The recordings were then layered into one video per team. There was no time limit for the planning process, leading to planning times between 1,5 and 4 hours. Data collection also included a pre-survey with demographic and self-assessment questions as well as a subsequent interview after the lesson planning but those will not be in the focus of this analysis. To capture variations in discussions during lesson planning that could arise from using the resources (or the other way round), both the digital actions on the screens and the conversations were analysed in 30 second intervals using a qualitative content analysis (Kuckartz, 2019). With two screens and two teachers per team, up to two codes could be assigned per interval

and subtheme: one for each teacher's digital action and one for their communication topic, if working individually. The categories for analysing the usage patterns of teachers using an online self-learning platform with MR while planning a digital learning environment for teaching combinatorics were based on both Evers et al.'s (2016) categories for PD at work and Beach's (2017) themes for teachers' SDOL, explained in the theoretical background. Evers et al.'s (2016) category *collaborating with colleagues with the aim of improving lessons* naturally influenced all categories in this study due to the setting of data collection. The categories from literature were then inductively expanded to better grasp the teachers' digital activities and topics of communication as explained in the following section.

Results

The inductively expanded categories and (if applicable) their theoretical bases are presented in the upper half of Figure 2. These categories with their assigned colours respectively were then used to sequentially analyse the teachers' planning process which is visualised in the bottom half of Figure 2. The sequential visualisation of the color-coded categories reveals patterns in the three teacher pairs' usage of the resources and their topics of communication, serving as illustrative examples rather than representative findings. These patterns will be labelled and further described in the following.

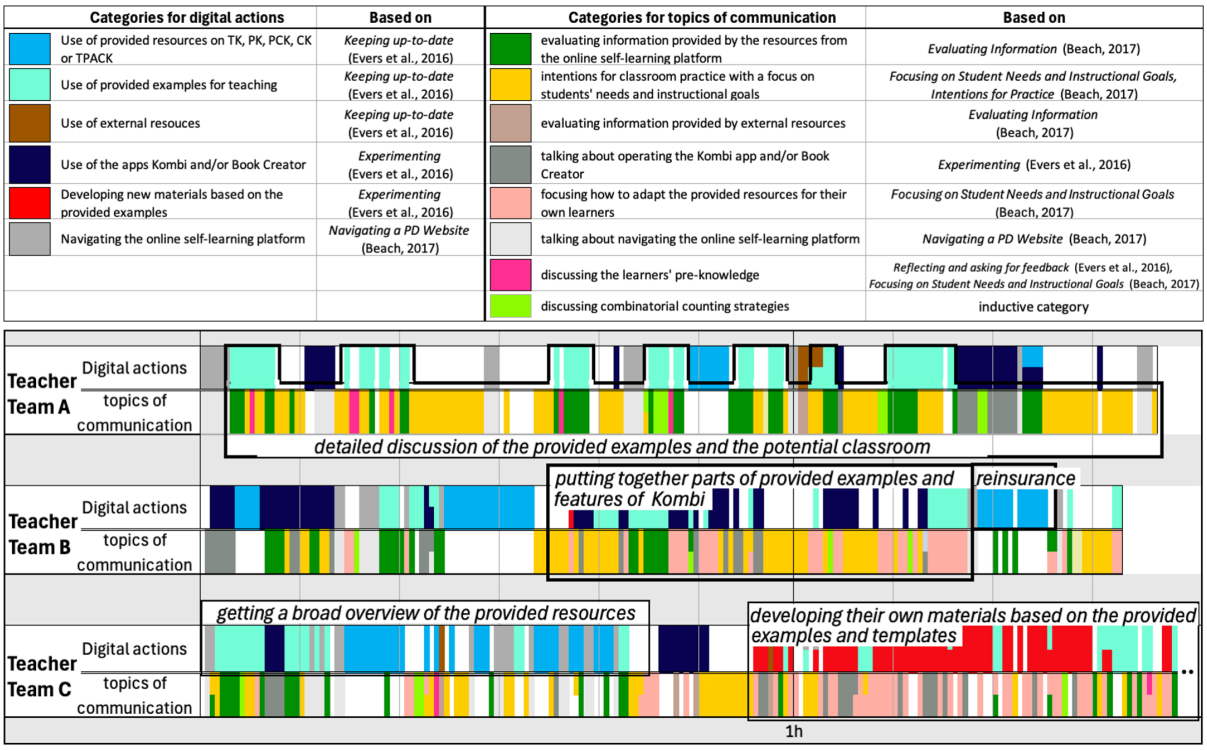

Figure 2: Inductive categories and their theoretical background and sequential visualisation of codes during the planning process with highlighted specific features of the usage patterns

The reflective example users: Team A extensively utilizes resources from the self-learning platform, particularly the provided examples (turquoise codes), to engage in deep discussions and reflections on the insights gained and their intentions for classroom practice (dark green and yellow codes).

Rather than adapting the examples, they plan to use them as they are, dedicating a significant portion of their planning time to anticipating student solutions to the combinatorial tasks and their use of the app and strategizing how to address them in their teaching like in the following illustrating statement:

> Ms. E.: The question might then arise: Do I always have to fill in the placeholders from scratch, or can I reuse the ones I already have? That's a structure I wouldn't specify for the children. It's something the more capable ones develop themselves, like: 'I don't want to drag everything in there anew every time; I just want to make adjustments because I know these three colours always go here, and three different ones above them.' For example—these three lower blocks. That's why I wouldn't address this top bar. The idea is that they recognize: I have this placeholder of two blocks, which I fill in with colours by dragging them in.

Those seeking reinsurance: Team B spends more time in the *Kombi* app (navy codes), anticipating learners' use of the app, compared to the other groups. They decide that they will have to adapt the examples for their year 2 learners, however, when discussing whether to design a new worksheet and digital research journal for their learners based on the templates, one of them states "I personally wouldn't dare to approach that just yet." Instead, they spend their remaining planning process making notes on how to put together different parts of provided examples and features of the *Kombi* app and implement them in their classroom practice (turquoise and navy codes, combined with coral and yellow codes). Since they often had difficulties consolidating their teaching ideas, they decided to validate their planning decisions with combinatorics-specific resources from the platform on how to promote systematic approaches to combinatorial listing and counting strategies, which they stated, "really helped to bring everything together, to summarize those scattered thoughts, and to help reformulate the goal in a different way."

The informed creatives: Team C focuses on acquiring an overarching understanding of the available resources during the initial 45 minutes (blue and turquoise codes). Following a comprehensive discussion centred around prospective pedagogical applications, they decide to design their own teaching materials based on the provided examples (turquoise codes) and templates (red codes). The remaining three hours of their planning process (partially omitted in Figure 1 for clarity in sequence comparison) they spend discussing their adaptions (coral codes), the operation of the apps (grey codes) and their intentions for classroom practice. This iterative process involves frequent transitions between revisiting the original examples and developing their own materials.

Discussion and Conclusion

The three cases discussed above, *The reflective example users*, *Those seeking reinsurance*, and *The informed creatives,* reveal distinct usage patterns of the MR on the online self-learning platform, leading to different documents according to Trouche et al.'s (2020) Documentational Approach to Didactics. First analyses of other teacher pairs of the PhD-study suggest that the described patterns can be found in other teacher teams' usage of the platform, however due to the small sample size, no statements can yet be made about the representativeness of the results. While Team A did not modify the provided examples, distinct adaptation processes emerged with Teams B and C, highlighting how they personalized the examples and required different resources at various planning stages. These patterns may be specific to planning combinatorics lessons, and further research is needed to explore whether these findings are topic-specific, focusing on the designed lessons and the teachers' use of

MR to support CK and PCK. In further analyses, the combinatorics-specific perspective will be brought to the forefront and interconnected with the technical perspective on lesson planning. Although these findings are preliminary, they emphasize the importance of allowing teachers flexibility in selecting resources, suggesting that a non-rigid sequence for accessing MR is well suited for informal use of online platforms aimed at supporting learner-centred lesson planning.

While Beach's (2017) model of SDOL and Evers et al.'s (2016) categories offered helpful insights for initial analysis, they had to be inductively expanded to be suitable for informal PD during lesson planning in a teacher team. The observed differences in usage patterns are likely influenced by factors such as teachers' experience with combinatorics, familiarity with digital technologies, expertise in digital learning design, TPACK, and students' knowledge levels. These differences, typical of teachers engaging informally with online platforms, reflect real-world teaching diversity and reinforce the validity of the findings. Future research could explore how these factors shape resource usage and how the platform can better support teachers with varying backgrounds, enhancing learner-centred lesson design. It is important to note that the sample is biased, as it consists of self-selected, highly motivated teachers; however, intrinsic motivation is central to informal PD.

The identified patterns might be useful user cases for the future development of online self-learning platforms to support lesson planning. Further analysis of the data will focus on teachers' design and redesign processes of digital MR and the challenges experienced by the teachers in the planning process. Additionally, important aspects yet remained unexamined in this study, such as the quality and effectiveness of the lessons designed by the teachers, as well as their professional learning outcomes. It is still unclear whether all observed usage patterns led to improved instructional practices. Future analyses will not only explore these questions but also aim to uncover key factors that impact the success of design and adaptation activities involving the provided MR. The overarching goal of the project is to gain a deeper understanding of the conditions that support informal teacher PD through these processes and to derive insights for the effective design of an online platform incorporating MR.

This study examines the dimensions of attending and interpreting within noticing competence and their respective levels, as demonstrated by 35 preservice secondary mathematics teachers through a narrative analysis of a video on fundamental concepts related to functions, using the Learning to Notice Framework and content analysis. The results indicate that, in the attending dimension, participants predominantly exhibit mixed or focused levels, while in the interpreting dimension, they tend to display a mixed level of competence. A detailed example of how these levels were identified is provided in the paper. Further research could explore the possibility of assigning a single level to each dimension, as some cases revealed varying levels within the same narrative, particularly given the preservice teacher status of the participants. Additionally, future studies could refine the descriptors of noticing levels to better capture the nuances of mathematical content.

Keywords: Teacher education, prospective teacher, function, narrative, content analysis.

Introduction

Numerous studies in mathematics education have highlighted the importance of developing preservice teachers' competence in perceiving and interpreting students' mathematical thinking (Scheiner, 2023). This competence, known as noticing, is closely linked to the noteworthy events that mathematics teachers observe in the classroom and how they interpret these events to support student learning (Lopez & Zakaryan, 2023; Mason, 2002; van Es & Sherin, 2021).

According to Sherin and van Es (2005), noticing should be integrated into teacher education programs, providing preservice teachers with opportunities to engage in practices that develop this essential competence, which is considered a key professional element (Mason, 2002; Sherin et al., 2011). Given their limited classroom experience, preservice teachers often face challenges in focusing on students' thinking and other noteworthy didactic events, interpreting their observations, and making decisions based on these insights (Mason, 2011). Therefore, it is crucial to foster and examine the noticing competence of preservice teachers (Sherin et al., 2011; van Es, 2011).

This paper is part of a larger project aimed at establishing relationships between the development of noticing and the specialized knowledge of preservice secondary mathematics teachers in Chile. We focus on a specific aspect of the project: determining the noticing levels of preservice teachers, and illustrating the complexities involved in this process. Scheiner (2016) notes that while some studies propose a linear relationship between noticing skills, others suggest a cyclical and ongoing dynamic. For instance, El Mohauyar (2024) identifies three distinct profiles of preservice elementary teacher noticing levels: average to high, low to moderate, and moderate.

Determining the noticing levels is relevant in teacher education programs because it provides insights that can inform decisions about potential improvements to help preservice teachers attend to students'

mathematical thinking. Consequently, the objective of this study is to determine the noticing levels of preservice secondary mathematics teachers through video analysis, using the levels adapted by Lee and Choy (2017) from van Es (2011). Videos have proven to be an effective tool for developing noticing dimensions, as van Es and Sherin (2021) argue that providing preservice mathematics teachers with opportunities to observe and analyze teaching practices fosters the development of these competencies. Additionally, this focus is particularly important, as research on noticing has predominantly concentrated on elementary school teachers.

Theoretical considerations

From a cognitive-psychological perspective, teacher noticing can be defined as the process of attending to relevant classroom events, interpreting these events, and, in some conceptualizations, using decision-making processes to act or respond based on those interpretations (Bastian et al., 2024; Sherin et al., 2011).

This paper builds on the *Learning to Notice Framework* proposed by van Es (2011), who identify two key dimensions of noticing: (1) attending, which refers to recognizing noteworthy features of classroom interactions, and (2) interpreting, which involves drawing on one's knowledge and experiences to make sense of what is observed. This framework is adopted because it provides a lens through which to examine what a teacher notices and interprets in a video recording of a lesson, including students' thinking, the didactic and pedagogical strategies employed, and the attention given to specific events.

Furthermore, Lee and Choy (2017) propose indicators that facilitate the identification of varying levels of attention and interpretation of noticing, building upon the work of van Es (2011). For each level, there are indicators of actions that could be evidenced by teachers (see Table 1), allowing for the determination of their level in each dimension.

Table 1: Dimensions and levels of Noticing

Dimension	Level	Level indicators
Attending (What teachers notice)	Baseline	Attend to irrelevant details that do not have direct impact on student learning Attend to whole class environment, behavior, generic content and learning and to teacher pedagogy
	Mixed	Primarily attend to teacher pedagogy Begin to attend to particular aspects of mathematical concepts and the difficulties associated with them Begin to attend to particular students' mathematical thinking and behaviors
	Focus	Attend to particular aspects of mathematics and relate students' confusion to the teaching approaches Attend to particular students' mathematical thinking
	Extended	Attend to the relationship between particular students' mathematical thinking and between teaching strategies and student mathematical thinking

Dimension	Level	Level indicators
Interpreting (How teachers notice)	Baseline	Form general impressions of what occurred Provide descriptive and evaluative comments Provide little or no evidence to support analysis
	Mixed	Form general impressions and highlight noteworthy events or details Provide primarily evaluative with some interpretive comments Begin to refer to specific events and interactions as evidence
	Focus	Provide interpretive comments Refer to specific students' difficulties, events and interactions as evidence Elaborate on these specific students' difficulties, events and interactions
	Extended	Provide interpretive comments Refer to specific events and interactions as evidence Elaborate on these specific students' difficulties, events, and interactions Make connections between events and principles of teaching and learning On the basis of interpretations, propose alternative pedagogical solutions

Note. Adapted from Lee and Choy (2017)

It is important to note that there are key indicators that distinguish between the different levels of noticing. These indicators are as follows: (1) at the baseline level, there is no consideration of students' mathematical thinking; (2) at the mixed level, attention to students' mathematical thinking is general, whereas at the focused level, it is directed toward specific instances of students' thinking; and (3) the distinction between the focused and extended levels lies in the fact that the extended level not only addresses specific instances of students' mathematical thinking but also connects them to teaching strategies. In other words, the extended level involves an analysis that goes beyond mathematical thinking, relating it to elements of didactic action.

Similarly, in terms of interpretation, the baseline level consists of descriptions without concrete evidence, while the transition to the mixed level involves presenting specific situations, usually accompanied by evaluative comments. As these comments become more interpretative and the specific situations are described in greater detail, the level progresses to focused. The highest level is reached when these interpretive comments lead to solutions for the events observed.

Accordingly, these categorizations will be used to assess the level of noticing competence demonstrated by preservice mathematics teacher in a video on the topic of functions.

Method

This descriptive study focuses on 35 preservice secondary mathematics teachers enrolled in a Bachelor of Mathematics Instruction program at a university in Chile. The program spans 10 semesters, during which students complete concurrent courses in mathematics, general pedagogy, and specialized didactics. At the time of data collection, participants were in their seventh semester, having already completed courses in calculus (three courses), real analysis, and calculus didactics,

among others. They were enrolled in the Classroom Situations Workshop, a course designed to engage them in video clubs and related activities that foster reflective practice.

In this paper, we present the results of an analysis based on a video clip and a single questionnaire question. The objective was to identify the elements that preservice teachers considered noteworthy in the observed video. The question, presented in written form, asked: "Identify three moments in the class that caught your attention (specify the time in the video), provide a detailed interpretation of each moment, and explain your position regarding each moment (e.g., whether you agree, whether you would have done something differently, etc.)." The request for three distinct moments was intended to guide preservice teachers in their task and to assess whether their identification of noteworthy events varied across different stages of the reflections. The final part of the question aimed to evaluate whether the participants' interpretations aligned with the criteria for the extended level, particularly in proposing alternative pedagogical solutions. Participants were allowed to watch the video as many times as needed and had the option to pause or revisit specific moments.

The video clip, which has a duration of six minutes and 27 seconds, features a secondary school mathematics teacher delivering a lesson on the review of basic concepts of functions. The teacher uses a projector and a PowerPoint presentation to explain the verbal definition of a function (see Figure 1), illustrating the relationship between sets through two representations: a Venn diagram and a graphical representation. Additionally, the concepts of image, pre-image, output set, input set, domain, co-domain, and range are discussed.

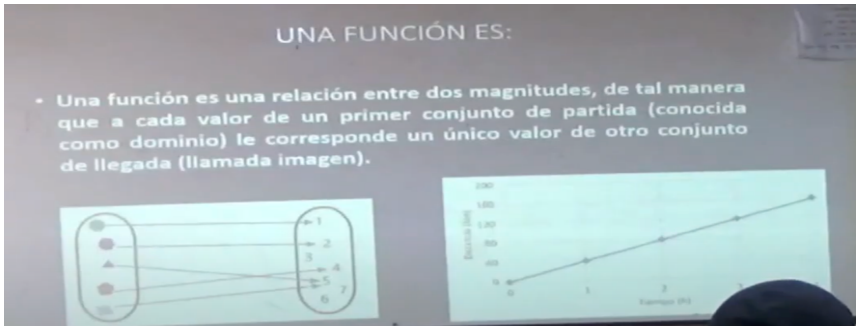

Figure 1: Capture of the initial moment of the video

Note. The following is a translation of the Spanish text from the figure: "A function is a relationship between two quantities, such that each value in the input set (the domain) corresponds to a single value in another set of outputs (the range)."

The narratives (Chapman, 2020) written by preservice teachers were selected for analysis to identify their noticing levels in the dimensions of attention and interpretation. Sentences and paragraphs that provided evidence of the level indicators outlined in Table 1 served as units of analysis. The operationalization of the noticing level indicators is based on content analysis (Bardin, 1996) of the notable events that preservice teachers observe and interpret. A higher frequency of any given indicator is sufficient to assign a corresponding level. For example, narratives that lack reflections on students' mathematical thinking are classified at the basic level, while those that include more detailed reflections are assigned a higher level of noticing. It is assumed that the level indicators follow a linear progression.

The authors of this paper identified evidence of the dimension and level indicators for the three narrated moments on an individual basis. These elements were then discussed, and consensus was reached to determine the final level assigned.

Results

Overall, the narratives of the 35 preservice teachers suggest that in the attending dimension, their responses are primarily categorized as either mixed or focused, while in the interpreting dimension, they tend to exhibit a mixed level of competence. It is also important to note that some participants demonstrated varying levels of noticing within the same narrative. Due to space constraints, this paper provides a detailed analysis of only one case to illustrate how the levels were assigned, as it was particularly relevant in displaying three distinct levels of interpretation.

The narrative produced by the selected preservice teacher, corresponding to the three moments in the video that captured his attention, are presented below.

Moment #1: 00:00-01:30

1 I would like to highlight a particular moment in the class when an interesting question came
2 up from a student: “Are the range and codomain the same thing?” Although some students
3 and the teacher answered that they are not the same thing, they pointed out that sometimes
4 they can coincide. In addition, the teacher emphasized the importance of having a clear
5 understanding of the concepts of domain, range, and codomain in order to move the topic
6 forward. In my opinion, although the student's question was addressed, it would have been
7 beneficial to provide a concrete example on the board to completely dispel the doubt at that
8 moment (later when an example is presented), but I want to emphasize the need to address
9 students' doubts in a timely manner (at the moment they ask the question) because I have
10 observed that sometimes it is difficult for them to express their concerns and, when they do,
11 they are often left with more questions if we do not provide a complete and concise answer.
12 This can discourage them from asking more questions or make it difficult for them to keep up
13 with the pace of the class because they start with unresolved doubts from the beginning.

In the initial four lines, there is evidence that the preservice teacher prioritizes the students' thinking processes, as evidenced by the highlighting of the question posed by the student and the subsequent emphasis placed on the necessity for the teacher to analyze the students' questions (lines 8 and 9). Furthermore, there are indications that the teacher is attending to aspects of mathematical concepts, as evidenced by the emphasis placed on the importance of understanding the basic concepts of functions for later topics (lines 4 and 5).

Additionally, the text points to elements of teacher pedagogy, as illustrated by the discussion of the benefits of using examples (line 6) and the incorporation of students' questions as part of the learning opportunities (lines 11, 12 and 13). Considering these indicators, it can be concluded that the teacher displays a mixed level of attention and interpretation.

Moment # 2: 02:30-03:45

14 First of all, what struck me about the teacher is that he points to the diagram on the left [Venn
15 diagram] as a “circle diagram”, although it is understood that for the students to understand
16 which [of the diagrams] he was referring to; it is necessary to promote technical language in
17 mathematics. Personally, I would have used that moment to teach the students that the diagram
18 has a name “mapping diagram” and that they can create such diagrams using functions.
19 Secondly, the teacher asks questions to make sure that the students correctly understand the

20 interpretation of the sagittal diagram, questions such as “What would be the domain in this
21 diagram, what would be the range, in this diagram do the range and codomain coincide?”, to
22 which the answers are quite enriching and correct. The students understand the diagram
23 perfectly and give a complete answer, although it was evident that they have difficulty in
24 differentiating “image and preimage”. Based on this, I emphasize the importance of
25 “evaluating” the course of the class according to the questions used by the teacher, since all
26 these data could be obtained thanks to the teacher's questions and the students' participation.

In this case, in lines 14 and 15, the preservice teacher expresses an intention to address aspects of mathematical concepts by emphasizing the use of appropriate mathematical language. Later, in lines 17 to 19, the teacher's pedagogical approach is described more concretely, with a particular focus on the use of questioning (line 20).

Furthermore, in line 12, he begins to recognize the difficulties the students are facing. At this point, the teacher’s level of attention is mixed, and his level of interpretation is at a baseline level, as evidenced by his evaluative rather than interpretative explanations. For example, he states that the students understand perfectly and provide complete answers, and that the data were obtained thanks to the teacher's questions.

Moment #3: 04:20-05:44

27 In this part of the video, I noticed that one student answered a question of the teacher
28 incorrectly, but most of the course recognized the error, to which several students answered
29 correctly, actions like this show that the course is really committed to the subject they are
30 teaching, as they can demonstrate the errors themselves and be able to justify them.
31 Afterwards, the teacher took the opportunity to give general feedback on the concept of
32 codomain and range, explaining with a concrete example from the blackboard where these
33 concepts do not coincide; personally, I think it was a good instance to emphasize this
34 difference of cases, as it gives feedback to students who may not have understood it so clearly,
35 and confirms the correct answers of the other students. Finally, a student asked, "What is the
36 difference between image and preimage?" Instead of answering directly, the teacher asked the
37 other students to give their answers. This practice is very important because it encourages
38 feedback among students, promotes collaboration, builds trust among peers, and contributes
39 to the assessment of student learning. Together, these practices create an enriching learning
40 environment that benefits the progress of all students.

In this concluding narrative, the preservice teacher identifies errors as a potential avenue for learning (lines 31 to 33) and demonstrates an awareness of student behavior, in this instance, by underscoring their engagement in the classroom (lines 30 to 32). Furthermore, he discusses the use of examples and counterexamples to contrast or clarify ideas (lines 32 and 34), thereby initiating attention to mathematical concepts. In lines 37 to 41, the trainee teacher emphasizes the importance of utilizing students' questions within the classroom setting and provides insights into the advantages to be gained from such scenarios. This illustrates a mixed level of attention and a focused level of interpretation. A summary of the findings is presented in Table 2.

Table 2: Levels of noticing evidenced in the narratives

Dimensions	Moment 1	Moment 2	Moment 3
Attending	Mixed	Mixed	Mixed
Interpreting	Mixed	Baseline	Focused

The results show consistency in the level of attention of this preservice teacher, but diversity in the levels of interpretation (see Table 2), despite the use of the same video for analysis.

Conclusions

This paper presents partial results of the research on the levels of noticing competence exhibited by preservice Chilean mathematics teachers. In the case presented, the level of attention demonstrated by the preservice teacher was mixed at the selected moments, while their level of interpretation differed at each of the three moments: moment 1 – mixed, moment 2 – basic, and moment 3 – focused. This final scenario renders the assignment of a noticing competence level within this dimension challenging, particularly when there is a diversity of levels within the same analyzed situation.

However, given that preservice teachers are still in training and developing their noticing competence (Kuntze et al., 2022), the evidence from the selected narrative, which shows a focused interpretive level in one of the moments described, suggests that this may eventually stabilize into a more consistent level of noticing. In general, these findings align with those of El Mouhayar (2024), who found that most preservice teachers exhibited noticing levels in the medium range, with a tendency toward moderate levels, which in this case corresponds to a mixed level. Another important point, which warrants further analysis, is the possibility that when observing other teachers, preservice teachers may concentrate on the actions of the teacher as a model for their future practice. This concentration could explain why some of them displayed baseline and mixed levels of attention.

It is also relevant to note that this study identifies certain challenges. Firstly, there is the complexity and yet unresolved issue of developing a strategy to establish a single level of noticing, rather than focusing on individual dimensions. This issue presents a valuable direction for future research, benefiting both scholars and those involved in teacher training programs. In these programs, decisions aimed at enhancing teaching competencies must be guided by tools that can accurately detect changes in teachers' noticing competence. Furthermore, this paper underscores the need for future research to refine the indicators for noticing dimensions, specifically to address particular mathematical objects.

Supporting pre-service teachers in learning to promote students' proving: the case of general conjectures

Reidun Persdatter Ødegaard

Norwegian University of Science and Technology, Trondheim, Norway; reidunp@ntnu.no

Leading mathematical discussions is an important teaching practice that allows students to develop their mathematical reasoning in collaboration with others. Aiming to provide PSTs with opportunities to learn this practice, four lessons for a mathematics teacher education course for elementary pre-service teachers (PSTs) were designed and implemented in an intervention in three iterations. Based on preliminary analyses, the design of the lessons was revised between each iteration. However, the design of the fourth lesson never successfully supported the PSTs in learning to lead discussions that reached a proof of a general conjecture. In this paper, the design of the fourth lesson and the challenges encountered in each implementation are discussed to provide directions for future interventions concerning classroom discussions and proving.

Keywords: Validity, class discussion, preservice teachers.

Introduction

An aim of teacher education is to prepare PSTs to teach with ambitious learning goals for the students, grounded in the expectation that all students are sense-makers and can be supported in reaching the goals (Lampert et al., 2013). For mathematics, ambitious teaching entails engaging students in problem-solving, sense-making, reasoning, and justifying (Forzani, 2014). Thus, providing students opportunities to develop a deep understanding of mathematics by focusing on reasoning and proving is central to ambitious teaching. However, learning to teach ambitiously is challenging due to the complexity of the mathematical content and the improvisational nature of teaching in a way responsive to students' thinking (Forzani, 2014). Moreover, learning to teach mathematics in a way that emphasises reasoning and proving is challenging (Stylianides & Stylianides, 2017). Efforts in teacher education should support PSTs in overcoming these challenges.

The practice-based approach to teacher education combines pedagogies of investigation and enactment of practice to support PSTs in learning to teach ambitiously (Ball & Cohen, 1999). By investigating representations of practice (e.g., videos, lesson plans, or students' work), PSTs are offered opportunities to observe and understand professional practice. Through approximations of practice (e.g., animations, role-plays, or school placement), PSTs are offered opportunities to enact professional practice in less complex conditions than authentic teaching (Grossman et al., 2009). Several studies have demonstrated that a practice-based approach to teacher education provides PSTs (and novice teachers) opportunities for learning to teach mathematics ambitiously (e.g., Lampert et al., 2013). However, varying degrees of complexity and authenticity in representations and approximations of practice provide PSTs with different learning opportunities (Grossman et al., 2009; Sapkota & Max, 2023). Thus, teacher educators need to consider the balance between more or less complex pedagogies for investigating and enacting practice.

As reasoning and proving is known to be challenging to teach (Stylianides & Stylianides, 2017), considerations of complexity and authenticity can be particularly important when implementing pedagogies for investigating and enacting practices related to reasoning and proving. In approximations relatively far from authentic practice, Arnesen and Valenta (2023) found opportunities for learning to promote proofs in mathematical discussions. However, Campbell and Elliot (2015) argue that approximations far from authentic practice risk oversimplifying teaching. At the same time, in a more authentic context, Buchbinder and McCrone (2020) found that PSTs struggled to enact a precise language for proving.

This study reports on a designed lesson in which PSTs investigated and, in a role-play, enacted a classroom discussion to prove a general conjecture. The lesson was implemented through an intervention in three iterations, and the design was revised based on initial analyses before the second and third iterations. However, the changes in design did not reach a balance in the complexity of the approximation to successfully support the PSTs in enacting a discussion that concluded with a proof of a general conjecture. In this paper, I discuss the lessons in terms of complexity and authenticity, answering the research question: *How do different aspects of complexity play out in three iterations of implementing role-plays of a discussion aiming at proving a general conjecture?* By discussing unsuccessful lesson designs, I make implications for the design of future interventions aiming to support PSTs in leading discussions that reach a proof of a general conjecture.

Theoretical framework

The complexity and authenticity of pedagogies in teacher education provide PSTs with different opportunities to learn to teach (Sapkota & Max, 2023). Authenticity and complexity have been defined in various ways. I follow Sapkota and Max's (2023) definition of authenticity as depending on the extent to which the pedagogies preserve the complexity of authentic teaching. As such, complexity and authenticity are codependent variables (Codreanu et al., 2020). The complexity of pedagogies for implementing investigation and enactment of practices in teacher education can be determined based on three dimensions: the nature of the practice, the context, and the scaffolding (Sapkota & Max, 2023). First, the nature of the practice varies from less complex when working with parts of practices, like practicing some teacher moves to elicit students' thinking, to more complex when enacting compound practices, like leading classroom discussions. Second, the context preserves less of the complexity of authentic teaching when the approximations are enacted in contexts outside of school. Such approximations include scriptwriting of imagined lessons, simulations, or role-plays. Third, the amount of scaffolding affects the complexity by providing, e.g., tools, frameworks, or teacher educator guidance, which is not available in authentic teaching.

A recognised pedagogy for supporting PSTs in learning to teach ambitiously is the learning cycle (McDonald et al., 2013), which combines representations and approximations of practice. The learning cycle is centred around a teaching practice and consists of four phases: investigating, planning, enacting, and reflecting (McDonald et al., 2013). The complexity and authenticity of the learning cycle are due to the adaptions and choices made by teacher educators. Learning cycles can evolve around more or less compound practices, be situated in teacher education or actual classrooms, and different kinds of support can be provided in the different phases of the cycle. Hence, teacher

educators need to balance the need for authentic learning experiences with the need to reduce complexity when implementing the learning cycle. PSTs need authentic learning opportunities to transfer the practices they learn into actual teaching (Codreanu et al., 2020). At the same time, lower complexity allows for isolating crucial aspects of the practice, removing the messiness of authentic practice (Grossman et al., 2009).

In this study, the design of a lesson implementing the learning cycle as a pedagogy for learning to lead classroom discussions that aim at proving a general conjecture is discussed. Leading mathematical discussions is a demanding teaching practice (Shaughnessy et al., 2019). Moreover, planning and enacting instruction about reasoning and proving is challenging (Stylianides & Stylianides, 2017), and proving general conjectures (statements about infinitely many cases) in a manner suitable to school mathematics is particularly challenging for PSTs (Rø & Arnesen, 2020). In this case, the complex nature of this practice was balanced with a less complex context: role-play, where the PSTs enact the roles of the teacher and students as if it was authentic teaching (Stürmer et al., 2024). Still, the scaffolding provided during the learning cycle plays an important part in balancing the complexity of the learning cycle, which is the focus of the following analyses.

Methods

This study is an intrinsic case study (Creswell & Poth, 2018), where the design of one lesson is a case of special interest because of the design challenges encountered. The lesson design analysed in this study was the last in a series of four lessons designed to provide PSTs opportunities to learn to elicit and promote students' reasoning and proving by implementing the learning cycle. The lessons were designed for a mathematics course in the first year of a five-year teacher education programme for primary school PSTs. Before the implementation of the intervention, the PSTs attended two lessons about reasoning and proving for primary school.

The lessons were implemented in an intervention through three iterations. Hence, each lesson was implemented three times. The four designed lessons were all implemented before moving to the next iteration. For example, after the fourth lesson was implemented the first time, lessons one, two, and three were implemented for the second time before the fourth lesson was implemented again. Since the overarching aim was to improve the design of the lessons, the iterations were implemented in a new group of PSTs, each group of approximately 30–40 PSTs. In each lesson, the PSTs were presented with a case from a classroom involving students' work presented as written work or in a video/transcript of a classroom discussion. Next, the PSTs planned how they would build on the students' work in classroom interactions before they enacted the plans in role-plays with one or two PSTs enacting the teachers, some PSTs enacting the students, and some PSTs observing the role-play. Last, the PSTs reflected on the enactments based on their experiences and observations. Each lesson lasted approximately two hours.

The four lessons involved different complexity. In the first two lessons, the nature of the enacted practice was that of a teacher eliciting one or two students' reasoning. In the last two lessons, the enacted practice was leading a mathematical discussion, which is a more complex practice. The context of the enactments was equal for all four lessons: role-plays situated in teacher education courses. The scaffolding provided varied in terms of the support provided by the teacher educator in

helping the PSTs unpack the mathematical content of each lesson. Moreover, the complexity of the mathematical ideas the classroom interactions were centred around varied. In the first lesson, the PSTs were asked to support students in developing conjectures based on similarities and differences. In the following two lessons, the PSTs were asked to support the students in explaining a strategy for an arithmetic problem. In the last lesson, the PSTs were asked to lead a whole class conjecture, reaching a proof of a general conjecture using a generic example. In generic examples, proofs of general conjectures are based on explaining a specific case and arguing for the properties of the case that are general (Rø & Arnesen, 2020). For the fourth lesson, which is the focus of this study, experiences from each iteration of implementation led to changes in the design regarding teacher educator support. These changes are described in the Results, along with the analyses of the lessons.

Changes were made based on initial analyses and reflections on the implementation of the lesson. Transcripts of the videotaped enactments were analysed in terms of problems encountered regarding general conjectures or mathematical discussions. Encountered problems were identified in instances where the PSTs explicitly or implicitly stated that they found it difficult, the discussion did not reach the goal of proving a general conjecture, or the enacted role-play did not meet the requirements of mathematical discussions. For instances identified as encountered problems, the enacted role-plays were analysed in terms of the design considerations made and discussed based on how the design played out in the enactment.

Results

For each iteration of implementation, I present the aim of the fourth lesson and the lesson design. For each of the three iterations of implementing the fourth lesson, the PSTs were presented with a transcription of a classroom discussion where students explained their strategy for an arithmetic problem. The PSTs were asked to build on the students' explanation when planning and enacting a discussion that generalised properties and proved a general conjecture. In the excerpts, T and S indicate that the PST enacted the teacher or student.

The first iteration

For the first iteration of implementing the fourth lesson, the aim was that the PSTs enacted a discussion that reached a proof of the general conjecture about distributivity in division: that you can split the dividend and divide each of the parts by the divisor before you add the quotients. In the first phase of the learning cycle, the PSTs were presented with a transcription of a fictive classroom discussion in which the students worked with the problem string 70:7, 21:7, and 91:7. The transcription of the classroom discussion ended with an explanation of the division strategy 91:7=70:7+21:7, using a measurement division context with bags of candy as a representation. The excerpt shows how the PSTs went from discussing validity to discussing the extent of validity.

Ane (T):	But why can we split it this way? I mean, does it apply to all division problems?
Simen (S):	Yes, if the number is very high.
Vilde (T):	Yes, because 91:7 is difficult, perhaps. So, we have made it easier. We have 70 and 21. But did we need to do it this way?
…	
Ane (T):	As long as it is 91 in total, is it true? Could you also split 50 candies? Is it possible? Does it work for all numbers?

Siri (S): Not if it isn't in the 7-times table.
Ane (T): Because then it doesn't work. So, what is important is that it is a number that is divisible by the number of candies in the bag.
Vilde (T): Yes, so we did talk about that no matter how we split 91, we still have the same amount. But then we can split it in 50?
Ane (T): Yes, we can actually split it in 50. And then realise that "oh, I miss some candies". We still have the 91, even if we take some from this pile of candy here … (hesitates)

Twice, Ane, enacting one of the teachers, asked if one can always split the dividend in a division problem. However, an explicit formulation of the general conjecture was never provided to support the PSTs. Consequently, the conjecture was never stated explicitly in the enacted discussion, and the PSTs' answers about the validity of the conjectures address the usefulness and the extent of validity (for the representation using candies). Furthermore, the enactment went from being a role-play to being a conversation about unpacking the mathematics. Hence, in this first iteration, the lack of scaffolding, in terms of not formulating a general hypothesis for the PSTs and using a representation for which the conjecture is not always true, led to the enactment losing track of the goal for the discussion and eventually being a discussion for the PSTs out of character.

The second iteration

Before the second iteration, the design of the lesson was changed to having the teacher educator present the given general conjecture. Additionally, the proof of the single-case conjecture that the PSTs were to generalise was based on a representation that would be true for all numbers. The aim of the lesson in the second iteration was that the PSTs enacted a discussion that reached a proof of the general conjecture "1 divided by any fraction is the inverted fraction". In the first phase of the learning cycle, the PSTs investigated a transcription of a classroom discussion about the problem 1:2/3, ending with an explanation of why the answer to 1:2/3 is the inverted fraction, 3/2. However, generalising and proving that 1 divided by any fraction is the inverted fraction is a complex mathematical idea, which led to problems in unpacking the mathematics, as illustrated below.

Nadia (T): OK, but what if we use another fraction, what happens then? Is it similar?
Anders (S): Yes.
Nadia (T): Why?
Lilja (S): Because it is the numerator bigger, sort of, so you need to divide by the numerator.
Nadia (T): So, you divide the answer from 1 divided by … Can you explain again?
Lilja (S): If you take another problem, for example, 1 divided by 3/5, then you first find that you get five 1/5s. Then you divide it by 3 because it is three times bigger than when the numerator is 1.
Dina (S): You divide 5 by 3, that's why it is 5/3?
Lilja (S): Yes.
Dina (S): Just checking that I follow.
Nadia (T): Okey, but will it always be this way? Or is there a relationship between the fractions and the answer? Anyone?

After Lilja justified that the conjecture was true, Nadia attempted to revoice her justification without being able to finish, so she asked Lilja to explain again. After Lilja explained again, the PSTs temporarily went out of their roles to unpack the mathematical content, e.g., seen in Dina's interest in understanding the justification herself, not as the student she enacted. At the end of the discussion, Nadia asked again if the conjecture was true, even though Lilja had already justified it. Moreover, she asked about the relationship between the numbers in the problem, which is a question that prompts

students to develop a conjecture, which, in this case, was already developed. Hence, the lack of scaffolding for unpacking the complex idea of inverse proportionality led to challenges in understanding the proof and what counts as proof.

The third iteration

The third iteration involved reasoning and proving processes in measuring. Based on experiences from the second lesson, the design of this lesson was changed to involve a much less complex mathematical idea and provide scaffolding by proving a similar conjecture in the given transcription of a mathematical discussion. The PSTs were asked to lead a discussion proving the conjecture that as long as the side lengths of the base rectangle (including lengths of decimal numbers) add up to the same circumference and the height is constant, the surface area of the walls of a prism remains unchanged. In the transcription investigated by the PSTs, the discussion reached a proof of the conjecture for side lengths of whole numbers. Providing the proof for whole numbers was intended as scaffolding for when the PSTs were asked to lead a discussion proving the extended conjecture, including rational numbers. In the excerpt below, the PSTs reached a proof of the general conjecture, but the PST who enacted the teacher did not position the students as sense-makers or ask them to explore or formulate the conjecture.

Amund (T): What do you think? Do you think it will always be 864 square meters when we have these measures? Yes?
…
Isak (S): Because we know that the height is 24 no matter what, and the circumference is 36. So, that is, you cannot change it, and if you multiply them, you get 864.
…
Amund (T): If I take five and a half and add five and a half, plus twelve and a half plus twelve and a half. What do you think the answer is then? Do not calculate it, what do you think? (Points at Gry).
Gry (S): 36
Amund (T): Why?
Gry (S): Because that is the circumference.
Amund (T): Yes, correct, it should always be 36. Then it is, then the height is 24, so we get 36 times 24, and that is 864.

In the excerpt above, Amund's questions directed the discussion towards the argument for the conjecture already given in the transcription they investigated. The PST's questions did not highlight the new conjecture: that the circumference can be made up of any (not necessarily integer) number as the side lengths. The new conjecture was mentioned by Amund as an example, and Amund also gave the proof. Suppose the PSTs considered the conjecture trivial (given the already proven similar conjecture). In that case, they might not have seen the need for formulating and validating it, and the teacher repeating could be a strategy to summarise the discussion. Hence, the scaffolding, making a conjecture about less complex mathematical content and providing a proof of a similar general conjecture, may have reduced the complexity of the approximation to such an extent that it lost authenticity and lacked opportunities for learning to teach.

Discussion

This study reveals the challenges of supporting PSTs in approximations of practices that involve complex mathematical processes. The scaffolding of proofs of general conjectures played out in three

different ways in the three iterations of implementation. First, not enough scaffolding was provided for the PSTs to unpack the mathematical content. Second, although providing more scaffolding to prove general conjectures, the mathematical ideas were so complex that more scaffolding was needed. Last, too much scaffolding regarding proofs of general conjectures was given, making the conjecture trivial to the PSTs. For the first two lessons, the lack of scaffolding consequently led to the approximation being too complex to provide opportunities for learning to lead mathematical discussions aiming at proofs of general conjectures. For the last lesson, too much scaffolding led to a less authentic approximation, hindering the PSTs' opportunities to learn a complex practice.

Although the changes in the design did not reach a balance in scaffolding suitable for supporting PSTs in learning to lead discussions reaching proofs of general conjectures in role-plays, implications for further interventions can be made. Based on the first iteration, I recommend providing a conjecture (in contrast to making the PSTs formulate it) and a representation on which to base the proof. Furthermore, the second and third iterations provide information about the amount of scaffolding used to unpack the mathematical content, demonstrating that the scaffolding must be on a continuum between preserving the mathematical complexity and making the mathematical ideas trivial. In line with Sapkota and Max's (2023) recommendations, further research should strive to find a balance in complexity that supports PSTs in learning to lead discussions aiming to prove general conjectures.

The results of this study contribute to the literature about practice-based approaches supporting PSTs in learning to teach reasoning and proving in several ways. First, by discussing authenticity in terms of complexity in detail, new insights about the design decisions teacher educators need to make is obtained. Although Grossman et al. (2009) suggest that less complex approximation allows for isolating and learning some aspects of the practice, the results in this study demonstrate that the complexity can be reduced too much. Second, using role-play is another approximation of practice than those reported earlier, as it is more complex than scriptwriting tasks (Arnesen & Valenta, 2023) and less complex than enactments in school (Buchbinder & McCrone, 2020). Last, the results contribute to already known challenges of learning to teach proof. In addition to struggling with enacting a precise language for proving (Buchbinder & McCrone, 2020) and proving general conjectures themselves (Rø & Arnesen, 2020), the PSTs met challenges regarding formulating conjectures, deciding the validity domain, and seeing the need for proving.

Several factors contribute to the complexity of pedagogies of enactments. In this study, scaffolding was the only factor experimented with, and future interventions should experiment with the nature of the practice and the context and possible relations between these dimensions when aiming to support PSTs in learning to promote students' reasoning and proving in classroom interactions.
